Agricultural Harvest Operations

(Revised and Updated, December 2013)

EMISSION INVENTORY SOURCE CATEGORY
Miscellaneous Processes / Farming Operations

EMISSION INVENTORY CODES (CES CODES) AND DESCRIPTION
620-615-5400-0000 (83980) Agricultural Harvest Operations

METHODS AND SOURCES

Particulate matter (PM) emissions from soil and plant material, also known as fugitive dust emissions, are entrained into the air during the harvesting of agricultural commodities. Emissions occur during a variety of harvest operations, including vehicle travel over soil, harvesting activities, and the processing of plant material and the underlying soil. Emissions vary during the year according to the intensity of harvest activities taking place, with the highest emissions occurring during the peak harvest months of summer and fall. The agricultural harvest operations source category includes estimates of emissions produced during harvest and the first post-harvest processing stage (packing houses, nut hullers and processors, cotton gins, dehydrators, feed and grain mills). This methodology does not estimate emissions from subsequent processing, canning or other similar activities.

ESTIMATION METHODOLOGY

ARB estimates harvesting PM emissions by multiplying the number of harvested acres (activity) by a crop specific emission factor. Harvested acreage data were subdivided by crop type and county/air basin/air district (COABDIS) for the entire state. The emission factors were developed from harvest emissions measurements in three crops, then scaled and assigned to all other crops. Crop specific PM₁₀ emissions are estimated directly from the activity and emission factors. The individual crop emissions are then summed to produce estimates of PM₁₀ emissions for each COABDIS. The fractions for the other PM components (PM_{2.5} and total PM) are calculated from a particle speciation profile.

Activity Data. For this update, 2005 harvested acreage from the U.S. Department of Agriculture's (USDA) National Agricultural Statistics Service (NASS) was used for all regions except for the San Joaquin Valley Air Basin (SJV Air Basin). NASS data are compiled from county level reports provided by the California County Agricultural Commissioners for more than 200 commodities identified by the California Department of Food and Agriculture (CDFA). For the SJV Air Basin, 2007 farmland acreage from the California Department of Conservation's Farmland Mapping and Monitoring Program

(FMMP) was allocated to the various crops based on the 2007 harvested acreage reports compiled by NASS. For all regions, acreage for pasture lands, mushrooms, greenhouse, nursery and flower crops, and forest firewood was excluded. Also excluded was crop specific acreage that was aggregated statewide as “Sum of Others”. These data, representing less than 1% of statewide harvested acreage, could not be reported due to disclosure of confidential business information. For counties split among two or more air basins, acreage was apportioned based on land surface areas [CARB, 2009 Almanac], except for Kern County, which was assigned 98% to the SJV Air Basin and 2% to the Mojave Desert Air Basin. Complete listings of the California crop acreage by COABDIS are provided in Appendix A

Crop Calendars. In the early 2000's, ARB staff and a group of agricultural experts in the SJV Air Basin developed 21 representative profiles that characterized the monthly distribution of annual land preparation and harvest activities for about 90 percent of California's crop acreage. Crops that were not specifically addressed were assigned a crop profile from a similar crop. More information on how crop profiles were developed is available in the background documents [CARB, April 2003].

Crop Specific Emission Factors. The three harvesting emission factors (lbs PM₁₀/acre/year), shown below in Table A, are based on testing conducted in California in almonds, cotton and wheat. The almond harvesting emission factor is revised in this update, based on studies conducted between 2002 and 2010 [Faulkner, 2010; Jones, 2008]. The emission factor for almond shaking is based on the average of shaking results from the Jones study, which used two testing methodologies. The emission factors for almond sweeping and pickup are from the Faulkner study. The cotton and wheat harvesting emission factors are from a 1994-1998 study performed by the University of California, Davis, under contract to the USDA [Flocchini, 2001]. Based on assumptions about the emission generation potential of crop specific harvesting practices, ARB developed nine scaled emission factors and assigned them to over 200 commodities.

Table A
Emission Factors for California Harvesting Operations

Agricultural Harvest Operation	Emission Factor (lbs PM₁₀/acre/year)
Almond	
Almond Shaking	3.47
Almond Sweeping	4.15
Almond Pickup	23.6
Almond Total	31.2
Cotton	
Cotton Picking	1.685
Cotton Stalk Cutting	1.685
Cotton Total	3.37
Wheat	
Combining	5.8

Crop Emissions. Crop emissions (lbs PM₁₀/year) are calculated by multiplying the annual number of crop specific harvested acres by the harvest emission factor for the associated crop:

$$\text{PM}_{10} \text{ Emissions}_{\text{crop}} = \text{Acres Harvested}_{\text{crop}} \times \text{PM}_{10} \text{ Emission Factor}_{\text{crop}}$$

Crop emissions are summed for total annual county emissions. Table B provides crop profiles, emission factor assumptions and harvesting emission factor assignments for each commodity harvested in 2005 (non-SJV Air Basin) and 2007 (SJV Air Basin).

Total PM and PM_{2.5} are derived from calculated PM₁₀ emissions using ARB's speciation profile #417 for agricultural tilling dust [Houck, 1989; Cowherd, 2005]. Particle size fractions are based on an average of dust measurements from 8 fields in the San Joaquin Valley and on 2006 updates to ARB PM_{2.5} speciation profiles [Gaffney, 2006] that apportioned more of the fine PM (<2.5 microns) into the coarse PM (>2.5 microns) category. Compared to the previous methodology, the updated particle size profile reduces the PM_{2.5}/PM₁₀ fraction from 22.2% to 15% and reduces the PM_{2.5}/total PM fraction from 10% to 6.8%.

Total PM emissions are back-calculated by dividing computed PM₁₀ emissions by the particle size fraction for <PM₁₀:

$$\text{Total PM} = \text{PM}_{10}/0.4543$$

PM_{2.5} emissions are calculated by multiplying total PM emissions by the particle size fraction for <PM_{2.5}:

$$\text{PM}_{2.5} = (\text{PM}_{10}/0.4543) \times 0.0681$$

Table 1 presents updated PM₁₀, PM_{2.5} and total PM emissions from agricultural harvest operations for 2005 (all regions except the SJV Air Basin) and Table 2 presents emissions for 2007 (SJV Air Basin). Emissions are summarized by COABDIS, along with associated harvested crop acreage.

Compared to the previous update [Gaffney, 2003], harvested acreage is essentially unchanged, while PM₁₀ harvest emissions have increased by 42% [Gaffney, 2003]. The increase is attributable to a comparable (43%) increase in almond and walnut acreage since 2000. These two crops are assigned the highest harvesting emission factor (almonds, 31.2 lbs PM₁₀/acre), due to the dust generated during harvest operations, primarily during first pick up.

TEMPORAL ACTIVITY

Monthly temporal activity profiles allocate emissions based on crop specific profiles that reflect the percentage of harvesting activities occurring each month. Temporal activity for each county is derived by summing the monthly harvesting emissions from all crops. Because the crop composite differs by county, each county's monthly profile is unique. No adjustments are made for rainfall as the crop calendars are assumed to reflect seasonal activity patterns.

Crop Activity Profiles. Each crop profile indicates the percentage of annual harvest operations that take place each month. Table 3 shows the temporal activity for all 20 crop profiles.

Emissions Activity Profiles. The activity profiles are used to distribute annual harvesting emissions to the summer months (May - October) and winter months (November - April). Table 4 presents the monthly temporal emissions profiles developed for each COABDIS, based on the composite of crop profiles and associated harvested acreage. Monthly emissions are calculated by multiplying annual county emissions by the monthly fraction.

GROWTH FORECASTING

In the prior update, this category had been grown by the projected county acreage for irrigated and non-irrigated agricultural lands, excluding native grazing land, as reported by the FMMP. Growth projections were revised for this update [Griffin, 2011]. For all regions of the state except the SJV Air Basin, growth reflects linear regressions of the 2000-2009 NASS harvested crop acreage for regions showing a definite trend (-3% to +3% annually) and no growth when the regression analysis showed either no observable trend or an unsustainable trend. For the SJV Air Basin, growth reflects linear regressions of 2000-2009 FMMP farmland acreage by COABDIS, applied to NASS harvested crop acreage for base year 2007. Growth for all regions is projected to 2020.

ASSUMPTIONS AND LIMITATIONS

1. The harvest operations emission factors developed in the SJV Air Basin are assumed to accurately represent emissions statewide.
2. Based on the relative geologic PM₁₀ generation potential of various harvest practices, three emission factors measured in almond, cotton and wheat were scaled and assigned to all harvest activities.
3. Crop calendar data collected for SJV crops and practices were extrapolated to the same crops in the remainder of the state. Existing crop profiles were used for the small percentage of crops for which updated information was not collected.
4. The current harvest emission factors assume that, for each crop, harvesting produces the same level of emissions under all conditions for all equipment.
5. SJV soils are assumed to accurately represent the particle size distribution of PM in agricultural fields statewide.
6. It is assumed that ARB's particle size speciation profile #417 (agricultural tilling dust) provides adequate size fractions for calculating PM_{2.5} and total PM emissions throughout California.

CHANGES IN METHOD AND EMISSION ESTIMATES

The significant changes in the harvesting emissions estimates for this update include:

- Harvested crop acreage data compiled by California County Agricultural Commissioners was updated for 2005 (non-SJV Air Basin regions) and 2007 (SJV Air Basin).
- The almond harvesting emission factor was reduced from 40.77 lbs PM₁₀/acre/year to 31.2 lbs PM₁₀/acre/year, based on recent emissions testing.
- An updated particle size fraction is used for ARB speciation profile #417 that reduces the PM_{2.5}/PM₁₀ fraction from 22.2% to 15%, and reduces the PM_{2.5}/ total PM from 1.0% to 0.068%.
- PM_{2.5} emissions are reported for the first time.
- County specific temporal profiles were updated, based on estimated PM₁₀ emissions for harvest operations and on crop specific activity profiles.
- New growth surrogates were adopted based on linear regressions of 2000-2009 harvested acreage.
- Compared to the prior update, estimated 2005 harvesting emissions have increased by about 42% due to a comparable increase in almond and walnut acreage since 2000.

COMMENTS AND RECOMMENDATIONS

Emission Factors. ARB, in consultation with agricultural experts from the SJV, used a subjective scaling approach to assign the three available PM emission factors to over 200 California crops. As additional harvest emissions data are collected, they will be incorporated into the methodology and the emissions estimates will be recalculated.

Environmental Conditions. Incorporation of environmental factors, such as relative humidity and soil moisture, into harvesting emission factors is still under exploration and may be considered for future methodology updates.

Speciation Profiles. Currently, ARB uses SJV test data as a statewide default. If available, future updates could include regional or county-specific particle size speciation profiles.

Growth. The assumptions concerning growth should be periodically reviewed to ensure that the growth surrogate accurately reflects the current status of California's agricultural lands.

SAMPLE CALCULATIONS

The following steps, along with the information in Table F, below, summarize the data computations needed to estimate PM emissions from agricultural harvest operations for 2007 in Fresno County.

- Step 1: Acreage. Using the data in Appendix A, enter the acreage for the crop of interest.
- Step 2: Crop specific emission factor. Using the data in Table 1, assign the appropriate emission factor for each crop.
- Step 3: Calculate Crop PM₁₀ emissions. Multiply the acres for each crop by the appropriate emission factor, and divide by 2000 lbs/ton to compute annual tons of PM₁₀ emissions.
$$\text{Emissions} = (\text{Acres} \times \text{Emission Factor})/2000$$
- Step 4: County total emissions. Sum the emissions for each crop to compute the total PM₁₀ emissions from harvest operations.

Step 5: Calculate total PM emissions. Divide computed PM₁₀ emissions by the particle size fraction provided in ARB speciation profile #417 for < PM₁₀:

$$\text{Total PM} = \text{PM}_{10}/0.4543$$

Step 6: Calculate PM_{2.5} emissions. Multiply total PM emissions by the particle size fraction for < PM_{2.5} provided in ARB speciation profile #417:

$$\text{PM}_{2.5} = (\text{PM}_{10}/0.4543) \times 0.0681$$

Table F
PM Emissions from 2007 Harvest Operations in Fresno County (Selected Crops)

Crop	Acres	Emission Factor (lbs PM ₁₀ /acre)	PM Emissions (tons/year)		
			PM ₁₀	Total PM	PM _{2.5}
Almonds, All	149,889.48	31.2	2,338.28	5,146.99	350.51
Cotton Lint, Pima,	126,256.52	3.37	212.74	468.29	31.89
Tomatoes, Processing	160,550.00	0.17	13.65	30.04	2.05
Wheat, All	43,027.40	5.80	124.78	274.66	18.70
Etc....					
Total	1,380,839		3,127.09	6,883.31	468.75
