Eight duplicate canister samples were collected. Comparisons of the analytical results for each duplicate pair are provided in Table 3.6-16 as the relative percent differences (% RPD) between analytes. Since each canister sample was analyzed by EPA Method TO-15 for VOCs and by ASTM D1946 for methane, Table 3.6-16 includes the results for both analytical techniques. The average percent relative differences for the duplicate canisters range between 11 to 61 percent. This is considered an acceptable result for field samples.

3.6.6 Analytical QC Results

To ensure high quality analytical results, TestAmerica™ performed several quality control checks during the analysis of each batch of canister samples received by them from the point source team. The most significant of these were: Method Blanks, Surrogate Recoveries, Laboratory Control Samples and Control Sample Duplicates, and Continuing Calibration Verification checks.

Method Blanks

Analytical method blanks were analyzed by TestAmerica™ either daily or after a certain number samples (i.e. after each batch of 20 samples). The method blank is treated like any other sample except that a clean material, free from any of the sample targets, is used. The results of the method blank indicate if any contaminants are present in the analytical system. The only compound that routinely appeared in the analytical method blanks associated with this project's canister samples was small amounts of methylene chloride, a common laboratory solvent. In calculating the canister emission factors the amount of methylene chloride detected in the method blank was subtracted from the reported methylene chloride result. Method blank results are provided for each canister sample result in the TestAmerica™ analytical reports provided in Appendix 3-C.

Surrogate Recoveries

A surrogate standard is a non-target analyte having a chemical structure similar to the target analytes that is added to a sample prior to extraction. Six surrogate standards were added to each point source canister sample prior to extraction and their percent recoveries were evaluated following analysis of the canister's contents. The surrogates monitor the efficiency of the extraction, the cleanup, and evaporation of the solvent if any has been used on the sample. Surrogate percent recoveries for each canister result together with acceptable recovery limits are provided with each of TestAmerica's™ analytical reports contained in Appendix 3-C.

Laboratory Control Samples and Control Sample Duplicates

The Laboratory Control Sample (LCS) is a clean matrix that is fortified with the target analytes and analyzed in the same manner as a batch of samples is analyzed. Since in this case the concentration of each analyte is known, the resulting values provide a measure of the accuracy of the system for each analyte. As a further measure of quality control, the LCS is analyzed in duplicate and the relative percent difference between the two results is calculated and evaluated against the laboratory's acceptance criteria. Both LCS and LCS duplicate results are provided towards the conclusion of each TestAmerica™ report.

Continuing Calibration Verification

Continuing Calibration Verification (CCV) checks are performed over specific time periods during sample analysis to confirm the instrument's calibration and performance. A CCV check was performed by TestAmerica™ with each batch of sample analyses. The results are evaluated as the percent recoveries of the known analyte concentrations making up the CCV spike. The results of each CCV check are reported under the heading "Calibration Check" in the TestAmerica™ documentation located in Appendix 3-C.

3.7 Point Source Testing Conclusions

Point source testing was conducted to determine how much air pollution is being released by natural gas exploration in Fort Worth, and if natural gas extraction and processing sites comply with environmental regulations. The point source testing program occurred in two phases, with Phase I occurring from August through October of 2010, and Phase II occurring in January and February of 2011. Under the point source testing program, field personnel determined the amount of air pollution released at individual well pads, compressor stations, and other natural gas processing facilities by visiting 388 sites, includes two repeat visits, and testing the equipment at each site for emissions using infrared cameras, toxic vapor analyzers (TVAs), Hi Flow Samplers, and evacuated canisters to collect emission samples for laboratory analysis.

TOC, VOC, and HAP emissions were calculated on an annual basis for each site as the sum of 1) direct canister sample results; 2) adjusted canister results using correlation equations; 3) tank and non-tank surrogate emission profiles; 4) engine emission data; and 5) default zero emission factors. Emissions associated with tank unloading, tank flashing, well snubbing, glycol

reboilers, flares or any type of maintenance/repair activities were not included in the calculated site emissions profiles.

Key findings from the point source testing program are as follows:

- A total of 2,126 emission points were identified in the four month field study: 192 of the emission points were Valves, 644 were Connectors and 1,290 were classified as Other Equipment. 1,330 emission points were detected with the IR camera (i.e. high level emissions) and 796 emission points were detected by Method 21 screening (i.e. low level emissions).
- At 96 sites, no emissions were detected by the IR camera. At 46 sites, no emissions were detected by either the IR camera or the TVA. Of these 46 sites, 38 had less than three wells and subsequently lower auxiliary equipment counts such as tanks, separators, valves, and connectors.
- Emissions from lift compressors have a significant impact on well pad emissions. Most lift compressors are mobile and are moved from site to site as needed. The addition of a lift compressor to a well pad site has the effect of raising TOC emissions four-fold while emitting an average 16 tons/yr of criteria pollutants.
- The largest source of fugitive emissions detected with the IR camera was leaking tank thief hatches. Emissions were detected at 252 tank thief hatches resulting in a combined TOC emission rate of 4,483 tons/yr. Some of these emissions were due to the operators simply leaving the hatches unsecured as shown in Figure 3.7-1 below. Many others, however, appeared to be due to lack of proper maintenance.

Figure 3.7-1. Thief Hatch Left Open

- Pneumatic Valve Controllers were the most frequent emission sources encountered at well pads and compressor stations. These controllers use pressurized natural gas to

actuate separator unloading valves. Under normal operation a pneumatic valve controller is designed to release a small amount of natural gas to the atmosphere during each unloading event. Due to contaminants in the natural gas stream, however, these controllers eventually fail (often within six months of installation) and begin leaking natural gas continually. The emissions from the 489 failed pneumatic valve controllers detected by the point source team result in a combined TOC emission rate of 3,003 tons per year.

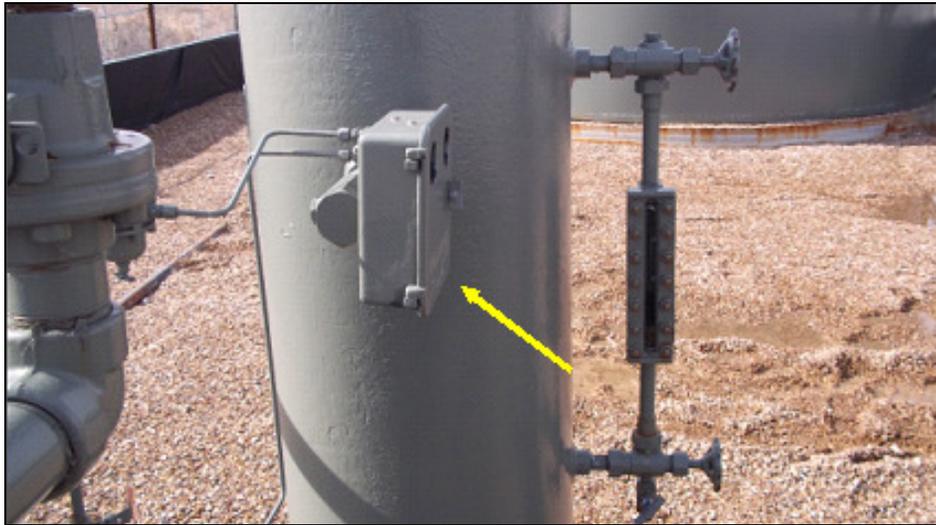

Figure 3.7-2. Pneumatic Valve Controller on Separator

- Emissions from 175 storage tank vents were detected by the IR camera accounting for a combined total of 2,076 tons of TOC per year. In numerous instances several tanks would be manifolded to one vent controlled by a pressure relief valve. In these cases, vent emissions detected with the IR camera indicated a failure of the pressure relief valve.

Figure 3.7-3. Storage Tank Vent

- Emissions from 257 leaking natural gas pressure regulators accounted for a combined TOC total of 614 tons/yr.

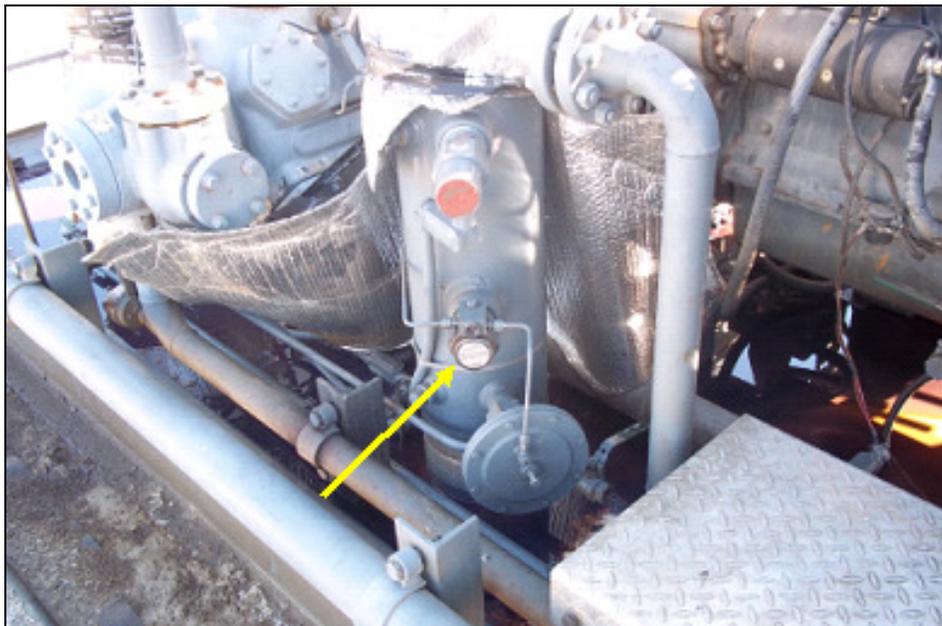

Figure 3.7-4. Natural Gas Pressure Regulator

- Fifty-five (55) instances of emissions from miscellaneous equipment were detected, accounting for a combined TOC emission rate of 731 tons/yr. Miscellaneous equipment includes pinholes, compressor shafts, sumps, knock-out pots, underground piping, glycol contactor controllers, pressure indicators, and quite frequently, holes or breaks in the tank roofs (Figure 3.7-5).

Figure 3.7-5. Hole in Tank Roof - Miscellaneous Emission Source

- No natural gas emissions associated with drilling and fracking activities were detected by the IR camera. Engine emissions associated with these activities were estimated based upon vendor data and published emission factors.
- Emissions were detected from a well completion activity with the IR camera. However, no measurements were taken using the TVA and Method 21 screening procedures and/or the highflow sampler due to safety considerations.
- Emissions were also detected at the Salt Water Treatment facility using the TVA. No emissions were detected using the IR camera. The emissions that were detected with the TVA resulted from minor fugitive emission components only. The Evaporative Unit was not able to be tested since it was out of service during the point source survey.
- Although there was little difference in average TOC emissions between dry and wet gas sites, average VOC and HAP emissions from wet gas sites proved to be considerably higher than dry gas sites as would be expected due to the additional storage and loading of condensate at wet gas sites.
- An Encana Oil & Gas Well Pad (Site ID PS-184) located at 10590 Chapin Road had the highest VOC emissions among well pads (22 tons/yr). This site had only a single well, with two tanks. However, it also had one large line compressor (Caterpillar G-399). Twelve (12) emission points were detected at this site with the IR camera: Four in the area of the separators, three on the tanks, and five at the compressor.

4.0 Air Dispersion Modeling

Existing well pads and compressor stations in the city of Fort Worth emit air pollutants that affect off-site air quality. Under Task 4, a modeling analysis was conducted to quantify downwind impacts from natural gas activities at facility property lines and beyond using the latest EPA-approved models and methodologies. Modeling was conducted for 91 pollutants for which emission rates were measured and/or estimated under the Point Source Testing task (Task 3). See Section 3 of this report for details on how the point source emission estimates were derived. The modeling did not include criteria pollutant emissions from natural gas combustion in the compressor engines, and only considered emissions data from the well pads. Emissions from other source types, such as onroad emissions, were not considered for this task.

The modeling results can also be used to assess the adequacy of existing setback distances; as well, they were also used in the public health evaluation performed under Task 7 of this project. The findings of the public health evaluation, including a detailed analysis of the modeling results and their implications relative to the city's required setback distances, can be found in Section 5 of this report.

This section has five sub-sections:

- 4.1 Modeling Scenarios and Source Parameters – A description of how the modeling scenarios were established is provided in this section.
- 4.2 Modeling Inputs and Options – This section provides the specific modeling inputs and options used to conduct the dispersion modeling.
- 4.3 Model Output – Summary tables showing the maximum 1-hour, 24-hour, and annual modeled impacts are provided in this section.
- 4.4 Electronic Modeling Files – This section provides electronic versions of the modeling input and output files.
- 4.5 Air Dispersion Modeling Conclusions – This section presents the conclusions of the air dispersion modeling task.

4.1 Modeling Scenarios and Source Parameters

There are over 500 individual well pads and compressor stations within the city of Fort Worth. While many of these sites are similar with respect to source types and emissions profiles, there is a wide variety of configurations of the emission sources at each site. For this analysis, as described in the Work Plan, four different scenarios were modeled that represent both average and potential worst-case estimates of modeled impacts based on actual emissions from source testing, source position relative to the property line, source alignments relative to one another, and associated downwash structure effects.

All emission sources observed during the point source testing were considered, and have been categorized and modeled as storage tanks, fugitive emission points, and compressor engines. A summary of these three source categories follows.

Storage tanks were modeled as pseudo-point sources, using an exit velocity of 0.001 meters per second and a stack diameter of 0.001 meters, along with ambient exhaust temperature. These stack parameters were chosen to produce conservative estimates of impacts from the tanks; such parameters effectively negate any airflow from the source, thereby eliminating the effect of vertical displacement on the plume. This approach is widely used in many states throughout the U.S., and is considered standard modeling practice for sources of this type. A hypothetical tank layout for each site, including tank diameters and heights, was used to determine the potential for downwash effects using AERMOD's included Plume Rise Model Enhancements (PRIME) algorithms. Based on ERG's understanding of the emission sources at each site, the tanks are the only sources that would significantly impede the free flow of air, so direction-specific source dimensions were only calculated for storage tanks. Figure 4.1-1 shows a battery of six storage tanks at a well pad (emissions associated with the horizontal separators shown on the right side of this image are accounted for with the fugitive emission points as discussed below).

Figure 4.1-1. Storage Tanks

All *fugitive emission points* were modeled as a single elevated area source. This source category includes estimated emissions from piping, valves, and connectors associated with emission sources such as wellheads, separators, or pneumatic liquid level controllers. A release height of 6 feet was assumed, representing the average height of all the piping and associated equipment. This source category included every emission type not modeled under the storage tank or compressor engine source category. Figure 4.1-2 shows a close-up view of equipment at a well pad or compressor station that may emit fugitive emissions.

Figure 4.1-2. Fugitive Emission Points

For *compressor engines*, emissions from the combustion of natural gas were modeled as standard point sources, using representative exhaust flow and temperature. Fugitive emissions of natural gas from piping associated with the gas compression process are included with the fugitive emission points discussed above. Figure 4.1-3 shows a compressor engine located at a compressor station.

Figure 4.1-3. Natural Gas Compression Engine

Table 4.1-1, below, summarizes the different types of source categories at well pads and compressor stations in Fort Worth, along with the modeling classification of each source.

Table 4.1-1. Source Types Modeled

| Source Category | Number of Modeled Sources per Well Pad or Compressor Station | Modeling Classification |
|--------------------------|--|-----------------------------------|
| Storage tanks | 5 to 10 | Pseudo-point source with downwash |
| Fugitive emission points | 1 | Elevated area source |
| Compressor engines | 0 to 6 | Point source |

The four modeling scenarios are described in more detail below.

4.1.1 Scenario 1 (Typical Well Pad)

This scenario represents a typical well pad without compression and includes storage tanks and fugitive emission points. Emission rates are based on point source testing conducted under Task 3. Typical well pad emission sources include storage tanks, wellheads, separators, and pneumatic devices. All identified emission sources at a well pad without compression have been included in this scenario. Specifically, this scenario includes the following:

- Five storage tanks, each 10 feet tall and 15 feet in diameter, modeled as pseudo-point sources.
- Storage tank emission rates based on the average, pollutant-specific storage tank emission rate observed at all well pad sites.
- Emission rates from fugitive emission points (wellheads, separators, pneumatic devices, piping, etc.) based on the average, pollutant-specific well pad emission rate observed during point source testing, modeled as a single elevated area source.
- Well pad measuring 200 feet by 200 feet.

Key Point: Scenario 1

Emission rates modeled under Scenario 1 represent the average emission rates from storage tanks and fugitive emission points from all well pads tested under this study.

Table 4.1-2 shows the emission rates used in the modeling demonstration for Scenario 1.

Table 4.1-2. Scenario 1 (Typical Well Pad) Model Input Emission Rates

^a Emission estimates are shown in this table using scientific notation. In scientific notation, the format "2.18E-05" is used to display a value of "0.0000218" by shifting the decimal place 5 places to the left using "E-" prefix. Likewise, the format "2.18E+05" would be used to display a value of "218,000" by shifting the decimal place 5 places to the right using "E+" prefix.

Figure 4.1-4 shows the layout of the typical well pad modeled under Scenario 1.

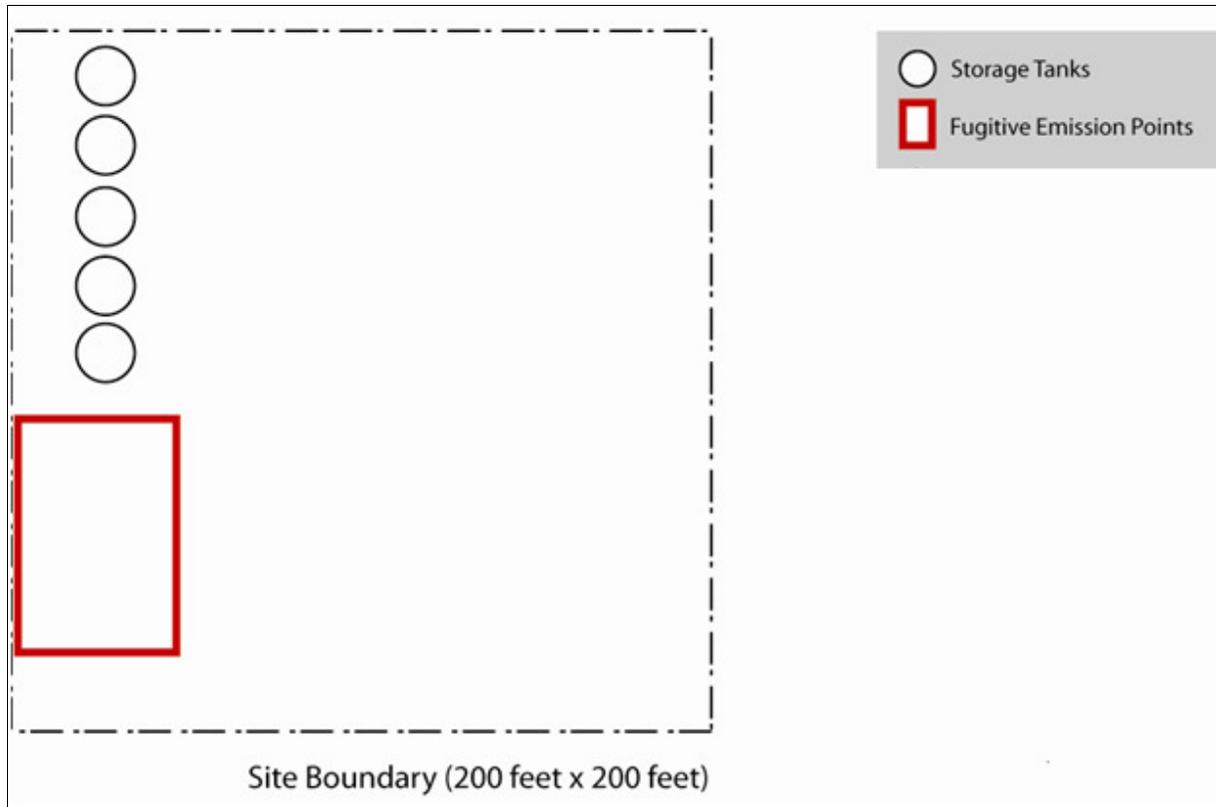

Figure 4.1-4. Scenario 1 Layout (Typical Well Pad)

4.1.2 Scenario 2 (Worst-Case Well Pad)

This scenario represents a worst-case well pad with storage tanks, fugitive emission points, and two compression engines (250 hp each). Emissions from combustion of natural gas in the compression engines are based on published emission factors, while emissions from storage tanks and fugitive emission points are based on point source testing. Specifically, this scenario includes the following:

Key Point: Scenario 2

Emission rates modeled under Scenario 2 represent the maximum emission rates from storage tanks and fugitive emission points from all well pads tested under this study.

- Ten storage tanks, each 10 feet tall and 15 feet in diameter, modeled as pseudo-point sources.
- Storage tank emission rates based on the maximum, pollutant-specific storage tank emission rate observed at all well pad sites.
- Two 250-hp compressor engines, uncontrolled, modeled as point sources.
- Emission rates from fugitive emission points (wellheads, separators, pneumatic devices, piping, etc.) based on the maximum, pollutant-specific well pad emission rate observed during point source testing, modeled as a single elevated area source.
- Well pad measuring 250 feet by 250 feet.

Table 4.1-3 shows the emission rates used in the modeling demonstration for Scenario 2.

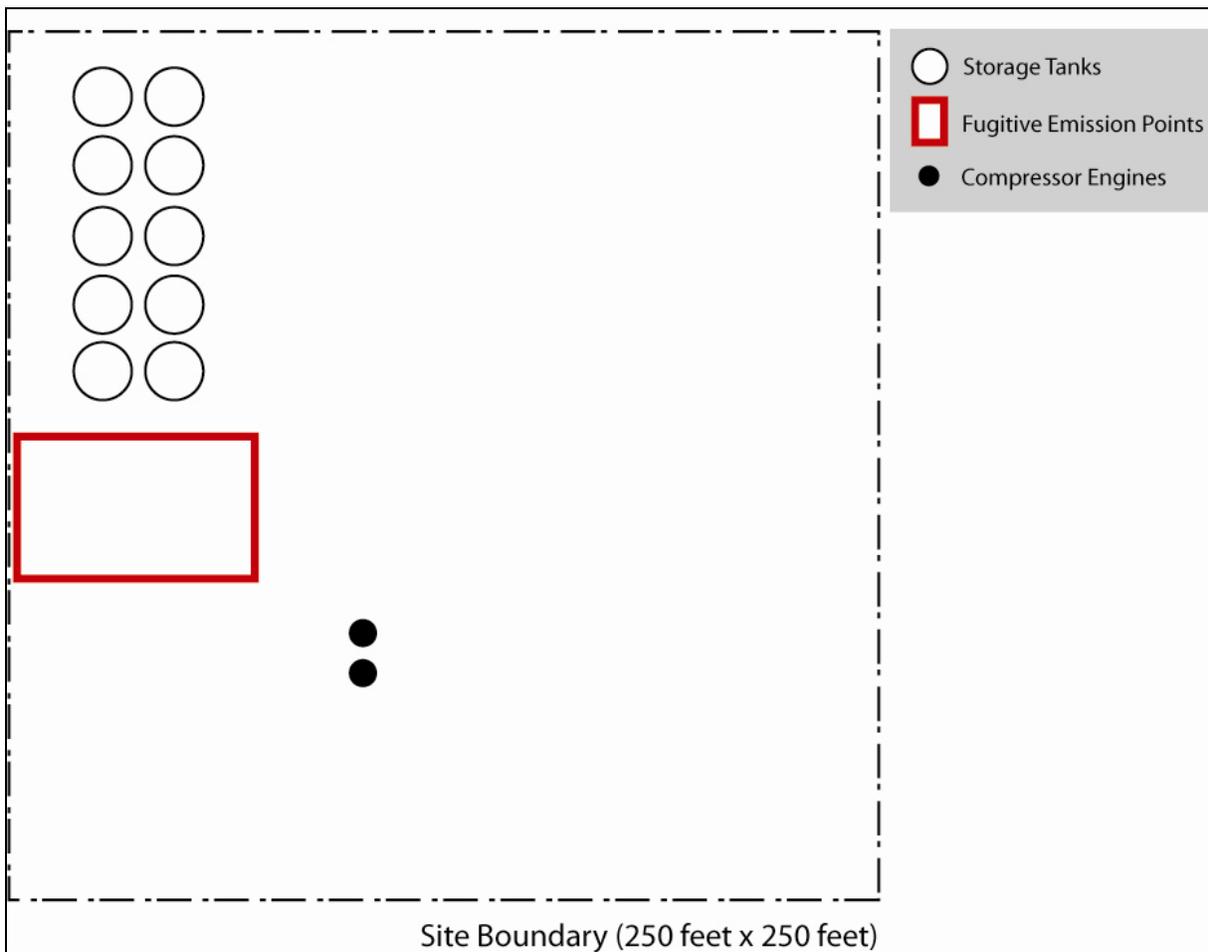

Figure 4.1-5. Scenario 2 Layout (Worst-Case Well Pad)

4.1.3 Scenario 3 (Worst-Case Compressor Station)

This scenario represents a worst-case compressor station with six compression engines (1,775 hp each). Emissions from combustion of natural gas in the compression engines are based on published emission factors, while emissions from storage tanks and fugitive emission points are based on point source testing. Specifically, this scenario includes the following:

Key Point: Scenario 3

Emission rates modeled under Scenario 3 represent the maximum emission rates from storage tanks and fugitive emission points from all compressor stations tested under this study.

- Storage tank emission rates based on the maximum, pollutant-specific storage tank emission rate observed at all compressor station sites.
- Eight tanks, each 10 feet tall and 15 feet in diameter, modeled as pseudo-point sources.
- Six 1,775-hp compressor engines, uncontrolled, modeled as point sources.
- Emission rates from all other sources (wellheads, separators, pneumatic devices, dehydrators, piping, etc.) based on the maximum, pollutant-specific compressor station emission rate observed during point source testing, modeled as a single elevated area source.
- Compressor station measuring 600 feet by 400 feet.

Table 4.1-4 shows the emission rates used in the modeling demonstration for Scenario 3.

Figure 4.1-6 shows the layout of the worst-case compressor station modeled under Scenario 3.

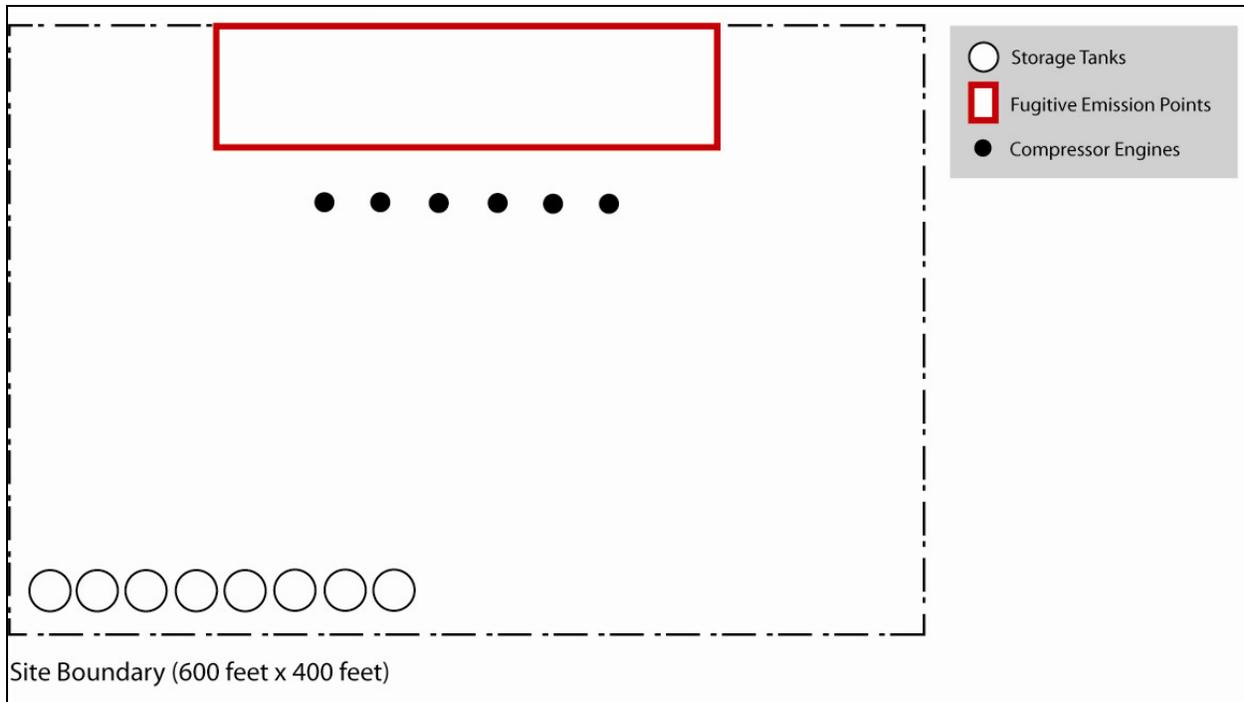

Figure 4.1-6. Scenario 3 Layout (Worst-Case Compressor Station)

4.1.4 Scenario 4 (Co-located Worst-Case Well Pad and Worst-Case Compressor Station)

This modeling scenario quantifies the combined impacts of the worst-case well pad in Scenario 2 and the worst-case compressor station in Scenario 3. This scenario assumes co-location of a well pad and a compressor station. The emission rates used in Scenario 4 are the same as used in Scenario 2 for the well pad and Scenario 3 for the compressor station.

Figure 4.1-7 shows the layout of the co-located well pad and compressor station modeled under Scenario 4.

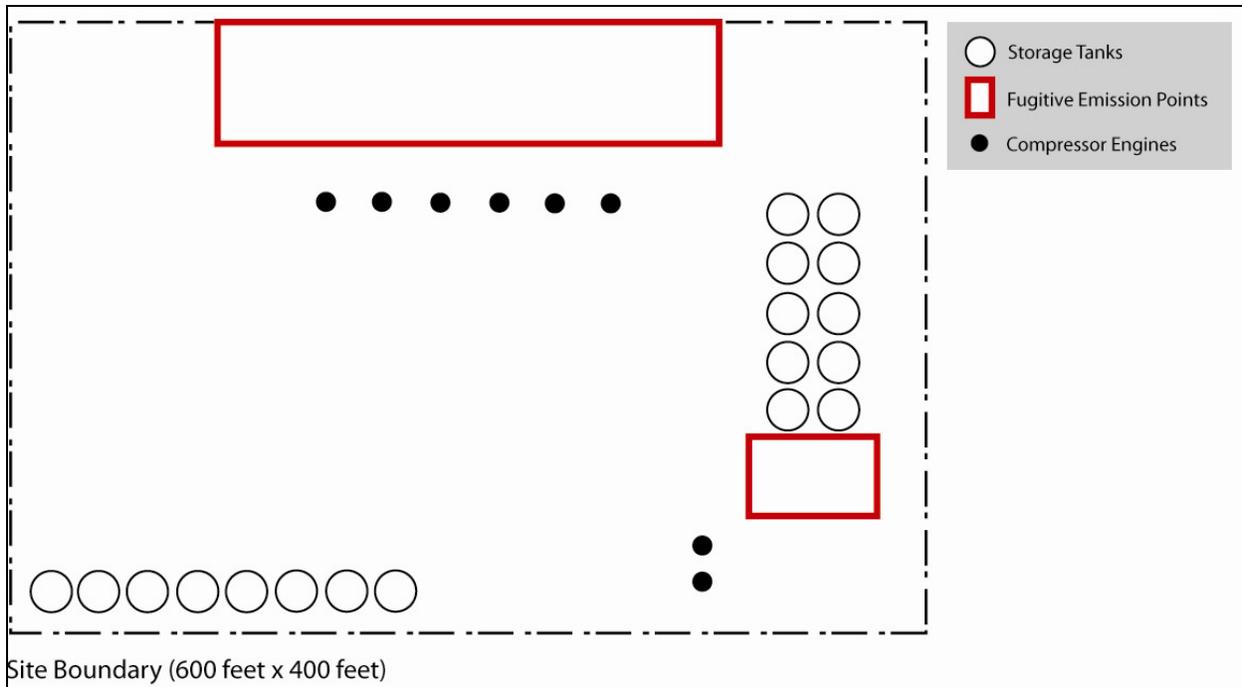

Figure 4.1-7. Scenario 4 Layout (Co-located Well Pad and Compressor Station)

4.2 Model Setup and Options

ERG used the latest version of the AMS/EPA Regulatory MODel (AERMOD), Version 11103, to estimate pollutant impacts for four different well pad and compressor station layouts. The modeling predicts, by scenario, 1-hour average, 24-hour average, and annual average concentrations for the pollutants listed in Section 4.1 above. Building downwash effects were simulated using the PRIME algorithm, which is included with AERMOD and is “designed to incorporate the two fundamental features associated with building downwash: enhanced plume dispersion coefficients due to the turbulent wake, and reduced plume rise caused by a combination of the descending streamlines in the lee of the building and the increased entrainment in the wake.”⁸ All model runs were constructed and executed using BEEST for Windows 9.90, a commercial dispersion modeling software package that combines AERMOD and its supporting programs into a single interface for use in model pre- and post-processing.

4.2.1 Receptor Grids

The modeling estimated air quality impacts at locations outside the property line of the well pads and compressor stations. Predictions were made from the property line out to a distance 2 kilometers away. Receptor grids of different resolutions were used to predict the maximum ambient concentrations around each site. ERG used 10-meter spacing along each site’s property fence line out to 40 meters; 25-meter spacing from 50 to 150 meters; 100-meter spacing from 200 meters to 1 kilometer; and 200-meter spacing between 1 and 2 kilometers. Because the terrain in the Fort Worth area is primarily flat, terrain heights of zero meters were assumed.

4.2.2 Meteorological Data and Surface Parameters

The meteorological data used in this analysis was obtained from TCEQ. It has been preprocessed to ensure data quality, and is approved for use in AERMOD for state and federal modeling analyses. It consists of a single year of surface data from Dallas–Fort Worth International Airport (about 10 miles east-northeast of the Fort Worth) and upper air observations from Stephenville, Texas (about 60 miles southwest of Fort Worth) for 1988. The associated albedo for this dataset is 0.150, while the Bowen ratio is 0.600; both of these were input to the model. A “medium” surface roughness of 0.5 meters, corresponding to rural/suburban areas, was selected; this choice is representative of a large portion of Tarrant County, where natural gas well pads are primarily situated.

4.3 Model Output

A summary of maximum impacts for each scenario, pollutant, and averaging period of interest are presented in Tables 4.3-1 through 4.3-4 below. In most cases, these outputs represent impacts at the fence line defined in each scenario. Figure 4.3-1 presents a graphical illustration of formaldehyde impacts for each of the four scenarios. Please see section 5 for a detailed analysis of the public health implication of the modeling findings, as well as additional modeling graphics.

Impacts for all receptors are contained within the modeling output files, which are described in further detail in Section 4.4. All modeled concentrations are presented in ppbv (with the exception of PAH as noted below).

Table 4.3-1. Modeled Impacts—Scenario 1 (Typical Well Pad)

| Pollutant | Max 1-Hour Average (ppbv) | Max 24-Hour Average (ppbv) | Max Annual Average (ppbv) |
|--|---------------------------|----------------------------|---------------------------|
| Acetone | 7.20E+00 | 1.44E+00 | 4.07E-01 |

4.4 Electronic Modeling Files

Modeling input and output files are provided electronically in Appendix 4-A. This includes files associated with AERMOD as well as its downwash processing program, BPIP-PRIME, along with meteorological files. AERMOD inputs and outputs follow a specific naming convention: “ScenXX_1988_Pollutant.ext,” where XX is the scenario of interest (01 through 04), *Pollutant* is an abbreviation for the compound modeled, and *ext* is the extension denoting the file type. BPIP-PRIME files follow a similar convention, “ScenXX-Prime.ext.” The various types of files included in Appendix 4-A are described below. Table 4.4-1 contains a crosswalk table which associates the compound abbreviations used in the BEEST modeling package with their proper chemical names.

Model Input Extensions

- **DTA**—AERMOD runstream files
- **PIP**—BPIP-PRIME inputs files
- **SFC**—Surface meteorological data
- **PFL**—Upper Air meteorological data

Model Output Extensions

- **GRF**—AERMOD detailed plot files
- **LST**—AERMOD detailed list files
- **SUM**—AERMOD summary files
- **TAB**—BPIP-PRIME detailed results
- **SO**—BPIP-PRIME block outputs for use in the model runstream

Table 4.4-1. BEEST Pollutant Abbreviation Crosswalk

| Pollutant Abbreviation | Pollutant Name |
|------------------------|---|
| 1122TCE | Tetrachloroethane, 1,1,2,2- |
| 112TCE | Trichloroethane, 1,1,2- |

Table 4.4-1. BEEST Pollutant Abbreviation Crosswalk (Continued)

| Pollutant Abbreviation | Pollutant Name |
|-------------------------------|--|
| NUNDEC | Undecane, <i>n</i> - |
| OXYL | Xylene, <i>o</i> - |
| PAH | Polycyclic Aromatic Hydrocarbons (PAH) |
| PERYLENE | Perylene |
| PHENAN | Phenanthrene |
| PHENOL | Phenol |
| PROPANE | Propane |
| PROPYCL2 | Propylene dichloride |
| PROPYL | Propylene |
| PYRENE | Pyrene |
| SECBUTYL | Butylbenzene, <i>sec</i> - |
| STYRENE | Styrene |
| TOLUENE | Toluene |
| VINLYBRO | Vinyl bromide |
| VINYLAACE | Vinyl acetate |
| VINYLCCL | Vinyl chloride |

4.5 Air Dispersion Modeling Conclusions

Air dispersion modeling was conducted using the emission estimates developed under Task 3 (Point Source Testing) to estimate how releases from natural gas sites affect off-site air pollution levels. The estimated off-site air pollution impacts are fully analyzed in Section 5 of this report to determine if the city's required setbacks (as published in City Ordinance No. 18449-02-2009) for natural gas exploration and production sites are adequate to protect public health.

5.0 Public Health Evaluation

This section evaluates the ambient air monitoring data and the dispersion modeling results from a public health perspective. The evaluation compares measured and modeled air pollution levels to TCEQ's health-based screening levels. Additional context and more detailed evaluations are presented for the pollutants with estimated or measured air concentrations greater than these screening levels. The monitoring and modeling results are also used to assess the adequacy of the city of Fort Worth's setback distances for sites with natural gas exploration and production activity. Text boxes throughout this section highlight important findings for specific topics. This section has five sub-sections:

- 5.1 Methodology – Describes the approach used to evaluate the air data.
- 5.2 Interpretation of Ambient Air Monitoring Data – Includes a health screening analysis for the measured air pollution levels.
- 5.3 Interpretation of Dispersion Modeling Data – Includes a health screening analysis for the modeled air pollution levels.
- 5.4 Additional Context for Selected Pollutants – Provides further perspective for pollutants selected for further evaluation.
- 5.5 Public Health Evaluation Conclusions – Concisely summarizes the public health evaluation.

5.1 Methodology

The point source testing identified numerous pollutants that natural gas exploration and production activities in Fort Worth release to the air. Once emitted, these pollutants move through the air to downwind locations where residents can be exposed. Air pollution levels at a given time and location in Fort Worth are ultimately influenced by emissions from a wide range of sources, not just releases from natural gas exploration and production activity. Examples of other sources that affect Fort Worth's outdoor air quality include industrial facilities, motor vehicles, and gasoline stations.

Key Point: Screening Methodology

This study presents measured and modeled air pollution levels for more than 150 different pollutants. Health-based screening levels are used to identify which pollutants are most important from a health perspective.

Several factors must be considered when evaluating the public health implications of outdoor air pollution levels. Which pollutants are found in the air and at what concentrations? Over what duration are people exposed? Are the exposed populations uniquely susceptible to the effects of air pollution? Environmental and health agencies use different approaches when evaluating the public health implications of exposure to outdoor air pollution. In cases with thousands of measurements and estimates of outdoor air quality for numerous pollutants, a commonly applied methodology is to use health-based screening levels to determine which subsets of pollutants are of potential health concern.

Health-based screening levels are developed from scientific studies that have examined links between air pollution and health effects. To ensure that screening levels are protective of public health, the agencies that derive these values set them at levels considerably lower than

concentrations found to have been associated with adverse health effects. This means that residents are generally not expected to experience health effects when exposed to air pollution levels that are lower than health-based screening levels—but also that the levels are not thresholds for toxicity. Measured or modeled air pollution levels above a health-based screening level are not necessarily harmful, but they do require a more detailed evaluation to assess public health implications. Broadly speaking, this document uses the health-based screening levels to identify the subset of pollutants that require more thorough health evaluations.

This report primarily relies on screening levels published by TCEQ for evaluating the implications of inhalation exposure to outdoor air pollution, considering both measured and estimated air pollution levels. TCEQ has published two sets of screening levels for use in evaluating outdoor air quality issues:

- *Effects Screening Levels (ESLs)*. For many years, TCEQ has published and updated its ESLs. These values are primarily used in the permitting process, particularly when reviewing dispersion modeling data. TCEQ has developed separate ESLs for short-term and long-term exposure durations, where short-term values are typically used for assessing 1-hour average concentrations and long-term values are typically used for assessing annual average concentrations. Most of TCEQ's ESLs were developed based on health effects, but some were developed to protect vegetation or based on odor detection. The ESLs are not regulatory standards, but are used to interpret potential exposures to air pollution, primarily pollution levels predicted by models.

TCEQ advises that estimated air quality impacts and ESLs should be interpreted as follows: “If predicted airborne levels of a constituent do not exceed the screening level, adverse health or welfare effects are not expected. If predicted ambient levels of constituents in air exceed the screening levels, it does not necessarily indicate a problem but rather triggers a review in more depth.” The complete set of ESLs is available at <http://www.tceq.texas.gov/toxicology/esl>.

- *Air Monitoring Comparison Values (AMCVs)*. In addition to ESLs, TCEQ has more recently developed AMCVs, which are pollutant-specific ambient air concentrations that the agency has established to protect human health and welfare. In contrast to ESLs, which are primarily used when evaluating air pollution levels predicted by models, AMCVs are used when conducting health screening evaluations of air monitoring data. The complete set of AMCVs is also available online at <http://www.tceq.texas.gov/toxicology/AirToxics.html#amcv>.

In this section, the modeled and measured air pollution levels are presented alongside the corresponding health-based ESLs and AMCVs. For pollutants with air concentrations above the TCEQ screening levels, additional context is provided in Section 5.4 by presenting screening levels published by ATSDR and EPA. All screening values used in this report were accessed from agency publications in March 2011.

5.2 Interpretation of Ambient Air Monitoring Data

This section presents a health screening analysis for this program's ambient air monitoring data—the air pollution levels that were measured at eight locations in Fort Worth in September and October, 2010. Ambient air monitoring data are particularly useful for health evaluations, because they represent direct measurements of the air pollution levels that residents actually breathe, without introducing the uncertainty of models. These measurements reflect contributions from many different local emission sources. While many pollutants found in the air samples are emitted from natural gas exploration and production activity, not every pollutant is associated with this source. The dispersion modeling analysis (Section 5.3) comments further on incremental air quality impacts attributable specifically to the well pads and compressor stations.

The section first evaluates the sensitivity of the monitoring methods (Section 5.2.1) and then compares the measured concentrations for nearly 150 pollutants to health-based screening levels, for both short-term (Section 5.2.2) and long-term (Section 5.2.3) exposure durations. The purpose of the health screening analysis is to identify the subset of pollutants requiring further evaluation. The section concludes by acknowledging limitations and uncertainties inherent in the screening of the ambient air monitoring data (Section 5.2.4).

5.2.1 Sensitivity of Monitoring Methods

An important consideration when evaluating ambient air monitoring data is whether the measurement methods are capable of detecting air pollution at levels of interest. As Section 2 of this report describes, all ambient air monitoring for this study was conducted with methods developed by EPA and widely used in air toxics monitoring programs nationwide. To assess whether the methods were adequately sensitive to support a health evaluation, this section compares the detection limits achieved in this monitoring program to the pollutants' lowest health-based screening levels published by TCEQ, considering both short-term and long-term values.

Key Point: Measurement Sensitivity

The ambient air monitoring program used highly sensitive measurement methods. For all but two pollutants, the methods were capable of detecting air concentrations at levels below TCEQ's most protective health-based screening values. Therefore, the air pollution measurements were sensitive enough to support health evaluations.

Table 5.2-1 compares the ranges of pollutant detection limits for the two laboratories that analyzed samples to the lowest health-based screening levels published by TCEQ, whether for short-term or long-term exposure durations. The ERG laboratory analyzed all samples collected from Sites S-1 through S-5, and the TestAmerica™ laboratory analyzed all samples collected from Sites S-6 and S-7. When planning this program, ERG's goal was to achieve detection limits lower than health-based screening values for as many pollutants as possible, but particularly for pollutants that had previously been identified as potential concerns for these operations (e.g., benzene, formaldehyde). Shading is used in the table to identify pollutants whose ranges of detection limits were not lower than TCEQ screening levels.

As Table 5.2-1 shows, the ERG laboratory's detection limits were below the TCEQ health-based screening values for every pollutant considered, including for benzene and

formaldehyde. With just two exceptions, TestAmerica's™ detection limits were also below the screening values. For just two pollutants (1,2-dibromoethane and hexachloro-1,3-butadiene), TestAmerica's™ detection limits were higher than the most protective health-based TCEQ screening values, but only by small margins. This is not a significant limitation for the study, because both pollutants are primarily synthetic chemicals that are not typically associated with natural gas reserves. The modeling results presented in Section 5.3 confirm that these pollutants are not found at levels of health concern near natural gas sites in Fort Worth. Overall, the comparisons in Table 5.2-1 demonstrate that the measurement methods used in the ambient air monitoring program achieved adequate sensitivity for comparing measured concentrations to TCEQ's health-based screening levels.

Table 5.2-1. Ranges of Detection Limits, by Laboratory

| Pollutant | Lowest TCEQ Short- or Long-Term Health-Based Screening Level (ppbv) | | Range of Detection Limits (ppbv) ^{a,b} | |
|----------------------------------|---|----------|---|--------------|
| | Value | Type | ERG Laboratory | TestAmerica™ |
| Acetaldehyde | 25 | AMCV/ESL | 0.006–0.009 | NM |

NM = not monitored.

No screening level = For these pollutants, TCEQ has not published an ESL or an AMCV.

^a The two laboratories that analyzed ambient air samples—ERG and TestAmericaTM—measured different pollutants.

The ERG laboratory measured a greater number of pollutants, primarily because ERG had sole responsibility for measuring the carbonyl and SNMOC samples. For VOCs, TestAmerica'sTM measurements considered the following pollutants that were not measured by ERG: allyl chloride, *n*-butanol, 1,4-dioxane, methanol, and vinyl acetate.

^b In the final two columns, bold font is used to indicate pollutants for which the range of detection limits was not lower than the lowest health-based screening value. Refer to Appendix 5-A for further information on how health-based screening values were selected for this program.

^c For ethane, propane, and propylene, TCEQ has not published specific values for AMCVs or ESLs, but has instead labeled these pollutants as “simple asphyxiants.” The principal concern for asphyxiants at sufficiently high concentrations is that they displace oxygen in the air. A concentration of 0.1% (by volume) is used in this table as a very conservative estimated screening level for these pollutants.

5.2.2 Health Evaluation for Measured 24-Hour Average Concentrations

As described previously, ambient air monitoring occurred for two months at eight locations throughout the city of Fort Worth, and concentrations were measured for nearly 150 pollutants. All measurements were based on 24-hour average samples, and more than 15,000 observations were recorded over the course of the program.

When evaluating the monitoring data, ERG first considered whether the highest measured 24-hour average concentrations exceeded TCEQ's *short-term* health-based screening levels. Throughout the monitoring program in 2010, ERG made these comparisons in order to promptly identify any indications of imminent health hazards, but none occurred. Comparing 24-hour average measurements to *long-term* health-based screening values is scientifically inappropriate and is not done in this report. For every pollutant considered in the ambient monitoring program, Table 5.2-2 lists the highest 24-hour average concentration detected during the program, the location where this value was detected, and the lowest short-term, health-based screening level published by TCEQ. For this evaluation, the hierarchy for selecting screening levels follows: First, if a pollutant has a short-term *health-based* AMCV, that value was used in Table 5.2-1, even if a different ESL is available. The preference for AMCVs over ESLs was applied here because this is an evaluation of ambient air monitoring data, not modeling data. Next, if a pollutant does not have a *health-based* AMCV, the table displays the pollutant's short-term *health-based* ESL. If neither value is available for the pollutant, short-term *odor-based* ESLs are used, if available. The table also indicates which pollutants have no TCEQ screening values. Shading is used in the table to identify pollutants that had at least one measured 24-hour average concentration higher than the TCEQ short-term screening level.

Key Point: Short-Term Air Pollution Measurements

The ambient air monitoring data provide no evidence of 24-hour average concentrations reaching levels of health concern. Out of more than 15,000 air pollution measurements, only one exceeded a TCEQ health-based screening level for short-term exposures; but that one measurement was of questionable quality and was for a pollutant not typically associated with natural gas activity.

Table 5.2-2. Highest Measured Concentrations and TCEQ Short-Term Screening Levels

| Pollutant | Highest Measured 24-Hour Average Concentration ^a | | Lowest TCEQ <i>Short-Term</i> Health-Based Screening Level ^b | |
|----------------------------------|---|--|---|-------------------------|
| | Value (ppbv) | Monitoring Site Where Highest Value Occurred | Value (ppbv) | Type of Screening Level |
| Acetaldehyde | 9.06 | S-4 | 250 | AMCV |
| Acetone | 8.20 | S-7 | 2,500 | AMCV |
| Acetylene | 3.57 | S-4 | 25,000 | AMCV |
| Acrylonitrile | Never detected | | 20 | ESL |

| Xylene, <i>o</i> - | 0.94 | S-2 | 1,700 | AMCV |

^a In the column for highest concentrations, pollutant concentrations less than 1 ppb are rounded to two significant figures, and “never detected” indicates that the pollutant was not detected in any of the samples collected during the ambient air monitoring program.

^b Refer to Section 5.2.2 for a description of the hierarchy used in this table for selecting short-term health-based screening values.

^c For these pollutants, TCEQ has not published short-term *health-based* screening values; the values shown in the table are short-term *odor-based* screening values.

^d For ethane, propane, and propylene, TCEQ has not published specific values for AMCVs or ESLs, but has instead labeled these pollutants as “simple asphyxiants.” The principal concern for asphyxiants at sufficiently high concentrations is that they displace oxygen in the air. A concentration of 0.1% (by volume) is used in this table as a very conservative estimated screening level for these pollutants.

^e Hexachloro-1,3-butadiene is shaded because its highest concentration was higher than TCEQ’s short-term ESL. However, as Section 5.2.2 describes, this particular measurement is of questionable quality.

With one exception, every measurement made during the program was lower than TCEQ's short-term health-based screening levels, suggesting that the pollution levels would not cause adverse health effects among exposed populations. As the exception, a single detection of hexachloro-1,3-butadiene exceeded TCEQ's short-term health-based ESL. For the air sample collected at Site S-6 on October 7, 2010, TestAmerica™ reported a hexachloro-1,3-butadiene concentration of 0.369 ppbv, and TCEQ's ESL is 0.2 ppbv. For further context on this issue, ERG plotted the results of all 129 ambient air monitoring measurements for this pollutant (Figure 5.2-1). The following important observations are made about these measurements:

- The highest detected concentration (0.369 ppbv) exceeded the short-term ESL (0.2 ppbv) by a relatively small margin. This was the only sample with a measured concentration higher than the ESL.
- The highest measurement is of questionable quality. When originally reporting this sample result, TestAmerica™ noted two data quality issues. First, the analytical report indicates that the measured concentration (0.369 ppb) is higher than the method detection limit, but lower than the laboratory's reporting limit. The report further indicated that "...the user of this data should be aware that this data is of limited reliability." Second, the testing laboratory reported that the sample was analyzed after the recommended holding time for this particular monitoring method had passed, which introduces additional uncertainty into the result.
- The 128 other measurements (see Figure 5.2-1), including every measurement at the two monitoring stations near the highest natural gas production activity, were all lower than the ESL; and 125 of these measurements were non-detects.
- For further context, ERG also considered the outputs from the dispersion modeling analysis, including those based on well pads found to have the highest emission rates throughout Fort Worth. The comparison (see Section 5.3.1) showed that the highest outputs predicted by the model were considerably lower than the average concentrations of hexachloro-1,3-butadiene observed during the ambient air monitoring data.

The most logical and consistent explanation for the above observations is that the single hexachloro-1,3-butadiene concentration above TCEQ's ESL is not a reliable measurement.

In summary, for every pollutant considered in this program, ERG concludes that the ambient air monitoring data provide no evidence of 24-hour average concentrations reaching levels of health concern for acute exposures. Few pollutants shown in Table 5.2-2 do not have published short-term health-based screening levels. However, with the exception of methane, these pollutants were detected at relatively low quantities. The measured methane concentrations ranked the highest of all pollutants considered, which was not a surprising result considering that measurements occurred in close proximity to active well pads. Though elevated, these methane concentrations did not approach values that would present a physical hazard (such as the lower explosive limit of 5%, or 50,000,000 ppbv) or an asphyxiation hazard, which are the two safety and health endpoints most frequently evaluated for this pollutant. A recent literature review

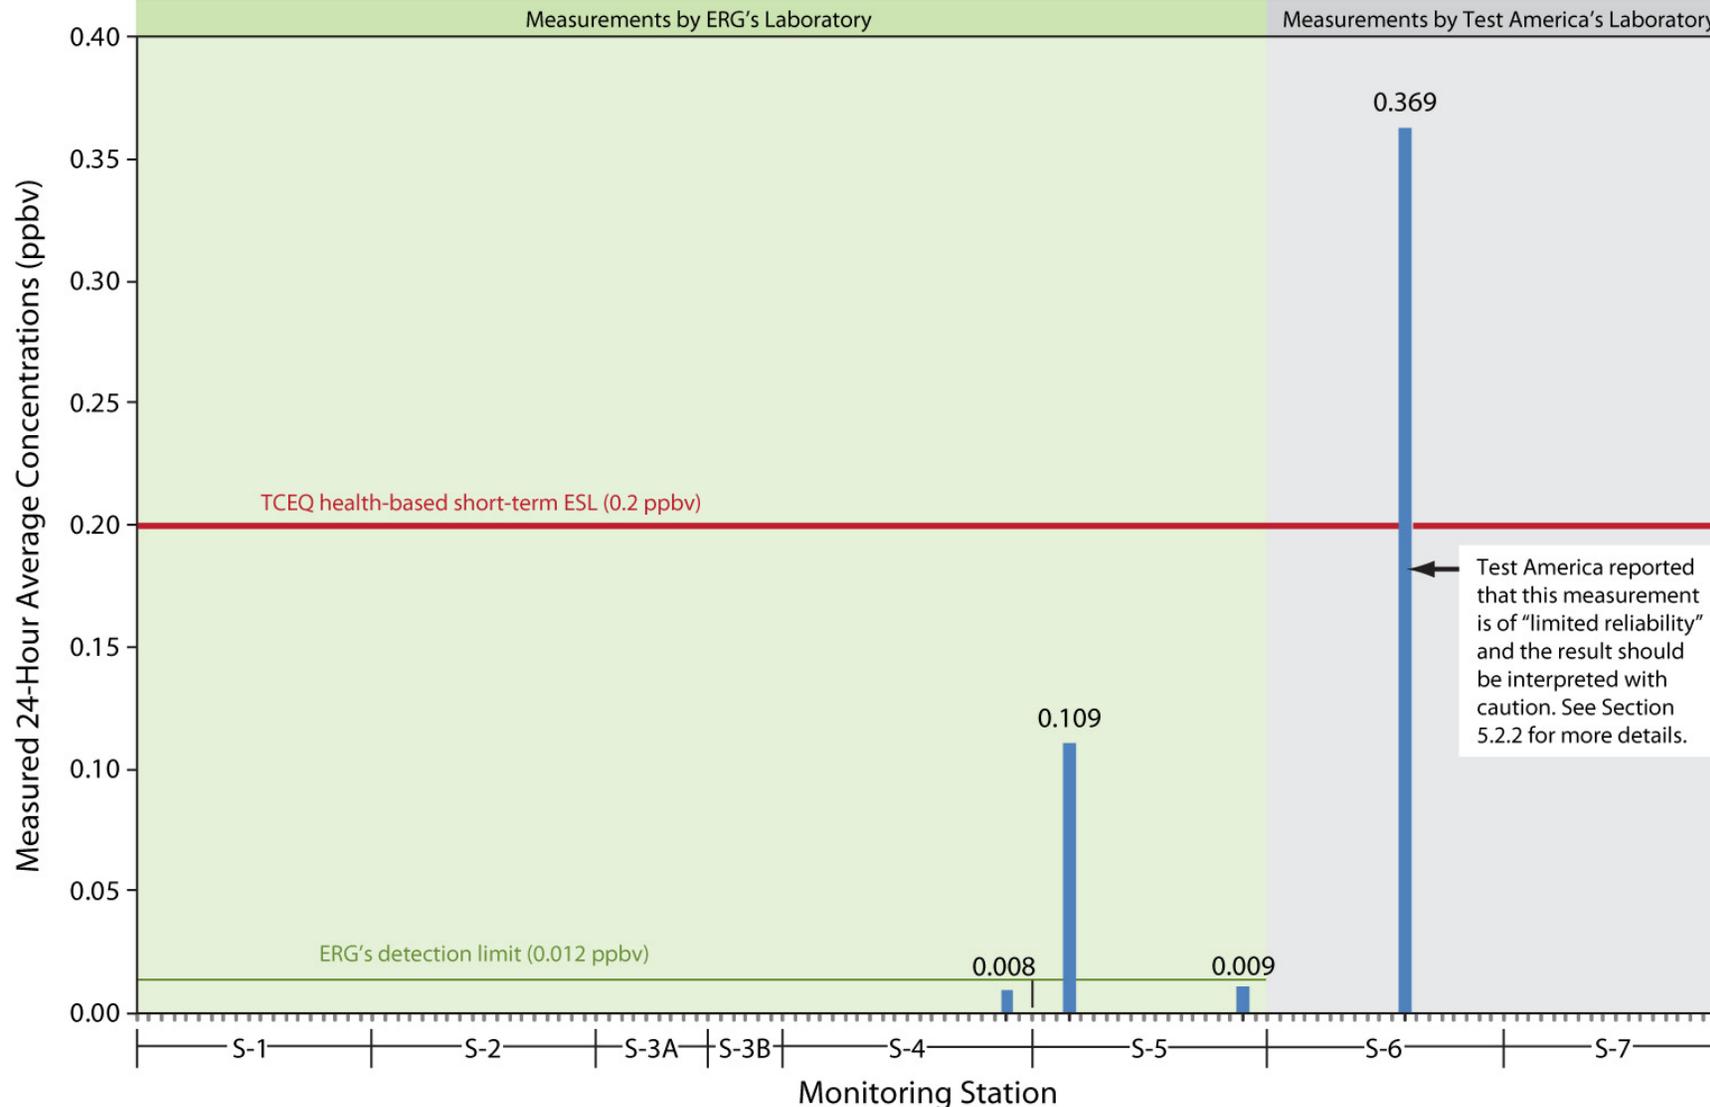

Figure 5.2-1. All Measurements of Hexachloro-1,3-Butadiene during the Ambient Air Monitoring Program

A tick mark is placed along the x-axis for every air sample that was analyzed for hexachloro-1,3-butadiene. The vertical columns display the measurement results for the four samples in which the pollutant was detected; the remaining 125 samples were non-detects. Detection limits are not displayed for the samples analyzed by TestAmerica™, because these values varied from one sample to the next.

documented in conference proceedings concluded that methane exhibits “no systemic toxicity” and supported the approach of assessing methane exposures by focusing on asphyxiation hazards.⁹ Similarly, the Canadian Centre for Occupational Health and Safety has concluded that “harmful effects are not expected following long-term exposure” to methane, though this same finding acknowledges a lack of information about underlying human studies.¹⁰ ERG conducted a supplemental literature search, but found no studies documenting adverse health effects in humans following long-term inhalation exposures to airborne methane.

5.2.3 Health Evaluation for Program-Average Concentrations

During this study, ambient air samples were collected every three days for two months. To assess the implications of longer-term exposures to the measured air pollution levels, ERG calculated average (i.e., arithmetic mean) concentrations for the individual pollutants at the eight different sites. These average concentrations represent two months of potential exposures, and were compared to longer-term health-based screening levels. The following paragraphs discuss this analysis.

When calculating average concentrations from individual sampling results, a decision must be made about how to handle non-detect observations, which are valid observations suggesting that a pollutant’s actual concentration in a sample had a value between zero and the detection limit. An approach commonly used when conducting health screening evaluations is to replace non-detects with a surrogate concentration of one-half the detection limit, and that approach is applied here. In cases where pollutants were detected in a large fraction of a site’s valid air samples, the approach used for replacing non-detects has little bearing on the magnitude of the calculated average concentrations, and the program-averages for the frequently detected pollutants are known to a high degree of confidence. On the other hand, for pollutants rarely detected in the air samples, there is considerable uncertainty associated with calculating the actual average concentrations—an observation revisited later in this section. Nonetheless, for sake of completeness, this analysis presents average concentrations for all pollutants detected in at least one sample.

Key Point: Program-Average Air Pollution Measurements

At the eight monitoring stations considered in this study, program-average concentrations for all but one pollutant were below levels of health concern. As the one exception, the program-average concentration of hexachloro-1,3-butadiene was higher than the TCEQ long-term effects screening level. However, this result is driven by a single unreliable measurement and is therefore of limited significance.

For every pollutant detected in the ambient air monitoring program, ERG compared the highest program-average concentrations to TCEQ’s corresponding long-term health-based screening levels. Table 5.2-3 lists the highest program-average concentration for each pollutant, the location where this value was observed, and the TCEQ screening level. For this evaluation, the hierarchy for selecting screening levels follows: If a pollutant has a long-term health-based AMCV, that value is used in Table 5.2-3 even if a different ESL is available; this preference again reflects the fact that TCEQ specifically derived AMCVs for evaluating ambient air monitoring data. Next, for pollutants that do not have AMCVs, the table displays the long-term health-based ESLs; and when no AMCV or ESL has been published for the pollutant, then “no screening level” appears in the table. Shading is used in the table to identify pollutants that had program-average concentrations higher than the TCEQ long-term screening level.

With one exception, every program-average concentration calculated for the pollutants listed in Table 5.2-3 is lower than the TCEQ long-term health-based screening values. This suggests that longer term exposure to the calculated program-average concentrations would not be expected to cause adverse health effects among exposed populations. The exception is again for hexachloro-1,3-butadiene. The calculated annual average concentration at monitoring site S-6 was 0.13 ppbv, which is higher than TCEQ's long-term ESL (0.02 ppbv). However, this calculated annual average concentration is highly uncertain, because it is driven entirely by a single measurement of questionable quality (see Section 5.2.2 and Figure 5.2-1) with the rest of the measurements at site S-6 being non-detects. ERG does not advise further evaluation of hexachloro-1,3-butadiene, given the extremely limited evidence of it being found in Fort Worth's air. ERG has no expectation of the chemical being found in underground shale formations, given that hexachloro-1,3-butadiene is a synthetic chemical that does not naturally occur in the environment.¹¹

Table 5.2-3. Program-Average Concentrations and TCEQ Long-Term Screening Levels

| Pollutant | Highest Program-Average Concentration ^a | | Lowest TCEQ Long-Term Health-Based Screening Level ^b | |

^a In the column for highest program-average concentrations, pollutant concentrations less than 1 ppb are rounded to two significant figures, and “never detected” indicates that the pollutant was not detected in any of the samples collected during the ambient air monitoring program.

^b Refer to Section 5.2.3 for a description of the hierarchy used in this table for selecting long-term health-based screening values. Several pollutants do not have any long-term screening values.

^c These program-average concentrations are highly uncertain, because the pollutant was detected in fewer than half of the samples at the site with the highest average. The values shown are heavily influenced by the use of surrogate values (one-half the detection limit) for the non-detects.

^d Hexachloro-1,3-butadiene is shaded because its highest concentration was higher than TCEQ’s short-term ESL. However, as Section 5.2.2 describes, this particular measurement is of questionable quality.

5.2.4 Measured Concentrations: Main Findings, Limitations, and Uncertainties

The ambient air monitoring program was designed to provide insights into the nature and magnitude of air pollution levels at eight locations in Fort Worth. The more than 15,000 individual measurements of outdoor air pollution levels allowed for a health evaluation that considered both peak and average air pollution levels. The program found no evidence of air pollution reaching levels of health concern at these eight monitoring locations. However, the ambient air monitoring program has some inherent limitations that should be acknowledged:

Key Point: Air Monitoring Data

Overall, the short-term and long-term air pollution levels measured during the monitoring program did not reach levels of public health concern. However, this finding pertains only to the pollutants considered in this study and the locations where measurements were made.

- The analyses throughout Section 5.2 are based strictly on the air samples that ERG collected at eight locations in Fort Worth over a two-month time frame. The data should not be used to make inferences about air quality during times when, and at locations where, samples were not collected. This does not mean that this study failed to meet its stated goals, because a dispersion modeling analysis was conducted to help characterize potential air pollution levels at locations that were not sampled. Thus, the interpretations of the modeling data (see Section 5.3) help address this inherent limitation of the monitoring program.
- The ambient air monitoring program considered nearly 150 air pollutants, including dozens that were also detected during point source testing. The coverage of the monitoring data is therefore very extensive, but not necessarily comprehensive. This program did not consider the complete range of air pollutants that might be emitted from natural gas sites. For example, the monitoring program did not measure acrolein, which the modeling (see Section 5.3) identified as a pollutant of potential concern for certain sites. Therefore, this study's findings apply only to the pollutants considered in the ambient air monitoring program and point source testing program, and should not be assumed to apply to a broader range of pollutants.

5.3 Interpretation of Dispersion Modeling Data

The dispersion modeling analysis conducted by ERG is an important complement to the ambient air monitoring data presented in Section 5.2. While the ambient air monitoring data has the advantage of directly measuring air pollution levels that residents might breathe, those data do not quantify how much different emission sources contribute to the measured concentrations. Further, the monitoring data do not characterize air quality for the entire range of well pad configurations. Dispersion modeling analysis was used to help fill these gaps. These models have the advantage of quantifying the incremental air quality impacts that can be attributed to natural gas exploration and production activity, based on the measured emission rates from the point source testing program. Section 4 of this report describes in detail the scope of the dispersion

modeling analysis, and the inputs and assumptions used; this section comments on the health implications of the modeling results.

5.3.1 Comparison of Modeled and Measured Air Pollution Levels

Before evaluating health implications, ERG first compared the air concentrations predicted by the model to the air concentrations measured during the monitoring program. This comparison was performed for a subset of pollutants that were considered for both the ambient air monitoring and point source testing programs. Table 5.3-1 presents these results.

Table 5.3-1. Monitor-to-Model Comparisons for Selected Pollutants

| Pollutant | Highest Program-Average Concentration Observed During the Monitoring Program (ppbv) | Highest Offsite Annual Average Concentration Predicted by the Dispersion Model (ppbv)^b |
|--------------------------|--|--|
| Acetaldehyde | 3.80 | 0.45 |
| Benzene | 0.69 | 3.99 |
| Butadiene, 1,3- | 0.092 | 0.037 |
| Carbon tetrachloride | 0.12 | 0.0016 |
| Chloroform | 0.050 | 0.00094 |
| Dibromoethane, 1,2- | 0.026 ^a | 0.00093 |
| Ethylbenzene | 0.24 | 0.22 |
| Formaldehyde | 1.14 | 4.40 |
| Hexachloro-1,3-butadiene | 0.13 ^a | 0.0050 |
| Tetrachloroethylene | 0.061 | 0.049 |
| Trichloroethane, 1,1,2- | 0.035 ^a | 0.00095 |
| Vinyl chloride | 0.046 ^a | 0.0021 |

^a These program-average concentrations are highly uncertain, because the pollutants were detected in fewer than half of the samples at the sites with the highest average concentrations. The values shown are heavily influenced by the surrogate values (one-half the detection limit) used for the non-detects.

^b For purposes of this table, “offsite” refers to any location at or beyond the facility fence lines for the modeling scenarios described in Section 4.

For many pollutants in the table, the highest program-average concentration observed during the monitoring program was considerably higher than the highest offsite annual average concentration predicted by the dispersion model—a trend that was particularly evident for the halogenated hydrocarbons. For purposes of this analysis, “offsite” refers to any location at or beyond the facility fence lines. Considering that the specific modeling results shown in Table 5.3-1 were based on the highest emission rates measured during the point source testing program, the substantially lower modeling results suggest that well pad and compressor stations emissions are not major contributors to the measured concentrations found during the ambient air monitoring program. In other words, even the highest emissions from well pads and compressor stations would not be expected to account for the levels measured in the ambient air for this subset of pollutants. ERG also considered the possibility that the modeling results might be biased low and therefore underestimating air quality impacts; however, this explanation does not appear to be likely, considering the fact that the modeling is based on the highest emission rates observed across all well pads that were tested. For the reasons stated above, ERG concludes that trace levels of halogenated hydrocarbons detected during the ambient air monitoring program cannot be attributed primarily to emissions from the natural gas exploration and production activity.

Conversely, for other pollutants listed in Table 5.3-1, the highest annual average concentration predicted by the modeling analysis was considerably higher than the highest program-average concentration calculated from the air sampling results. For benzene, the modeled concentration was nearly 6 times greater than the highest measured value; for formaldehyde, the measured and modeled values differed by nearly a factor of 4. For these two pollutants, the differences between the measured and modeled results most likely reflect the different scenarios portrayed by these data points. Specifically, the modeled values are estimates of the highest offsite annual average concentrations at the well pad or compressor station with the highest emissions—or the highest concentrations at or beyond the facility fence lines. On the other hand, the measured concentrations were intended to reflect some of the highest site-related air quality impacts; however, the monitoring generally did not occur at fence line locations, and the point source testing revealed that the ambient air monitoring stations were not close to some of the highest-emitting well pads. This discrepancy most likely explains why, for these two pollutants, the modeled concentrations were considerably higher than the measured ones.

5.3.2 Health Evaluation for Modeled 1-Hour Average Concentrations

As Section 4 describes, the dispersion modeling analysis was conducted for four different hypothetical scenarios, including some anticipated to represent the worst-case conditions for offsite air quality impacts. As noted previously, “offsite” in this section refers to any receptor location at or beyond the facility fence lines for the four modeling scenarios. Modeling was conducted for nearly 90 pollutants, depending on the scenario. Potential short-term air quality impacts are assessed here using the highest 1-hour average

Key Point: Short-Term Modeling

A model estimated how emissions from certain well pad and compressor station configurations affect local air quality. Of all pollutants considered, only acrolein, benzene, and formaldehyde had estimated 1-hour average concentrations greater than TCEQ’s short-term ESLs. The model output suggested that estimated methylene chloride concentrations might also exceed health-based screening levels, but this was based on a suspect measurement and is not a robust finding.

concentrations output by the dispersion model for any location at or beyond the fence lines of the modeled well pads and compressor stations. Fence line concentrations were considered for the short-term evaluation, because access restrictions do not prevent residents from walking alongside the production operations at these sites. The modeling estimates are based on the highest emission rates observed during the point source testing, combined with the meteorological conditions anticipated to lead to the least dispersion.

For every pollutant considered in the modeling analysis, Table 5.3-2 compares the highest estimated 1-hour average concentrations to TCEQ's health-based short-term screening levels. For this evaluation, the hierarchy for selecting screening levels follows: First, if a pollutant has a short-term *health-based* ESL, that value was used in Table 5.2-1, even if a different AMCV is available. The preference for ESLs over AMCVs was applied here because this is an evaluation of dispersion modeling data, not ambient air monitoring data. Next, if a pollutant does not have a *health-based* ESL, the table displays the pollutant's short-term *health-based* AMCV. If neither value is available for the pollutant, short-term *odor-based* ESLs are used, if available. The table also indicates which pollutants have no TCEQ screening values. Shading is used in the table to identify pollutants that had at least one estimated 24-hour average concentration higher than the TCEQ short-term screening level.

Table 5.3-2. Modeled 1-Hour Average Concentrations and TCEQ Short-Term Screening Levels

Table 5.3-2. Modeled 1-Hour Average Concentrations and TCEQ Short-Term Screening Levels (Continued)

| Pollutant ^a | Highest Estimated 1-Hour Average Concentration Beyond Well Pad Fence Lines (ppbv) | Lowest TCEQ <i>Short-Term Health-Based Screening Level</i> ^b | |
|------------------------|---|---|-------------------------|
| | | Value (ppbv) | Type of Screening Level |
| Vinyl chloride | 0.027 | 7,800 | ESL |
| Xylene, <i>m,p</i> - | 179 | 1,700 | AMCV |
| Xylene, <i>o</i> - | 10.6 | 1,700 | AMCV |

^a Acrolein, benzene, formaldehyde, and methylene chloride are shaded because their highest estimated 1-hour average concentrations were higher than TCEQ's short-term ESL. Refer to Section 5.3.2 for further information on these pollutants. Data are presented for all individual pollutants considered in the modeling analysis. As the exception, estimated concentrations are not presented for benzo(a)pyrene, benzo(k)fluoranthene, and perylene. For these pollutants, the estimated concentrations were so low that the model rounded the values to zero.

^b Refer to Section 5.3.2 for a description of the hierarchy used in this table for selecting short-term health-based screening values. AMCVs are used for those pollutants that do not have health-based ESLs.

^c For these pollutants, TCEQ has not published short-term *health-based* screening values; the values shown in the table are short-term *odor-based* screening values.

^d For ethane, propane, and propylene, TCEQ has not published specific values for AMCVs or ESLs, but has instead labeled these pollutants as "simple asphyxiants." The principal concern for asphyxiants at sufficiently high concentrations is that they displace oxygen in the air. A concentration of 0.1% (by volume) is used in this table as a very conservative estimated screening level for these pollutants.

The highest offsite air quality impacts were found for Scenarios 2, 3, and 4 in the modeling analysis. For pollutants emitted primarily by tanks, modeling Scenario 2 yielded the highest offsite 1-hour average concentration, primarily because this scenario had tanks placed along the northern fence line and southerly winds (i.e., winds blowing from south to north) prevail in Fort Worth. On the other hand, for pollutants released largely by engines, Scenarios 3 and 4 predicted the highest offsite air quality impacts, because these scenarios considered the largest engines.

As Table 5.3-2 shows, four pollutants considered in the modeling analysis had at least one estimated 1-hour average concentrations greater than lowest short-term health-based TCEQ screening levels. When reviewing these results, it is important to remember that the model estimates are based on the least favorable meteorological conditions for dispersion and for the highest-emitting well pads and compressor stations. Modeling Scenario 1, which was based on typical well pad emissions, had considerably lower estimated air quality impacts—and no 1-hour average concentrations greater than short-term screening levels.

ERG further examined the underlying modeling outputs and screening levels, and notes the following important observations:

- *Benzene.* ERG modeled air quality impacts of benzene at hundreds of offsite locations, commonly referred to as receptors. In Scenarios 1 and 3, every estimated 1-hour average concentration at every receptor was below TCEQ's short-term ESL. In Scenarios 2 and 4, only a single receptor—out of the hundreds modeled—had at least one estimated 1-hour average concentration greater than the ESL, and this occurred at just one receptor located at the fence line within a few feet of the tanks themselves. Receptors just 30 feet downwind showed no concentrations above the ESL. Further, at this one receptor, estimated 1-hour average benzene concentrations above the ESL occurred no more than 6 hours per year, and these values (54–59.5 ppbv) were only marginally above the health-protective ESL (54 ppbv). Recalling that these estimates are based on the highest emission rates measured in the point source testing program, the available modeling data suggest that only the single well pad found to have the highest benzene emissions would likely lead to offsite concentrations above the short-term ESL, and this would occur infrequently and only within a few feet of the highest-emitting tanks. ERG's main recommendation for benzene (see Section 5.5) is that city officials periodically review TCEQ's "auto-GC" sampling data for sites throughout the Barnett Shale formation, and evaluate whether any benzene concentrations ever exceed short-term screening levels. Should this occur, city officials should confer with TCEQ about proper interpretation of the monitoring data and the health implications for the particular monitoring site and for unmonitored locations.
- *Acrolein and formaldehyde.* These two pollutants are combustion by-products emitted by engines at the well pads and compressor stations. The magnitude of emissions—and offsite air quality impacts—depends on the type of engines used. Modeling Scenario 2 considered the smaller "lift engines," which typically fall between 150 and

250 hp. For this scenario, highest 1-hour average concentrations of acrolein and formaldehyde exceeded TCEQ's short-term ESL, but this only occurred at fence line locations for acrolein and at receptors within 100 feet of fence lines for formaldehyde. On the other hand, Scenarios 3 and 4 considered the larger "line engines," which operate at roughly 1,500 hp. For these scenarios, 1-hour average concentrations of acrolein greater than TCEQ's short-term ESL extended approximately 400 feet from the fence lines, and 1-hour average concentrations of formaldehyde greater than TCEQ's ESL were estimated to occur up to 750 feet beyond the fence lines. In the case of formaldehyde, the highest offsite 1-hour average concentration was estimated to be nearly 3 times higher than TCEQ's short-term ESL. Section 5.4 presents further information on the health implications of the estimated concentrations for these pollutants.

- *Methylene chloride.* As Table 5.3-2 shows, the highest estimated 1-hour average concentration of methylene chloride (145 ppbv) is higher than TCEQ's short-term ESL (75 ppbv). However, the modeling output for methylene chloride is based on an emissions measurement of suspect quality. Specifically, the emission rate used in the modeling analysis is based on a sample (#B015) collected on September 20, 2010, at a well pad (Site #PS-075). However, the analytical report for this sample includes two qualifiers. First, the laboratory reported a "B" qualifier, which indicates that methylene chloride was also detected in the method blank, raising questions about contamination of the sampling equipment. Second, the laboratory reported a "J" qualifier, which means the measured concentration was higher than the MDL but lower than the laboratory's reporting limit; the analytical report further states that "...the user of [J-qualified] data should be aware that this data is of limited reliability." For these reasons, ERG concludes that the highest estimated methylene chloride concentration shown in Table 5.3-2 is of questionable quality. If this one sample were omitted from the emissions estimation analysis, the next highest 1-hour average concentrations of methylene chloride predicted by the model would be substantially lower than TCEQ's short-term ESL. Accordingly, ERG does not recommend further evaluation of this pollutant.

Overall, the highest estimated 1-hour average concentrations predicted by the dispersion model are below TCEQ's health-based short-term screening levels for nearly every pollutant considered. For reasons stated above, ERG concludes that further evaluation is warranted for the air quality impacts of acrolein and formaldehyde, which had 1-hour concentrations above screening levels beyond the fence line of any site with operating lift engines or line engines. Section 5.4 provides further insights on these two pollutants.

5.3.3 Health Evaluation for Modeled Annual Average Concentrations

ERG assessed potential long-term exposures to site-related pollutants by evaluating the highest annual average concentrations output by the dispersion model. This comparison considered all locations more than 200 feet from fence lines of well pads and compressor stations. This downwind distance was selected because, although most gas well must be at least 600 feet from residences, city variances allow setback distances as low as 200 feet. The comparisons presented here represent a worst-case scenario: a full-time resident living just 200 feet from the highest-emitting well pads and compressor stations.

Key Point: Long-Term Modeling

A model was used to estimate annual average air quality impacts caused by emissions from well pads and compressor stations. Of all pollutants considered, only acrolein and formaldehyde had estimated annual average concentrations at locations at least 200 feet from fence lines greater than TCEQ screening levels. These air quality impacts are greatest for well pads and compressor stations with large line engines.

For every pollutant considered in the modeling analysis, Table 5.3-3 compares the highest estimated annual average concentrations to TCEQ's health-based, long-term screening levels. For this evaluation, the hierarchy for selecting screening levels follows: If a pollutant has a long-term health-based ESL, that value is used in Table 5.3-3, even if a different AMCV is available for the pollutant. This preference again reflects the fact that TCEQ specifically derived ESLs for evaluating dispersion modeling data, whereas AMCVs are the screening levels of choice when assessing ambient air monitoring data. The few pollutants that do not have long-term ESLs do not have any TCEQ health-based screening values, as indicated in the table. Shading is used in the table to identify pollutants that had at least one estimated annual average concentration at distances more than 200 feet from the fence lines higher than the TCEQ long-term screening level.

As Table 5.3-3 shows, only two pollutants considered in the modeling analysis—acrolein and formaldehyde—had estimated annual average concentrations greater than TCEQ's health-based, long-term ESLs. Across all pollutants, the highest annual average concentrations reported in the table were all observed for modeling Scenarios 2, 3, or 4. In contrast, Scenario 1, which was based on typical well pad emissions, had considerably lower estimated air quality impacts—and no annual average concentrations greater than long-term screening levels at any locations beyond the fence lines. Further information follows for the two pollutants with estimated annual average concentrations greater than screening levels:

- *Acrolein*. The highest annual average concentration of acrolein at locations at least 200 feet from fence lines predicted by the model (0.33 ppbv) was higher than TCEQ's health-based, long-term ESL (0.066 ppbv). However, considering receptors at least 200 feet from fence lines, only Scenarios 3 and 4 had at least one estimated annual average concentration of acrolein greater than TCEQ's ESL. This suggests that emissions from the larger line engines account for the only instances where estimated acrolein levels exceeded TCEQ's long-term ESL.

Table 5.3-3. Modeled Annual Average Concentrations and TCEQ Long-Term Screening Levels

^a Acrolein and formaldehyde are shaded because their highest estimated annual average concentrations were higher than TCEQ's long-term ESL. Refer to Sections 5.2.3 and 5.2.4 for further information on these pollutants. Data are presented for all individual pollutants considered in the modeling analysis. As the exception, estimated concentrations are not presented for benzo(a)pyrene, benzo(k)fluoranthene, and perylene. For these pollutants, the estimated concentrations were so low that the model rounded the values to zero.

^b Refer to Section 5.2.3 for a description of the hierarchy used in this table for selecting long-term health-based screening values. Several pollutants do not have any long-term screening values.

- *Formaldehyde.* The highest annual average concentration of formaldehyde predicted by the modeling analysis beyond 200 feet from a fence line was 4.34 ppbv—higher than TCEQ’s health-based, long-term ESL (2.7 ppbv). Estimated annual average concentrations greater than the long-term ESL were observed for Scenarios 3 and 4, but not at distances more than 600 feet from the fence lines.

In summary, for receptors at least 200 feet from fence lines, the highest estimated annual average concentrations predicted by the dispersion model are below TCEQ’s health-based long-term ESL for every pollutant and modeling scenario considered, except for acrolein and formaldehyde in Scenarios 3 and 4. This indicated that air emissions from line engines account for the highest estimated air quality impacts. Because this study relied upon estimated emission rates for these engines, consideration should be given to gathering additional information (e.g., measured emission rates from compressor engines, ambient air monitoring data downwind from the highest-emitting sites) to gain greater confidence in the conclusions for these pollutants. Sections 5.4 and 5.5 provide further insights on this issue.

5.3.4 Adequacy of Setback Limits

Taken together, monitoring and modeling data provide a basis for assessing the adequacy of the city of Fort Worth’s setback distances. The minimum setback distance required is 600 feet, though variances can lead to setbacks as low as 200 feet. The critical issue in evaluating setback distances is the extent to which air quality impacts decrease with distance from the facilities.

For some emission sources at well pads, particularly the tanks and fugitive emissions, estimated offsite air quality impacts peak at the fence line and decrease considerably with downwind distance. For instance, in Scenario 2, the highest annual average concentration of benzene at the fence line was 3.99 ppbv; the highest value at distances 200 feet from the fence line was 0.24 ppbv, falling to 0.04 ppbv at the 600-foot setback distance. Therefore, for this scenario, the annual average concentration decreased by 99% from the fence line to the setback distance. For pollutants emitted primarily or entirely by line engines and lift engines, the concentration gradient was notably less pronounced. In the case of acrolein for Scenario 4, for example, the maximum annual average concentration at the 600-foot setback distance was only 55% lower than the maximum offsite value.

Key Point: Setback Distances

For nearly every pollutant considered, the 600-foot setback distance appears to be adequately protective of public health, even for the highest-emitting sites. However, for sites with large line engines: (1) estimated annual average concentrations of acrolein are higher than TCEQ’s long-term ESLs at distances more than 600 feet from the fence line, and (2) for formaldehyde, estimated 1-hour average concentrations are higher than TCEQ’s short-term ESLs at some locations beyond the setback distance. Section 5.4 provides further context on these two pollutants.

To assess the setback distances, ERG focused on estimated air quality impacts at receptors 600 feet from fence lines, and additional insight is provided on distances as short as 200 feet, given the variances that can apply. A given well pad or compressor station’s air quality impacts depend on the nature and extent of the site’s emissions sources—the number and placement of tanks; the number, type, and size of engines; and so on. ERG’s assessment of the

setback distances is framed around the modeling results for the four scenarios defined in Section 4. For every scenario considered, Figures 5.3-1 through 5.3-3 illustrate how estimated annual average concentrations varied with location for acrolein, benzene, and formaldehyde. These pollutants were selected for the displays because they are the only site-related pollutants that had at least one offsite modeling result greater than a screening value.

ERG's assessment of the adequacy of the setback distances follows:

- *Well pads with tanks and fugitive emissions, but no engines.* The modeling results indicate that the setback distances are adequate for well pads equipped with tanks and fugitive emission sources, but no engines. Even in modeling analyses framed around the highest-emitting tanks and fugitive emissions, the setback distances were adequate for all pollutants considered (e.g., see Figure 5.3-1). Every estimated 1-hour average concentration at all offsite receptors was less than TCEQ's short-term ESLs, and every estimated annual average concentration at locations more than 200 feet from fence lines was less than TCEQ's long-term ESLs.
- *Well pads with tanks and lift engines.* Scenario 2 in the modeling analysis considered a well pad with two 250-hp lift engines. It also considered the highest measured emission rates for tanks and fugitive emissions. For this configuration, estimated annual average concentrations of all pollutants were lower than TCEQ's long-term ESL for receptor locations at least 200 feet from site fence lines. Further, estimated 1-hour average concentrations of all pollutants were lower than TCEQ's short-term ESL for receptor locations at least 600 feet from sites. While not an issue for the setback distances, some estimated 1-hour average concentrations of acrolein and formaldehyde exceeded TCEQ's short-term ESL, but this was limited to distances within 100 feet of the fence lines.
- *Well pads and compressor stations with line engines.* The primary issues for sites with line engines are emissions of acrolein and formaldehyde. For acrolein, estimated annual average concentrations exceed TCEQ's long-term ESL for several hundred feet beyond the 600-foot setback (see Figure 5.3-2). For formaldehyde, estimated annual average concentrations were below TCEQ's long-term ESL at all locations beyond the setback (see Figure 5.3-3), but some estimated 1-hour average concentrations were higher than the short-term ESL at a small number of receptors beyond the setback. While the estimated concentrations for these pollutants were higher than health-protective screening values, the modeled air quality impacts are lower than levels that have been actually associated with adverse health effects (see Section 5.4).

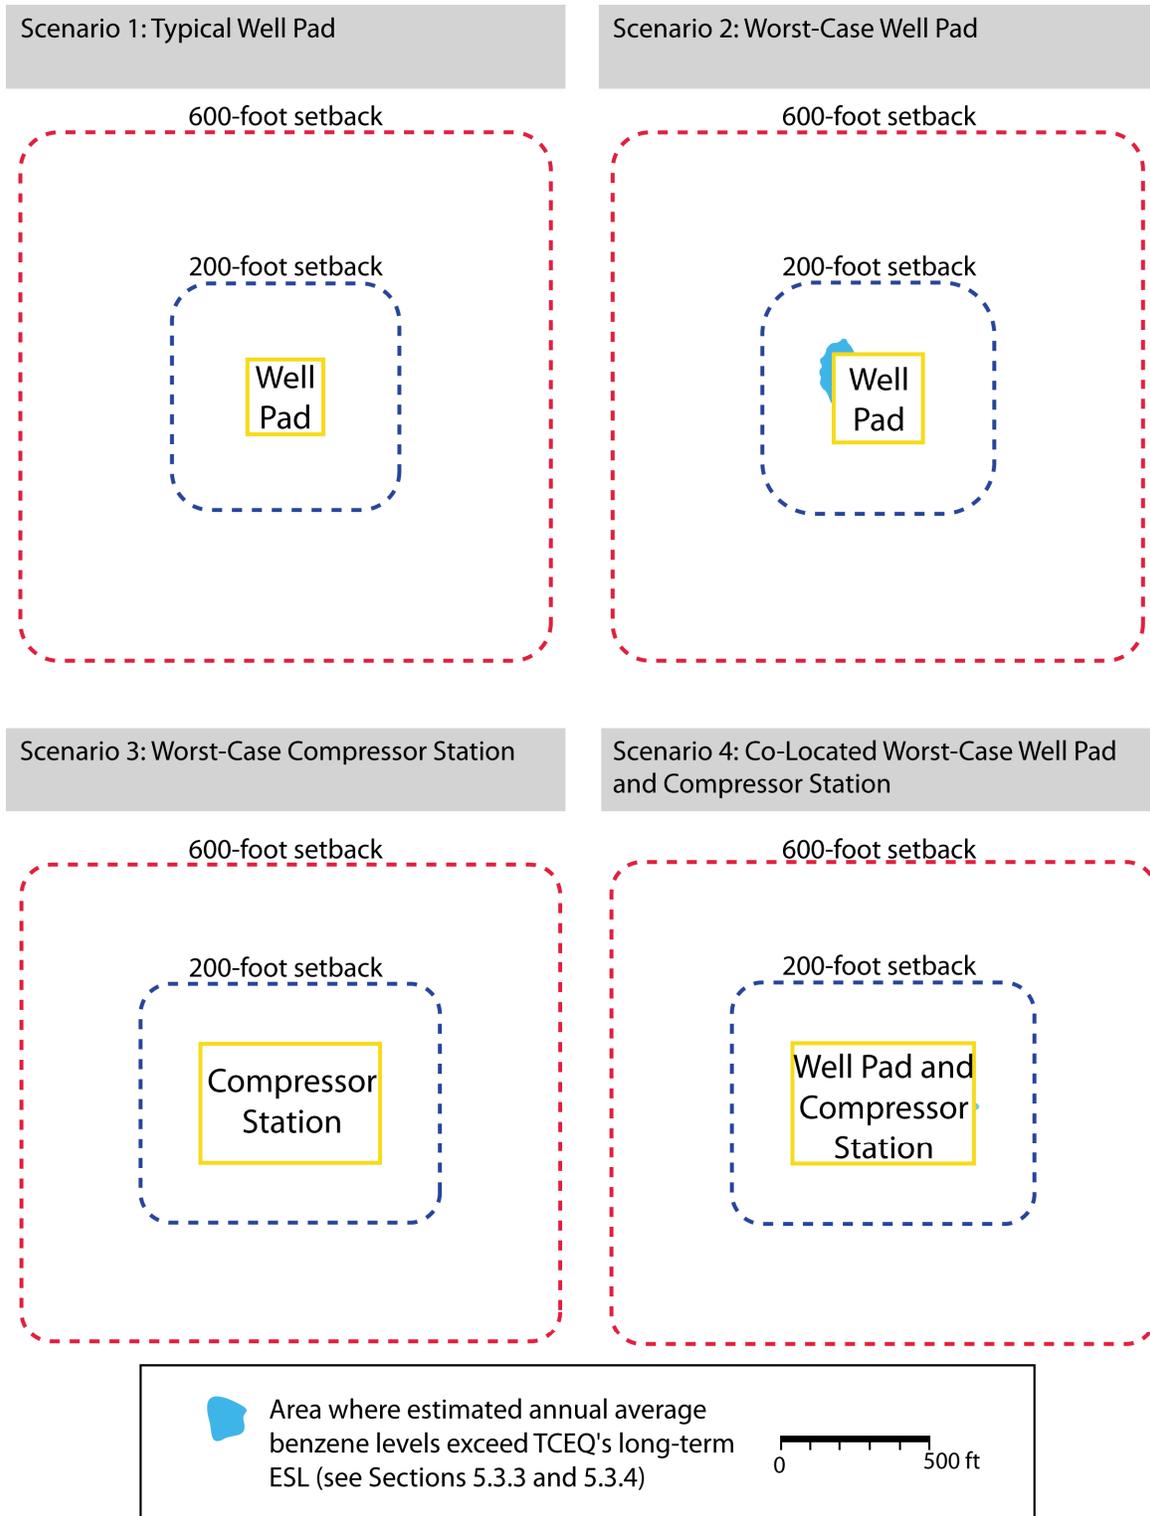

Figure 5.3-1. Locations of Estimated Annual Average Benzene Concentrations Greater Than TCEQ's Long-Term ESL, by Modeling Scenario

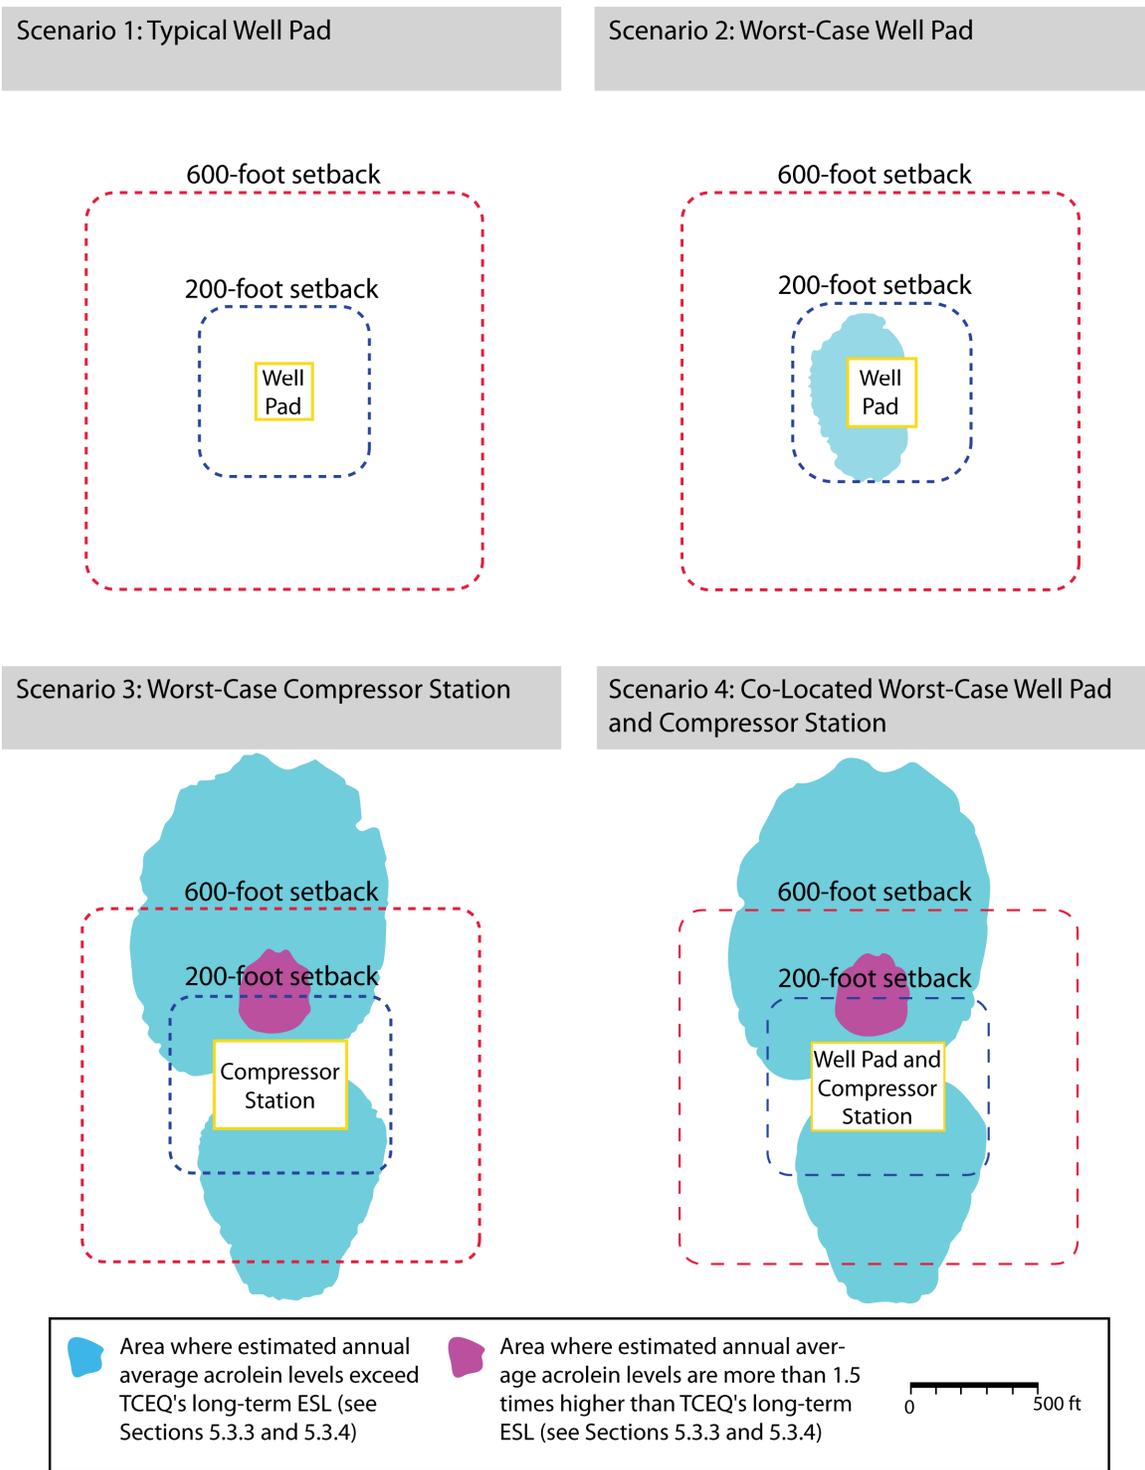

Figure 5.3-2. Locations of Estimated Annual Average Acrolein Concentrations Greater Than TCEQ’s Long-Term ESL, by Modeling Scenario

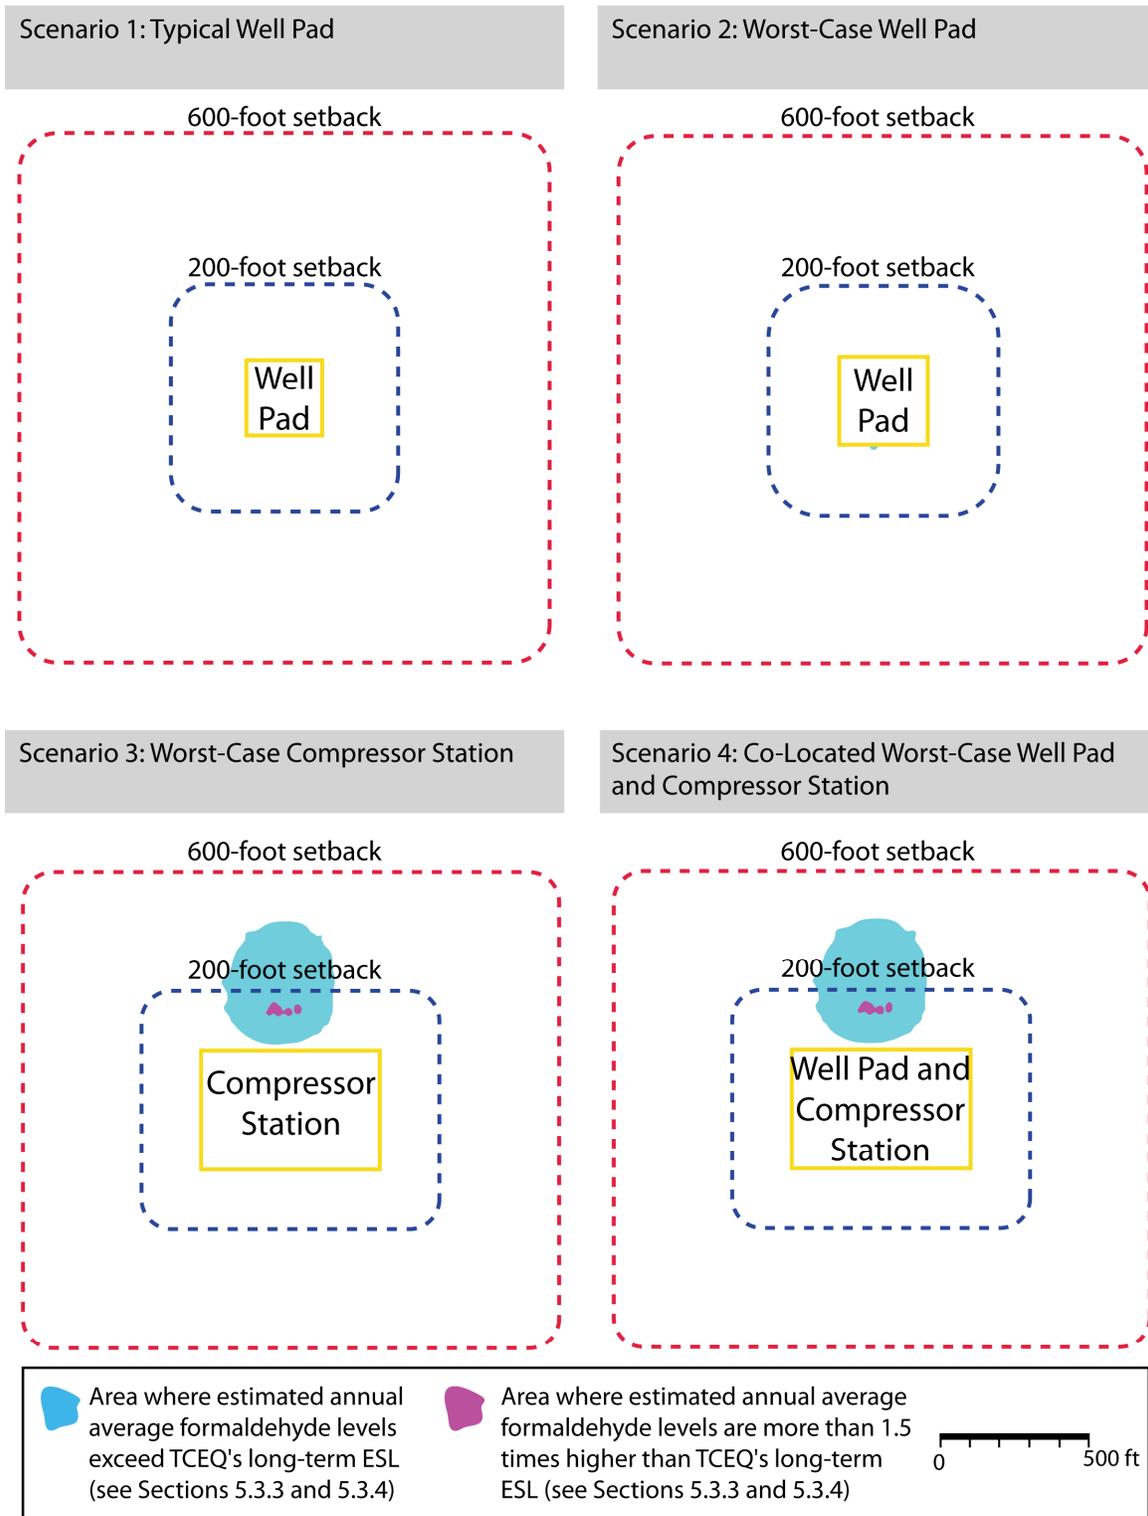

Figure 5.3-3. Locations of Estimated Annual Average Formaldehyde Concentrations Greater Than TCEQ's Long-Term ESL, by Modeling Scenario

In summary, for the overwhelming majority of sites considered in this study, the modeling analysis indicates that Fort Worth's 600-foot setback distance is adequate. For the relatively few sites with multiple, large line engines, the modeling analysis found some areas beyond the setbacks to have estimated acrolein and formaldehyde concentrations greater than TCEQ's ESLs. For both pollutants, ERG's modeling is based entirely on estimated emission rates, and not measured values. This underscores the value of obtaining more detailed acrolein and formaldehyde emissions data for line engines and focused ambient air monitoring to validate these findings. Such studies would provide greater confidence in the adequacy and protectiveness of the city's setbacks.

5.3.5 Modeled Concentrations: Main Findings, Limitations, and Uncertainties

The information presented throughout Section 5.3 is based entirely on the dispersion modeling analysis. Unlike ambient air monitoring data, which are direct measurements of air pollution levels, models provide estimates of ambient air concentrations. The accuracy of the modeling outputs depends on many factors, but especially on the representativeness of the emissions data input to the model. Emission rates for this study were based on measured and estimated data: emissions from tanks and fugitive sources were directly measured during the point source testing program, and emissions from lift engines and line engines were estimated using standard computational algorithms and EPA-published emission factors. For some pollutants, most notably acrolein and formaldehyde, the estimated offsite ambient air concentrations from the model are based entirely on the estimated emissions from lift engines and line engines. While these estimates were generated using the best information available to ERG, the methodologies may not adequately represent the types of engines typically used at well pads and compressor stations in Fort Worth. Because acrolein and formaldehyde are two pollutants of concern for this study, consideration should be given to reducing uncertainties associated with the estimated concentrations. This could be achieved by either additional point source testing at sites with line engines or air monitoring for these compounds downwind from a line engine site known to burn the largest quantities of natural gas.

Additionally, the modeling conducted for this study only evaluated dispersion, or the movement of the pollutants through the air from their sources to offsite receptors. Many of the pollutants emitted at the well pads and compressor stations are known to react in the air and form other pollutants, and this was not considered in the modeling analysis. Supplemental analyses using photochemical models might be warranted to more fully investigate the full range of air quality impacts on local air quality (e.g., consideration of contributions to ozone formation and other processes).

5.4 Additional Context for Selected Pollutants

The earlier analyses in this section identified acrolein and formaldehyde as the pollutants that are most likely to have site-related air quality impacts greater than TCEQ health-based screening levels at locations beyond the 600-foot setbacks. Additionally, estimated ambient air concentrations of benzene were found to exceed short-term screening levels in the immediate vicinity of the highest-emitting tanks. This section presents additional context for these pollutants, which includes comparisons to air pollution levels measured elsewhere in Texas and

further insights into toxicity. Finally, this section presents information on two pollutants that had estimated 1-hour average concentrations greater than *odor-based* short-term screening levels.

- *Benzene*. For additional perspective on benzene, ERG compared program-average concentrations calculated for all eight monitoring stations to 2010 annual average levels measured by TCEQ at 45 other locations statewide (see Figure 5.4-1). For the other statewide monitoring stations, 2010 statistical data summaries were downloaded from TCEQ's Texas Air Monitoring Information System.¹² ERG only considered sites that employed 24-hour average canister sampling technology—the same sampling approach used in the ambient air monitoring program. Further, ERG excluded any sites that had fewer than 40 valid 24-hour air samples over the calendar year, due to the large number of missing or invalid measurements for these sites. In the few cases where more than one monitor was placed at a given site, data from the monitor with the higher number of valid samples were used in this analysis.

Figure 5.4-1 shows how program-average concentrations of benzene from this study compared to annual average concentrations measured elsewhere in Texas. The figure lists the names of the cities where the other monitoring occurred. While some comparison stations are located near large petrochemical refineries and industrial complexes, several other comparison stations were located in residential and commercial settings away from such larger sources.

For seven out of eight monitoring stations in this study, the program-average benzene concentrations ranked relatively low when compared to 2010 annual averages for other monitors in Texas. However, program-average benzene levels at site S-4 ranked 11th out of the 53 sites shown in the figure. The relatively high ranking for this site likely reflects contributions from a nearby compressor station and well pad, and mobile source activity near the monitor. Overall, Figure 5.4-1 provides no evidence that benzene levels measured during this study were unusually elevated when compared to other monitoring stations in Texas. More importantly, the program-average concentrations for the Fort Worth monitoring stations are all lower than TCEQ's long-term health-based AMCV.

- *Acrolein*. As noted previously, acrolein was not a target analyte for the ambient air monitoring program. Even though many parties have previously measured airborne levels of acrolein at other locations in Texas and nationwide, recent studies have identified important data quality concerns associated with the ambient air monitoring methods that had been widely used for this pollutant. In December 2010, EPA summarized these concerns and began flagging past air measurements of acrolein as “unverified” if certain canister cleaning practices, calibration standards, and timely analysis were not applied.¹³

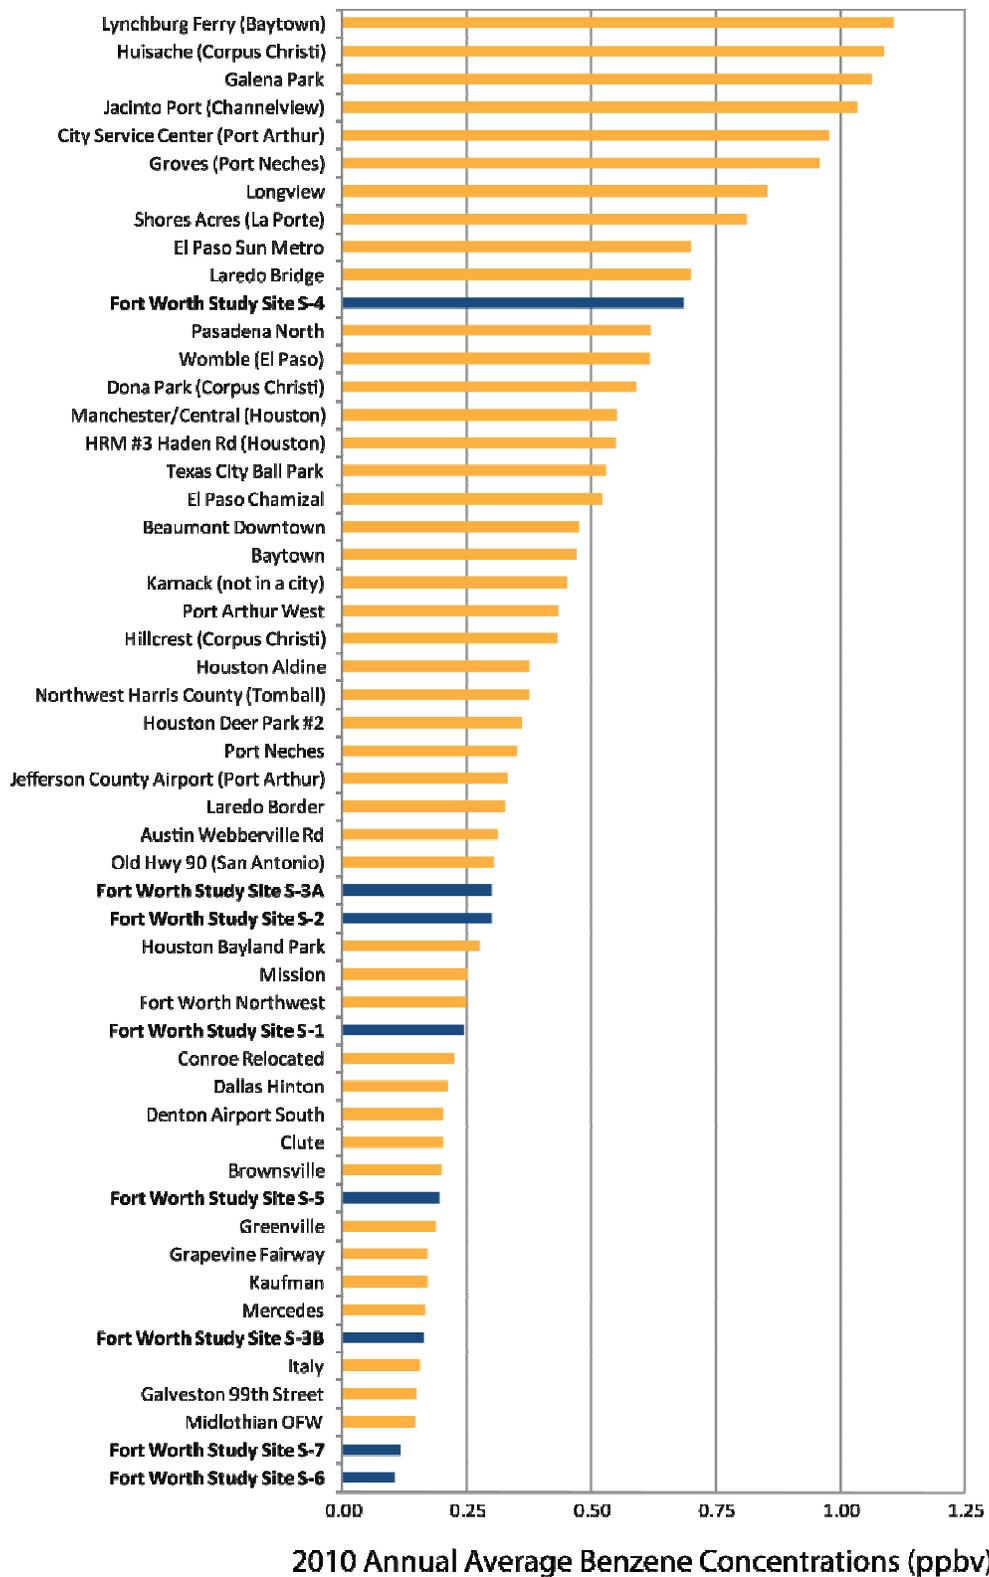

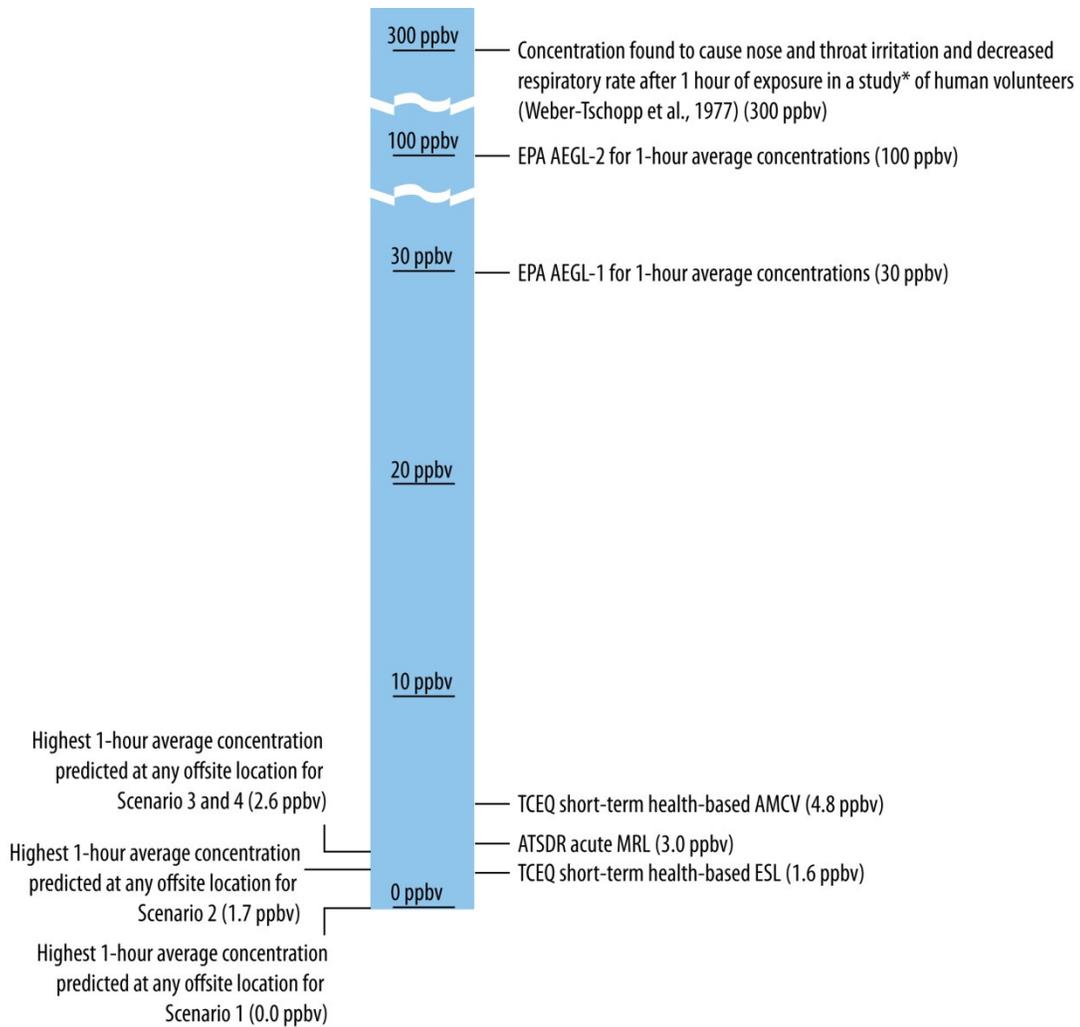

Figure 5.4-1. Comparison of Program-Average Benzene Concentrations in Fort Worth to 2010 Annual Average Benzene Concentrations Statewide (see Section 5.4)

Due to these and other data quality concerns that have been expressed for past measurements, the focus of this section is on acrolein toxicity. Extensive information is available on various non-cancer respiratory effects that have resulted from inhalation exposures to acrolein^{14,15}, and the following paragraphs assess whether the estimated acrolein air quality impacts are expected to result in adverse health effects, both for acute and chronic exposure durations. According to ATSDR, only limited, weak evidence is available suggesting that acrolein is carcinogenic¹², and no agencies have developed quantitative approaches for evaluating cancer risks for this pollutant. Potential cancer effects associated with acrolein exposures are therefore not evaluated here.

The assessment of acute, non-cancer effects is based on an earlier finding in this section indicating that lift engines and line engines are expected to contribute up to 2.6 ppbv to the highest offsite 1-hour average concentrations of acrolein. Figure 5.4-2¹⁶ compares this estimated air quality impact to screening levels published by multiple agencies. Most notably, the estimated 1-hour average air quality impact of 2.6 ppbv is lower than ATSDR's acute Minimal Risk Level (3.0 ppbv), which is defined as an exposure concentration that is likely to be without appreciable risk of non-cancer health effects. Further, the highest modeling result is more than 100 times below the lowest exposure concentration that has been documented to cause health effects in humans. It is therefore unlikely that even the highest 1-hour average concentration would be expected to cause adverse health effects among the general population.

Figure 5.4-3¹⁷ presents similar information on acrolein toxicity, but considering longer-term (e.g., annual) exposure scenarios. The highest annual average concentration estimated by the dispersion model varied considerably across model scenarios. For well pads with tanks and small lift engines, the highest annual average concentration predicted for receptors beyond the 600-foot setback distance was 0.012 ppbv—lower than health-based screening values published both by ATSDR and TCEQ. For sites having multiple, large line engines, which are represented by Scenarios 3 and 4, the highest annual average acrolein concentration beyond the 600-foot setback distance was 0.15 ppbv. While greater than certain screening values published by ATSDR, EPA, and TCEQ, this annual average concentration is still considerably lower than the lowest exposure concentration found to cause adverse health effects in laboratory studies.

Of all pollutants considered, acrolein was one of only two found to have estimated air quality impacts greater than highly protective screening levels at locations beyond the setback distances. The many layers of health-protective assumptions suggest that the estimated air concentrations would not lead to adverse health effects among residents who live beyond the setbacks. However, additional air sampling of acrolein is recommended to confirm these findings.

Definitions:

ATSDR Minimal Risk Level (MRL): "An estimate of daily human exposure to a hazardous substance that is likely to be without an appreciable risk of adverse non-cancer health effects."

EPA Acute Exposure Guideline Level (AEGL)-1: "The airborne concentration . . . of a substance above which it is predicted that the general population, including susceptible individuals, could experience notable discomfort, irritation, or certain asymptomatic non-sensory effects. However, the effects are not disabling and are transient and reversible upon cessation of exposure."

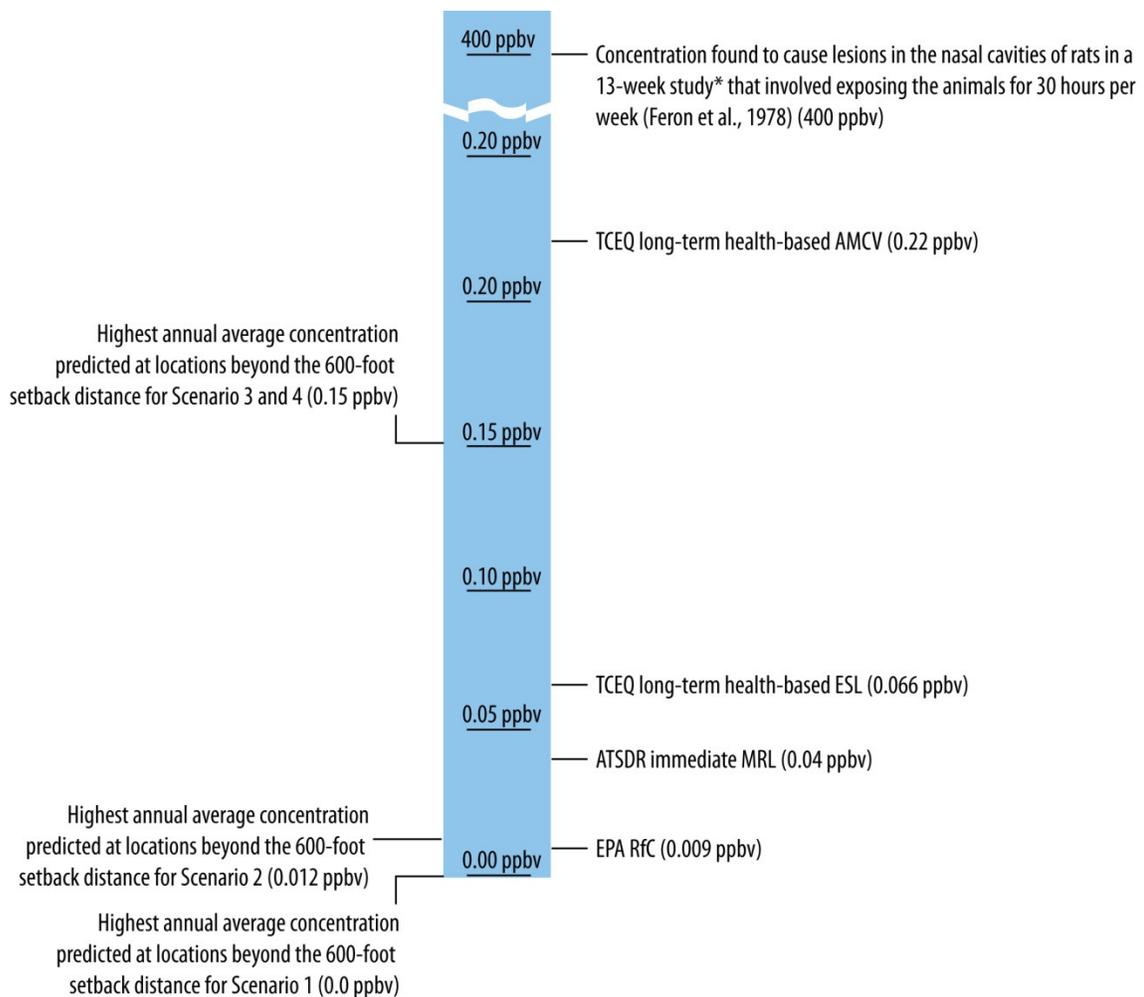

EPA Acute Exposure Guideline Level (AEGL)-2: "The airborne concentration . . . of a substance above which it is predicted that the general population, including susceptible individuals, could experience irreversible or other serious, long-lasting adverse health effects."

TCEQ ESL: "Used in TCEQ's air permitting process to evaluate air dispersion modeling's predicted impacts. . . If predicted airborne levels of a constituent do not exceed the screening level, adverse health or welfare effects are not expected. If predicted ambient levels of constituents in air exceed the screening levels, it does not necessarily indicate a problem but rather triggers a review in more depth."

TCEQ AMCV: "Chemical-specific air concentrations set to protect human health and welfare. Exposure to an air concentration at or below the AMCVs is not likely to cause adverse health effects in the general public, including sensitive subgroups such as children, the elderly, pregnant women, and people with pre-existing health conditions."

* The study described at the top of this figure was used to derive some of the screening levels shown.

Figure 5.4-2. Toxicity of Acrolein: Short-Term Exposures

Definitions:

ATSDR Minimal Risk Level (MRL): "An estimate of daily human exposure to a hazardous substance that is likely to be without an appreciable risk of adverse non-cancer health effects."

EPA Reference Concentration (RfC): "An estimate . . . of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime."

TCEQ ESL: "Used in TCEQ's air permitting process to evaluate air dispersion modeling's predicted impacts. . . If predicted airborne levels of a constituent do not exceed the screening level, adverse health or welfare effects are not expected. If predicted ambient levels of constituents in air exceed the screening levels, it does not necessarily indicate a problem but rather triggers a review in more depth."

TCEQ AMCV: "Chemical-specific air concentrations set to protect human health and welfare. Exposure to an air concentration at or below the AMCVs is not likely to cause adverse health effects in the general public, including sensitive subgroups such as children, the elderly, pregnant women, and people with pre-existing health conditions."

* The study described at the top of this figure was used to derive some of the screening levels shown.

Figure 5.4-3. Toxicity of Acrolein: Long-Term Exposures

- *Formaldehyde.* For additional context on measured and estimated formaldehyde levels, ERG compared program-average concentrations calculated for the two monitoring stations with available sampling data to 2010 annual average levels measured by TCEQ at six other locations statewide (see Figure 5.4-4). Data for the other monitoring stations were accessed from TCEQ's Texas Air Monitoring Information System¹² and processed following the same methodology that is documented for the benzene analysis. As Figure 5.4-4 shows, formaldehyde is routinely monitored at far fewer stations in comparison to benzene. However, at every other TCEQ station that met the site selection criteria, annual average concentrations of formaldehyde in 2010 were higher than the program-average concentrations calculated for monitoring sites S-4 and S-5. This suggests that the formaldehyde levels measured during the Fort Worth Natural Gas Air Quality Study were not elevated in comparison to other monitoring locations in Texas.

ERG also considered the health implications of the measured and modeled air quality impacts. This was done for both non-cancer health effects (for acute and chronic exposure durations) and for potential cancer effects (chronic exposures only). Figure 5.4-5¹⁸ provides additional context on the health implications of short-term inhalation exposures to formaldehyde. All measured 24-hour average concentrations during the ambient air monitoring program were considerably lower than the most health-protective screening levels. Further, the highest 1-hour average concentration predicted by the model for the highest-emitting site (34 ppbv) was not only lower than ATSDR's Minimal Risk Level, but substantially below the lowest concentration that has been shown to cause adverse acute health effects in humans. Accordingly, the peak formaldehyde air quality impacts identified in this study are not expected to cause acute health effects among city residents.

For chronic exposure durations, the highest program-average formaldehyde concentration calculated from the monitoring data and the highest annual average formaldehyde concentration estimated by the dispersion model were both lower than every applicable non-cancer screening level published by ATSDR and TCEQ. Therefore, even when considering the highest-emitting sites, the long-term air quality impacts of formaldehyde are not expected to cause adverse non-cancer effects. Figure 5.4-6¹⁹ provided additional context on the health implications of long term inhalation exposures to formaldehyde. ERG also considered cancer endpoints, given that formaldehyde has been classified as a human carcinogen. According to risk levels currently published on EPA's Integrated Risk Information System (IRIS),¹ formaldehyde concentrations between 0.06 ppbv and 6 ppbv are expected to have theoretical lifetime cancer risks between 1 in 1,000,000 and 1 in 10,000. This risk range is common for urban settings, and the theoretical cancer risks for Fort Worth are lower than those for every other monitoring site shown in Figure 5.4-4.

¹ New scientific information is continually becoming available on the links between certain air pollutants and adverse health effects. This is particularly true for formaldehyde, for which EPA, the National Academy of Sciences, and other entities have very recently published updates and reviews of the chemical's toxicity and carcinogenicity. However, EPA's final formaldehyde inhalation assessment was not available at the time this report was completed.

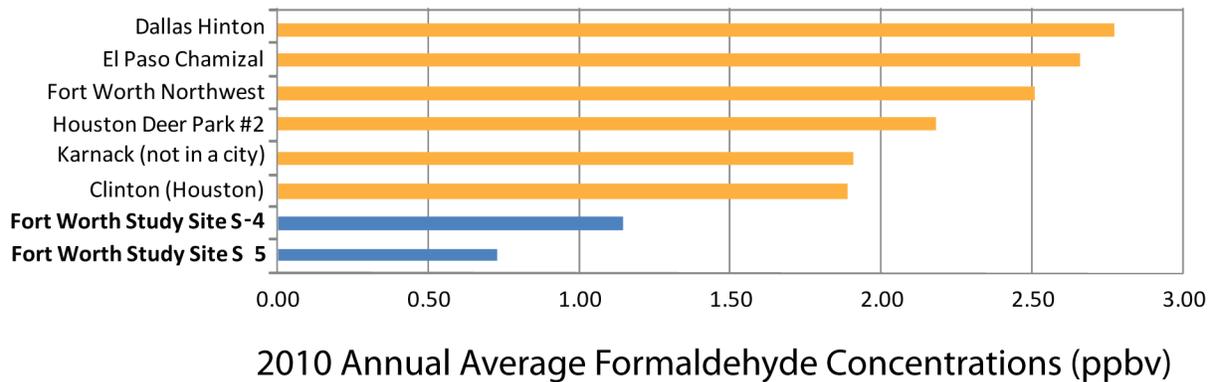

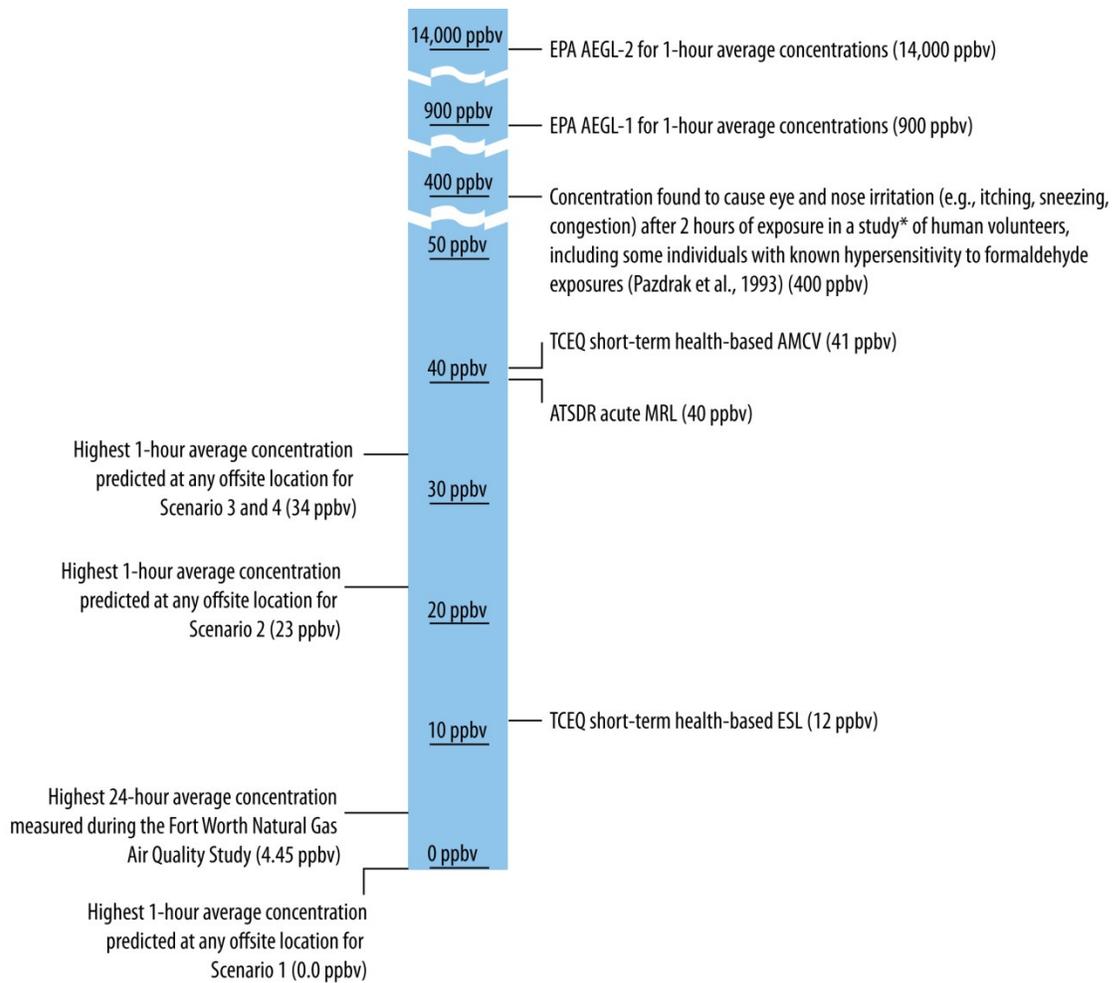

Figure 5.4-4. Comparison of Program-Average Formaldehyde Concentrations in Fort Worth to 2010 Annual Average Formaldehyde Concentrations Statewide (see Section 5.4)

- *Pollutants above odor-based screening levels.* Throughout this section, health-based screening levels were used to interpret the ambient air monitoring data and dispersion modeling results, but many pollutants emitted from well pads and compressor stations also have odor-based screening levels. Though not documented in the previous summary tables, ERG compared every measured and modeled ambient air concentration to pollutant-specific odor-based screening levels, where available. Every 24-hour average concentration measured during the monitoring program was lower than TCEQ's short-term odor-based ESLs. However, two pollutants—toluene and *m,p*-xylene—had estimated 1-hour average concentrations in certain modeling scenarios that exceeded the odor-based ESLs. This effect was highly localized to tanks at the highest-emitting sites and was predicted to occur just a few hours per year. While the peak levels of toluene and *m,p*-xylene would be expected to result in odorous conditions, neither pollutant had estimated short-term concentrations above health-based screening levels.

Figure 5.4-6. Toxicity of Formaldehyde: Long-Term Exposures

5.5 Public Health Evaluation Conclusions

The ambient air monitoring conducted in Fort Worth found dozens of air pollutants above detection limits. However, this is not uncommon for urban air quality, due to the complex mixture of emissions sources found in our country's metropolitan areas. The presence of a pollutant in Fort Worth's air likely reflects contributions from many different sources. Quantifying the extent to which natural gas exploration and production activity contributes to air quality is a complicated task, due to the confounding effect of other emission sources, such as motor vehicles, gasoline stations, and industrial sources. It is for this reason that the Fort Worth Natural Gas Air Quality Study considered two different approaches to evaluate air quality impacts from natural gas exploration and production activity.

First, ERG considered findings from the ambient air monitoring program, which directly measured air pollution levels at eight locations throughout Fort Worth. The ambient air monitoring data did not reveal any evidence of pollutants associated with natural gas exploration and production activity reaching concentrations above applicable screening levels: The highest 24-hour average concentrations of all site-related pollutants were lower than TCEQ's health-based short-term screening levels, and the program-average concentrations of all site-related pollutants were lower than TCEQ's health-based long-term screening levels. Even though the ambient air monitoring data provided useful insights into local air quality, review of modeling data was needed to consider potential air quality impacts at locations where and times when monitoring did not occur.

Next, ERG conducted a dispersion modeling analysis, which estimated air quality impacts that can be attributed specifically to emissions from well pads and compressor stations. These estimates were derived from measured emissions for tanks and fugitive sources and estimated emissions from compressor engines. The model was run for four different equipment configurations at well pads and compressor stations, and some modeling scenarios were based on the highest emission rates measured during the point source testing program. Most notably, the worst-case scenario assumed that the highest measured emission rates of all pollutants occurred at a single hypothetical site. The modeling analysis confirmed that benzene emissions from tanks could lead to air pollution levels slightly higher than TCEQ's short-term ESL, but this occurred infrequently and only in very close proximity to the highest-emitting tanks. The modeling also indicated that sites containing multiple, large line engines can emit acrolein and formaldehyde at levels that would cause offsite ambient air concentrations to exceed TCEQ's short-term and long-term screening levels over various distances. For all remaining pollutants considered, the modeling found no evidence of short-term or long-term air quality impacts at levels of health concern.

ERG considered both the modeling and monitoring results when assessing the adequacy of Fort Worth's setback limits. The details of this analysis depend on multiple factors, including the pollutant, exposure duration, and well pad equipment configuration. Table 5.5-1 documents ERG's main findings for different combinations of these factors. Overall, ERG concluded that the 600-foot setback distances are adequately protective of public health. Greater confidence in this finding can be gained through further study of acrolein and formaldehyde air quality impacts

near sites with multiple, large line engines, especially when variances to the 600-foot setbacks are being considered for these higher-emitting facilities. TCEQ has recently completed an ambient air monitoring study that considered acrolein and formaldehyde levels in Fort Worth.²⁰ The week-long monitoring effort found no evidence of acrolein and formaldehyde exceeding short-term health-based screening levels, but that study was limited in scope and duration. Routine monitoring over a longer duration near a site with multiple, large lift engines is encouraged.

Table 5.5-1. Key Findings for Health Evaluation

| Pollutant | Exposure Duration ^a | Key Findings from Screening Evaluation, by Equipment Configuration | Additional Context | Recommendations |
|-----------|--------------------------------|---|--|---|
| Benzene | Short-term | <p><i>For sites with the highest-emitting tanks:</i> Receptors less than 30 feet from the highest emitting tanks had maximum 1-hour concentrations marginally above the short-term ESL.</p> <p><i>For all remaining sites:</i> Estimated offsite 1-hour average benzene levels were lower than TCEQ’s short-term ESL for the overwhelming majority of well pad and compressor station configurations.</p> | These results are generally consistent with the findings of the ambient air monitoring program. Additionally, long-term average benzene levels in Fort Worth ranked relatively low when compared to those measured at other locations statewide. | Compare any future sampling results (e.g., from TCEQ’s “auto-GC” monitors) to screening levels. |
| | Long-term | <p><i>For every equipment configuration:</i> For all receptors at least 200 feet from fence lines, annual average concentrations were found to be lower than TCEQ’s screening values, even for the highest-emitting sites (see Figure 5.3-1).</p> | | |
| Acrolein | Short-term | <p><i>For sites with no engines:</i> Acrolein emissions were not measured, but are not expected due to the lack of combustion.</p> | The modeling results are based on the best available information, but no long-term ambient air monitoring data are available to verify or validate the modeling results. TCEQ conducted a week-long carbonyl monitoring program in December 2010, which found no acrolein levels above ESLs, but that program was limited in scope and duration. | Acrolein is one of only two pollutants that had estimated air quality impacts above ESLs beyond the setback distances. This occurred only for sites with multiple, large line engines. Routine monitoring downwind from one of the larger facilities would provide greater confidence in the adequacy of the city’s setback limits. |
| | | <p><i>For sites with lift or line engines:</i> All modeling simulations involving engines found some offsite 1-hour average concentrations greater than TCEQ’s short-term ESL. The spatial extent and frequency of these elevated concentrations increased with the number and size of engines at a given site. For sites with multiple, large line engines, estimated 1-hour average concentrations above the ESL occurred up to 400 feet beyond the fence lines.</p> | | |
| | Long-term | <p><i>For sites with multiple, large line engines:</i> Estimated annual average concentrations exceeded the long-term ESL at locations several hundred feet beyond the 600-foot setback. Though greater than highly protective screening levels, the estimated air quality impacts did not reach concentrations that have been shown to cause adverse health effects.</p> <p><i>For all other sites:</i> For all receptors at least 200 feet from fence lines, annual average concentrations were found to be lower than TCEQ’s screening values, even for the highest-emitting sites (see Figure 5.3-2).</p> | | |

Table 5.5-1. Key Findings for Health Evaluation (Continued)

| Pollutant | Exposure Duration ^a | Key Findings from Screening Evaluation, by Equipment Configuration | Additional Context | Recommendations |
|---|--------------------------------|---|---|---|
| Formaldehyde | Short-term | <i>For sites with no engines:</i> Formaldehyde emissions were not measured, but are not expected due to the lack of combustion. | The findings for long-term exposures are consistent with the program-average formaldehyde levels from the monitoring program. Further, when compared to other active monitoring sites in Texas, the program-average concentrations measured in this study ranked the lowest. TCEQ conducted a week-long carbonyl monitoring program in December 2010, which found formaldehyde levels below ESLs, but that program was limited in scope and duration. | Formaldehyde is one of only two pollutants that had estimated air quality impacts above ESLs beyond the setback distances. This occurred only for sites with multiple, large line engines. Routine monitoring downwind from one of the larger facilities would provide greater confidence in the adequacy of the city's setback limits. |
| | | <i>For sites with lift or line engines:</i> All modeling simulations involving engines found some offsite 1-hour average concentrations greater than TCEQ's short-term ESL. The spatial extent and frequency of these elevated concentrations increased with the number and size of engines. For sites with multiple, large line engines, estimated 1-hour average concentrations above the ESL occurred up to 750 feet beyond the fence lines, and the peak values were nearly 3 times higher than TCEQ's short-term ESL. However, even the highest estimated air quality impacts did not reach concentrations that have been shown to cause adverse health effects. | | |
| | Long-term | <i>For every equipment configuration:</i> For all receptors at least 600 feet from fence lines, annual average concentrations were found to be lower than TCEQ's screening values, even for the highest-emitting sites (see Figure 5.3-3). | | |
| All other pollutants considered in this study | Short- and long-term | <i>For every equipment configuration considered:</i> Estimated 1-hour average and annual average concentrations were lower than TCEQ's health-protective screening values at every offsite location, even for the highest-emitting sites. | This result is supported by the ambient air monitoring data, which found no site-related pollutants above screening levels. | Compare any future sampling results (e.g., from TCEQ's "auto-GC" monitors) to screening levels. |

^a For purposes of this table, "short-term" exposures are evaluated based on the highest estimated 1-hour average concentrations; and "long-term" exposures are evaluated based on program-average concentrations calculated from the monitoring data and annual average concentrations estimated by the dispersion model.

6.0 Regulatory Assessment

Under this task, facility-level emission estimates developed under Task 3 (point source testing) for well pads, compressor stations, and natural gas processing and treatment plants were evaluated against various federal and state air quality regulatory thresholds and standards applicable to these types of facilities. Regulatory standards considered include EPA's operating and construction permit rules, National Emissions Standard for Hazardous Air Pollutants (NESHAPs), and New Source Performance Standards (NSPS); TCEQ's permit-by-rule, standard permit, and other regulations applicable to upstream oil and gas facilities; and the city of Fort Worth's Gas Well Drilling Ordinance.

This section has four sub-sections:

- 6.1 Federal Air Quality Rules – A description of potentially applicable U.S. EPA air quality rules are provided here.
- 6.2 Texas Commission on Environmental Quality Air Quality Rules – This section provides a discussion of potentially applicable TCEQ air quality rules.
- 6.3 City of Fort Worth Air Quality Rules – The city of Fort Worth's Gas Well Drilling Ordinance (Ordinance No. 18449-02-2009) is discussed in this section.
- 6.4 Regulatory Assessment Conclusions – Provides a summary of the results of the regulatory assessment.

6.1 Federal Air Quality Rules

EPA regulates air emissions from stationary sources such as well pads and compressor stations through a variety of regulatory mechanisms. In brief, these are:

- Operating permit rules
- Construction permit rules
- NSPS
- NESHAPs
- The Greenhouse Gas Reporting Program

These air quality regulations are discussed individually in Sections 6.1.1 through 6.1.5.

6.1.1 Operating Permits

Operating permits are legally enforceable documents that permitting authorities issue to air pollution sources *after* the sources begin to operate. Depending on the magnitude of emissions from a facility, there are different types of operating permits available, with the largest sources (typically those emitting over 100 tons per year (tpy) of a regulated pollutant such as VOCs) required to obtain a Title V Operating permit. In Texas, these permits are issued by TCEQ as discussed below in Section 6.2.

6.1.2 Construction Permits

Construction permits are legally enforceable documents that permitting authorities issue to air pollution sources *before* construction. EPA regulations applicable to all new sources are included under the New Source Review (NSR) provisions, which are broken down into regulations for attainment areas and regulations for nonattainment areas. Tarrant County is considered a nonattainment area for ozone, which requires more stringent control of VOC and NO_x emissions.

The state of Texas implements the federal NSR rules through its construction permit program. Under Title 30 of the Texas Administrative Code (TAC), Chapter 116, Subchapter B, oil and gas exploration and production facilities may be authorized to construct through TCEQ's Permit-by-Rule (PBR), Standard Permit, or NSR permitting process. These types of permits are discussed in more detail below in Section 6.2.

6.1.3 New Source Performance Standards

NSPS regulations apply to new, modified, or reconstructed emission sources categorized by source type. For the oil and gas industry, the potentially applicable NSPS include the following:

- Subpart A—General Requirements (including flares)
- Subparts K and Ka—Storage Vessels for Petroleum Liquids
- Subpart Kb—Volatile Organic Liquid Storage Vessels (including Liquid Storage)
- Subpart GG—Stationary Gas Turbines
- Subpart KKK—Equipment Leaks of VOC from Onshore Natural Gas Processing Plants
- Subpart LLL—Onshore Natural Gas Processing: SO₂ Emissions
- Subpart IIII—Stationary Compression Ignition Internal Combustion Engines
- Subpart JJJJ—Stationary Spark Ignition Internal Combustion Engines
- Subpart KKKK—Stationary Combustion Engines

A brief discussion of each of these regulations follows. Where possible, a preliminary determination of compliance and applicability status with respect to the sites visited under the point source task has been made. However, a formal and comprehensive compliance and applicability assessment is not possible for each facility without a complete record of construction, monitoring, and recordkeeping activities.

Subparts K and Ka—Storage Vessels for Petroleum Liquids. These regulations apply to storage vessels for volatile organic liquids (including petroleum) built or modified after June 11, 1973 (Subpart K), or after May 18, 1978 (Subpart Ka). These rules apply to storage tanks with a design capacity greater than 40,000 gallons. None of the tanks visited under Task 3 have

capacities greater than 40,000 gallons, so it appears that none of the visited tanks are subject to these rules.

Subpart Kb—Volatile Organic Liquid Storage Vessels (Including Liquid Storage). This regulation applies to storage vessels for volatile organic liquids (including petroleum) built or modified after July 23, 1984 (Subpart Kb) and with a capacity greater than 19,800 gallons. Six tanks that were visited under Task 3 appear to have capacities greater than 19,800 gallons. However, the rule does not apply to “Vessels with a design capacity less than or equal to 1,589.874 m³ (~420,000 gallons) used for petroleum or condensate stored, processed, or treated prior to custody transfer.” Therefore, this rule does not appear to apply to any storage tanks visited under Task 3.

Subpart GG—Stationary Gas Turbines. This regulation applies to stationary gas turbines with a heat input at peak load greater than 10 million British thermal units (Btu) per hour. This rule limits NO_x and SO₂ emissions from subject facilities. ERG did not identify any gas turbines under Task 3.

Subpart KKK—Equipment Leaks of VOC from Onshore Natural Gas Processing Plants. This regulation applies to onshore natural gas processing plants as defined as “any processing site engaged in the extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both.” This rule requires VOC leak detection and repair at facilities that remove natural gas liquids from field gas. Site PS-159 (the Crosstex Amine Treatment Center) could be subject to this rule. However, status of compliance with the monitoring requirements under this rule cannot be determined using the data obtained at the time of the survey.

Subpart LLL—Onshore Natural Gas Processing: SO₂ Emissions. This regulation applies to sweetening units (process devices that remove hydrogen sulfide (H₂S) and CO₂ contents from sour natural gas) and sulfur recovery units at facilities that process natural gas. Sour natural gas is natural gas with an H₂S concentration greater than 0.25 grains per 100 standard cubic feet. The natural gas in the Barnett Shale is not considered to be sour natural gas, so this rule does not appear to apply to any facilities in Fort Worth.

Subpart IIII—Stationary Compression Ignition Internal Combustion Engines. This regulation applies to compression ignition internal combustion engines of various sizes, dependent upon date of construction. Much of this regulation is applicable to engine manufacturers themselves, not the engine users. This rule limits combustion emissions (hydrocarbons, NO_x, CO, and PM) from subject engines, which were not tested as part of this project. While this rule may apply to engines used at natural gas well pads and compressor stations in Fort Worth, no applicability or compliance determination can be made at this time.

Subpart JJJJ—Stationary Spark Ignition Internal Combustion Engines. This regulation, similar to Subpart IIII, applies to stationary spark ignition internal combustion engines of various sizes, dependent upon date of construction. Much of this regulation is applicable to engine manufacturers themselves, not the engine users. This rule limits combustion emissions (VOC, NO_x, and CO) from subject engines, which were not tested as part of this project. While this rule

may apply to engines used at natural gas well pads and compressor stations in Fort Worth, no applicability or compliance determination can be made at this time.

Subpart KKKK—Stationary Combustion Turbines. This regulation applies to stationary combustion turbines constructed, modified, or reconstructed after February 18, 2005. This rule limits NO_x and SO₂ emissions from subject facilities. ERG did not identify any gas turbines under Task 3.

6.1.4 National Emission Standards for Hazardous Air Pollutants

NESHAPs regulate HAPs from new and existing stationary sources. For the oil and gas industry, the potentially applicable NESHAPs include the following:

- Subpart H—Organic Hazardous Air Pollutants for Equipment Leaks
- Subpart V—Equipment Leaks (Fugitive Emission Sources)
- Subpart HH—Oil and Natural Gas Production Facilities
- Subpart VV—Oil-Water Separators and Organic-Water Separators
- Subpart HHH—Natural Gas Transmission and Storage Facilities
- Subpart YYYY—Stationary Combustion Turbines
- Subpart ZZZZ—Stationary Reciprocating Internal Combustion Engines

A brief discussion of each of these rules follows. Where possible, a preliminary determination of compliance and applicability status with respect to the sites visited under the point source task has been made. However, a formal and comprehensive compliance and applicability assessment is not possible for each facility without a complete record of construction, monitoring, and recordkeeping activities.

Many of the NESHAP regulations apply only to major HAP sources, those defined as emitting greater than 10 tpy of any single HAP, or 25 tpy of all HAPs combined. As a result of the point source testing task, three potential major HAP sources were identified, including two compressor stations (Site IDs PS-118 and PS-119) and the gas processing plant (Site ID PS-159). All of these facilities were determined to be major HAP sources due to formaldehyde emissions from their compressor engines. Due to the conservative nature of the emissions estimation approach used for these engines (24-hour-per-day, 365-day-per-year operation of all the engines at the facility without controls), a full compliance evaluation would need to be made to definitively conclude whether or not these facilities are major sources of HAP.

Subpart H—Organic Hazardous Air Pollutants for Equipment Leaks. This regulation applies to sources subject to other NESHAP rules under 40 CFR Part 63 that specifically point back to this rule. As such, any applicability under Subpart H would be referenced in the rules discussed below.

Subpart V—Equipment Leaks (Fugitive Emission Sources). This regulation applies to pumps, compressors, pressure relief devices, sampling connection systems, open-ended valves or

lines, valves, connectors, surge control vessels, bottoms receivers, and control devices or systems that are intended to operate in volatile HAP service. However, this rule is only triggered when the fluid or gas flowing through the equipment contains at least 10% by weight of a volatile HAP. No sources visited under Task 3 have volatile HAP concentrations of 10% or greater.

Subpart HH—Oil and Natural Gas Production Facilities. This regulation applies to oil and gas production facilities. There are different requirements for major and minor HAP sources, based on the magnitude of emissions. Requirements for major HAP sources include controlling HAP from tanks with flash emissions, controlling equipment leaks, and controlling glycol dehydrators. As discussed above, there are three potential major HAP sources that were visited that may be subject to the major source provisions of this regulation.

For minor HAP sources, there are limited requirements under this rule for triethylene glycol dehydration units, and those requirements are dependent upon the throughput or benzene emissions. For sources with benzene emissions less than 1 tpy, the only requirement is to maintain records verifying the benzene emission rate. There was one source visited under Task 3 that was estimated to emit over one tpy of benzene, the gas processing plant (PS-159). The remainder of the sites emitted less than one tpy of benzene. The only requirement applicable to these sources would be to keep records (as defined under the rule) of benzene emissions.

Subpart VV—Oil-Water Separators and Organic-Water Separators. This regulation applies to facilities that control air emissions from oil-water and organic-water separators. However, it only applies when another NESHAP subpart references it. No such facilities have been identified under this project.

Subpart HHH—Natural Gas Transmission and Storage Facilities. This regulation applies to owners and operators of natural gas transmission and storage facilities that transport or store natural gas before it enters the pipeline to a local distribution company or a final end user, and that are major sources of HAPs. A compressor station that transports natural gas prior to the point of custody transfer or to a natural gas processing plant (if present) is not considered a part of the natural gas transmission and storage source category. If applicable, this rule would require control of emissions from any glycol dehydration unit that emits more than 1 tpy of benzene. As mentioned above, the gas processing plant (PS-159) was the only facility estimated to emit over one tpy of benzene, with estimated benzene emissions at 1.2 tpy.

Subpart YYYY—Stationary Combustion Turbines. This regulation applies to stationary combustion turbines located at major sources of HAPs. ERG did not identify any stationary combustion turbines under Task 3.

Subpart ZZZZ—Stationary Reciprocating Internal Combustion Engines. This regulation applies to stationary reciprocating internal combustion engines located at major and area sources of HAPs. The applicability of this rule depends on both the construction date and the size of the engine. For many of the engines subject to this rule in Fort Worth, the only requirements are to comply with 40 CFR part 60 subpart IIII for compression ignition engines, or 40 CFR part 60 subpart JJJJ for spark ignition engines, as discussed in Section 6.1.3. Certain engines may also be required to specifically control formaldehyde emissions.

6.1.5 Greenhouse Gas Reporting Program

On November 8, 2010, EPA signed a rule that finalizes reporting requirements for the petroleum and natural gas industry under 40 CFR Part 98, the regulatory framework for the Greenhouse Gas Reporting Program. In short, Subpart W of Part 98 requires petroleum and natural gas facilities that emit 25,000 metric tons or more of CO₂ equivalent per year to report annual methane and CO₂ emissions from equipment leaks and venting, and emissions of CO₂, methane, and nitrous oxide from gas flaring and from onshore petroleum and natural gas production stationary and portable combustion emissions and combustion emissions from stationary equipment involved in natural gas distribution. However, this rule does not require facilities to report their emissions until March 31, 2012, at which time emissions for the 2011 calendar year will need to be reported for subject facilities.

Based on the results of the point source testing, there are several facilities with methane emissions from equipment leaks and venting that emit over 8,000 metric tons of CO₂ equivalents per year. In addition, emissions from compressor engine exhausts are likely to account for a significant amount of CO₂ (a single 2,000 hp engine may emit over 7,000 metric tons of CO₂ equivalents per year), which would result in many of the larger compressor stations exceeding the annual threshold of 25,000 metric tons of CO₂ equivalent emissions. As such, it appears that several facilities in the city of Fort Worth will be required to report their greenhouse gas emissions to EPA under this rule beginning in 2012.

However, it should be noted that there is some uncertainty as to the applicability of this rule, and EPA is currently actively providing guidance and rule interpretation to the oil and gas industry as they prepare to begin reporting emissions next year.

6.2 Texas Commission on Environmental Quality Air Quality Rules

Like EPA, TCEQ regulates air emissions from stationary sources related to upstream oil and gas facilities through a variety of regulatory mechanisms:

- PBRs
- Standard permits
- NSR permits
- Control of Air Pollution from Visible Emissions and Particulate Matter
- Control of Air Pollution from Sulfur Compounds
- Standards of Performance for Hazardous Air Pollutants and for Designated Facilities and Pollutants
- Control of Air Pollution from Volatile Organic Compounds
- Control of Air Pollution from Nitrogen Compounds
- Federal operating permits

These air quality regulations are discussed individually in Sections 6.2.1 through 6.2.9. Where possible, a preliminary determination of compliance and applicability status with respect

to the sites visited under the point source task has been made. However, a formal and comprehensive compliance and applicability assessment is not possible for each facility without a complete record of construction, monitoring, and recordkeeping activities.

6.2.1 Permit-by-Rules

PBRs are an abbreviated permitting mechanism provided by TCEQ to authorize emissions from new construction or modifications to existing facilities. PBR requirements are grouped by source types (e.g., stationary turbines and engines) and codified under Title 30 of the Texas Administrative Code (TAC), Chapter 106 (30 TAC 106). The most common PBR used to authorize new construction or modifications involving oil and gas exploration and production facilities is found under 30 TAC 106, Subchapter O, Section 106.352, "Oil and Gas Handling and Production Facilities." TCEQ updated this PBR in February 2011, significantly expanding the requirements for oil and gas handling and production facilities located in the Barnett Shale, including Tarrant County. Per the rule, these new requirements took effect in April 2011 and apply only to new or modified emissions sources.

Key Point: Permit-By Rule

TCEQ's PBR for Oil and Gas Handling and Production Facilities is the primary regulatory mechanism applicable to natural gas well pads and compressor stations in Fort Worth.

The new requirements include more stringent control requirements and emission limits. In addition to more stringent site-wide emission limits, the revised PBR requires a health effects demonstration using calculated emission limits based on ESLs for certain toxins and source specific characteristics. The maximum emission rates allowed by the new PBR for Level 2 Requirements are summarized in Table 6.2-1.

Table 6.2-1. New PBR Emission Rates

| Pollutant | Steady-state lb/hr | < 30 psig periodic lb/hr up to 300 hr/yr | ≥ 30 psig periodic lb/hr up to 300 hr/yr | Total tpy |
|--------------------------------------|-----------------------|---|---|-----------|
| Total VOC | | | | 25 |
| Total crude oil or condensate VOC | 100 | 145 | 318 | |
| Total natural gas VOC | 356 | 750 | 1,500 | |
| Benzene | 3.35 | 7 | 15.4 | 4.8 |
| Hydrogen sulfide | 6 | 6 | 9.8 | 25 |
| Sulfur dioxide | 63 | 93.2 | | 25 |
| Nitrogen oxides | 54.4 | | | 250 |
| Carbon monoxide | 57 | | | 250 |
| PM _{2.5} | 12.7 | | | 10 |
| PM ₁₀ | 12.7 | | | 15 |

The ESL based emission limits are site and source specific based on the source characteristics and the distance of the source relative to the nearest off-site receptor.

Based on the emission estimates developed under Task 3, most of the facilities surveyed would likely meet the new site-wide emissions limits if they were applicable, except for two compressor stations (Site IDs PS-118 and PS-127) and the gas processing facility (Site ID PS-159). The emissions estimates for CO from these three sites are above the CO lb/hr emission limits. A complete comparison to the new ESL based emission limits cannot be determined using the data collected during the point source testing.

As the new PBR rule was not in effect at the time of the point source testing, it is likely that most of the emissions sources located at the sites tested in Task 3 were previously authorized and were operating under the old PBR requirements outlined in 30 TAC Section 106.352(l). Under the old PBR requirements, total emissions could not exceed 25 tpy each of SO₂, all other sulfur compounds combined, or all VOCs combined or 250 tpy each of NO_x and CO. Total emissions of sulfur compounds, excluding sulfur oxides, from all vents could not exceed 4.0 pounds per hour. Through the point source testing task, three potential sources were identified, including two compressor stations (Site IDs PS-118 and PS-119) and the gas processing plant (Site ID PS-159), with site-wide emissions exceeding the 25 tpy VOC limit. Additionally, estimated CO emissions from two compressor stations (Site IDs PS-118 and PS-127) and the gas processing plant (Site ID PS-159) exceed the 250 tpy threshold. For each of these facilities, it appears that emissions from the natural gas compressor engines cause them to exceed PBR thresholds.

30 TAC Section 106.352(l) also requires compressors and flares to meet the requirements of §106.492 and §106.512 of 30 TAC (relating to flares and stationary engines and turbines, respectively). 30 TAC §106.512 limits NO_x emissions, depending on engine type (rich-burn or lean-burn), fuel type (gas-fired, dual fuel-fired, liquid fuel-fired) and manufacturing date.

Compliance with the emission specification requirements under the PBR rules cannot be determined using the data obtained at the time of the survey. Records of manufacturing dates and the dates in which existing sources were last modified would be required to complete a full compliance assessment for any individual facility.

6.2.2 Standard Permit

Similar to PBRs, standard permits are an abbreviated permitting mechanism provided by TCEQ to authorize emissions from new construction or modifications. However, standard permits generally require more stringent emission controls meeting what is considered the best available control technology (BACT). New construction or modifications involving oil and gas exploration and production facilities permitted by standard permit must meet the requirements provided under 30 TAC Chapter 116, Subchapter F, Section 116.620, "Installation and/or Modification of Oil and Gas Facilities." The standard permit issued by TCEQ often includes site-specific requirements including, but not limited to, site-wide and/or source-specific emission limits. While some of the facilities visited in Task 3 may have been authorized under a standard permit, no information on these was available during this review.

6.2.3 New Source Review Permits

New construction or projects involving modifications to existing facilities that cannot meet the requirements of an applicable PBR or standard permit must be authorized prior to start of construction under 30 TAC Chapter 116, Subchapter B, "New Source Review Permits." This permitting mechanism requires installation of either BACT or lowest achievable emission reductions, depending on whether the source is located in an attainment or a non-attainment area. Tarrant County is located in a non-attainment area for ozone, so the latter would be required for project sources emitting VOCs and NO_x; BACT would be required for all other project-related criteria pollutants. NSR permits also require two public notice periods and a health impacts review to evaluate to potential health impacts from certain toxins associated with the project-related emissions. The NSR permit issued by TCEQ often includes site-specific requirements including, but not limited to, site-wide and/or source-specific emission limits. NSR permits issued for the sites visited under Task 3 were considered outside the scope of this study, and were therefore not reviewed.

6.2.4 Control of Air Pollution from Visible Emissions and Particulate Matter

This rule regulates the amount of visible emissions and particulate matter that are permissible from any source operated in Texas. Visible emissions from stationary vents are not allowed to exceed opacities greater than 30% averaged over a six-minute period, 20% averaged over a six-minute period for any source on which construction was begun after January 31, 1972, or 15% averaged over a six-minute period for any source having a total flowrate greater than or equal to 100,000 actual cubic feet per minute, unless an optical instrument capable of measuring the opacity of emissions is installed in the vent. No visible emissions were observed from stationary vents located at the sites visited under Task 3. Visible emissions from a process gas flare used in routine or scheduled facility operations are not allowed for more than five minutes in any two-hour period. Two sites visited during Task 3 operated flares; however, compliance status with the requirements under this rule cannot be determined using the data obtained at the time of the survey. Compliance status with this requirement cannot be determined for the vents visited using the data obtained at the time of the survey. However, considering the nature of material (i.e., natural gas) being managed at the sites studied, the particulate matter emission rate limits specified are not expected to be exceeded.

6.2.5 Control of Air Pollution from Sulfur Compounds

This rule regulates the amount of sulfur compound emissions, particularly SO₂, H₂S, sulfuric acid, and total reduced sulfur, that are permissible from certain sources operated in Texas. Those sulfur compounds applicable to the operation of oil and gas facilities are SO₂ and H₂S. SO₂ emissions from a source or sources operated on a property or multiple sources operated on contiguous properties cannot cause an exceedance of a net ground level concentration of 0.4 parts per million by volume (ppmv) averaged over any 30-minute period. H₂S from a source or sources operated on a property or multiple sources operated on contiguous properties are also limited; the specific limit depends on the affected downwind sources.

Compliance with the ground-level concentration requirements under this rule cannot be determined using the data obtained at the time of the survey. As mentioned previously, the natural gas in the Barnett Shale is not considered to be sour natural gas, so this rule does not appear to apply to any facilities in Fort Worth.

6.2.6 Standards of Performance for Hazardous Air Pollutants and for Designated Facilities and Pollutants

This rule simply incorporates, by reference, all of the federal NESHAPs that regulate HAPs from new and existing stationary sources. Section 6.1.4 lists and briefly describes the potentially applicable NESHAPs for the oil and gas industry.

6.2.7 Control of Air Pollution from Volatile Organic Compounds

This rule regulates the amount of VOCs that are permissible from sources operated in Texas. The rule requirements are organized by source type under 30 TAC Chapter 115 and only apply to sources located in non-attainment areas specified in the rule. Those parts of the rule that are potentially subject to upstream oil and gas facilities are Subchapter B, Division 1, "Storage of VOCs"; Subchapter C, Division 1, "Loading and Unloading of VOCs"; and Subchapter D, Division 3, "Fugitive Emission Control in Petroleum Refining, Natural Gas/Gasoline Processing, and Petrochemical Processes in Ozone Non-attainment Areas." Storage tanks containing VOCs including, but not limited to, crude or condensate must control emissions using control technologies specified in the rule. Control options vary depending on the size of the tank and its configuration. Loading of certain VOC materials must be controlled by a vapor control system that maintains a control efficiency of at least 90%, a vapor balance system, or pressurized loading. This rule also requires VOC leak detection and repair at natural gas/gasoline processing operations. Site PS-159 (the Crosstex Amine Treatment Center) could be subject to this rule.

Compliance status with the control and monitoring requirements under this rule cannot be determined using the data obtained at the time of the survey.

6.2.8 Control of Air Pollution from Nitrogen Compounds

This rule regulates the amount of nitrogen compounds that are permissible from sources operated in Texas. Similar to 30 TAC Chapter 115, the rule requirements for this chapter are organized by source type under 30 TAC Chapter 117 and only apply to sources located in non-attainment areas specified in the rule. Those parts of the rule that are most commonly subject to upstream oil and gas facilities are found under Subchapter D, "Combustion Control at Minor Sources in Ozone Non-attainment Areas." For the Dallas-Fort Worth area, including Tarrant County, NO_x emissions from stationary internal combustion engines at any minor stationary source of NO_x (a source that emits less than 250 tpy) are limited, depending on engine type and construction date. Most engines at sites visited under Task 3 would be subject to a limit of 0.50 grams of NO_x per hp per hour.

Compliance with the emission specification requirements under this rule cannot be determined using the data obtained at the time of the survey. Records of manufacturing dates and

the dates in which existing sources were last modified would be required to complete a full compliance assessment for any individual engine.

6.2.9 Federal Operating Permits

The Title V Federal Operating Permit Program is regulated under 30 TAC Chapter 122. Title V operating permits are required for any site that is a major source. A major source is a site which that emits, or has the potential to emit, 100 tpy or more of any air pollutant. A site is also considered a major source if it emits or has the potential to emit, in the aggregate, 10 tpy or more of any single hazardous air pollutant listed under the federal Clean Air Act or 25 tpy or more of any combination of hazardous air pollutants listed under the Act. One of the primary objectives of the Title V operating program is to assimilate in one document all of the requirements to which a facility is subject. The Title V permit serves as the key verification and documentation of a facility's compliance with all applicable requirements of the Texas and federal Clean Air Acts. Permit holders must annually certify compliance with the permit terms and conditions and submit semi-annual deviation reports in which they self-disclose known non-compliance activities during the reporting period.

Five potential major sources were identified, including three compressor stations (Site IDs PS-118, PS-119, PS-127), the gas processing plant (Site ID PS-159), and one well pad (Site ID 238). All of these facilities were determined to be major sources due to formaldehyde and/or CO emissions from their compressor engines. However, due to the conservative nature of the emissions estimation approach used for these engines (24-hour-per-day, 365-day-per-year operation of all the engines at the facility without controls), a full compliance evaluation would need to be made to definitively conclude whether or not these facilities are major sources and subject to the Title V Federal Operating Program.

6.3 City of Fort Worth Air Quality Rules

The city of Fort Worth's Gas Well Drilling Ordinance (Ordinance No. 18449-02-2009) has one provision that requires air emissions control. Under Section 15-42 of this ordinance, tank batteries with a rolling annual aggregate emissions rate of 25 tpy or more of VOC must use vapor recovery equipment with a 95% recovery efficiency. Based on the results of the point source testing under Task 3, two compressor stations (Site IDs PS-118 and PS-119) and the gas processing plant (Site ID PS-159) have facility-wide VOC emissions greater than 25 tpy. However, the majority of the VOC emissions at these sites come from non-tank emission points and the natural-gas-fired compression engines, and none of these facilities have VOC emissions from their storage tank batteries exceeding 25 tpy. Therefore, based on the results of Task 3, this rule does not appear to apply to any of the tested facilities.

6.4 Regulatory Assessment Conclusions

A regulatory assessment was conducted based on the results of the point source testing to determine if any facilities exceeded regulatory thresholds. For many of the rules potentially applicable to oil and gas sources in Fort Worth, we were unable to make a definitive determination on whether the source was subject to the rule, and/or whether the source was in

compliance with the rule. A full compliance evaluation for any individual site is an involved process that requires research into historical construction, operating, and production records and was beyond the scope of this study. However, based on the emission estimates developed under Task 3, the sources listed in Table 6.4-1 may exceed the regulatory thresholds discussed above.

Table 6.4-1. Sources Above Regulatory Thresholds

| Site ID | Site Type | VOC (tons/yr) | CO (tons/yr) | Total HAP (tons/yr) | Formaldehyde (tons/yr) |
|---------|---------------------|------------------|-----------------------|------------------------|---------------------------|
| PS-159 | Processing Facility | 80 ^a | 1,039 ^{b, c} | 47 ^d | 32 ^e |
| PS-118 | Compressor Station | 43 ^a | 270 ^{b, c} | 25 ^d | 17 ^e |
| PS-119 | Compressor Station | 38 ^a | 240 ^c | 22 | 15 ^e |
| PS-127 | Compressor Station | 24 | 545 ^{b, c} | 14 | 9 |
| 238 | Well Pad | 14 | 219 ^c | 8 | 6 |

^a This site potentially exceeds the 25 tpy VOC threshold under 30 TAC 106, Subchapter O, Section 106.352.

^b This site potentially exceeds the 250 tpy CO threshold under 30 TAC 106, Subchapter O, Section 106.352.

^c This site potentially exceeds the 100 tpy CO threshold under the federal Title V Operating Permit Program.

^d This site potentially exceeds the 25 tpy total HAP threshold under the federal Title V Operating Permit Program.

^e This site potentially exceeds the 10 tpy single HAP threshold under the federal Title V Operating Permit Program.

7.0 Full Build-Out Estimates

Over the last five years, there has been a dramatic increase in natural gas production in the Barnett Shale, and in the city of Fort Worth itself. The expansion of the natural gas industry within the city is expected to continue into the future, and emissions from these activities are also expected to increase. ERG has developed estimates of total emissions from natural gas production from 2010 to 2018, based on the results of the point source testing task. As described below, ERG projects that emissions from natural gas production will peak in 2012 and 2013, and will slowly decline over time as the known natural gas reserves in the Barnett Shale are depleted. In this context, “full build-out” means the point at which natural production will result in the maximum annual emissions. For purposes of this evaluation, total emissions from natural gas production activity are assumed to correlate to total natural gas production levels.

Key Point: Full Build-Out Estimates
ERG projects that emissions from natural gas production operations in Fort Worth will peak in 2012 and 2013 before beginning to decline.

This evaluation includes emissions from production activities (all emission sources found at producing well pads, compressor stations, and the gas processing plant), but does not include emissions from pre-production activities such as site construction, exploration (drilling), stimulation (fracking), or well completion.

One drilling operation, one fracking operation, and one well completion operation were visited under the point source testing task, and emissions estimates were developed for each of these operations. However, this information was insufficient to extrapolate to all drilling, fracking, and completion operations occurring in 2010 due to the variability in how these operations are conducted from well to well, and from operator to operator. Additionally, the single saltwater treatment facility located in Fort Worth was also visited. However, emissions at the time of the visit were determined to be very small (less than half a pound of VOC per year).

This section has five sub-sections:

- 7.1 Factors Affecting Natural Gas Production – This section describes the various factors that must be considered when predicting future natural gas production.
- 7.2 Methodology for Forecasting Natural Gas Production – A description of the methodology used to estimate future natural gas production is provided in this section.
- 7.3 2010 Base Year Emissions Inventory – Describes how the current (2010) emissions inventory was compiled.
- 7.4 2010 through 2018 Projected Emissions Inventories – This section describes how the emissions estimates for 2011 – 2018 were calculated.
- 7.5 Full Build-Out Estimates Conclusions – This section presents the conclusions of the full build-out component of this study.

7.1 Factors Affecting Natural Gas Production

Estimating the future production of natural gas depends upon several factors. The primary factors include the amount of recoverable natural gas in the Barnett Shale formation, the ability of operators to access the gas with available drilling and fracturing methods (amounts technically recoverable), and the economics of the extraction process (amounts economically recoverable). Other operational factors include the number of existing producing wells, the depletion rate of existing wells, the number of new wells drilled, and the initial production from new wells, all of which contribute to the amounts of gas technically recoverable. These operational factors depend on the wellhead price of natural gas (price received by producers) and the costs of extracting the gas.

Key Point: Drilling and Permit Activity

By 2010, the number of active drill rigs and the number of well pad permits issued by the City of Fort Worth were down nearly 60% from their 2008 highs.

While the amount of recoverable gas in the Barnett Shale is finite, there will still be technically recoverable natural gas decades from now. However, the rate at which this gas is extracted will depend on the price received and the costs of drilling wells, installing production infrastructure such as pipelines and compressor stations, and the costs of operating these facilities.

The amount of recoverable gas in the Barnett Shale area is unknown. Current estimates of gas reserves in the Barnett Shale vary from 25 to 30 trillion cubic feet. This is not an absolute figure, as estimates of proven reserves and recoverable reserves change year by year. Reserve estimates increase as new data is obtained from exploration and drilling activities, while gas reserves are depleted as gas is extracted from existing wells. The Barnett Shale is unique in that it is the first domestic shale gas play to be extensively drilled and developed. Therefore, there is a wealth of information available about the size of the resource. In 2007, the Perryman Group estimated economically recoverable reserves of gas in the Barnett Shale at 2 trillion cubic feet and technically recoverable reserves at 30 trillion cubic feet.²¹ The U.S. Energy Information Administration's most recent estimate of shale gas reserves for the three Texas Districts (Districts 5, 7B, and 9) that include Barnett Shale acreage is 26.47 trillion cubic feet.²²

Figure 7.1-1 shows natural gas production in the entire Barnett Shale and in Tarrant County since 1993.²³ Notice that, over time, production of shale gas in Tarrant County has mirrored the larger trend in the entire Barnett Shale region. Due to the availability of county-level data from the Railroad Commission of Texas, this analysis uses current and projected production data for Tarrant County as a surrogate to reflect current and projected production data for the city of Fort Worth.

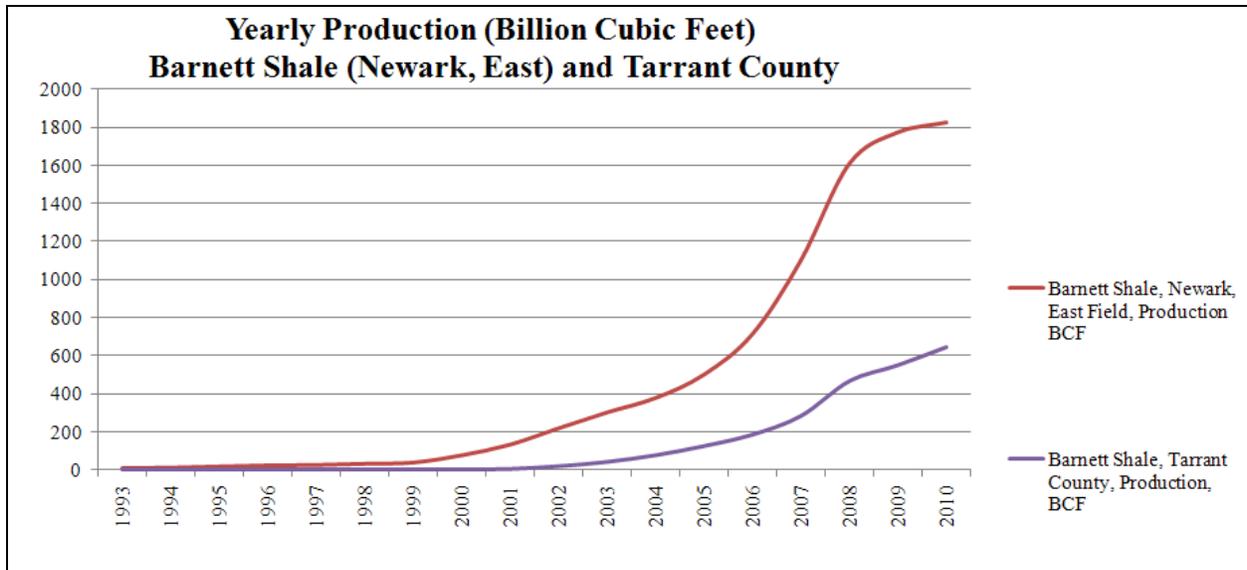

Figure 7.1-1. Natural Gas Production in the Barnett Shale and Tarrant County (1993–2010)

The price received for natural gas (the wellhead price) has a significant effect on the extent of exploration and the amount of gas produced. Higher wellhead prices stimulate increased exploration, drilling, and production. Figure 7.1-2 shows the monthly wellhead price of natural gas during the previous decade in which the shale gas underneath Tarrant and neighboring counties began to be extracted in significant amounts.²⁴ As can be seen in the figure, wellhead prices have fluctuated significantly over this time and peaked in 2008 before falling by more than 50% to current levels.

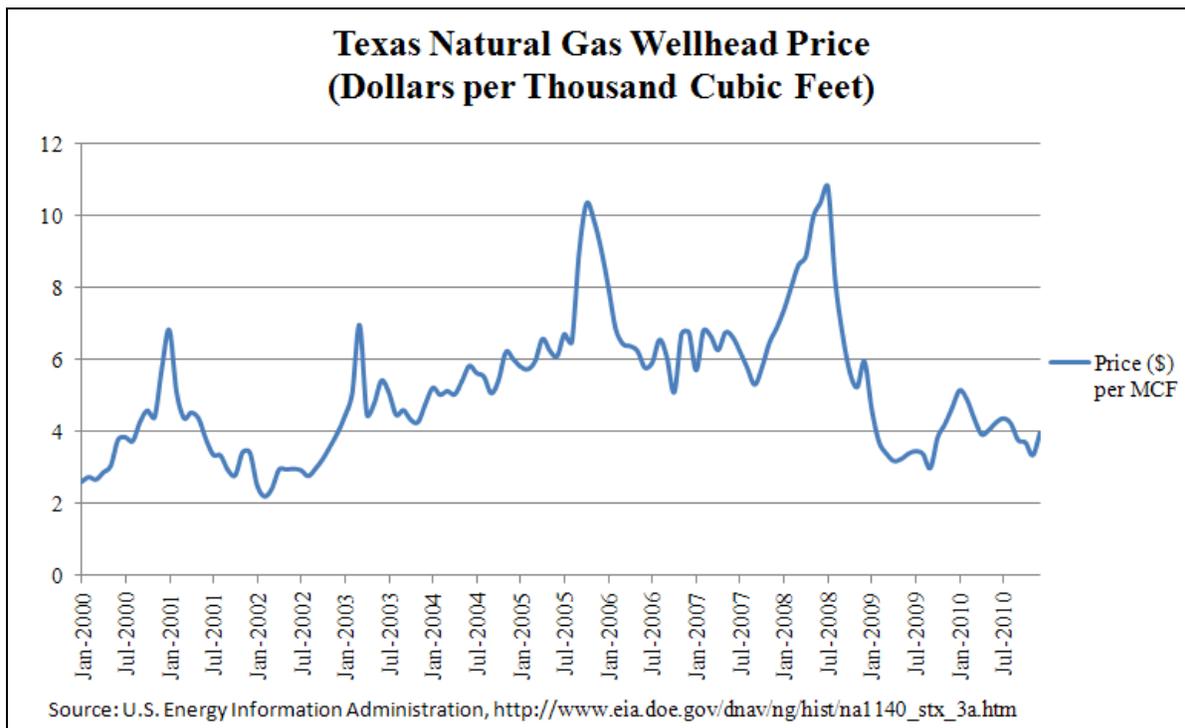

Figure 7.1-2. Texas Natural Gas Wellhead Price (2000–2010)

The U.S. Energy Information Administration, in its *Annual Energy Outlook Overview 2011*,²⁵ has forecast natural gas prices for the next 25 years. The Administration predicts that the average wellhead price for natural gas will increase by an average of 2.1% per year, to \$5.00 per million Btu in 2024 and to \$6.26 per million Btu in 2035 (2009 dollars). It should be noted that these estimates fall below the average wellhead natural gas prices between 2005 and 2008, indicating a less desirable economic climate for producers to invest in new drilling and production compared to the prices during the peak in these activities as discussed below.

Due to the depletion of existing wells, new wells must be drilled on a continuing basis to ensure a constant supply of natural gas. However, with current gas prices remaining relatively low, it may not make economic sense for producers to continue to invest in new production. Figure 7.1-3 shows the relationship between wellhead prices and drilling and permit activity over the last 10 years.

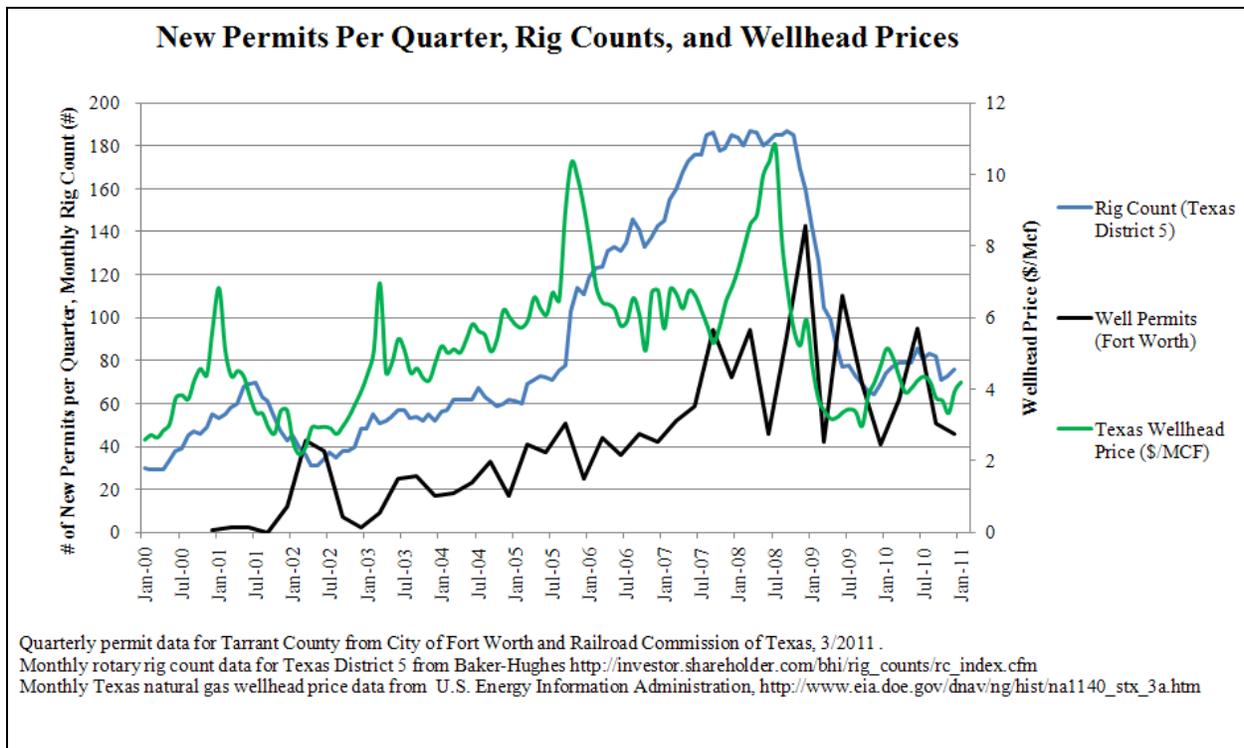

Figure 7.1-3. Permits, Rig Counts, and Wellhead Gas Prices in Tarrant County (2000–2010)

As shown in the figure, the number of active drilling rigs in District 5 (which includes Tarrant County) decreased dramatically in response to the drop in natural gas wellhead price beginning in August 2008.²⁶ Likewise, the number of well pad permits processed by the city of Fort Worth peaked shortly after the peak in natural gas wellhead price in 2008 and have trended downward since then. Prices dropped below \$7 per thousand cubic feet in September 2008, below \$6 per thousand cubic feet in October 2008. By 2010, both District 5 rig counts and the number of well pad permits issued by the city of Fort Worth were down nearly 60% from their highs in 2008.

7.2 Methodology for Forecasting Natural Gas Production

To estimate future emissions, an estimate of future natural gas production for the target years of 2010 through 2018 must be developed. In 2008, Tristone Capital estimated future production of shale gas in nine shale gas basins in the U.S. and Canada, including the Barnett Shale, for a 10-year period from 2008 to 2018.²⁷ Figure 7.2-1 shows Tristone’s estimates of future production for these eight shale gas plays.

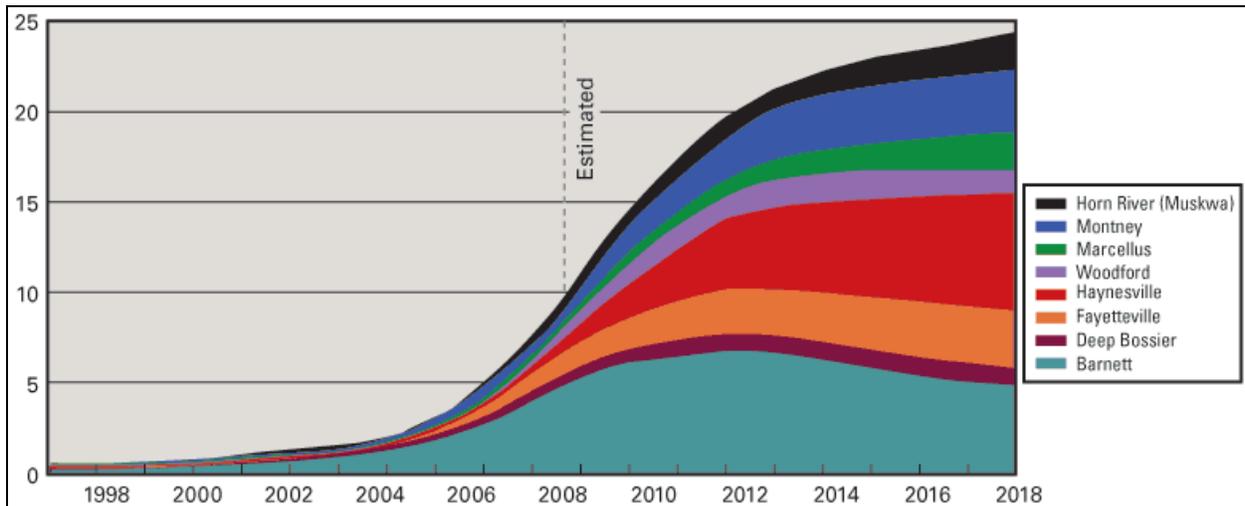

Figure 7.2-1. Projected Production in Eight Shale Plays (BCF) (1998–2018)

Tristone’s estimate of future production from the Barnett Shale is reproduced in Figure 7.2-2 as the purple dashed line in the graph. This data is compared with actual production data for the Barnett Shale as taken from the Railroad Commission of Texas (the solid red line). Actual production data for Tarrant County is also presented in the graph (the solid green line), as is projected production data for Tarrant County (the dashed turquoise line). To develop the projected production data for Tarrant County, it was assumed that the percentage growth in production in Tarrant County would increase (or decrease) at the same rate as the Barnett Shale as a whole.

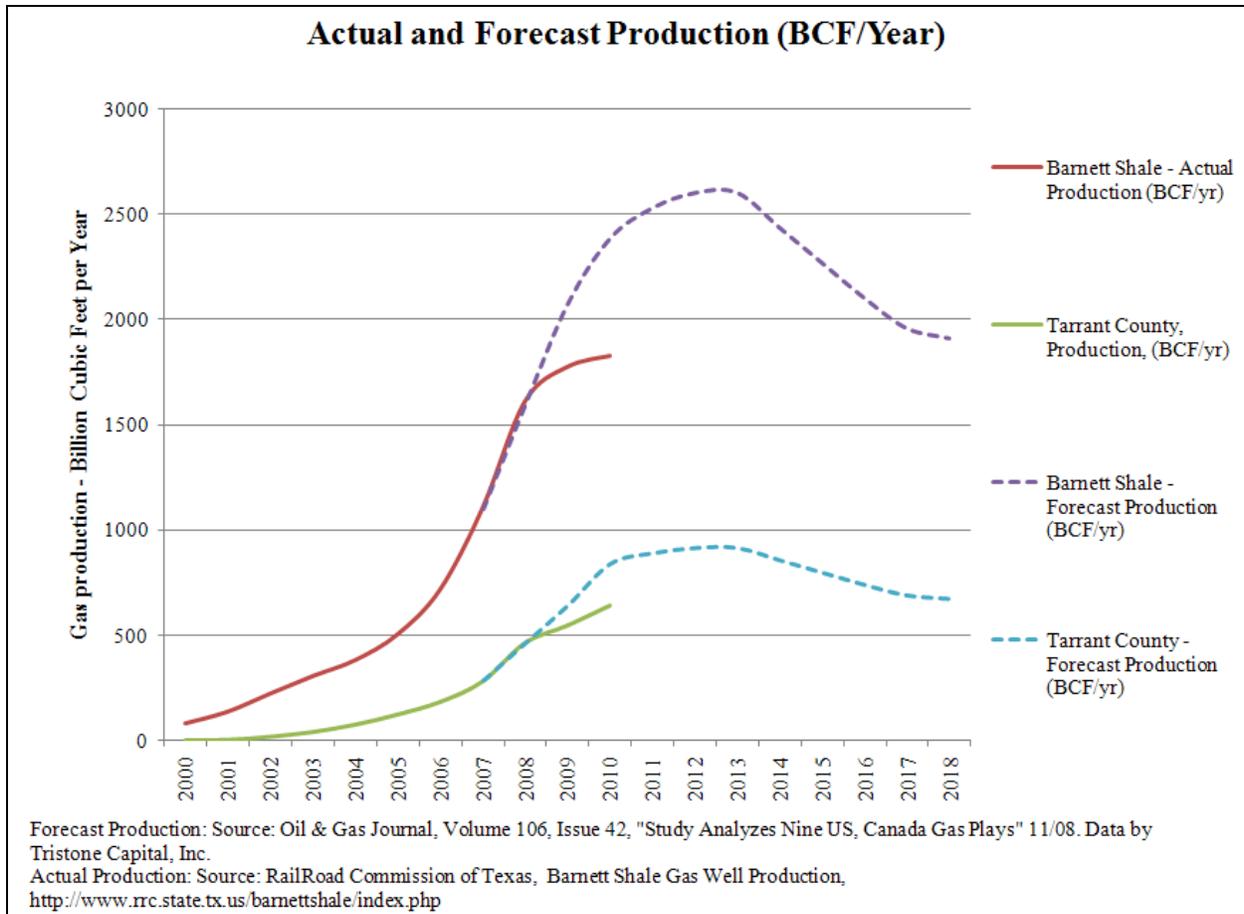

Figure 7.2-2. Barnett Shale and Tarrant County Actual and Projected Natural Gas Production (2000–2018)

As can be seen in the graph, Tristone’s estimates closely align with actual production through 2009, then appear to overestimate production. This may be attributed to the dramatic decrease in natural gas prices between 2008 and 2009, resulting in a decrease in drilling activity. Note that this decrease occurred after Tristone had published its projected trends in natural gas production activity. Therefore, ERG believes Tristone’s projections provide a conservative estimate of the peak natural gas production in the city of Fort Worth and has based the full build-out emissions inventory on this data, as described below.

7.3 2010 Base Year Emissions Inventory

Under Task 2 of the Fort Worth Natural Gas Air Quality Study, point source testing was conducted at 388 sites, including 375 well pads, eight compressor stations, and the gas processing plant. These data were used to calculate average emission rates for well pads and compressor stations. ERG used these average emission rates to develop a complete 2010 base year emissions inventory from natural gas production in the city of Fort Worth by multiplying the average emissions per well pad (and compressor station) by the total number of well pads (and compressor stations) operating in 2010. As documented in the Final Point Source Test Plan (October 4, 2010) there were 489 active well pads in the city of Fort Worth at the

commencement of this study. While data from the city of Fort Worth indicated there were 13 active compressor stations in Fort Worth at the start of this study, there were a total of 30 compressor stations either permitted, under construction, or already in service in 2010. Therefore, for purposes of developing the 2010 base year emissions inventory, it was assumed that there were 30 active compressor stations in Fort Worth in 2010.

Table 7.3-1 shows the average emissions for an individual well pad as determined from the point source testing, as well as the projected total 2010 base year emissions across all 489 well pads in the city of Fort Worth.

Table 7.3-1. 2010 Base Year Well Pad Emissions Inventory

| Pollutant | 2010 Base Year Average Well Pad Emissions (tons/yr) | 2010 Base Year Total Well Pad Emissions (tons/yr) |
|------------------------|--|--|
| TOC | 33.34 | 16,302.29 |
| VOCs | 0.68 | 332.71 |
| Total HAPs | 0.31 | 152.36 |
| Methane | 32.30 | 15,795.98 |
| PM | 0.03 | 13.57 |
| NO _x | 0.55 | 266.76 |
| CO | 4.77 | 2,330.62 |
| SO ₂ | 0.002 | 0.97 |
| Acenaphthene | 4.50E-06 | 2.20E-03 |
| Acenaphthylene | 1.87E-05 | 9.14E-03 |
| Acetaldehyde | 2.83E-02 | 1.38E+01 |
| Acetone | 2.52E-03 | 1.23E+00 |
| Acrolein | 2.63E-02 | 1.29E+01 |
| Anthracene | 2.43E-06 | 1.19E-03 |

7.4 2010 through 2018 Projected Emissions Inventories

Using the projected production data shown in Figure 7.2-2, growth factors (relative to the 2010 base year) were developed for years 2010 through 2018. Table 7.4-1 shows these factors, and indicates that projected peak production will occur in 2012 and 2013.

Table 7.4-1. Growth Factors for Years 2010–2018

| Year | Growth Factor |
|------|---------------|
| 2010 | 1.00 |
| 2011 | 1.06 |
| 2012 | 1.09 |
| 2013 | 1.09 |
| 2014 | 1.02 |
| 2015 | 0.95 |
| 2016 | 0.88 |
| 2017 | 0.82 |
| 2018 | 0.80 |

The growth factors shown in Table 7.4-1 were then used to project the 2010 base year emissions inventory to the years 2011 through 2018. Table 7.4-2 shows the resultant emissions inventory for each pollutant for each year.

Table 7.4-2. Projected Emissions for Years 2010–2018

| Pollutant | 2010 (tons/yr) | 2011 (tons/yr) | 2012 (tons/yr) | 2013 (tons/yr) | 2014 (tons/yr) | 2015 (tons/yr) | 2016 (tons/yr) | 2017 (tons/yr) | 2018 (tons/yr) |

7.5 Full Build-Out Estimates Conclusions

Emissions from the production of natural gas in the city of Fort Worth are projected to peak in 2012 and 2013, and in 2015 are projected to decrease to below 2010 levels. The projected peak emission levels occurring in 2012 and 2013 are expected to be 9% higher than emissions during the 2010 baseline year.

As discussed above, natural gas production is primarily dependent on the price that producers will receive. This concept is reflected in the demonstrated relationship between drilling rig and permit activity and natural gas prices. If the wellhead price for natural gas remains relatively low, as it is now, producers do not have economic incentive to invest in new exploration and drilling. Under this scenario, it is expected that total production from currently producing wells and leased wells not yet in production (but currently in development) will increase in the short term, followed by a slow decline.

Should wellhead prices for natural gas unexpectedly increase in future years, natural gas production and associated air emissions may be greater than projected. However, it is important to note that the longer natural gas prices remain flat, the lower the peak production rate will be, even with a spike in the price of natural gas. This is because the overall size of the resource, or the reserves, is finite, and the reserve decreases in size as each year passes. The data used in this analysis shows that, based on a reserve estimate of 30 trillion cubic feet of natural gas in the Barnett Shale, approximately one-third has already been depleted, and over 75% will have been recovered by the end of 2018.

Key Point: Barnett Shale

Based on a reserve estimate of 30 trillion cubic feet of natural gas, over 75% of the available natural gas in the Barnett Shale is projected to be recovered by the end of 2018.

8.0 Conclusions and Recommendations

Commencing with planning activities in July 2010 and field activities in August 2010, the Fort Worth Natural Gas Air Quality Study was a multi-phase project aimed at characterizing the air quality impacts of natural gas exploration and production, determining any potential health risks associated with those impacts, quantifying the total amount of pollutants being emitted, and determining if natural gas sites were in compliance with air quality regulations.

Two primary raw data collection activities were used: 1) an ambient air monitoring network, and 2) a systematic point source testing program. Point source testing data were then used to perform air dispersion modeling, and measured and modeled air concentrations were used in the public health evaluation. Each of these tasks was designed to help city officials answer the following questions:

- How much air pollution is being released by natural gas exploration in Fort Worth?
- Do sites comply with environmental regulation?
- How do releases from these sites affect off-site air pollution levels?
- Are the city's required setbacks for these sites adequate to protect public health?

Section 8.1 provides a summary of the conclusions for each task of this study, Section 8.2 includes answers to the four primary study questions, and Section 8.3 provides specific recommendations for ensuring that emissions from natural gas sites do not cause unhealthy air pollution levels.

8.1 Task Level Conclusions

As discussed previously, the Fort Worth Natural Gas Air Quality Study was multi-faceted and included Ambient Air Monitoring, Point Source Testing, Air Dispersion Modeling, a Public Health Evaluation, a Regulatory Assessment, and Full Build-Out Estimates. The key findings for each of these tasks are provided below.

Key findings of the Ambient Air Monitoring task include:

- 169 ambient air samples from 8 locations in Fort Worth were collected and analyzed, resulting in over 15,000 ambient air data points generated for this study.
- Methane, ethane, propane, and butane were the pollutants found at highest concentrations. However, more toxic pollutants (e.g., benzene) were also found, but generally at much lower levels.
- Concentrations measured at Site S-4 (located in a high-level activity area near compressor stations, well pads, and mobile sources) were generally higher than at the other sites.
- Concentrations measured at Sites S-6 and S-7 (both located within 350 of active well pads) were surprisingly low relative to the other sites.

- Wind patterns observed during the sampling period were consistent with historical wind patterns, indicating proper placement of the ambient air monitors.

Key findings of the Point Source Testing task include:

- At 96 sites, no emissions were detected by the IR camera. Most of these sites contained 3 wells or less.
- The largest source of fugitive emissions detected with the IR camera was leaking tank thief hatches.
- Pneumatic Valve Controllers were the most frequent emission sources encountered at well pads and compressor stations.
- Compressor engines have a significant impact on emissions, especially the large line compressors found at compressor stations.
- There was little difference in average TOC emissions between dry and wet gas sites, but average VOC and HAP emissions from wet gas sites proved to be considerably higher.

Key findings of the Public Health Evaluation task (including analysis of the emissions concentrations predicted under the Air Dispersion Modeling task) include:

- Benzene emissions from tanks could lead to air pollution levels slightly higher than TCEQ's short-term ESL, but only in very close proximity to the highest-emitting tanks.
- Large line engines can emit acrolein and formaldehyde at levels that would cause offsite ambient air concentrations to exceed TCEQ's short-term and long-term screening levels over various distances. This finding is based entirely on estimated emission rates.
- Trace levels of halogenated hydrocarbons detected during the ambient air monitoring program are not likely to be attributable to emissions from natural gas exploration and production activity.

Key findings of the Regulatory Assessment task include:

- Five sites had cumulative VOC emissions greater than the PBR trigger level of 25 tons/yr and/or CO emissions greater than the major source threshold of 100 tons/yr.

Key findings of the Full Build-Out Estimates task include:

- Emissions from the production of natural gas in the city of Fort Worth are projected to peak in 2012 and 2013 at 9% above 2010 levels.

- Total VOC emissions from the production of natural gas in the city of Fort Worth are estimated to peak at approximately 1,012 tons per year in 2012.
- Total HAP emissions from the production of natural gas in the city of Fort Worth are estimated to peak at approximately 550 tons per year in 2012.
- Total methane emissions from the production of natural gas in the city of Fort Worth are estimated to peak at approximately 20,742 tons per year in 2012.

8.2 Study Question Answers

How much air pollution is being released by natural gas exploration in Fort Worth?

During the point source testing, field personnel determined the amount of air pollution released at individual well pads, compressor stations, and other natural gas processing facilities by visiting 388 sites and testing the equipment at each site for emissions. Table 8.2-1 shows the average emissions of TOC, VOCs, and HAPs for each site type that was visited. In the table, the emissions of HAPs are a subset of emissions of VOCs, and the emissions of VOCs are a subset of the TOC emissions. The primary air pollutant emitted at all sites was methane, which is not considered a VOC but constitutes over 94% of the TOC estimate for all sites combined.

Table 8.2-1. Average Emissions by Site Type

| Site Type | Average TOC (tons/yr) | Average VOC (tons/yr) | Average HAP (tons/yr) |
|------------------------------|--------------------------|--------------------------|--------------------------|
| Well Pad | 16 | 0.07 | 0.02 |
| Well Pad with Compressor(s) | 68 | 2 | 0.9 |
| Compressor Station | 99 | 17 | 10 |
| Processing Facility | 1,293 | 80 | 47 |
| Saltwater Treatment Facility | 1.5 | 0.65 | 0.4 |

Under Task 7 (full build-out estimates), the results of the point source testing task were used to estimate total emissions from the gas processing plant and all well pads and compressor stations in the city of Fort Worth. Table 8.2-2 summarizes city-wide emissions from these operations.

Table 8.2-2. Total City-Wide Emissions from Natural Gas Production Activity, by Pollutant Category

| Pollutant | Total Compressor Station Emissions (tons/yr) | Total Well Pad Emissions (tons/yr) | Total Gas Processing Plant Emissions (tons/yr) | Total Emissions (tons/yr) |
|------------|--|---------------------------------------|--|---------------------------------|
| TOC | 2,988 | 16,302 | 1,293 | 20,584 |
| VOCs | 516 | 333 | 80 | 929 |
| Total HAPs | 305 | 152 | 47 | 505 |

Table 8.2-2. Total City-Wide Emissions from Natural Gas Production Activity, by Pollutant Category (Continued)

| Pollutant | Total Compressor Station Emissions (tons/yr) | Total Well Pad Emissions (tons/yr) | Total Gas Processing Plant Emissions (tons/yr) | Total Emissions (tons/yr) |
|-----------------|--|------------------------------------|--|---------------------------|
| Methane | 2,081 | 15,796 | 1,152.60 | 19,030 |
| PM | 10.94 | 13.57 | 1.00 | 25.51 |
| NO _x | 588.88 | 266.76 | 87.74 | 943.38 |
| CO | 4,544.19 | 2,330.62 | 1,038.90 | 7,913.71 |
| SO ₂ | 2.17 | 0.97 | 0.34 | 3.48 |

Do sites comply with environmental regulations?

A number of federal and state air quality regulations could apply to well pads and compressor stations. Each of the potentially applicable rules is discussed in Section 6. While a comprehensive, site-specific regulatory analysis was not possible for each site visited, some broad observations have been made based on the results of the point source testing.

In particular, the primary environmental regulation that would be applicable to the facilities visited under Task 3 is TCEQ's permit-by-rule for oil and gas handling and production facilities. This regulation allows certain sources a streamlined permitting process if they have emissions below 25 tpy of VOCs and 250 tpy of CO. Sites with emissions of CO greater than 100 tpy, of any single HAP greater than 10 tpy, or any combination of HAPs greater than 25 tpy would also be required to operate under a Title V operating permit.

As a result of the point source testing task, five potential sources were identified with site-wide emissions estimates exceeding these thresholds. These larger emitting sites generally had more compressor engine capacity, resulting in higher VOC and CO emissions when compared to sites with fewer, or smaller, engines. Table 8.2-3 lists the sites with estimated emissions exceeding regulatory thresholds.

Table 8.2-3. Sources Above Regulatory Thresholds

| Site ID | Site Type | VOC (tons/yr) | CO (tons/yr) | Total HAP (tons/yr) | Formaldehyde (tons/yr) |
|---------|---------------------|-----------------|-----------------------|---------------------|------------------------|
| PS-159 | Processing Facility | 80 ^a | 1,039 ^{b, c} | 47 ^d | 32 ^e |
| PS-118 | Compressor Station | 43 ^a | 270 ^{b, c} | 25 ^d | 17 ^e |
| PS-119 | Compressor Station | 38 ^a | 240 ^c | 22 | 15 ^c |
| PS-127 | Compressor Station | 24 | 545 ^{b, c} | 14 | 9 |
| 238 | Well Pad | 14 | 219 ^c | 8 | 6 |

^a This site potentially exceeds the 25 tpy VOC threshold under 30 TAC 106, Subchapter O, Section 106.352.

^b This site potentially exceeds the 250 tpy CO threshold under 30 TAC 106, Subchapter O, Section 106.352.

^c This site potentially exceeds the 100 tpy CO threshold under the federal Title V Operating Permit Program.

^d This site potentially exceeds the 25 tpy total HAP threshold under the federal Title V Operating Permit Program.

^e This site potentially exceeds the 10 tpy single HAP threshold under the federal Title V Operating Permit Program.

How do releases from these sites affect off-site air pollution levels?

Under Task 2 of this project, ambient air monitoring was conducted to measure concentrations of selected air toxics present in the air outside the property boundaries of air emissions sources such as a natural gas well pads and compressor stations. Over 160 air samples were collected in September and October of 2010, resulting in over 15,000 data points being generated for this study. Table 8.2-4 provides a summary of these measured off-site air pollution levels for selected pollutants.

Table 8.2-4. Off-Site Air Pollution Levels for Selected Pollutants as Determined Through the Ambient Air Monitoring Network

| Pollutant | Number of Detects | Number of Samples | Average of Detects (ppbv) ^a | Minimum Detected Value (ppbv) | Maximum Detected Value (ppbv) |
|----------------------|-------------------|-------------------|--|-------------------------------|-------------------------------|
| Acetaldehyde | 40 | 40 | 2.813 | 0.83 | 9.06 |
| Benzene | 121 | 129 | 0.291 | 0.0635 | 1.83 |
| Butadiene, 1,3- | 86 | 129 | 0.057 | 0.01 | 0.304 |
| Carbon disulfide | 92 | 92 | 0.243 | 0.008 | 1.64 |
| Carbon tetrachloride | 126 | 129 | 0.112 | 0.053 | 0.142 |
| Formaldehyde | 40 | 40 | 0.931 | 0.41 | 4.45 |
| Tetrachloroethylene | 81 | 129 | 0.043 | 0.01 | 0.218 |

^a These averages only include the average of the detected values for each pollutant.

Under Task 4 of this project, a dispersion modeling was used to predict the downwind concentrations of pollutants emitted from well pads and compressor stations. The modeling provided valuable insights into air quality at locations where, and at times when, ambient air samples were not collected. The modeling was conducted for typical and “worst-case” emissions scenarios. Table 8.2-5 summarizes predicted off-site air concentrations for selected pollutants.

Table 8.2-5. Off-Site Air Pollution Levels for Selected Pollutants as Determined Through Air Dispersion Modeling

| Pollutant | Highest Estimated 1-Hour Average Concentration Beyond Well Pad Fence Lines (ppbv) | Highest Estimated 24-Hour Average Concentration Beyond Well Pad Fence Lines (ppbv) | Highest Estimated Annual Average Concentration at Locations 200 Feet Beyond Fence Lines (ppbv) |
|----------------|---|--|--|
| Acrolein | 2.62 | 1.43 | 0.33 |
| Benzene | 59.5 | 13.4 | 0.24 |
| Butadiene, 1,3 | 0.29 | 0.16 | 0.036 |
| Formaldehyde | 34.7 | 18.9 | 4.34 |

Are the city's required setbacks for these sites adequate to protect public health?

ERG conducted a health screening evaluation to evaluate the health implications of air emissions from natural gas exploration and production activity. This evaluation was based on protective health-based screening values, primarily those published by TCEQ, though consideration was also given to EPA and ATSDR values for the pollutants of greatest concern. The ambient air monitoring data revealed no site-related pollutants with 24-hour average concentrations or program-average concentrations above TCEQ's health-based screening levels. The modeling analysis identified three pollutants—acrolein, benzene, and formaldehyde—with estimated 1-hour average or annual average concentrations above screening levels at some offsite locations. This was most prevalent for sites with multiple, large line compressor engines. However, due to the highly protective nature of the health-based screening values, none of the estimated concentrations reached levels expected to be associated with adverse health effects.

The modeling analysis served as the basis for evaluating the adequacy of setback distances. For the overwhelming majority of sites considered in this study, the modeling results indicate that Fort Worth's 600-foot setback distance is adequate. More specifically, for sites with no engines and for sites with smaller lift engines, no pollutants were found to have estimated 1-hour maximum or annual average concentrations above TCEQ's applicable health-based screening levels beyond the setback distances. For the relatively few sites with multiple, large line engines, the modeling analysis found some areas beyond the setbacks to have estimated acrolein and formaldehyde concentrations greater than TCEQ's ESLs, though not reaching concentrations expected to cause adverse health effects. For both pollutants, ERG's modeling is based entirely on estimated emission rates, and not measured values. This underscores the value of obtaining more detailed acrolein and formaldehyde emissions data for line engines and focused ambient air monitoring to validate these findings. Such studies would provide greater confidence in the adequacy and protectiveness of the city's setbacks.

8.3 Recommendations

Although this study did not reveal any significant health threats beyond setback distances, it is important to remember that the sources of concern for this project—natural gas exploration and production activity—are located in residential settings throughout a metropolitan area. Though the most toxic pollutants these sources emit are released in relatively low quantities, all reasonable precautions to reduce emissions from the well pads and compressor stations should be made. This is particularly important for tanks and line compressor engines, because these two sources accounted for the greatest portion of the risks observed for the pollutants selected for further evaluation. Such precautions would include the installation and operation of the following air pollution control equipment:

Vapor Recovery Units on storage tanks – storage tanks are the highest source of benzene emissions, and vapor recovery units could reduce these emissions by 90% or more. This would be most beneficial at wet gas sites with higher condensate production.

3-way catalysts and/or catalytic oxidizers on compressor station compressor engines – the large compressor engines located at compressor stations are the main source of acrolein and

formaldehyde, the two pollutants of greatest concern from a public health perspective. 3-way catalysts are primarily NO_x control technologies, but have a co-benefit of reducing CO and VOC emissions. Catalytic oxidizers are used to control CO and VOC emissions.

Electric compressor engines – As many of the compressor stations in Fort Worth are located in an urban setting, easy access to the electric grid also provides an opportunity to eliminate emissions from compressor engines completely through the use of electric motors.

Low bleed or no bleed pneumatic valve controllers – Pneumatic valve controllers were the most frequent fugitive emission source found during the point source testing task. Under EPA's voluntary Natural Gas STAR Program, the use of low bleed valve controllers and electric valve controllers is encouraged and has proven effective in reducing VOC (and methane) emissions from natural gas operations.

In addition to these air pollution control equipment recommendations, enhanced inspection and maintenance of equipment at natural gas sites can help ensure that preventable emissions are greatly reduced or eliminated. At a small subset of sites, the point source testing team noted signs of malfunctioning equipment that likely caused increased emissions. For example, some hatches atop tanks were ajar and not closed, and corrosion had apparently caused a hole to form on the roof of at least one tank.

The emission estimates used in this study for acrolein and formaldehyde are based on the best emissions information currently available for compressor engines – emission factors from U.S. EPA's Compilation of Air Pollutant Emission Factors (AP-42).²⁸ As control of acrolein and formaldehyde emissions from compressor engines is not explicitly required under any current regulation, no control efficiency was assumed in our estimates. Options available to confirm our assumptions and findings with regards to these pollutants include:

- Contact compressor station owners and operators to establish the frequency at which their engines have installed controls, and to obtain any existing stack testing results
- Analyze the findings of TCEQ's Phase II Barnett Shale Area Special Inventory efforts to establish the frequency at which compressor engines have installed controls
- Conduct point source stack testing at the exhaust of compressor engines to characterize acrolein and formaldehyde emissions
- Conduct focused ambient air monitoring of acrolein and formaldehyde emissions in close proximity to the larger compressor stations

Finally, ERG fully supports continued ambient air monitoring in and around the city of Fort Worth in order to confirm the key findings of this report. In particular, the results of TCEQ's ongoing monitoring efforts in the Barnett Shale should be monitored for any changes in air quality in Fort Worth as worsening air quality may require additional response such as additional controls or site maintenance requirements.

1.0 Purpose

In general, EPA has found significant widespread noncompliance with Leak Detection and Repair (LDAR) regulations and more specifically, noncompliance with Method 21 requirements. In 1999, EPA estimated that, as a result of this noncompliance, an additional 40,000 tons of VOCs are emitted annually from valves at petroleum refineries alone.

This document is intended for use by regulated entities as well as compliance inspectors to identify some of the problems identified with LDAR programs focusing in on Method 21 requirements and describe the practices that can be used to increase the effectiveness of an LDAR program. Specifically, this document explains:

- The importance of regulating equipment leaks;
- The major elements of an LDAR program;
- Typical mistakes made when monitoring to detect leaks;
- Problems that occur from improper management of an LDAR program; and
- A set of best practices that can be used to implement effective an LDAR program.

Some of the elements of a model LDAR program, as described in Section 7.0, are required by current Federal regulations. Other model LDAR program elements help ensure continuous compliance although they may not be mandated from a regulatory standpoint. Furthermore, State or local requirements may be more stringent than some elements of the model LDAR program, such as with leak definitions. Prior to developing a written LDAR program plan, all applicable regulations should be reviewed to determine and ensure compliance with the most stringent requirements.

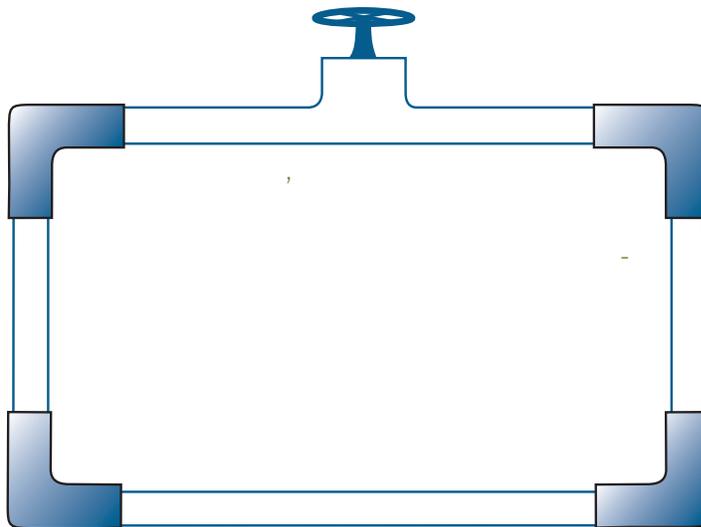

2.0 Why Regulate Equipment Leaks?

EPA has determined that leaking equipment, such as valves, pumps, and connectors, are the largest source of emissions of volatile organic compounds (VOCs) and volatile hazardous air pollutants (VHAPs) from petroleum refineries and chemical manufacturing facilities. The Agency has estimated that approximately 70,367 tons per year of VOCs and 9,357 tons per year of HAPs have been emitted from equipment leaks. Emissions from equipment leaks exceed emissions from storage vessels, wastewater, transfer operations, or process vents.

VOCs contribute to the formation of ground-level ozone. Ozone is a major component of smog, and causes or aggravates respiratory disease, particularly in children, asthmatics, and healthy adults who participate in moderate exercise. Many areas of the United States, particularly those areas

where refineries and chemical facilities are located, do not meet the National Ambient Air Quality Standard (NAAQS) for ozone. Ozone can be transported in the atmosphere and contribute to nonattainment in downwind areas.

Some species of VOCs are also classified as VHAPs. Some known or suspected effects of exposure to VHAPs include cancer, reproductive effects, and birth defects. The highest concentrations of VHAPs tend to be closest to the emission source, where the highest public exposure levels are also often detected. Some common VHAPs emitted from refineries and chemical plants include acetaldehyde, benzene, formaldehyde, methylene chloride, naphthalene, toluene, and xylene.

3.0 Sources, Causes And Control Of Equipment Leaks

A typical refinery or chemical plant can emit 600-700 tons per year of VOCs from leaking equipment, such as valves, connectors, pumps, sampling connections, compressors, pressure-relief devices, and open-ended lines.

Table 3.1 shows the primary sources of emissions from components subject to equipment leak regulations. In a typical facility, most of the emissions are from valves and connectors because these are the most prevalent components and can number in the thousands (Table 3.2). The major cause of emissions from valves and connectors is seal or gasket failure due to normal wear or improper maintenance.

Previous EPA studies have estimated that valves and connectors account for more than 90% of emissions from leaking equipment with valves being the most significant source (Table 3.3). Newer information suggests that open-ended lines and sampling connections may account for as much as 5-10% of total VOC emissions from equipment leaks.

3.1 How are emissions from equipment leaks reduced?

Facilities can control emissions from equipment leaks by implementing a leak detection and repair (LDAR) program or by modifying/replacing leaking equipment with “leakless” components. Most equipment leak regulations allow a combination of both control methods.

- Leaks from open-ended lines, compressors, and sampling connections are usually fixed

by modifying the equipment or component. Emissions from pumps and valves can also be reduced through the use of “leakless” valves and “sealless” pumps. Common leakless valves include bellows valves and diaphragm valves, and common sealless pumps are diaphragm pumps, canned motor pumps, and magnetic drive pumps. Leaks from pumps can also be reduced by using dual seals with or without barrier fluid.

- Leakless valves and sealless pumps are effective at minimizing or eliminating leaks, but their use may be limited by materials of construction considerations and process operating conditions. Installing leakless and sealless equipment components may be a wise choice for replacing individual, chronic leaking components.

LDAR is a work practice designed to identify leaking equipment so that emissions can be reduced through repairs. A component that is subject to LDAR requirements must be monitored at specified, regular intervals to determine whether or not it is leaking. Any leaking component must then be repaired or replaced within a specified time frame.

Table 3.1 – Sources of equipment leaks.

Pumps are used to move fluids from one point to another. Two types of pumps extensively used in petroleum refineries and chemical plants are centrifugal pumps and positive displacement, or reciprocating pumps.

Valves are used to either restrict or allow the movement of fluids. Valves come in numerous varieties and with the exception of connectors, are the most common piece of process equipment in industry.

Connectors are components such as flanges and fittings used to join piping and process equipment together. Gaskets and blinds are usually installed between flanges.

Sampling connections are utilized to obtain samples from within a process.

Compressors are designed to increase the pressure of a fluid and provide motive force. They can have rotary or reciprocating designs.

Pressure relief devices are safety devices designed to protect equipment from exceeding the maximum allowable working pressure. Pressure relief valves and rupture disks are examples of pressure relief devices.

Open-ended lines are pipes or hoses open to the atmosphere or surrounding environment.

Leaks from pumps typically occur at the seal.

Leaks from valves usually occur at the stem or gland area of the valve body and are commonly caused by a failure of the valve packing or O-ring.

Leaks from connectors are commonly caused from gasket failure and improperly torqued bolts on flanges.

Leaks from sampling connections usually occur at the outlet of the sampling valve when the sampling line is purged to obtain the sample.

Leaks from compressors most often occur from the seals.

Leaks from pressure relief valves can occur if the valve is not seated properly, operating too close to the set point, or if the seal is worn or damaged. Leaks from rupture disks can occur around the disk gasket if not properly installed.

Leaks from open-ended lines occur at the point of the line open to the atmosphere and are usually controlled by using caps, plugs, and flanges. Leaks can also be caused by the incorrect implementation of the block and bleed procedure.

Table 3.2 – Equipment component counts at a typical refinery or chemical plant.

| Component | Range | Average |
|------------------------|--------------|---------|
| Pumps | 10 – 360 | 100 |
| Valves | 150 – 46,000 | 7,400 |
| Connectors | 600 – 60,000 | 12,000 |
| Open-ended lines | 1 – 1,600 | 560 |
| Sampling connections | 20 – 200 | 80 |
| Pressure relief valves | 5 – 360 | 90 |

Table 3.3 – Uncontrolled VOC emissions at a typical facility.

| Component | Average Uncontrolled VOC Emissions (ton/yr) | Percent of Total Emissions |
|------------------------|---|----------------------------|
| Pumps | 19 | 3 |
| Valves | 408 | 62 |
| Connectors | 201 | 31 |
| Open-ended lines | 9 | 1 |
| Sampling connections | 11 | 2 |
| Pressure relief valves | 5 | 1 |
| Total | 653 | |

Source: Emission factors are from Protocol for Equipment Leak Emission Estimates, EPA-453/R-95-017, Nov 1995, and equipment counts in Table 3.2.

More recent data indicates that open-ended lines and sampling connections each account for approximately 5-10% of total VOC emissions.

3.2 What regulations incorporate LDAR programs?

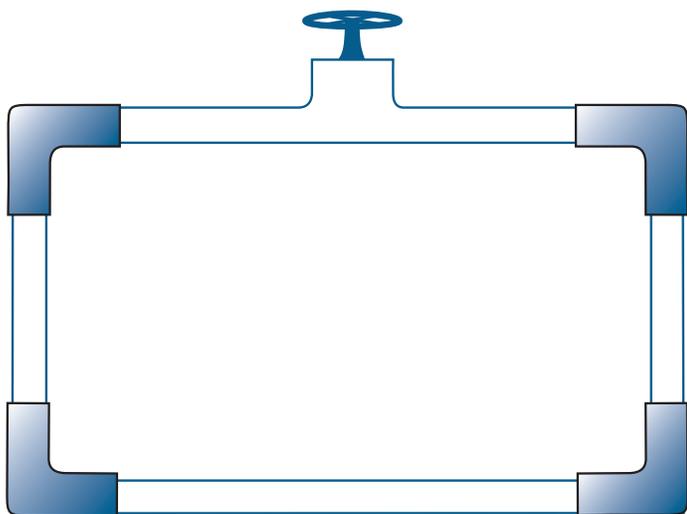

LDAR programs are required by many New Source Performance Standards (NSPS), National Emission Standards for Hazardous Air Pollutants (NESHAP), State Implementation Plans (SIPs), the Resource Conservation and Recovery Act (RCRA), and other state or local requirements. There are 25 federal standards that require facilities to implement LDAR programs. Appendix A shows the 25 federal standards that require the implementation of a formal LDAR program using Method 21. Appendix B lists 28 other federal regulations that require some Method 21 monitoring, but do not require LDAR programs to be in place.

- NSPS (40 CFR Part 60) equipment leak standards are related to fugitive emissions of VOCs and apply to stationary sources that commence construction, modification, or reconstruction after the date that an NSPS is proposed in the Federal Register.
- NESHAP (40 CFR Parts 61, 63, and 65) equipment leak standards apply to both new and

existing stationary sources of fugitive VHAPs.

- RCRA (40 CFR Parts 264 and 265) equipment leak standards apply to hazardous waste treatment, storage, and disposal facilities.
- Many state and local air agencies incorporate federal LDAR requirements by reference, but some have established more stringent LDAR requirements to meet local air quality needs.

A facility may have equipment that is subject to multiple NSPS and NESHAP equipment leaks standards. For example, a number of manufacturing processes listed in the Hazardous Organic NESHAP (HON) equipment leak standard (40 CFR 63, Subpart H) may utilize equipment for which other NESHAP or NSPS equipment leak standards could apply (such as 40 CFR 60, Subpart VV). In addition, one process line may be subject to one rule and another process line subject to another rule. Facilities must ensure that they are complying with the proper equipment leak regulations if multiple regulations apply.

4.0 What Are the Benefits of an LDAR Program?

When the LDAR requirements were developed, EPA estimated that petroleum refineries could reduce emissions from equipment leaks by 63% by implementing a facility LDAR program. Additionally, EPA estimated that chemical facilities could reduce VOC emissions by 56% by implementing such a program.

Table 4.1 presents the control effectiveness of an LDAR program for different monitoring intervals and leak definitions at chemical process units and petroleum refineries.

Emissions reductions from implementing an LDAR program potentially reduce product losses, increase safety for workers and operators, decrease exposure of the surrounding community, reduce emissions fees, and help facilities avoid enforcement actions.

Example – Emissions reductions at a typical SOCM facility.

Applying the equipment modifications and LDAR requirements of the HON to the sources of uncontrolled emissions in the typical facility presented in Tables 3.2 and 3.3 would reduce the emissions per facility by approximately 582 tons per year of emissions, an 89% reduction.

Table 4.1 – Control effectiveness for an LDAR program at a chemical process unit and a refinery.

| Equipment Type and Service | Control Effectiveness (% Reduction) | | |
|--|--|---|---|
| | Monthly Monitoring 10,000 ppmv Leak Definition | Quarterly Monitoring 10,000 ppmv Leak Definition | 500 ppm Leak Definition ^a |
| Chemical Process Unit | | | |
| Valves – Gas Service ^b | 87 | 67 | 92 |
| Valves – Light Liquid Service ^c | 84 | 61 | 88 |
| Pumps – Light Liquid Service ^c | 69 | 45 | 75 |
| Connectors – All Services | | | 93 |
| Refinery | | | |
| Valves – Gas Service ^b | 88 | 70 | 96 |
| Valves – Light Liquid Service ^c | 76 | 61 | 95 |
| Pumps – Light Liquid Service ^c | 68 | 45 | 88 |
| Connectors – All Services | | | 81 |

Source: Protocol for Equipment Leak Emission Estimates, EPA-453/R-95-017, Nov 1995.

^a Control effectiveness attributable to the HON-negotiated equipment leak regulation (40 CFR 63, Subpart H) is estimated based on equipment-specific leak definitions and performance levels. However, pumps subject to the HON at existing process units have a 1,000 to 5,000 ppm leak definition, depending on the type of process.

^b Gas (vapor) service means the material in contact with the equipment component is in a gaseous state at the process operating conditions.

^c Light liquid service means the material in contact with the equipment component is in a liquid state in which the sum of the concentration of individual constituents with a vapor pressure above 0.3 kilopascals (kPa) at 20°C is greater than or equal to 20% by weight.

4.1 Reducing Product Losses

In the petrochemical industry, saleable products are lost whenever emissions escape from process equipment. Lost product generally translates into lost revenue.

4.2 Increasing Safety for Facility Workers and Operators

Many of the compounds emitted from refineries and chemical facilities may pose a hazard to exposed workers and operators. Reducing emissions from leaking equipment has the direct benefit of reducing occupational exposure to hazardous compounds.

4.3 Decreasing Exposure for the Surrounding Community

In addition to workers and operators at a facility, the population of a surrounding community can be affected by severe, long-term exposure to toxic air pollutants as a result of leaking equipment. Although most of the community exposure may be episodic, chronic health effects can result from long-term exposure to emissions from leaking equipment that is either not identified as leaking or not repaired.

4.4 Potentially Reducing Emission Fees

To fund permitting programs, some states and local air pollution districts charge annual fees that are based on total facility emissions. A facility with an effective program for reducing leaking equipment can potentially decrease the amount of these annual fees.

4.5 Avoiding Enforcement Actions

In setting Compliance and Enforcement National Priorities for Air Toxics, EPA has identified LDAR programs as a national focus. Therefore, facilities can expect an increased number and frequency of compliance inspections and a closer review of compliance reports submitted to permitting authorities in an effort by the Agency to assess LDAR programs and identify potential LDAR problems. A facility with an effective LDAR program decreases the chances of being targeted for enforcement actions and avoids the costs and penalties associated with rule violations.

Example – Cost of product lost.

In previous rulemaking efforts, EPA has estimated that the average value of product lost due to equipment leaks is \$1,370 per ton.^a

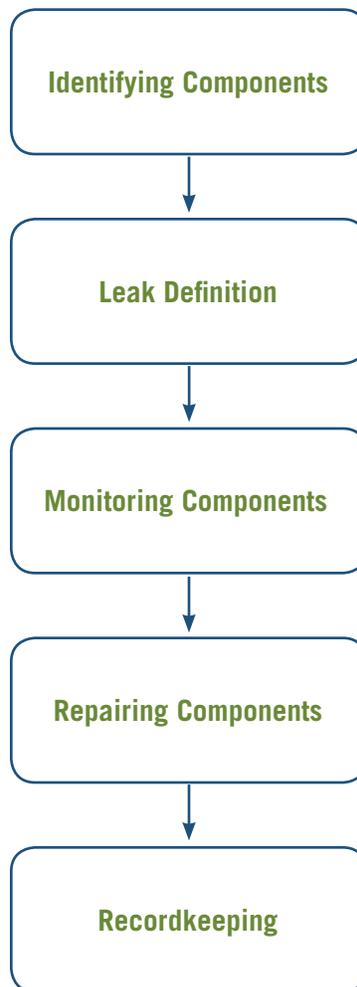

Applying this cost factor results in a potential savings of \$730,000 per year per facility.

Emission Standards Division, US EPA, Office of Air and Radiation, OAQPS, Research Triangle Park, NC. Nov 1992.

5.0 Elements of an LDAR Program

The requirements among the regulations vary, but all LDAR programs consist of five basic elements, which are discussed in detail in Sections 5.1 through 5.5.

For each element, this section outlines the typical LDAR program requirements, common compliance problems found through field inspections, and a set of best practices used by facilities with effective LDAR programs.

Current Requirements

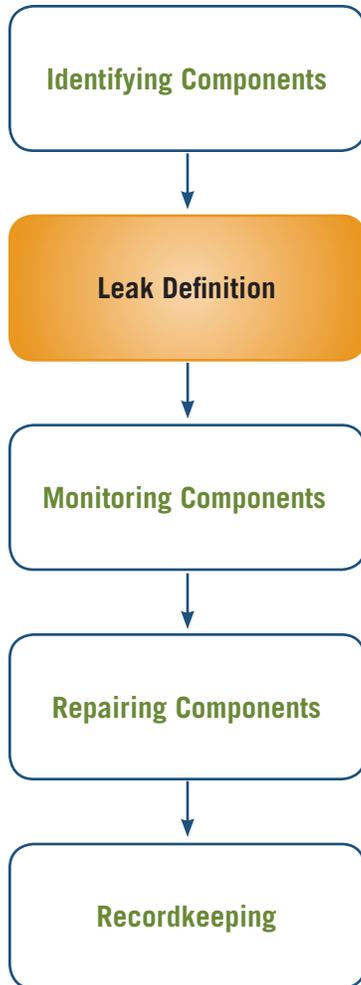

- Assign a unique identification (ID) number to each regulated component.
- Record each regulated component and its unique ID number in a log.
- Physically locate each regulated component in the facility, verify its location on the piping and instrumentation diagrams (P&IDs) or process flow diagrams, and update the log if necessary. Some states require a physical tag on each component subject to the LDAR requirements.
- Identify each regulated component on a site plot plan or on a continuously updated equipment log.
- Promptly note in the equipment log when new and replacement pieces of equipment are added and equipment is taken out of service.

Common Problems

- Not properly identifying all regulated equipment components.
- Not properly documenting exempt components (e.g., <300 hour exemption and <5 (or <10) weight % HAP).

Best Practices

- Physically tag each regulated equipment component with a unique ID number.
- Write the component ID number on piping and instrumentation diagrams.
- Institute an electronic data management system for LDAR data and records, possibly including the use of bar coding equipment.
- Periodically perform a field audit to ensure lists and diagrams accurately represent equipment installed in the plant.

Current Requirements

- Method 21 requires VOC emissions from regulated components to be measured in parts per million (ppm). A leak is detected whenever the measured concentration exceeds the threshold standard (i.e., **leak definition**) for the applicable regulation.
 - Leak definitions vary by regulation, component type, service (e.g., light liquid, heavy liquid, gas/vapor), and monitoring interval.
 - Most NSPS have a leak definition of 10,000 ppm. Many NESHAP use a 500-ppm or 1,000-ppm leak definition.
- Many equipment leak regulations also define a leak based on visual inspections and observations (such as fluids dripping, spraying, misting or clouding from or around components), sound (such as hissing), and smell.

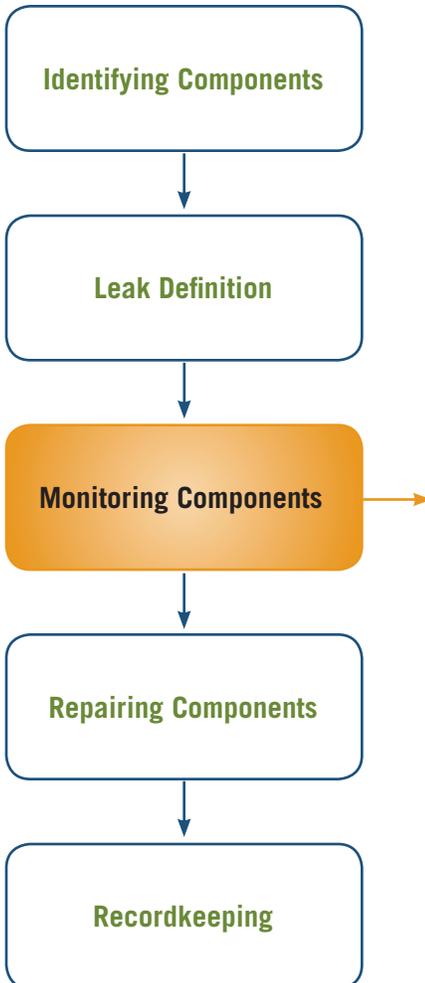

Note: The LDAR requirements specify weekly visual inspections of pumps, agitators, and compressors for indications of liquids leaking from the seals.

Common Problems

- Using the wrong leak definition for a particular component due to confusion at facilities where multiple LDAR regulations apply.

Best Practices

- Utilize a leak definition lower than what the regulation requires.
- Simplify the program by using the lowest leak definition when multiple leak definitions exist.
- Make the lowest leak definition conservative to provide a margin of safety when monitoring components.
- Keep the lowest leak definition consistent among all similar component types. For example, all valves in a facility might have a leak definition of 500 ppm.

The **monitoring interval** is the frequency at which individual component monitoring is conducted. For example, valves are generally required to be monitored once a month using a leak detection instrument, but the monitoring interval may be extended (e.g. to once every quarter for each valve that has not leaked for two successive months for Part 60 Subpart VV, or on a process unit basis of once every quarter for process units that have less than a 2% leak rate for Part 63 Subpart H).

Current Requirements

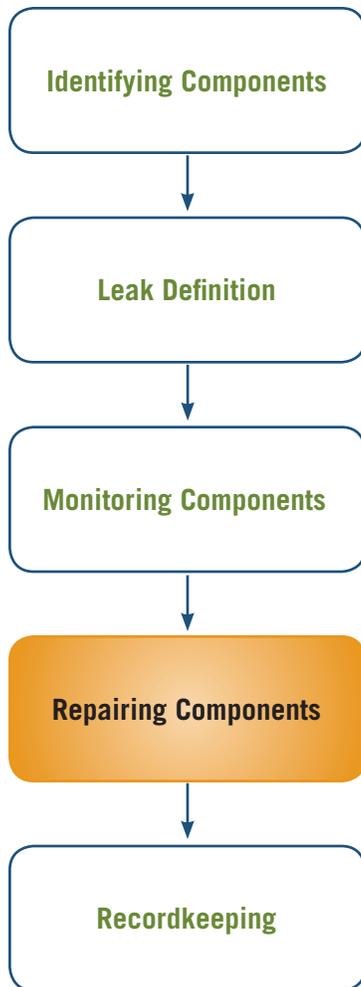

- For many NSPS and NESHAP regulations with leak detection provisions, the primary method for monitoring to detect leaking components is EPA Reference Method 21 (40 CFR Part 60, Appendix A).
- Method 21 is a procedure used to detect VOC leaks from process equipment using a portable detecting instrument.
- Appendix C of this guide explains the general procedure and Appendix D presents the complete Method 21 requirements.
- Monitoring intervals vary according to the applicable regulation, but are typically weekly, monthly, quarterly, and yearly. For connectors, the monitoring interval can be every 2, 4, or 8 years. The monitoring interval depends on the component type and periodic leak rate for the component type.

Common Problems

- Not following Method 21 properly.
- Failing to monitor at the maximum leak location (once the highest reading is obtained by placing the probe on and around the interface, hold the probe at that location approximately two times the response rate of the instrument).
- Not monitoring long enough to identify a leak.
- Holding the detection probe too far away from the component interface. The reading must be taken at the interface.
- Not monitoring all potential leak interfaces.
- Using an incorrect or an expired calibration gas.
- Not monitoring all regulated components.
- Not completing monitoring if the first monitoring attempt is unsuccessful due to equipment being temporarily out of service.

Best Practices

- Although not required by Method 21, use an automatic (electronic) data logger to save time, improve accuracy, and provide an audit record.
- Audit the LDAR program to help ensure that the correct equipment is being monitored, Method 21 procedures are being followed properly, and the required records are being kept.
- Monitor components more frequently than required by the regulations.
- Perform QA/QC of LDAR data to ensure accuracy, completeness, and to check for inconsistencies.
- Eliminate any obstructions (e.g., grease on the component interface) that would prevent monitoring at the interface.
- If a rule allows the use of alternatives to Method 21 monitoring, Method 21 should still be used periodically to check the results of the alternative monitoring method.

Current Requirements

- Repair leaking components as soon as practicable, but not later than a specified number of calendar days (usually 5 days for a first attempt at repair and 15 days for final attempt at repair) after the leak is detected.
- First attempts at repair include, but are not limited to, the following practices where practicable and appropriate:
 - Tightening bonnet bolts
 - Replacing bonnet bolts
 - Tightening packing gland nuts
 - Injecting lubricant into lubricated packing
- If the repair of any component is technically infeasible without a process unit shutdown, the component may be placed on the Delay of Repair list, the ID number is recorded, and an explanation of why the component cannot be repaired immediately is provided. An estimated date for repairing the component must be included in the facility records.

Note: The “drill and tap” method for repairing leaking valves is generally considered technically feasible without requiring a process unit shutdown and should be tried if the first attempt at repair does not fix the leaking valve. See section 6.7 for a discussion of “drill and tap”.

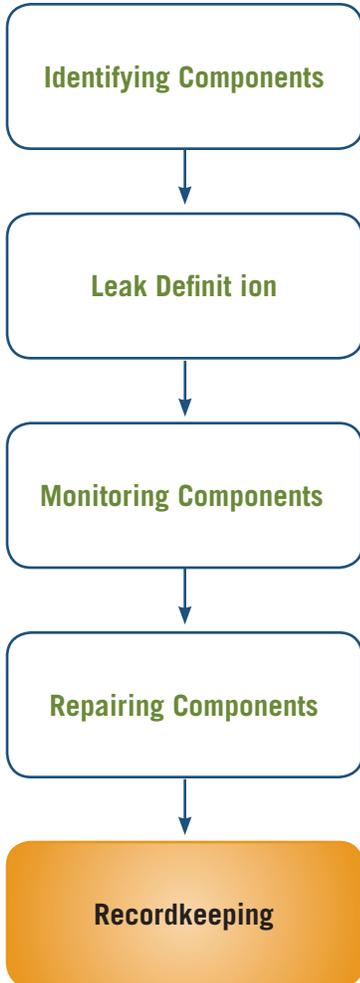

- The component is considered to be repaired only after it has been monitored and shown not to be leaking above the applicable leak definition.

Common Problems

- Not repairing leaking equipment within the required amount of time specified by the applicable regulation.
- Improperly placing components on the Delay of Repair list.
- Not having a justifiable reason for why it is technically infeasible to repair the component without a process unit shutdown.
- Not exploring all available repair alternatives before exercising the Delay of Repair exemption (specifically as it pertains to valves and “drill and tap” repairs).

Best Practices

- Develop a plan and timetable for repairing components.
- Make a first attempt at repair as soon as possible after a leak is detected.
- Monitor components daily and over several days to ensure a leak has been successfully repaired.
- Replace problem components with “leakless” or other technologies.

Current Requirements

For each regulated process:

- Maintain a list of all ID numbers for all equipment subject to an equipment leak regulation.
- For valves designated as “unsafe to monitor,” maintain a list of ID numbers and an explanation/review of conditions for the designation.
- Maintain detailed schematics, equipment design specifications (including dates and descriptions of any changes), and piping and instrumentation diagrams.
- Maintain the results of performance testing and leak detection monitoring, including leak monitoring results per the leak frequency, monitoring leakless equipment, and non-periodic event monitoring.

For leaking equipment:

- Attach ID tags to the equipment.
- Maintain records of the equipment ID number, the instrument and operator ID numbers, and the date the leak was detected.
- Maintain a list of the dates of each repair attempt and an explanation of the attempted repair method.
- Note the dates of successful repairs.
- Include the results of monitoring tests to determine if the repair was successful.

Common Problems

- Not keeping detailed and accurate records required by the applicable regulation.
- Not updating records to designate new components that are subject to LDAR due to revised regulations or process modifications.

Best Practices

- Perform internal and third-party audits of LDAR records on a regular basis to ensure compliance.
- Electronically monitor and store LDAR data including regular QA/QC audits.
- Perform regular records maintenance.
- Continually search for and update regulatory requirements.
- Properly record and report first attempts at repair.
- Keep the proper records for components on Delay of Repair lists.

6.0 What Compliance Problems Have Been Found With Current LDAR Programs?

Many regulatory agencies determine the compliance status of LDAR programs based on a review of submitted paperwork. Some conduct walk-through inspections to review LDAR records maintained on site and perform a visual check of monitoring practices. However, a records review will not show if monitoring procedures are being followed. Similarly, the typical walkthrough inspection will not likely detect improper monitoring practices since operators will tend to ensure that they are following proper procedures when they are being watched.

EPA's National Enforcement Investigations Center (NEIC) conducted a number of sampling investigations of LDAR programs at 17 petroleum refineries. Appendix E summarizes the comparative monitoring results, and Appendix F contains a copy of the 1999 Enforcement Alert that explains the monitoring results. The investigations consisted of records review and comparative leak monitoring (comparing the leak rate found by NEIC to the facility's historic leak rate) at a subset of the facility's total components. These investigations have shown a pattern of significantly higher equipment leak rates (5%) than what the refineries reported (1.3%). While there have been improvements since 1999, facility audits are still showing significantly elevated leak rates, especially in the chemical manufacturing industries.

The discrepancy in leak rates indicates that monitoring staff may not be complying with Method 21 procedures. Failure to accurately detect leaks may be due to a lack of internal quality control oversight or management accountability for the LDAR pro-

grams regardless of whether the monitoring is done by contractors or in-house personnel.

Each leak that is not detected and repaired is a lost opportunity to reduce emissions. In the October 1999 Enforcement Alert, EPA estimates that an additional 40,000 tons of VOCs are emitted annually from petroleum refineries because leaking valves are not found and repaired.

Several important factors contribute to failing to identify and repair leaking components:

1. Not identifying all regulated components/units in inventory

If a facility does not properly identify all of its regulated components, some leaks may go unidentified. Unidentified components may leak or have existing leaks that will worsen over time if the components are not properly identified, monitored and repaired. Facilities can fail to identify regulated components when new processes are constructed, existing process are modified, or new or revised equipment leak regulations are published.

2. Not monitoring components

In some cases, the number of components reported to have been monitored may indicate problems with monitoring procedures. What facility inspectors have found:

- A data logger time stamp showed valves being monitored at the rate of one per second with two valves occasionally be-

ing monitored within the same 1-second period.

- At one facility, a person reported monitoring 8,000 components in one day (assuming an 8-hour work day, that represents one component every 3.6 seconds).
- Records evaluations showed widely varying component monitoring counts, suggesting equipment might not always be monitored when required.
- Equipment was marked “temporarily out of service” because the initial inspection attempt could not be performed. However, the equipment was in service for most of the period, and no subsequent (or prior) inspection attempts were performed to meet the monitoring requirement.

However, even when records show a realistic number of components are being monitored, if there are no oversight or accountability checks, then there is no guarantee that components are actually being monitored.

3. Insufficient time to identify a leak

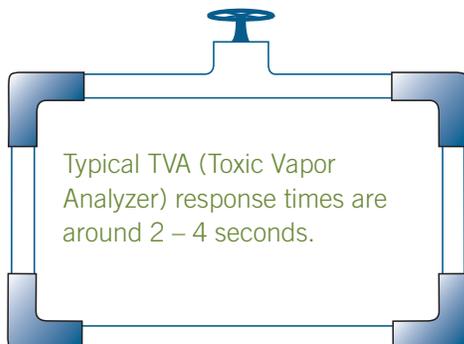

In other cases, facilities are not following proper monitoring procedures, resulting in a lower number of leaking components being reported.

- If a worker moves the probe around the component interface so rapidly that the instrument does not have time to properly respond, then a component may never be identified as leaking.
- If a worker fails to find the maximum leak location for the component and then does not spend twice the response time at that location, then the monitoring instrument will not measure the correct concentration of hydrocarbons and the leak may go undetected. **Optical leak imaging shows the importance of identifying the maximum leak location, as hydrocarbons are quickly dispersed and diluted by air currents around the component.**

4. Holding the probe away from the component interface

The probe must be placed at the proper interface of the component being analyzed. Placing the probe even 1 centimeter from the interface can result in a false reading, indicating that the component is not leaking, when in fact it is leaking. Eliminate any issues (e.g., grease on the component interface) that prevent monitoring at the interface (e.g., remove excess grease from the component before monitoring or use a monitor that won't be impacted by the grease and is easy to clean).

For equipment with rotating shafts (pumps and compressors), Method 21 requires the probe be placed within 1 centimeter of the

shaft-seal interface. Placing the probe at the surface of the rotating shaft is a safety hazard and should be avoided.

5. Failing to properly maintain monitoring instrument

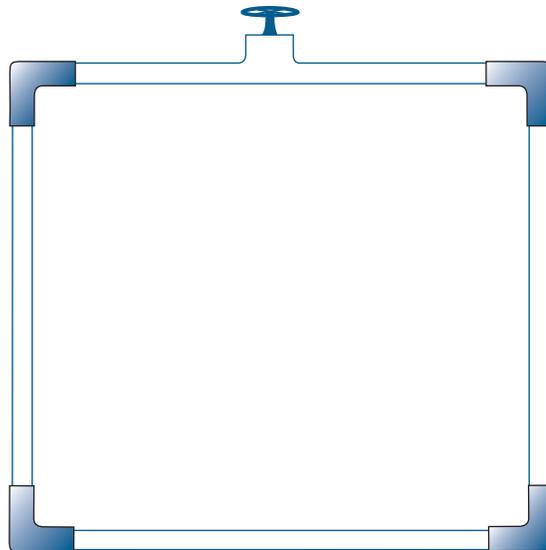

Factors that may prevent the instrument from identifying leaks are:

- Not using an instrument that meets the specifications required in Method 21, section 6.
- Dirty instrument probes;
- Leakage from the instrument probes;
- Not zeroing instrument meter;
- Incorrect calibration gases used; and
- Not calibrating the detection instrument on a daily basis.

6. Improperly identifying components as “unsafe” or “difficult” to monitor

Components that are identified as being “unsafe to monitor” or “difficult to monitor” must be identified as such because there is a safety concern or an accessibility issue that prevents the component from being successfully monitored.

All unsafe or difficult-to-monitor components must be included on a log with identification numbers and an explanation of why the component is “unsafe to monitor” or “difficult to monitor.” Monitoring can be deferred for all such components, but the facility must maintain a plan that explains the conditions under which the components become safe to monitor or no longer difficult to monitor.

7. Improperly placing components/units on the “Delay of Repair” list

Generally, placing a leaking component on the “Delay of Repair” list is permissible only when the component is technically infeasible to repair without a process unit shutdown (e.g., for valves the owner/operator must demonstrate that the emissions from immediate repair will be greater than waiting for unit shutdown).

Repair methods may exist, such as “drill and tap” for valves, that allow leaks to be fixed while the component is still in service. Failing to consider such repair methods before exercising the “Delay of Repair” list may constitute noncompliance with repair requirements (usually 15 days under federal LDAR standards).

Components placed on the “Delay of Repair” list must be accompanied by their ID numbers and an explanation of why they have been placed on the list. These components cannot remain on the list indefinitely – they must be repaired by the end of the next process unit shutdown.

Drill and Tap is a repair method where a hole is drilled into the valve packing gland and tapped, so that a small valve and fitting can be attached to the gland. A packing gun is connected to this fitting and the small valve is opened allowing new packing material to be pumped into the packing gland.

Many companies consider this a permanent repair technique, as newer, pumpable packing types are frequently superior to the older packing types they replace. Packing types can be changed and optimized for the specific application over time.

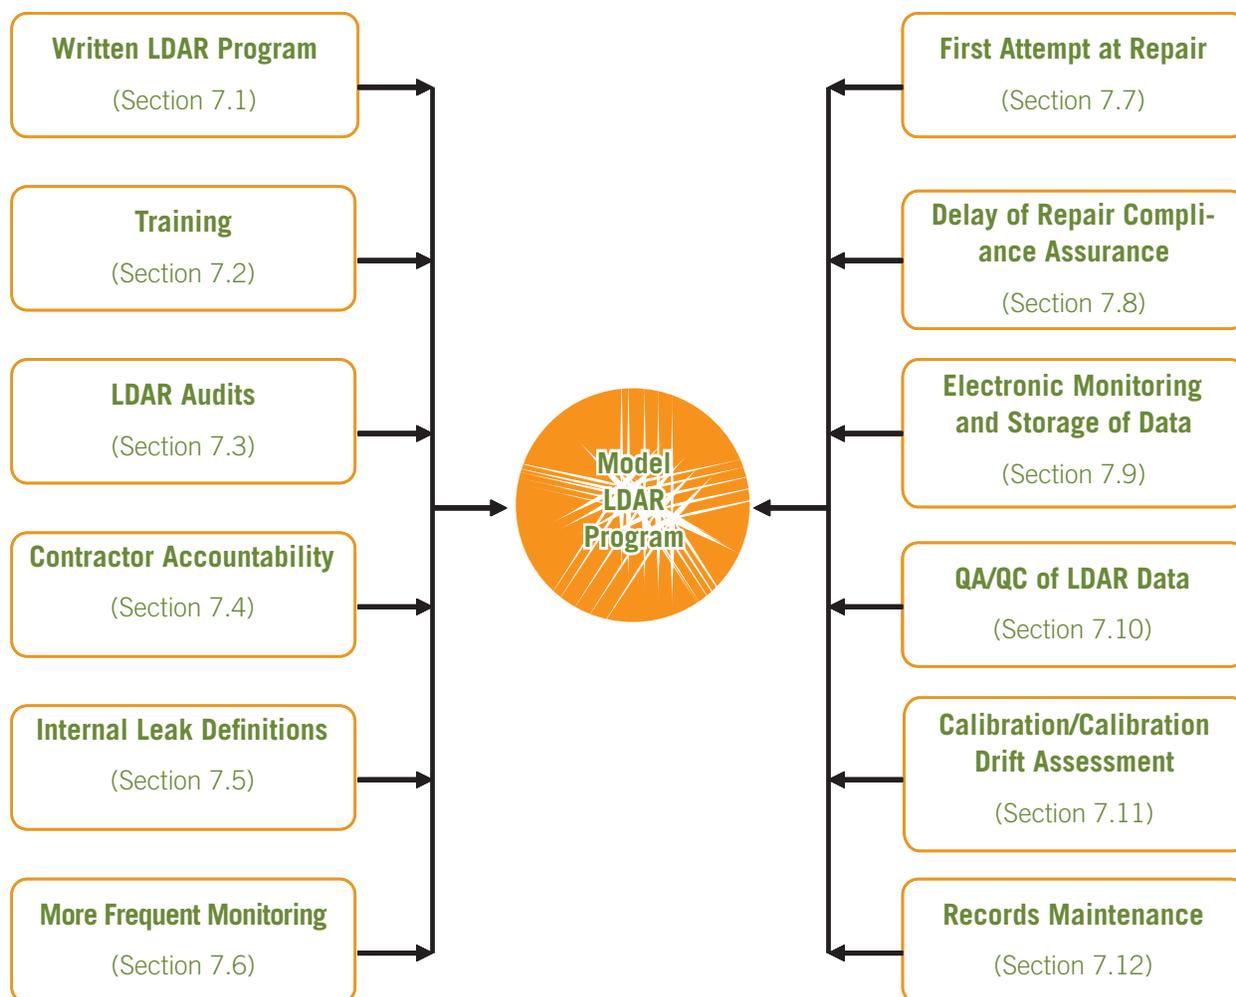

7.0 Model LDAR Program

Experience has shown that facilities with an effective record of preventing leaks integrate an awareness of the benefits of leak detection and repair into their operating and maintenance program. This section outlines some of the major elements of successful LDAR programs. These program elements were developed from:

- Evaluation of best practices identified at facilities with successful LDAR programs, and
- Analysis of the root causes of noncompliance

at facilities that were found to have recurring violations of LDAR regulatory requirements.

LDAR programs that incorporate most or all of the elements described in the following sections have achieved more consistent results in their LDAR programs, leading to increased compliance and lower emissions.

7.1 Written LDAR Program

A written LDAR program specifies the regulatory requirements and facility-specific procedures for recordkeeping certifications, monitoring, and repairs. A written program also delineates the roles of each person on the LDAR team as well as documents all the required procedures to be completed and data to be gathered, thus establishing accountability. The plan should identify all process units subject to federal, state, and local LDAR regulations and be updated as necessary to ensure accuracy and continuing compliance.

Elements:

- An overall, facility-wide leak rate goal that will be a target on a process-unit-by-process-unit basis;
- A list of all equipment in light liquid and/or in gas/vapor service that has the potential to leak VOCs and VHAPs, within process units that are owned and maintained by each facility;
- Procedures for identifying leaking equipment within process units;
- Procedures for repairing and keeping track of leaking equipment;
- A process for evaluating new and replacement equipment to promote the consideration of installing equipment that will minimize leaks or eliminate chronic leakers;
- A list of “LDAR Personnel” and a description of their roles and responsibilities, including the person or position for each facility that has the authority to implement improvements to the LDAR program; and
- Procedures (e.g., a Management of Change program) to ensure that components added to each facility during maintenance and construction are evaluated to determine if they are subject to LDAR requirements, and that affected components are integrated into the LDAR program.

Within thirty (30) days after developing the written facility-wide LDAR program, submit a copy of the Program to EPA and to the appropriate state agency.

7.2 Training

A training program will provide LDAR personnel the technical understanding to make the written LDAR program work. It also will educate members of the LDAR team on their individual responsibilities. These training programs can vary according to the level of involvement and degree of responsibility of LDAR personnel.

Elements:

- Provide and require initial training and annual LDAR refresher training for all facility employees assigned LDAR compliance responsibilities, such as monitoring technicians, database users, QA/QC personnel, and the LDAR Coordinator;
- For other operations and maintenance personnel with responsibilities related to LDAR, provide and require an initial training program that includes instruction on aspects of LDAR that are relevant to their duties (e.g., operators and mechanics performing valve packing and unit supervisors that approve delay of repair work). Provide and require “refresher” training in LDAR for these personnel at least every three years.
- Collect training information and records of contractors, if used.

7.3 LDAR Audits

Whether LDAR monitoring is done in house or contracted to third parties outside the company, the potential exists for LDAR staff not to adhere correctly to the LDAR program. Internal and third-party audits of a facility LDAR program are a critical component of effective LDAR programs. The audits check that the correct equipment is being monitored, Method 21 procedures are being followed, leaks are being fixed, and the required records are being kept. In short, the audits ensure that the LDAR program is being conducted correctly and problems are identified and corrected.

Elements:

- Review records on a regular cycle to ensure that all required LDAR-related records, logs, and databases are being maintained and are up to date.
- Ensure and document that the correct equipment is included in the LDAR program and that equipment identified as leaking is physically tagged with the equipment ID number.
- Observe the calibration and monitoring techniques used by LDAR technicians, in particular to ensure the entire interface is checked and the probe is held at the interface, not away from the interface.
- Retain a contractor to perform a third-party audit of the facility LDAR program at least once every four (4) years.
- Perform facility-led audits every four (4) years.
 - Use personnel familiar with the LDAR program and its requirements from one or more of the company's other facilities or locations (if available).
 - Perform the first round of facility-led LDAR audits no later than two (2) years after completion of the third-party audits outlined above, and every four (4) years thereafter.
 - This rotation ensures that the facility is being audited once every two (2) years.
- If areas of noncompliance are discovered, initiate a plan to resolve and document those issues.
- Implement, as soon as practicable, steps necessary to correct causes of noncompliance, and prevent, to the extent practicable, a recurrence of the cause of the noncompliance.
- Retain the audit reports and maintain a written record of the corrective actions taken in response to any deficiencies identified.

7.4 Contractor Accountability

Contractors performing monitoring are frequently compensated for the number of components they monitor, which might provide an incentive to rush through monitoring procedures and not adhere to Method 21 requirements for response time, monitoring distance, etc. If this happens, some equipment leaks may not be detected. To overcome this potential problem, facilities should have in place sufficient oversight procedures to increase the accountability of contractors.

Elements:

- Write contracts that emphasize the quality of work instead of the quantity of work only.
- Require contractors to submit documentation that their LDAR personnel have been trained on Method 21 and facility-specific LDAR procedures.
- Ensure that the contractor has a procedure in place to review and certify the monitoring data before submitting the data to the facility.
- Review daily results of contractor work to ensure that a realistic number of components are being monitored.
- Perform spot audits in the field to ensure that Method 21 procedures are being followed. This can include spot-checking monitored components with another hydrocarbon analyzer or following LDAR personnel as they perform monitoring.
- Have periodic reviews of contractor performance (e.g., quarterly or semi-annually) to resolve issues and correct problems.

7.5 Internal Leak Definition for Valves and Pumps

The varying leak definitions that can apply to different process units and components can be confusing and lead to errors in properly identifying leaks. To counter this potential problem, operate your LDAR program using an internal leak definition for valves and pumps in light liquid or gas vapor service. The internal leak definition would be equivalent to or lower than the applicable definitions in your permit and the applicable federal, state, and local regulations. Monitoring against a uniform definition that is lower than the applicable regulatory definition will reduce errors and provide a margin of safety for identifying leaking components. The internal leak definition would apply to valves and pumps (and possibly connectors) in light liquid or gas vapor service.

Elements:

- Adopt a 500-ppm or lower internal leak definition for VOCs for all valves in light liquid and/or gas vapor service, excluding pressure relief devices.
- Adopt a 2,000-ppm or lower internal leak definition for pumps in light liquid and/or gas/vapor service.
- Record, track, repair, and monitor leaks in excess of the internal leak definition. Repair and monitor leaks that are greater than the internal leak definitions but less than the applicable regulatory leak definitions within thirty (30) days of detection.

Consent Decrees between EPA and many chemical facilities subject to the HON require using a 250-ppm leak definition for valves and connectors and a 500-ppm leak definition for pumps.

Note: If a state or local agency has lower leak definitions, then the internal leak definition should be set to the lowest definition or even lower to include/allow for margin of error.

7.6 More Frequent Monitoring

Many regulations allow for less frequent monitoring (i.e. skip periods) when good performance (as defined in the applicable regulation) is demonstrated. Skip period is an alternative work practice found in some equipment leak regulations and usually applies only to valves and connectors. After a specified number of leak detection periods (e.g., monthly) during which the percentage of leaking components is below a certain value (e.g., 2% for NSPS facilities), a facility can monitor less frequently (e.g., quarterly) as long as the percentage of leaking components remains low. The facility must keep a record of the percentage of the component type found leaking during each leak detection period.

Experience has shown that poor monitoring rather than good performance has allowed facilities to take advantage of the less frequent monitoring provisions. To ensure that leaks are still being identified in a timely manner and that previously unidentified leaks are not worsening over time, implement a plan for more frequent monitoring for components that contribute most to equipment leak emissions.

Elements:

- Monitor pumps in light liquid and/or gas vapor service on a monthly basis.
- Monitor valves in light liquid and/or gas vapor service – other than difficult-to-monitor or unsafe-to-monitor valves – with no skip periods.

Consent Decrees between EPA and many chemical facilities subject to the HON require semiannual monitoring of connectors.

7.7 Repairing Leaking Components

To stop detected leaks while they are still small, most rules require a first attempt at repair within 5 days of the leak detection and a final repair within 15 days. However, any component that cannot be repaired within those time frames must be placed on a “Delay of Repair” list to be repaired during the next shutdown cycle.

First attempts at repair include, but are not limited to, the following best practices where practicable and appropriate:

- Tightening bonnet bolts;
- Replacing bonnet bolts;
- Tightening packing gland nuts; and
- Injecting lubricant into lubricated packing.

Elements:

- Schedule the “first attempt at repair” of those components that the monitoring personnel are not authorized to repair consistent with the existing regulatory requirements.
- Monitor the component for which a “first attempt at repair” was performed no later than the next regular business day to ensure the leak has not worsened.
- If the first attempt at repair has not succeeded then other methods, such as “drill and tap” should be employed where feasible. Drill and tap procedures are no longer considered extraordinary practices.

7.8 Delay of Repair Compliance Assurance

Any component that cannot be repaired during the specified repair interval must be placed on a “Delay of Repair” list to be repaired during the next shut-down cycle. Delay of repair compliance assurance procedures ensure that the appropriate equipment is justifiably on the “Delay of Repair” list and that facilities have a plan to fix these components.

Elements:

- Have the unit supervisor approve in advance and certify all components that are technically infeasible to repair without a process unit shut-down.
- Continue to monitor equipment that is placed on the “Delay of Repair” list in the facility’s regular LDAR monitoring. For leaks above the internal leak definition rate and below the regulatory rate, put the equipment on the “Delay of Repair” list within 30 days.
- Implement the following repair policies and procedures within 15 days of implementing the written LDAR program:
 - For valves, other than control valves or pressure relief valves, that are leaking at a rate of 10,000 ppm or greater and cannot be feasibly repaired without a process unit shutdown, use “drill and tap” repair methods to fix the leaking valve, unless you can determine and document that there is a safety, mechanical, or major environmental concern posed by repairing the leak in this manner.
 - Perform up to two “drill and tap” repair attempts to repair a leaking valve, if necessary, within 30 days of identifying the leak.

7.9 Electronic Monitoring and Storage of LDAR Data

Electronic monitoring and storage of LDAR data will help evaluate the performance of monitoring personnel (via time/date stamps), improve accuracy, provide an effective means for QA/QC, and retrieve records in a timely manner for review purposes. Incorporate and maintain an electronic database for storing and reporting LDAR data. Use data loggers or other data collection devices during all LDAR monitoring.

Elements:

- Use best efforts to transfer, on a daily basis, electronic data from electronic data logging devices to the database.
- For all monitoring events in which an electronic data collection device is used, include a time and date stamp, operator identification, and instrument identification.
- Paper logs can be used where necessary or more feasible (e.g., small rounds, re-monitoring fixed leaks, or when data loggers are not available or broken), and should record, at a minimum, the monitoring technician, date, and monitoring equipment used.
- Transfer any manually recorded monitoring data to the database within 7 days of monitoring.
- Review records to identify “problem” components for preventative maintenance (repair prior to anticipated failure) or for replacement with “leakless” technology.

7.10 QA/QC of LDAR Data

QA/QC audits ensure that Method 21 procedures are being followed and LDAR personnel are monitoring the correct components in the proper manner. Develop and implement a procedure to ensure QA/QC review of all data generated by LDAR monitoring technicians on a daily basis or at the conclusion of each monitoring episode.

Elements:

Some QA/QC procedures include:

- Daily review/sign-off by monitoring technicians of the data they collected to ensure accuracy and validity.
- Periodic review of the daily monitoring reports generated in conjunction with recordkeeping and reporting requirements.
- Quarterly QA/QC of the facility's and contractor's monitoring data including:
 - Number of components monitored per technician;
 - Time between monitoring events; and
 - Abnormal data patterns.

7.11 Calibration/Calibration Drift Assessment

Always calibrate LDAR monitoring equipment using an appropriate calibration gas, in accordance with 40 CFR Part 60, EPA Reference Test Method 21.

Elements:

- Conduct calibration drift assessments of LDAR monitoring equipment at the end of each monitoring shift, at a minimum.
- Conduct the calibration drift assessment using, at a minimum, approximately 500 ppm of calibration gas.
- If any calibration drift assessment after the initial calibration shows a negative drift of more than 10% from the previous calibration, re-monitor all valves that were monitored since the last calibration with a reading of greater than 100 ppm. Re-monitor all pumps that were monitored since the last calibration with a reading of greater than 500 ppm.

7.12 Records Maintenance

Organized and readily available records are one potential indication of an effective LDAR program. Well-kept records may also indicate that the LDAR program is integrated into the facility's routine operation and management. The equipment leak regulations specify recordkeeping and reporting requirements; incorporating the elements below will help ensure your facility LDAR records are thorough and complete.

Elements:

Records to maintain:

- A certification that the facility implemented the “first attempt at repair” program.
- A certification that the facility implemented QA/QC procedures for review of data generated by LDAR technicians.
- An identification of the person/position at each facility responsible for LDAR program performance as defined in the written program.
- A certification that the facility developed and implemented a tracking program for new valves and pumps added during maintenance and construction defined in the written program.
- A certification that the facility properly completed calibration drift assessments.
- A certification that the facility implemented the “delay of repair” procedures.
- The following information on LDAR monitoring:
 - (1) The number of valves and pumps present in each process unit during the quarter;
 - (2) The number of valves and pumps monitored in each process unit;
 - (3) An explanation for missed monitoring if the number of valves and pumps present exceeds the number of valves and pumps monitored during the quarter;
 - (4) The number of valves and pumps found leaking;
 - (5) The number of “difficult to monitor” pieces of equipment monitored;
 - (6) A list of all equipment currently on the “Delay of Repair” list and the date each component was placed on the list;
 - (7) The number of repair attempts not completed promptly or completed within 5 days;
 - (8) The number of repairs not completed within 30 days and the number of components not placed on the “Delay of Repair” list; and
 - (9) The number of chronic leakers that do not get repaired.
- Records of audits and corrective actions. Prior to the first third-party audit at each facility, include in your records a copy of each audit report from audits conducted in the previous calendar year and a summary of the actions planned or taken to correct all deficiencies identified in the audits.
- For the audits performed in prior years, identification of the auditors and documentation that a written plan exists identifying corrective action for any deficiencies identified and that this plan is being implemented.

Appendix C Method 21 General Procedure

Failure of facilities to follow Method 21 can lead to them not properly identifying and subsequently repairing leaking components. It is critical for facilities to refer to the complete text of Method 21 (see Appendix D) for detailed explanations of each general procedure found below and how to properly perform each step.

1. Evaluate Instrument Performance

Performance criteria for the monitoring instrument:

- For each VOC measured, the response factor should be <10 unless specified in the applicable regulation. Response factor is the ratio of the known concentration of a VOC compound to the observed meter reading when measured using an instrument calibrated with the reference compound specified in the applicable regulation.
- The calibration precision should be <10 percent of the calibration gas value. Calibration precision is the degree of agreement between measurements of the same known value, expressed as the relative percentage of the average difference between the meter readings and the known concentration to the known concentration.
- The response time should be ≤30 seconds. Response time is the time interval from a step change

in VOC concentration at the input of the sampling system to the time at which 90% of the corresponding final value is reached as displayed on the instrument readout meter.

2. Calibrate Instrument

Before each monitoring episode:

- Let the instrument warm up.
- Introduce the calibration gas into the instrument probe.
- Adjust the instrument meter readout to match the calibration gas concentration value.

3. Monitor Individual components

When monitoring components:

- Place the probe at the surface of the component interface where leakage could occur.
- Move the probe along the interface periphery while observing the instrument readout.
- Locate the maximum reading by moving the probe around the interface.
- Keep the probe at the location of the maximum reading for 2 times the response factor.
- If the concentration reading on the instrument readout is above the applicable leak definition, then the component is leaking and must be repaired.

Appendix D Method 21—Determination of Volatile Organic Compound Leaks

1.0 Scope and Application

1.1 Analytes.

| Analyte | CAS No. |
|---------------------------------------|-------------------------|
| Volatile Organic Compounds (VOC)..... | No CAS number assigned. |

1.2 Scope. This method is applicable for the determination of VOC leaks from process equipment. These sources include, but are not limited to, valves, flanges and other connections, pumps and compressors, pressure relief devices, process drains, open-ended valves, pump and compressor seal system degassing vents, accumulator vessel vents, agitator seals, and access door seals.

1.3 Data Quality Objectives. Adherence to the requirements of this method will enhance the quality of the data obtained from air pollutant sampling methods.

2.0 Summary of Method

2.1 A portable instrument is used to detect VOC leaks from individual sources. The instrument detector type is not specified, but it must meet the specifications and performance criteria contained in Section 6.0. A leak definition concentration based on a reference compound is specified in each applicable regulation. This method is intended to locate and classify leaks only, and is not to be used as a direct measure of mass emission rate from individual sources.

3.0 Definitions

3.1 Calibration gas means the VOC compound used to adjust the instrument meter reading to a known value. The calibration gas is usually the reference compound at a known concentration approximately equal to the leak definition concentration.

3.2 Calibration precision means the degree of agreement between measurements of the same known value, expressed as the relative percentage of the average difference between the meter readings and the known concentration to the known concentration.

3.3 Leak definition concentration means the local VOC concentration at the surface of a leak source that indicates that a VOC emission (leak) is present. The leak definition is an instrument meter reading based on a reference compound.

3.4 No detectable emission means a local VOC concentration at the surface of a leak source, adjusted for local VOC ambient concentration, that is less than 2.5 % of the specified leak definition concentration. That indicates that a VOC emission (leak) is not present.

3.5 Reference compound means the VOC species selected as the instrument calibration basis for specification of the leak definition concentration. (For example, if a leak definition concentration is 10,000 ppm as methane, then any source emission that results in a local concentration that yields a meter reading of 10,000 on an instrument meter calibrated with methane would be classified as a leak. In this example, the leak definition concentration is 10,000 ppm and the reference compound is methane.)

3.6 Response factor means the ratio of the known concentration of a VOC compound to the observed meter reading when measured using an instrument calibrated with the reference compound specified in the applicable regulation.

3.7 Response time means the time interval from a step change in VOC concentration at the input of the sampling system to the time at which 90 percent of the corresponding final value is reached as displayed on the instrument readout meter.

4.0 Interferences [Reserved]

5.0 Safety

5.1 Disclaimer. This method may involve hazardous materials, operations, and equipment. This test method may not address all of the safety problems associated with its use. It is the responsibility of the user of this test method to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to performing this test method.

5.2 Hazardous Pollutants. Several of the compounds, leaks of which may be determined by this

method, may be irritating or corrosive to tissues (e.g., heptane) or may be toxic (e.g., benzene, methyl alcohol). Nearly all are fire hazards. Compounds in emissions should be determined through familiarity with the source. Appropriate precautions can be found in reference documents, such as reference No. 4 in Section 16.0.

6.0 Equipment and Supplies

A VOC monitoring instrument meeting the following specifications is required:

6.1 The VOC instrument detector shall respond to the compounds being processed. Detector types that may meet this requirement include, but are not limited to, catalytic oxidation, flame ionization, infrared absorption, and photoionization.

6.2 The instrument shall be capable of measuring the leak definition concentration specified in the regulation.

6.3 The scale of the instrument meter shall be readable to $\pm 2.5\%$ of the specified leak definition concentration.

6.4 The instrument shall be equipped with an electrically driven pump to ensure that a sample is provided to the detector at a constant flow rate. The nominal sample flow rate, as measured at the sample probe tip, shall be 0.10 to 3.0 l/min (0.004 to 0.1 ft³/min) when the probe is fitted with a glass wool plug or filter that may be used to prevent plugging of the instrument.

6.5 The instrument shall be equipped with a probe or probe extension or sampling not to exceed 6.4 mm (1/4 in) in outside diameter, with a single end opening for admission of sample.

6.6 The instrument shall be intrinsically safe for operation in explosive atmospheres as defined by the National Electrical Code by the National Fire Prevention Association or other applicable regulatory code for operation in any explosive atmospheres that may be encountered in its use. The instrument shall, at a minimum, be intrinsically safe for Class 1, Division 1 conditions, and/or Class 2, Division 1 conditions, as appropriate, as defined by the example code. The instrument shall not be operated with any safety device, such as an exhaust flame arrestor, removed.

7.0 Reagents and Standards

7.1 Two gas mixtures are required for instrument calibration and performance evaluation:

7.1.1 Zero Gas. Air, less than 10 parts per million by volume (ppmv) VOC.

7.1.2 Calibration Gas. For each organic species that is to be measured during individual source surveys, obtain or prepare a known standard in air at a concentration approximately equal to the applicable leak definition specified in the regulation.

7.2 Cylinder Gases. If cylinder calibration gas mixtures are used, they must be analyzed and certified by the manufacturer to be within 2 % accuracy, and a shelf life must be specified. Cylinder standards must be either reanalyzed or replaced at the end of the specified shelf life.

7.3 Prepared Gases. Calibration gases may be prepared by the user according to any accepted gaseous preparation procedure that will yield a mixture accurate to within 2 percent. Prepared standards must be replaced each day of use unless it is demonstrated that degradation does not occur during storage.

7.4 Mixtures with non-Reference Compound Gases. Calibrations may be performed using a compound other than the reference compound. In this case, a conversion factor must be determined for the alternative compound such that the resulting meter readings during source surveys can be converted to reference compound results.

8.0 Sample Collection, Preservation, Storage, and Transport

8.1 Instrument Performance Evaluation. Assemble and start up the instrument according to the manufacturer's instructions for recommended warmup period and preliminary adjustments.

8.1.1 Response Factor. A response factor must be determined for each compound that is to be measured, either by testing or from reference sources. The response factor tests are required before placing the analyzer into service, but do not have to be repeated at subsequent intervals.

8.1.1.1 Calibrate the instrument with the reference compound as specified in the applicable regulation. Introduce the calibration gas mixture to the analyzer and record the observed meter reading. Introduce zero gas until a stable reading is obtained. Make a total of three measurements by alternating between the calibration gas and zero gas. Calculate the response factor for each repetition and the average response factor.

8.1.1.2 The instrument response factors for each of the individual VOC to be measured shall be less than 10 unless otherwise specified in the applicable regulation. When no instrument is available that meets this specification when calibrated with the reference VOC specified in the applicable regula-

tion, the available instrument may be calibrated with one of the VOC to be measured, or any other VOC, so long as the instrument then has a response factor of less than 10 for each of the individual VOC to be measured.

8.1.1.3 Alternatively, if response factors have been published for the compounds of interest for the instrument or detector type, the response factor determination is not required, and existing results may be referenced. Examples of published response factors for flame ionization and catalytic oxidation detectors are included in References 1–3 of Section 17.0.

8.1.2 Calibration Precision. The calibration precision test must be completed prior to placing the analyzer into service and at subsequent 3-month intervals or at the next use, whichever is later.

8.1.2.1 Make a total of three measurements by alternately using zero gas and the specified calibration gas. Record the meter readings. Calculate the average algebraic difference between the meter readings and the known value. Divide this average difference by the known calibration value and multiply by 100 to express the resulting calibration precision as a percentage.

8.1.2.2 The calibration precision shall be equal to or less than 10 % of the calibration gas value.

8.1.3 Response Time. The response time test is required before placing the instrument into service. If a modification to the sample pumping system or flow configuration is made that would change the response time, a new test is required before further use.

8.1.3.1 Introduce zero gas into the instrument sample probe. When the meter reading has sta-

bilized, switch quickly to the specified calibration gas. After switching, measure the time required to attain 90 % of the final stable reading. Perform this test sequence three times and record the results. Calculate the average response time.

8.1.3.2 The instrument response time shall be equal to or less than 30 seconds. The instrument pump, dilution probe (if any), sample probe, and probe filter that will be used during testing shall all be in place during the response time determination.

8.2 Instrument Calibration. Calibrate the VOC monitoring instrument according to Section 10.0.

8.3 Individual Source Surveys.

8.3.1 Type I—Leak Definition Based on Concentration. Place the probe inlet at the surface of the component interface where leakage could occur. Move the probe along the interface periphery while observing the instrument readout. If an increased meter reading is observed, slowly sample the interface where leakage is indicated until the maximum meter reading is obtained. Leave the probe inlet at this maximum reading location for approximately two times the instrument response time. If the maximum observed meter reading is greater than the leak definition in the applicable regulation, record and report the results as specified in the regulation reporting requirements. Examples of the application of this general technique to specific equipment types are:

8.3.1.1 Valves. The most common source of leaks from valves is the seal between the stem and housing. Place the probe at the interface where the stem exits the packing gland and sample the stem circumference. Also, place the probe at the interface of the packing gland take-up flange seat and sample

the periphery. In addition, survey valve housings of multipart assembly at the surface of all interfaces where a leak could occur.

8.3.1.2 Flanges and Other Connections. For welded flanges, place the probe at the outer edge of the flange-gasket interface and sample the circumference of the flange. Sample other types of nonpermanent joints (such as threaded connections) with a similar traverse.

8.3.1.3 Pumps and Compressors. Conduct a circumferential traverse at the outer surface of the pump or compressor shaft and seal interface. If the source is a rotating shaft, position the probe inlet within 1 cm of the shaft-seal interface for the survey. If the housing configuration prevents a complete traverse of the shaft periphery, sample all accessible portions. Sample all other joints on the pump or compressor housing where leakage could occur.

8.3.1.4 Pressure Relief Devices. The configuration of most pressure relief devices prevents sampling at the sealing seat interface. For those devices equipped with an enclosed extension, or horn, place the probe inlet at approximately the center of the exhaust area to the atmosphere.

8.3.1.5 Process Drains. For open drains, place the probe inlet at approximately the center of the area open to the atmosphere. For covered drains, place the probe at the surface of the cover interface and conduct a peripheral traverse.

8.3.1.6 Open-ended Lines or Valves. Place the probe inlet at approximately the center of the opening to the atmosphere.

8.3.1.7 Seal System Degassing Vents and Accumulator Vents. Place the probe inlet at approximately the center of the opening to the atmosphere.

8.3.1.8 Access door seals. Place the probe inlet at the surface of the door seal interface and conduct a peripheral traverse.

8.3.2 Type II—“No Detectable Emission”. Determine the local ambient VOC concentration around the source by moving the probe randomly upwind and downwind at a distance of one to two meters from the source. If an interference exists with this determination due to a nearby emission or leak, the local ambient concentration may be determined at distances closer to the source, but in no case shall the distance be less than 25 centimeters. Then move the probe inlet to the surface of the source and determine the concentration as outlined in Section 8.3.1. The difference between these concentrations determines whether there are no detectable emissions. Record and report the results as specified by the regulation. For those cases where the regulation requires a specific device installation, or that specified vents be ducted or piped to a control device, the existence of these conditions shall be visually confirmed. When the regulation also requires that no detectable emissions exist, visual observations and sampling surveys are required. Examples of this technique are:

8.3.2.1 Pump or Compressor Seals. If applicable, determine the type of shaft seal. Perform a survey of the local area ambient VOC concentration and determine if detectable emissions exist as described in Section 8.3.2.

8.3.2.2 Seal System Degassing Vents, Accumulator Vessel Vents, Pressure Relief Devices. If applicable,

observe whether or not the applicable ducting or piping exists. Also, determine if any sources exist in the ducting or piping where emissions could occur upstream of the control device. If the required ducting or piping exists and there are no sources where the emissions could be vented to the atmosphere upstream of the control device, then it is presumed that no detectable emissions are present. If there are sources in the ducting or piping where emissions could be vented or sources where leaks could occur, the sampling surveys described in Section 8.3.2 shall be used to determine if detectable emissions exist.

8.3.3 Alternative Screening Procedure.

8.3.3.1 A screening procedure based on the formation of bubbles in a soap solution that is sprayed on a potential leak source may be used for those sources that do not have continuously moving parts, that do not have surface temperatures greater than the boiling point or less than the freezing point of the soap solution, that do not have open areas to the atmosphere that the soap solution cannot bridge, or that do not exhibit evidence of liquid leakage. Sources that have these conditions present must be surveyed using the instrument technique of Section 8.3.1 or 8.3.2.

8.3.3.2 Spray a soap solution over all potential leak sources. The soap solution may be a commercially available leak detection solution or may be prepared using concentrated detergent and water. A pressure sprayer or squeeze bottle may be used to dispense the solution. Observe the potential leak sites to determine if any bubbles are formed. If no bubbles are observed, the source is presumed to have no detectable emissions or leaks as applicable. If any bubbles are observed, the instrument techniques of Section 8.3.1 or 8.3.2 shall be used to determine if a leak exists, or if the source has detectable emissions, as applicable.

9.0 Quality Control

| Section | Quality control measure | Effect |
|------------|---|--|
| 8.1.2..... | Instrument calibration precision check. | Ensure precision and accuracy, respectively, of instrument response to standard. |
| 10.0..... | Instrument calibration. | |

10.0 Calibration and Standardization

10.1 Calibrate the VOC monitoring instrument as follows. After the appropriate warmup period and zero internal calibration procedure, introduce the calibration gas into the instrument sample probe. Adjust the instrument meter readout to correspond to the calibration gas value.

Note: If the meter readout cannot be adjusted to the proper value, a malfunction of the analyzer is indicated and corrective actions are necessary before use.

October 1999

Proper Monitoring Essential to Reducing 'Fugitive Emissions' Under Leak Detection and Repair Programs

The Clean Air Act requires refineries to develop and implement a Leak Detection and Repair (LDAR) program to control fugitive emissions. Fugitive emissions occur from valves, pumps, compressors, pressure relief valves, flanges, connectors and other piping components.

Comparison monitoring con-

ducted by the U.S. Environmental Protection Agency's (EPA) National Enforcement Investigations Center (NEIC) shows that the number of leaking valves and components is up to 10 times greater than had been reported by certain refineries (see Table, Page 2). EPA believes this great disparity between what refineries are reporting and what EPA is finding may be attributable to refineries not monitoring in the manner prescribed in 40 CFR Part 60, Appendix A, Method 21.

Federal regulations require refiners to routinely monitor for leaks and to fix any equipment found leaking. Failure to identify leaking equipment results in necessary repairs not being made and continuing fugitive emissions of volatile organic chemicals (VOCs) and other hazardous chemicals. EPA estimates that the failure to identify and repair leaks at petroleum refineries could be resulting in additional VOC emissions of 80 million pounds annually. VOCs contribute to ground-level ozone, a principal component of smog, which can cause significant health and environmental problems.

What the Law Requires

Specific requirements for refinery fugitive emissions are identified in 40 CFR Part 60, New Source Performance Standards (NSPS), and 40

CFR Parts 61 and 63, National Emission Standards for Hazardous Air Pollutants (NESHAP). Many State and local air agencies incorporate federal requirements but some have established more stringent requirements as authorized by law. The various regulations require refineries to implement an LDAR program to reduce fugitive emissions from valves, pumps, compressors, pressure relief valves, flanges, connectors, and other

EPA estimates that leaks not found and repaired could be resulting in additional volatile organic chemical emissions of 80 million pounds annually.

piping components.

Valves are usually the single largest source of fugitive emissions. Emissions from any single piece of equipment are usually small. Based on the large number of equipment components that can leak and are subject to LDAR requirements, however, cumulative emissions can be very large. To obtain a proper reading of emissions from leaking components the monitoring equipment must be calibrated cor-

About

Enforcement Alert

"Enforcement Alert" is published periodically by the Office of Regulatory Enforcement to inform and educate the public and regulated community of important environmental enforcement issues, recent trends and significant enforcement actions.

This information should help the regulated community anticipate and prevent violations of federal environmental law that could otherwise lead to enforcement action. Reproduction and wide dissemination of this newsletter is encouraged.

See Page 4 for useful EPA Websites and additional resources.

rectly and held at the component interface where leakage could occur (e.g., at the seal between the valve stem and housing) for a sufficient length of time to obtain a valid measurement.

LDAR Programs Should Consist of Several Processes

LDAR programs are generally comprised of four processes. Regulations vary but usually require refineries to:

- Identify components to be included in the program;
- Conduct routine monitoring of identified components;
- Repair any leaking components; and
- Report monitoring results.

Compliance issues associated with each of these processes have resulted in numerous enforcement actions by EPA Regional offices, State agencies, or local air boards, depending on the specific regulations. Common violations include:

- Failure to identify process units and components that must be monitored;
- Failure to follow prescribed monitoring procedures;
- Use of incorrect or expired calibration gasses;

- Failure to repair components within specified timeframes; and
- Failure to submit quarterly reports and maintain appropriate calibration and/or monitoring records.

Refinery Monitoring Reports; What EPA is Finding

During the past several years, NEIC has monitored for leaking components at refineries. For 17 facilities investigated by NEIC, the average leak rate reported by the facilities was

1.3 percent. The average leak rate determined by NEIC and confirmed by the facilities was 5.0 percent. One explanation for this difference in leak rates may be found in a report published by the Bay Area Air Quality Management District ("Rule Effectiveness Study"). The Bay Area Air Quality Management District determined that when valves were inspected at a distance of one centimeter (0.4 inches) from the component instead of at the interface with the component, as the regulations require,

Comparative Monitoring Results

| Refinery | Company Monitoring: Valves/Leaks | NEIC Monitoring: Valves/Leaks | Leak Rate: Company/NEIC (%) | Emissions Rate: Company/NEIC (lb/hr) | Potential Emissions: Undetected Leaks (lb/hr) |

Enforcement Alert

Continued from page 2

57 percent of the leaking valves would be missed when monitoring above the 500 ppm level.

Fugitive emissions account for 22 percent of all emissions from non-refineries but account for more than 55 percent of all refinery emissions identified in the 1996 Toxic Release Inventory (TRI). Since TRI includes only "reportable" hydrocarbons, total fugitive emissions were significantly larger than the 33 million pounds then identified by reporting refineries.

The failure to identify leaks means that they remain unrepaired and will continue to release VOCs and hazardous substances into the atmosphere. Emission estimates using a 50/50 split between components in gas/light liquid service (see *Table, Page 2*) suggest that these 17 refineries' annual fugitive emissions could be more than 6,000 tons per year greater than previously believed. Extrapolating this difference to all refineries larger than the smallest refinery investigated by NEIC also suggests that there may be an additional 80 million pounds of VOCs

being emitted each year because refinery leaks are not being identified properly and repaired promptly, as required by LDAR programs. Significantly and as recognized by industry, fugitive emissions can be reduced by up to 90 percent if leaks are detected and repaired in a timely manner.

Regulatory Impacts of Inadequate Fugitive Monitoring

By not fully identifying all leaking components, refineries are likely causing the unnecessary release of excess hydrocarbons. The impacts of these additional hydrocarbon releases may result in:

- Additional VOC emissions that could worsen local or transboundary smog problems;
- Under reporting of fugitive emissions on the annual Toxic Reporting Inventory;
- Under reporting of various TRI chemicals on annual Form R submissions; and
- Delayed or denied permits for expansion.

Most LDAR regulations allow for decreased monitoring frequency if certain performance standards are consistently achieved. Monitoring frequency is decreased from quarterly to annual monitoring if less than two percent of the valves within a process unit are found leaking. Conversely, if greater than two percent of the valves are found to be leaking, monitoring must be conducted quarterly. EPA monitoring showing a greater than two percent leak rate has resulted in refineries reverting back to quarterly monitoring.

Improving Leak Detection Monitoring Reliability

Although not required under current LDAR programs, several practices appear to improve the reliability of monitoring data and LDAR compliance:

- Energetic LDAR coordinators (advocates) with the responsibility and authority to make things happen;
- Continuing education/refresher programs for plant operators. Plant operators can have a major impact on LDAR compliance;
- Diligent and well-motivated monitoring personnel;
- Use of a lower than required leak definition. Several refineries use a leak definition lower than the regulatory limit. For example, several refineries use a 500 ppm limit rather than the regulatory limit of 10,000 ppm;
- More frequent monitoring than required. Rather than monitoring annually, some refineries monitor quarterly. More frequent monitoring also may permit lower emissions to be reported on the annual Toxic Reporting Inventory and/or Form Rs; and
- Established Quality Assurance/Quality Control procedures. Several refineries have initiated a program to check the monitoring results submitted by the monitoring team (in-house or contractor).

EPA's Office of Enforcement and Compliance Assurance is encouraged by efforts currently underway by the National Advisory Committee on Environmental Policy and Technology (NACEPT) petroleum refining workgroup to find more cost-effective ways to identify significant leaks

EPA'S Y2K Enforcement Policy

EPA's "Y2K Enforcement Policy is

designed to encourage the expeditious testing of computer associated hardware and software that may be potentially vulnerable to Y2K problems.

Under this policy, which was published in the Federal Register on March 10, 1999, EPA intends to waive 100 percent of the civil penalties and recommend against criminal prosecution for environmental violations resulting from Y2K testing designed to identify and eliminate Y2K-related malfunctions. To receive the policy's benefits (e.g., waiver of penalties due to testing), regulated entities must address specific criteria and conditions identified in the policy.

For more about the Y2K Enforcement Policy, contact Gary Jonesi, Office of Regulatory Enforcement, (202) 564-4002 or E-mail: jonesi.gary@epa.gov.

SUBMITTED VIA FACSIMILE (307) 777-5616

Mr. Steven A. Dietrich, Administrator
Wyoming Department of Environmental Quality
Air Quality Division
Herschler Building, 2-E
122 West 25th Street
Cheyenne, WY 82002

**SUBJECT: Comments on Proposed Regulation
WAQSR, Chapter 8, Nonattainment Area Regulations
Section 6, Upper Green River Basin Permit By Rule for Existing Sources**

Dear Mr. Dietrich:

Jonah Energy LLC (Jonah Energy) appreciates the opportunity to provide the following comments for consideration to the Wyoming Department of Environmental Quality (WDEQ) Air Quality Division (AQD) on the Wyoming Air Quality Standards and Regulations (WAQSR) proposed Chapter 8, Section 6 Upper Green River Basin Permit By Rule for Existing Sources. Jonah Energy currently operates in the Jonah Field in Sublette County, Wyoming. As an oil and gas company with significant operations in the Upper Green River Basin and many employees that live in the area impacted by the proposed regulations, Jonah Energy recognizes that a shared responsibility has led to improved air quality in the Upper Green River Basin. We are supportive of a timely implementation of the proposed rule to further aid in continued emission reductions in the Upper Green River Basin. We support the rule as proposed, with some minor suggested changes outlined below.

Jonah Energy has reviewed the latest version of the proposed Chapter 8, Section 6 Upper Green River Basin Permit by Rule for Existing Sources and found we are currently in compliance with the proposed Chapter 8, Section 6 regulation emission control requirements, Leak Detection and Repair (LDAR) requirements and recordkeeping requirements, as applicable to our current operations. Each month, Jonah Energy conducts infrared camera surveys using a FLIR[®] camera at each of our production facility locations. Since the implementation of Jonah Energy's Enhanced Direct Inspection & Maintenance (EDI&M) Program in 2010, we have conducted over 16,000 inspections and have repaired thousands of leaks that were identified by the FLIR camera. Estimated gas savings from the repair of leaks identified

often exceeds the labor and material cost of repairing the identified leaks. The EDI&M program has removed hundreds of tons of volatile organic compound (VOC) emissions since its inception.

The result of Jonah Energy's EDI&M Program has significantly reduced VOC and hazardous air pollutant (HAP) emissions to the Upper Green River Basin airshed, has reduced the amount of sales gas lost due to leaks going undetected, and has reduced the number and severity of enforcement actions from the WDEQ due to fugitive leaks.

We request the WDEQ and EQC consider making the following modification to Section 6(c) of the proposed rule relating to Emptying Frequency of Emergency and Blowdown Tank Liquids:

From:

Section 6(c) Flashing Emissions at an Existing Facility or Source as of January 1, 2014

(C) Emergency, open-top and/or blowdown tanks shall not be used as active storage tanks but may be used for temporary storage.

(II) If emergency, open-top and/or blowdown tanks are utilized, they must be emptied within seven (7) calendar days."

To:

Section 6(c) Flashing Emissions at an Existing Facility or Source as of January 1, 2014

"(C) Emergency, open-top and/or blowdown tanks shall not be used as active storage tanks but may be used for temporary storage.

(II) If emergency, open-top and/or blowdown tanks are utilized; they must be pumped out via the truck loadout line within seven (7) calendar days after the liquid volume reaches __ bbls over the truck loadout line, or no less frequently than monthly for any liquid level above the truck loadout line."

Discussion

We agree with the premise of only utilizing emergency, open-top, and/or blowdown tanks (collectively Blowdown Tanks) for temporary storage to minimize the flashing emissions related to their use. However, emptying the tanks every seven days will not prevent these flash emissions as they occur almost immediately upon emptying liquids into the tank and as the language is currently written in the

proposed rule, applicable tanks with minor amounts of fluid discharged to them would be required to be emptied within seven days. In addition, we suggest changing the term “emptied” to the phrase “pumped out via the truck loadout line” meaning liquids must be removed from tanks down to the liquid level of the truck load out line, which represents the practical limit of pumping fluid from the tank.

Fluid volumes associated with individual blowdown or emergency events can be variable. Low volume discharges to the Blowdown Tank is not able to be pumped by typical water hauling trucks if the fluid level is below the truck loadout line of the Blowdown Tank (located 1 foot 10 inches above the tank bottom for our 210 bbl. Blowdown Tanks.)

Given the number of possible discharges to Blowdown Tanks, including some with volumes less than a barrel, compliance with this requirement would require substantial additional truck traffic from both water haulers, to unload volumes above the truck loadout line, and/or vacuum trucks, to unload volumes below the truck loadout line. We believe the increased emissions from truck traffic may not justify the environmental benefit from emptying these tanks as frequently as within 7 days.

Establishing a volume threshold, a time limit within which to pump down that designated volume, and routine record keeping could be a viable alternative to just a straight time limit. Our operators routinely gauge tanks for a variety of purposes. We could easily have them gauge Blowdown Tanks after each use and maintain monthly logs showing current Blowdown Tank volumes that would be available for WDEQ’s inspection and verification. WDEQ would be able to spot check an operator’s Blowdown Tank logs by gauging tanks to verify liquid level reported on the logs.

In this way, Blowdown Tanks are emptied when there is a sufficient liquid level to justify truck traffic and/or within a specific time frame, such as not less frequently than monthly for liquid levels above the truck loadout line. We would be happy to discuss this in more detail with WDEQ to establish proposed language and process.

Jonah Energy appreciates WDEQ’s consideration of our comments and would welcome working with the Agency on items mentioned herein or raised during the public comment process. Should you have any questions, please feel free to contact me directly.

Respectfully,

A handwritten signature in black ink, appearing to read "Paul Ulrich".

for Paul Ulrich

SUBJECT: Comments on Proposed Regulation
WAQSR, Chapter 8, Nonattainment Area Regulations
Section 6, Upper Green River Basin Permit By Rule for Existing Sources

Dear Mr. Dietrich:

Jonah Energy LLC (Jonah Energy) appreciates the opportunity to provide the following comments for consideration to the Wyoming Department of Environmental Quality (WDEQ) Air Quality Division (AQD) on the Wyoming Air Quality Standards and Regulations (WAQSR) proposed Chapter 8, Section 6 Upper Green River Basin Permit By Rule for Existing Sources. Jonah Energy currently operates in the Jonah Field in Sublette County, Wyoming. As an oil and gas company with significant operations in the Upper Green River Basin and many employees that live in the area impacted by the proposed regulations, Jonah Energy recognizes that a shared responsibility has led to improved air quality in the Upper Green River Basin. We are supportive of a timely implementation of the proposed rule to further aid in continued emission reductions in the Upper Green River Basin. We support the rule as proposed, with some minor suggested changes outlined below.

Jonah Energy has reviewed the latest version of the proposed Chapter 8, Section 6 Upper Green River Basin Permit by Rule for Existing Sources and found we are currently in compliance with the proposed Chapter 8, Section 6 regulation emission control requirements, Leak Detection and Repair (LDAR) requirements and recordkeeping requirements, as applicable to our current operations. Each month, Jonah Energy conducts infrared camera surveys using a FLIR® camera at each of our production facility locations. Since the implementation of Jonah Energy's Enhanced Direct Inspection & Maintenance (EDI&M) Program in 2010, we have conducted over 16,000 inspections and have repaired thousands of leaks that were identified by the FLIR camera. Estimated gas savings from the repair of leaks identified

BEFORE THE AIR QUALITY CONTROL COMMISSION, STATE OF COLORADO

**IN THE MATTER OF PROPOSED REVISIONS TO REGULATION NUMBER 3,
PARTS A, B AND C, REGULATION NUMBER 6, PART A, AND REGULATION
NUMBER 7**

**REBUTTAL STATEMENT OF NOBLE ENERGY, INC. AND ANADARKO
PETROLEUM CORPORATION**

I. Executive Summary to Rebuttal Statement

Noble Energy, Inc. and Anadarko Petroleum Corporation (“Noble and Anadarko”) provide the following executive summary of their Rebuttal Statement.

As stated in their Prehearing Statement, Noble and Anadarko support the proposed revisions to Regulation 7 (“Proposed Rules”), with minor technical clarifications. The Proposed Rules will achieve enhanced air quality benefits at an acceptable cost. The Proposed Rules set forth science-based, common-sense measures to reduce VOC and hydrocarbon emissions that have already been adopted by some operators in the oil and natural gas industry.

The Proposed Rules represent input from a wide variety of stakeholders, including Noble and Anadarko. Noble and Anadarko participated with other stakeholders to submit comments, factual information and regulatory proposals to the Air Pollution Control Division (“the Division”) during the informal stakeholder process. Noble and Anadarko have continued to do so since the publication of the Proposed Rules. Other parties have likewise submitted information and proposed regulatory language. Prior revisions to Regulation 7 provide a precedent for the Commission to adopt regulatory text that has been agreed upon by two or more parties.¹ The Commission and Division have provided sufficient opportunities for public participation in the rulemaking process over the past year and have incorporated many proposals from multiple parties into the Proposed Rules.

Many aspects of the Proposed Rules are being vigorously debated by parties who seek to make the proposed revisions more or less stringent in various respects. This allows for a healthy debate on the pros and cons of the various requirements in the Proposed Rules, and helps to inform the Commission on the issues raised by the parties. As set forth in more detail below, Noble and Anadarko believe the science-based, feasible and cost effective Proposed Rules strike an appropriate balance on a wide range of issues raised by the stakeholders and parties to this rulemaking, and should be adopted as proposed with only minor technical clarifications as deemed appropriate.

¹ Regulation 7 § XIX.K (“In the course of this proceeding, the Division and certain parties supported a compromise proposal regarding the control of condensate tanks. The Commission finds this proposal to be appropriate with certain changes noted herein.”) (December 12, 2008).

In addition to explanations of their objections to certain overarching issues raised in various prehearing statements, contained below in this Rebuttal Statement, Noble and Anadarko also provide a table as **Attachment A** that summarizes Noble's and Anadarko's responses to these and other significant issues raised in other parties' prehearing statements. This table is intended to provide the Commission with an easy reference to Noble's and Anadarko's responses to the significant issues raised in this rulemaking.

II. The Rulemaking Complies With the Procedural Requirements of the Colorado Administrative Procedure Act and Colorado Air Pollution Prevention and Control Act

A. Colorado Administrative Procedure Act

The rulemaking has adhered to the procedures set forth at Section 103 of the Colorado Administrative Procedure Act ("Colorado APA"). C.R.S. § 24-4-103. When the Division began to contemplate proposing revisions to Regulations 3, 6 and 7, it announced its intentions and formed a stakeholder group as described in Section 24-4-103(2). "Meeting Notice: Stakeholders Interested in Air Pollution Reporting and Permitting Requirements and Oil & Gas Operations," APCD (Dec. 27, 2012). The Division began to meet regularly with stakeholders in January 2013 and has continued to do so throughout the rulemaking process.

The Division published the Proposed Rules, factual presentations, public comments and related materials on its website. The Division submitted a plain language statement concerning the subject matter of the rulemaking to the Department of Regulatory Agencies. C.R.S. § 24-4-103(2.5)(a). The Division is preparing and will timely file a cost-benefit analysis and Regulatory Impact Analysis. *Id.*

After the stakeholder meetings, the Commission initiated the formal rulemaking process by publishing in the Colorado Register a notice of Public Rulemaking Hearing, and soliciting public input. 36 Colo. Reg. 23 (December 10, 2013). The Commission provided the public a thorough and complete opportunity to participate in the rulemaking process in accordance with C.R.S. § 24-4-103(3)(a).

The lengthy stakeholder process, which spanned nearly eleven months, fully complied with the procedural requirements of the Colorado APA. The Division solicited and responded to input from a broad spectrum of stakeholders, resulting in the Proposed Rules. The Proposed Rules are proof of the success of the stakeholder process as it contains input, either wholesale or in part, received by a wide spectrum of stakeholders. Moreover, the Division continues to solicit and receive input from parties to refine its Proposed Rules. Furthermore, the current rulemaking process allows additional opportunity for all parties to participate and present testimony and evidence on aspects of the Proposed Rules that are of concern.

Adoption of the Proposed Rules would be consistent with the standards for agency action set forth in the Colorado APA. Agency action must be reasonable and supported by substantial evidence in the record. *Bd. of Assessment Appeals v. AM/FM Int'l*, 940 P.2d 338, 347 (Colo. 1997); *Pilgrim Rest Baptist Church, Inc. v. Prop. Tax Adm'r*, 971 P.2d 270, 272 (Colo. App. 1998); *Echo-Star Satellite, L.L.C. v. Arapahoe County Bd. of Equaliz.*, 171 P.3d 633, 636 (Colo.

App. 2007). Agency action will be upheld on appeal if it is not arbitrary or capricious. Courts have explained that unless a reasonable person considering all the evidence of record would be compelled to reach a different result, the agency decision must be upheld. *Ramseyer v. Colo. Dept. of Soc. Servs.*, 895 P.2d 1188, 1192 (Colo. App. 1995); *see also W. Colo. Congress v. Umetco Minerals*, 919 P.2d 887, 891 (Colo. App. 1996). The Commission may adopt the Proposed Rules because there is substantial evidence in the record to support a conclusion that the Proposed Rules meet the requirements of the Colorado APA and Colorado Air Pollution Prevention and Control Act (the “Act”).

A decision by the Commission to adopt the Proposed Rules would be entitled to deference. *Dept. of Rev. v. Woodmen of the World*, 919 P.2d 806, 817 (Colo. 1996); *Kramer v. Colo. Dept. of Rev.*, 964 P.2d 629, 630 (Colo. App. 1998). The Commission’s decision in cases where the factual questions are “fairly debatable” will be upheld so long as the Commission’s decision is supported by competent evidence and the record does not show a clear abuse of discretion. *Bd. of County Comm’rs v. Simmons*, 177 Colo. 347, 494 P.2d 85, 87 (1972). In rulemaking cases where the relevant issues are primarily founded on policy choices rather than factual determinations, deference to the agency’s administrative expertise is appropriate. *Brighton Pharmacy, Inc. v. Colo. State Pharmacy Bd.*, 160 P.3d 412, 416 (Colo. Ct. App. 2007) (citation omitted).

The cases cited above make it clear that the Commission is not obligated to resolve the parties’ factual disputes. It is reasonable and appropriate for the Commission to adopt a proposal that strikes an appropriate balance between more stringent and less stringent regulatory options. Such is the case with the Proposed Rules.

B. Colorado Air Pollution Prevention and Control Act

The rulemaking also satisfies the procedural requirements found in the Act. C.R.S. § 25-7-101 *et seq.* As detailed further below and in testimony to be presented at the hearing, the Proposed Rules contain requirements that are technically feasible to reduce, prevent, and control air pollution in Colorado, as required by the Act. C.R.S. § 25-7-102. At the same time, the Proposed Rules are structured to be economically reasonable, with benefits that bear a “reasonable relationship to the economic, environmental and energy impacts and other costs.” C.R.S. § 25-7-102. As described in more detail in Section VI, the Proposed Rules meet this balance.

Additionally, the Division timely provided an Initial Economic Impact Analysis (“EIA”) and other documents in compliance with C.R.S. §25-7-110.5(1), and has since submitted an Updated EIA with its Prehearing Statement on January 6, 2014. The Updated EIA is properly based on “reasonably available data” concerning the costs and benefits of the Proposed Rules, as discussed further below in Section V.

III. The Division Has Demonstrated a Basis and Need for the Proposed Rules

Noble and Anadarko believe that the factual record is well developed to support this rulemaking. Among other information, the Division provided statewide oil and natural gas production data, VOC emission inventories, and reports projecting growth in the oil and natural

gas industry. Noble and Anadarko concur that oil and natural gas production in Colorado has grown in recent years and is presently projected to continue to grow with respect to their operations. The Proposed Rules are supported by an ample scientific and factual record that “demonstrates the need for the regulation” as required by the Colorado APA, C.R.S. § 24-4-103(4)(b)(I).

IV. The Commission Is Authorized to Regulate the VOC and Hydrocarbon Emissions Contemplated by This Rulemaking

Anadarko and Noble support the Commission’s authority to regulate VOCs and hydrocarbons in this rulemaking. The Commission’s authority is set forth in the Act. C.R.S. §§ 25-7-102, 25-7-105(1). The Colorado legislature has specifically stated that it is the State’s policy “to use all available practical methods . . . to achieve the maximum practical degree of air purity” in order to foster the “health, welfare, comfort, and convenience of the inhabitants of the state.” C.R.S. § 25-7-102. State law tasks the Commission with legal oversight “to reduce, prevent, and control air pollution.” *Id.* In that capacity, the Commission here seeks to promulgate emission control regulations applicable to VOCs and hydrocarbons.

Section 109 charges the Commission with adopting emission control regulations such as VOCs and hydrocarbons. C.R.S. § 25-7-109(2)(c). Specifically, the language provides:

(2) Such emission control regulations may include, but shall not be limited to, regulations pertaining to:

(c) Sulfur oxides, sulfuric acids, hydrogen sulfide, nitrogen oxides, carbon oxides, hydrocarbons, fluorides, and any other chemical substance;

Id.; see also C.R.S. § 25-7-103(1.5) (defining air pollutant as “any . . . gas which is emitted into or otherwise enters the atmosphere, including, but not limited to, any physical, chemical, biological, radioactive (including source material, special nuclear material, and by-product material)” and including “any precursors to the formation of any air pollutant” to the extent recognized by EPA).

The Commission is properly exercising its authority to regulate the emission sources contemplated by this rulemaking. First, the Commission is authorized to adopt “such rules and regulations as are consistent with the legislative declaration set forth in section 25-7-102” including “[e]mission control regulations in conformity with section 25-7-109.” C.R.S. §§ 25-7-105(1) and (1)(b). Second, Section 109 provides the Commission with the authority to promulgate regulations requiring “the use of effective practical air pollution controls” for, *inter alia*, “each category of significant sources of air pollutants.” C.R.S. § 25-7-109(1)(a). With this rulemaking, the Commission is acting under its express statutory authority to further broaden leak monitoring and repair to incorporate hydrocarbons in addition to VOCs.

The Proposed Rules are consistent with State policy relating to promulgation of air quality control programs because the controls required “bear a reasonable relationship to the economic, environmental, and energy impacts and other costs of such measures.” C.R.S. § 25-7-102. Regulation of hydrocarbons under the Proposed Rules satisfies this policy because the additional costs for regulating hydrocarbons are acceptable, while serving to broaden the scope of transparency, understanding, and accountability for emissions related to the oil and natural gas industry. The value added here not only extends beyond increased environmental stewardship for industrial operations, but further seeks to promote the protection of Colorado’s air quality through the expanded regulation of VOCs and hydrocarbons while maintaining the economic viability of a critical industry to both the State and nation. Noble and Anadarko contend that the Proposed Rules, while tough, do not impose unmanageable burdens on their oil and natural gas operations. In Colorado, Noble and Anadarko already use technologies such as flares and combustors that are effective and widely used to control VOCs. These same controls also control hydrocarbon emissions. By way of the proposed regulations, the control of both VOCs and hydrocarbons will be better documented and more transparent. Similarly, the proposed regulations expand on other control measures, including, but not limited to, leak detection and repair, auto igniters, low bleed pneumatic devices, and best management practices for maintenance and liquids unloading, which also serve to further reduce hydrocarbon emissions as well as VOCs. The Proposed Rules addressing dual control of both VOCs and hydrocarbons present a reasonable cost for the benefits added.

Minimizing leak occurrences and duration will have long-term effects of offsetting some costs of the Proposed Rules by preventing the loss of valuable product which further enhances the economic consideration of the Proposed Rules. Other policy considerations include that the Proposed Rules will lead to increased accountability for hydrocarbon emissions, more transparency, and thereby build public trust and understanding of hydrocarbon emissions.

While further evidence will be introduced at the hearing on the Proposed Rules, the Proposed Rules satisfy the legislative expectation that controls to treat hydrocarbons be available and technically feasible and that control costs are in line with the economic impacts. *See* C.R.S. § 25-7-109(1)(b)(IV). The controls and other requirements in the Proposed Rules are already being implemented at many oil and natural gas operations, thus demonstrating that such controls are available and technically feasible.

Finally, the Proposed Rules also satisfy Section 25-7-102, which sets forth State policy that regulations be based on a current and accurate inventory of actual emissions. Substantial data about VOC and hydrocarbon emissions from oil and natural gas sources are available and have been presented to the Commission. The State already receives extensive emissions reporting data from the oil and natural gas industry, and the Commission also has received several exhibits estimating emissions of hydrocarbons, including methane and ethane. These data cumulatively provide sufficient detail about hydrocarbon emissions in the State to fulfill the legislative declaration requiring use of current and accurate inventory of emissions.

V. The Proposed Rules Are Cost Effective

The data provided in the Updated EIA and the EIA itself satisfy the statutory requirement that the Proposed Rules be cost effective. C.R.S. § 25-7-109(1)(b)(IV). Noble and Anadarko

have undertaken analyses of their own estimated costs to comply with the Proposed Rules as offered herein. Those cost estimates are contained in **Exhibits A and B**, filed with this Rebuttal Statement. This cost data support the Division’s position that the costs of the Proposed Rules are reasonable and cost effective on the basis of dollars per ton of VOC removed.

As evidenced herein and as will be further supported during the hearing, the proposed requirements to control both VOCs and hydrocarbons are readily available to operators, are technically feasible and show that the costs are reasonably related to the benefits. A number of measures illustrate the availability, feasibility, and cost effectiveness of the Proposed Rules. In many cases, the controls and other requirements set forth in the Proposed Rules are already being implemented by oil and natural gas operators. Thus, as an example, where flares or combustion devices are used to control VOC emissions, the Proposed Rules would not generally impose additional costs to control and reduce hydrocarbons. In addition, the Division estimates in the Updated EIA that the cost effectiveness of controlling methane and ethane at compressor stations and well production facilities would be \$321 per ton and \$516 per ton of reduced emissions, respectively. Accordingly, the economic costs of regulating hydrocarbon emissions are low and, indeed, cost effective. *See* C.R.S. § 25-7-109(1)(b)(VII).

A. The Division’s Cost and Cost Effective Estimates Are Appropriate

The Division calculated the costs and cost effectiveness of instrument based monitoring for tanks, compressor stations and well production facilities. The Division’s average cost and cost effectiveness estimates are summarized in the table below.

Division Cost and Cost Effectiveness Estimates

| | Annualized Cost per Facility | \$/ton VOC Removed |
|----------------------------|------------------------------|--------------------|
| Tanks | \$3,949 | \$391 |
| Compressor stations | \$3,720 | \$667 |
| Well production facilities | \$2,199 | \$819 |

Source: APCD Updated EIA, Tables 16, 25 and 27.

The Division appropriately did not include repair and remonitoring costs in its Updated EIA. Noble and Anadarko projections based on the Proposed Rules with assumptions for minor technical clarifications indicate that remonitoring costs will not increase significantly from current levels. Cost effective measures such as the one found in Section XVII.F.8.b of the Proposed Rules that do not require the use of an IR camera for remonitoring keep the costs reasonable and within the required statutory bounds for costs. Method 21 could be used to satisfy the remonitoring requirement, which provides an alternative for the use of a screening procedure to determine whether a source has no detectable emissions. Method 21, “Determination of

Volatile Organic Compound Leaks” § 8.3.3, *available at* <http://www.epa.gov/ttn/emc/promgate/m-21.pdf>.

Based on the information and analyses conducted to date by Noble and Anadarko, the Proposed Rules should not significantly affect the cost of repairs to operators. The companies anticipate that many leaks will likely be discovered and corrected on the spot at minimal cost by the workers performing instrument based monitoring. Also, the repair costs currently incurred under existing monitoring programs could legitimately be excluded from any estimate of the costs of the Proposed Rules.

B. Noble’s and Anadarko’s Cost and Cost Effectiveness Estimates Support the Division’s Estimates

Based on a review of the Proposed Rules with an understanding that minor technical clarifications may be warranted, Noble’s estimates of cost and cost effectiveness support the Division’s Updated EIA. Based on company-specific historic data and certain estimated values, Noble anticipates that LDAR monitoring at well production facilities would cost between approximately \$260 and \$430 per inspection, with cost effectiveness between approximately \$50/ton and \$380/ton VOC removed, depending on the facility size, emission estimates, and other factors.

Similarly, assuming only minor technical clarifications are made to the Proposed Rules, Anadarko’s cost estimates also support the Division’s Updated EIA. Based on company-specific historic data and certain estimated values, Anadarko anticipates that LDAR monitoring would cost approximately \$450 per inspection at well production facilities, and approximately \$1,260 per inspection at compressor stations, depending on the facility size, estimated values, and other factors. Anadarko also estimated the cost of the additional AVO inspections that would be required under the Proposed Rules to be approximately \$135 per inspection. The per inspection cost is lower than LDAR inspections, but due to the high number of AVO inspections, this requirement would increase Anadarko’s annual well production facility monitoring costs by more than approximately \$3.5 million from current levels overall.

The estimates of cost and cost effectiveness submitted by Noble and Anadarko are preliminary and are subject to change as they continue to evaluate the requirements in the Proposed Rules, and any subsequent revisions thereto.

C. Factors Affecting Estimates of Costs and Cost Effectiveness

In reviewing the various prehearing statements of parties as well as that of the proponent of the Proposed Rules, cost and cost effectiveness is the subject of much scrutiny and disagreement. Noble and Anadarko believe that the Division has taken a reasonable position with respect to costs and cost effectiveness of the current Proposed Rules and have data that support the Division’s position. Adoption of other positions could have a significant impact on the figures reported in the Updated EIA. The list below identifies some examples for the Commission’s consideration that could have a significant impact on the Cost and Cost Effectiveness estimates.

1. Time Required to Perform Inspections

The Division assumed IR inspections would be 50% faster than Method 21 inspections for compressor stations and well production facilities, and solicited data on this issue to further inform its analysis. APCD Updated EIA at 16. Noble and Anadarko's experience indicates that travel time has as much or more impact on the time needed for LDAR inspections than the number of components, especially for smaller facilities. Nonetheless Noble and Anadarko find the Division's overall time estimates to be reasonable.

The Division estimates that well production facilities would require an average of 4.75 hours to inspect. Based on company-specific historic data, Noble estimates that one inspector can inspect two to three well production facilities per day and Anadarko estimates that one inspector can inspect up to three well production facilities per day. These estimates are in line with the Division's projections.

2. Emission Reductions From LDAR and STEM Requirements

While Noble and Anadarko do not have complete data on the reductions in VOC and hydrocarbon emissions that will result from the LDAR and STEM programs in the Proposed Rules, they believe these are reasonable, cost effective approaches to reduce VOC and hydrocarbon emissions from oil and natural gas operations. As such, they support these requirements in the Proposed Rules. While some parties contend that the Division's estimate of emission reductions that would be achieved by the Proposed Rules is too high, other parties assert that the Division's estimates are too low. In the absence of a widely accepted protocol for estimating the emission reductions achievable through instrument based monitoring, Noble and Anadarko submit that it is reasonable for the Commission to rely on the Division's emission reduction estimates.

3. Ongoing Benefit of Leak Inspections

The Division assumed that the emissions reduction achieved by the STEM and LDAR programs would remain constant every year. Some parties have asserted that there is a declining benefit from STEM and LDAR inspections, thereby significantly increasing the cost per ton of VOC removed in subsequent years, while other parties have asserted that emission reductions rise as inspections become more frequent.

Based on data collected from its own LDAR monitoring experience, Trihydro estimates the initial component leak rate frequency (before the first LDAR inspection) at new and modified gas processing plants to be 1.7%. WPX – PHS Ex. A. The leak rate frequency falls to 0.4% after the first monitoring period and averages 0.3% over 12 consecutive calendar quarters. *Id.* The Trihydro report appears to be reliable because it is based on actual measured data. While it does support a decline after the first monitoring period, the Trihydro report then evidences a steady state of leak detection after that.

Given the limited data available, and that the only available data supports a limited one-time reduction in leak rate frequency, it is reasonable for the Commission to rely on the Division's assumption that LDAR emission reductions remain constant each year, until further data is developed.

VI. The Proposed Rules Strike an Appropriate Balance

The Proposed Rules strike a balance as required by statute and as illustrated by the competing interest of the parties. The Proposed Rules may not meet each and every party's demands; however, they represent a strong compromise that benefits the environment, while also permitting ongoing development of valuable natural resources. The Commission should adopt the Proposed Rules with only minor technical clarifications because the Proposed Rules are carefully crafted to fulfill the policy goals of C.R.S. § 25-7-102. The Proposed Rules are designed to achieve the maximum practical degree of air purity, are among the most stringent air quality regulations for oil and natural gas facilities in the nation, and would result in Colorado being the first state to directly regulate methane. Gov. Hickenlooper Press Release, "Colorado set to become first state to regulate detection, reduction of methane emissions associated with oil and gas drilling," (Nov. 18, 2013). At the same time, the Proposed Rules are structured to be practical and economically reasonable, with benefits that bear a "reasonable relationship to the economic, environmental and energy impacts and other costs." C.R.S. § 25-7-102. The terms of the Proposed Rules are effective and practical, as required by C.R.S. § 25-7-109(1)(a).

Evidenced by the issues raised in the various parties' prehearing statements, the Proposed Rules find common ground. They do not represent a perfect solution to all involved, but the State is not required to promulgate rules blessed by all stakeholders involved. Rather, the State must adhere to the statutory requirement to protect air quality by means the State determines to be practical and economically reasonable. To illustrate this point, some of the issues where the Prehearing Statements evidence diverging views are described below.

A. Emission Reductions and Costs

The Division projects the Proposed Rules would substantially reduce VOC emissions. Some parties have asserted that the actual emission reductions would be far smaller than projected by the Division because the Division overestimated the current level of VOC emissions, or because the regulation would be less effective than projected. Some parties also argued that the projected reduction in VOCs is not necessary because the VOC reduction might not lead to lower ambient ozone concentrations.

Other parties have asserted that larger emission reductions will or may be obtained, both by using different estimates of the projected emission reductions and arguing that greater reductions could and should be achieved by accelerating the LDAR compliance dates, increasing LDAR inspection frequency, and making the LDAR requirements applicable to additional components.

As discussed above, some parties contended that instrument based inspection costs are significantly higher than the Division's estimates. Other parties asserted that instrument based inspections are profitable. The fact that other parties are arguing for both higher and lower costs and higher and lower emission reductions than the Division relied on in its analysis of the Proposed Rules provides further evidence that the Division's Proposed Rules are balanced. As also discussed above, the Noble and Anadarko data supports the Division's cost estimates, and its finding that the Proposed Rules are cost effective.

B. Frequency of LDAR Inspections

The proposed monitoring schedule varies from one-time monitoring at the smallest facilities to monthly monitoring at the largest. The proposed schedule appropriately places greater compliance burdens on facilities that have higher levels of air emissions.

Some parties seek to increase or decrease the frequency of inspections. For example, one party argues that tank and well production facilities with less than six tons per year of emissions should be inspected every two years, rather than one time over the life of the facility. Another party contends that facilities near buildings or outdoor activities should be subject to more frequent inspections. Conversely, yet another party seeks to add a skip monitoring provision that would reduce LDAR frequency if inspections indicate declining levels of discovered leaks; facilities where the number of leaks remains below certain thresholds would reduce their monitoring frequency over time. Thus, again, these divergent views on more frequent and less frequent inspections suggest that the inspection frequency in the Proposed Rule is a balanced approach that accommodates the competing interests of the parties.

C. Implementation Dates

The Proposed Rules contain compliance dates that are intended to implement the rule as expeditiously as possible, while allowing oil and natural gas operators sufficient time to buy and install equipment and to make necessary changes to their operations to begin the extensive new LDAR and STEM requirements, and implement new control requirements. The implementation deadlines reflect concerns that sufficient quantities of IR cameras and emission control devices might not be immediately available from vendors.

Some parties argue that implementation should be delayed beyond the dates in the Proposed Rules. Conversely, other parties seek to accelerate the implementation dates and compliance deadlines. Noble and Anadarko believe that the Proposed Rules contain a reasonable and achievable implementation schedule that balances the concerns of various stakeholders. Noble and Anadarko also believe that the phased implementation schedule set forth in the Proposed Rules is necessary to allow industry to acquire the necessary equipment to ensure successful compliance with the regulation.

Some parties have raised a concern with meeting the leak detection rate of 500 ppm and have proposed a delay in the implementation of that requirement. However, it has been Noble's and Anadarko's experience that vendors have indicated they can presently meet the 500 ppm leak detection rate. Thus, again, the Proposed Rules' implementation schedule is technically feasible and reasonable.

Additional bases of disagreement among the parties, with some wanting a more stringent rule, and others wanting a less stringent rule, are summarized and set forth in a table, attached to this Rebuttal Statement and incorporated herein as if fully set forth herein. **Attachment A.** As this table demonstrates, the rules could be made less stringent or they could be made more stringent. The important point is that a complex rule such as the Proposed Rules forces the Commission to make a large number of decisions about discrete technical issues. Parties can and do have diverse viewpoints about the most appropriate decision for each issue. Given these

divergent viewpoints, there is no single best course of action for the Commission to take. The Colorado APA does not hold the Commission to such an exacting standard. Instead, the Commission's charge is to make reasonable decisions that comply with the statute, are within its scope of authority, and are supported by substantial evidence in the record as a whole. *Dept. of Rev. v. Woodmen of the World*, 919 P.2d 806, 817 (Colo. 1996); *Kramer v. Colo. Dept. of Rev.*, 964 P.2d 629, 631 (Colo. App. 1998); *Ohlson v. Weil*, 953 P.2d 939, 941 (Colo. App. 1997). Thus, the guiding posts for adoption of regulations will focus on evidentiary support that shows the regulations to be protective of the environment, be balanced, be cost effective, and be feasible for operators to implement.

VII. The Proposed Rules Should be Adopted Without Further Substantive Changes

The Proposed Rules impose significant new costs and control requirements on the oil and natural gas industry, and require implementation of entirely new monitoring and recordkeeping programs to document the new LDAR, STEM and AVO inspections. This entails the ordering of large quantities of new monitoring instruments and equipment, hiring and training large numbers of new personnel, setting up extensive new recordkeeping systems that interface with existing monitoring and recordkeeping conducted at the facilities -- all in the space of a one to two-year time frame. The scope and extent of this program is unprecedented and will require significant effort to properly implement and conform to these new monitoring and recordkeeping requirements.

Noble and Anadarko are supportive of the Proposed Rules for the reasons detailed above and as expressed in their joint Prehearing Statement, and believe the commitments represented by the Proposed Rules, with consideration only of further minor technical clarifications being incorporated, are reasonable and cost effective. However, the companies oppose any attempt to make the Proposed Rules more stringent. Noble and Anadarko do not support changes to the Proposed Rules that would impose either fewer or additional requirements or the expansion or contraction of currently proposed monitoring and recordkeeping requirements in any manner that would impact the carefully, properly balance approach to ensure protection of the environment through controls that are technically feasible and cost effective.

Further expansion of already ambitious proposed regulations would jeopardize the industry's ability to implement this new precedent setting monitoring and control program. Further contraction of the ambitious proposed regulations would impact the potential achievement of further air quality benefits at an acceptable cost. The companies believe the Proposed Rules, with minimal technical clarifications, are structured to strike an appropriate and fair balance of costs and requirements with the benefits of reduced VOC and hydrocarbon emissions from oil and natural gas operations in the state of Colorado. There is a tipping point for industry, beyond which more stringent requirements will simply overwhelm the industry's ability to implement meaningful monitoring and control requirements.

For these reasons, Noble and Anadarko urge the Commission to resist attempts to alter the careful balance achieved in the Proposed Rules. Some parties have submitted alternate proposals that would substantially affect this balance. Such proposals are not factually supported or warranted. Many of these proposals simply assert that additional requirements could be imposed or proposed requirements could be reduced without any detailed analysis supporting the

additional requirements. Some proposals are accompanied by (faulty) cost data and arguments that the weaker or stricter requirements would either ensure cost effectiveness or be cost effective. A careful review and analysis of these competing cost analyses fail to support such claims. For all of the reasons stated above, Noble and Anadarko urge the Commission to retain the balance represented by the Proposed Rules.

A. STEM Monitoring and LDAR Inspections Should Not be More Frequent

Inspection frequencies should not be increased from those stated in the Proposed Rules. The Proposed Rules call for significantly more inspections than are currently required. They would impose new requirements to use infrared cameras or other instrument based monitoring techniques. The Commission should adopt the proposed STEM and LDAR inspection requirements. Their effectiveness may be reviewed after more data is collected. STEM or LDAR frequency may be adjusted in a future rulemaking as needed after sufficient data is gathered from the implementation of the requirements from the Proposed Rules.

No legitimate rationale has been presented for increasing inspection frequencies. One party seeks to increase inspection frequencies by revising the way compressor station emissions are determined. The party proposes to use a facility's total potential to emit ("PTE") to determine the inspection frequency, rather than fugitive emissions. However, the only reason provided for this change is that relying on PTE would push compressor stations into a higher tier, resulting in more inspections. Fugitive emissions provide a reasonable proxy for the size and significance of compressor station emissions, and should be used to determine frequency as proposed.

The Commission should reject the arbitrary and unsupported requests for greater inspection frequencies.

B. STEM and LDAR Inspection Phase-in Timelines Should Not be Accelerated or Eliminated

Some parties have advanced conclusory statements that the implementation dates for STEM and LDAR inspections should be earlier than proposed. These parties did not provide any convincing justification for their positions. The parties asserted their unsupported belief that the proposed dates are too far in the future, and that STEM and LDAR inspections could begin sooner.

No attempt has been made to show that an earlier deadline is feasible or would allow adequate time for facilities to implement the Proposed Rules' significant new requirements. The proposed earlier deadline would impose an unreasonable burden. The cumulative burden of simultaneously beginning and implementing the extensive instrument based monitoring program at all operations without the proposed implementation schedule would render the STEM and LDAR program requirements infeasible and impracticable.

C. Additional Recordkeeping and Reporting Requirements Should Not be Imposed

Several parties seek to impose additional recordkeeping or reporting requirements. The parties' alternate proposals would require that STEM plans be submitted to the Division; require all STEM-related records be retained for five years; extend LDAR records retention from two years to five years; and require companies to maintain pneumatic controller records for five years instead of three.

The Division's proposed recordkeeping requirements appropriately balance compliance costs with the Division's ability to inspect facilities and review records. Compiling and maintaining records places a significant burden on owners and operators. Receiving, managing and reviewing reports places a substantial burden on the Division. The Commission should consider the fact that recordkeeping and reporting have value only to the extent they enhance air quality. The purpose and rationale for any such requirements should be clearly articulated. Records lose their value over time and should be destroyed when they are no longer necessary or useful. Reports should not be submitted to the Division unless the Division has the resources to timely review them, while continuing to perform its existing duties. It is quite common for regulatory programs to require that records be kept and made available for inspection, with no submission requirement.

No basis was provided for the various proposals to extend the records retention periods other than the parties' unsupported opinion that two- and three-year retention periods are too short. The proposal to submit STEM reports to the Division is likewise unjustified. The Division's Updated EIA estimates that 5,312 tanks would be subject to STEM. The proposal fails to address whether or how the Division might review or utilize this volume of reports. The parties' alternate recordkeeping proposals are unwarranted and should be rejected.

VIII. The Proposed Rules Do Not Require A Photochemical Modeling-Based Justification

There is no requirement to perform photochemical modeling before revising State-only regulations that limit the emission of VOCs from a source category. The Act requires the Commission to find that "the rule shall result in a demonstrable reduction in air pollution." C.R.S. § 25-7-110.8(1)(b). This demonstration must be supported by substantial evidence in the record as a whole. *Bd. of Assessment Appeals v. AM/FM Int'l*, 940 P.2d 338, 347 (Colo. 1997); *Pilgrim Rest Baptist Church, Inc. v. Prop. Tax Adm'r*, 971 P.2d 270, 272 (Colo. App. 1998); *Echo-Star Satellite, L.L.C. v. Arapahoe County Bd. of Equaliz.*, 171 P.3d 633, 636 (Colo. App. 2007). Emission inventories and projections that the Proposed Rules will substantially reduce VOC emissions are sufficient to demonstrate a reduction in air pollution. The statute does not specifically require photochemical modeling.

The Commission has the authority to limit VOC emissions as a forward-looking measure to facilitate future attainment of the ozone standards without a detailed calculation of the resulting change in ozone concentrations. The Commission has discretion to make this policy choice, and its administrative expertise is entitled to deference. *Brighton Pharm., Inc. v. Colo. State. Pharm. Bd.*, 160 P.3d 412, 416 (Colo. App. 2007)(citations omitted). The Commission made a similar choice in 2006 when it placed statewide VOC limits on tanks, dehydrators and

engines. The Statement of Basis and Purpose accompanying the 2006 revision did not cite photochemical ozone modeling as a basis for that revision. Regulation 7 § XIX.J. Similarly, there is no such requirement for the adoption of the Proposed Rules.

IX. Response to the Division's Proposed Revisions

The Division submitted certain technical corrections, clarifications, and substantive changes to the Proposed Rules. Several of these changes appear to adopt language proposed by DCP Midstream from its Prehearing Statement, including certain new definitions, new provisions for compressor seals and open-ended valves or lines, and emission reductions from glycol dehydrators. Noble and Anadarko support these revisions.

X. Exhibits and Attachments

Noble and Anadarko submit the following exhibits and attachments for the Commission's consideration as it evaluates the information and testimony presented at the hearing:

1. Noble cost spreadsheet. **Exhibit A.**
2. Anadarko cost spreadsheet. **Exhibit B.**
3. Noble and Anadarko Responses to Significant Issues Raised in Prehearing Statements. **Attachment A.**
4. Legal Memorandum Opposing Expansion of Regulation to Address Hazardous Air Pollutants. **Attachment B.**
5. Legal Memorandum Opposing Conservation Group's Request for an Order Requiring the Division to Perform Ozone Modeling and Propose an Ozone Plan that Demonstrates Ozone Attainment. **Attachment C.**

XI. Rebuttal Witnesses

Witnesses who may testify at the hearing on behalf of Noble and Anadarko include:

1. Denise Kennedy
Holland & Hart, LLP
Attorney for Noble and Anadarko
2. Brian Lockard
Director, EHSR, US Onshore
Noble
3. Chad Schlichtemeier
EHS Manager
Anadarko

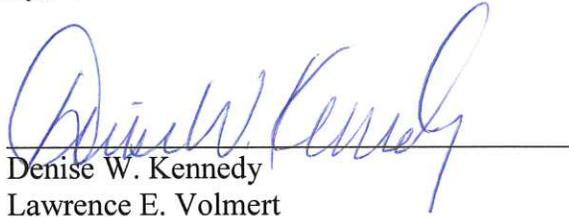

These witnesses were previously identified as witnesses for Noble and Anadarko's case in chief. They may testify regarding the legal and factual issues raised in Noble and Anadarko's Prehearing Statement, Rebuttal Statement, or both.

XII. Written Testimony

At this time, Noble and Anadarko do not have written testimony to present. Consistent with the hearing officer's statements at the Prehearing Conference, Noble and Anadarko reserve the right to present additional written testimony prior to the hearing date.

Respectfully submitted this 30th day of January, 2014.

BEFORE THE AIR QUALITY CONTROL COMMISSION, STATE OF COLORADO

In the Matter of Proposed Revisions to Ambient Air Quality Standards Regulation, Regulation Numbers 3, 7, and 11 for the Denver Metropolitan and North Front Range Ozone Action Plan

FINAL JOINT PREHEARING STATEMENT OF ANADARKO PETROLEUM CORPORATION, NOBLE ENERGY, INC., and WILLIAMS PRODUCTION RMT COMPANY

Anadarko Petroleum Corporation (“Anadarko”), Noble Energy, Inc. (“Noble”), and Williams Production RMT Company (“Williams”) (collectively the “Well Operators”) jointly submit this Final Prehearing Statement (“Final Statement”) pursuant to the Air Quality Control Commission’s (“AQCC” or the “Commission”) procedural rules, 5 CCR 1001-1, Section 1.5.5(5)(c), in connection with the Commission’s consideration of proposed revisions to the Ambient Air Quality Standards Regulations, Regulation Numbers 3, 7, and 11, for the Denver Metropolitan and North Front Range Ozone Action Plan (“Ozone Action Plan”).

Some of the Well Operators have been actively involved in the rulemaking process surrounding ozone dating back to adoption of controls to meet the obligations of the former 8-hour ozone Early Action Compact (“EAC”) in 2004, and have supported Colorado’s prior efforts to achieve compliance with the 8-hour ozone NAAQS in the non-attainment area (“NAA”). The Well Operators continue to support Colorado’s goal of achieving long-term compliance, and wish to promote Environmental Protection Agency’s (“EPA’s”) future classification of the Denver Metropolitan and Northern Front Range areas as “attainment” for the 8-hour ozone National Air Ambient Quality Standard. They have participated in most, if not all, of the numerous stakeholder meetings held as part of the ozone State Implementation Plan (“SIP”) development process for more than a year, and while the Well Operators do support many aspects of the Ozone Action Plan, they oppose the adoption by this Commission of other portions for reasons set forth and to be set forth in their witnesses testimony, their exhibits, and this Final Statement.

This Final Statement contains: an Executive Summary (Section I); statement of factual and legal issues (Section II); a list of issues to be resolved by the Commission (Section III); a list of the exhibits that will be introduced at the hearing, including the Well Operators’ Alternate Proposals and supporting documentation (Section IV); a list of witnesses submitting written testimony, some or all of whom may be called to summarize that testimony and respond to questions at the hearing (Sections V and VI); a brief description of the Alternate Proposals advocated by the Well Operators (Section VII); reservations made by the Well Operators (Section VIII); and a brief conclusion (Section IX).

I. EXECUTIVE SUMMARY

A. The Well Operators

1. Denver-Julesburg Basin (“DJ Basin”) Operators.

Anadarko and Noble are two of the largest oil and gas producers in DJ Basin northwest of Denver, a more than 600-square-mile area that is the sixth-largest natural gas producing field in the country. Their combined production accounts for approximately 65% of the gas and condensate production in the DJ Basin.

Anadarko operates over 3,600 active natural gas wells, over 2,000 wellhead tank batteries and multiple compressor stations with various types of natural gas compression, dehydration, and condensate removal and storage equipment. Anadarko currently has installed and operates approximately 808 flares and 15 vapor recovery units (“VRU”) to comply with the present Regulation Number 7 requirements. Anadarko currently installs approximately five (5) emission control devices (“ECD”) per week (to control new wells and refracs) at a cost of \$15,000.00 per ECD, for a total of \$75,000.00 per week. On average it costs Anadarko \$3,500.00 per week to maintain compliance with Regulation Number 7, which includes reporting, inspections, and spreadsheet maintenance, but excludes the capital and installation costs of ECDs.

Noble operates over 5,000 active natural gas wells and over 2,700 wellhead tank batteries in the DJ Basin. Noble currently has installed and operates approximately 1,288 flares at a total capital cost of \$13,722,500.00 and installation cost of \$2,060,800.00. In addition to the flares, Noble has installed 113 VRUs at a total capital cost of \$2,825,000.00 and installation cost of \$452,000.00. Including these costs, maintenance, inspection, reporting and spreadsheet maintenance costs, Noble estimates its total costs for complying with the present Regulation Number 7 at \$2,100,000.00 per year.

2. West Slope Operators.

Williams operates active natural gas wells in the Piceance and San Juan Basins located on the Western Slope of Colorado and its facilities include, among others, wellhead tank batteries that collect and store natural gas condensate. Williams operate reciprocating internal combustion engines (“RICE”) to drive compressor units in its natural gas gathering systems, compressor stations and gas processing plants in the Piceance Basin.

Noble also operates over 150 natural gas wells in the Piceance Basin located in Garfield and Mesa Counties on the Western Slope of Colorado. Its facilities there include, among others, wellhead tank batteries that collect and store natural gas condensate.

B. Rulemaking Considerations

As this Commission well knows, there are a number of legal requirements to which its rulemaking is subject. Although the Commission is to have “maximum flexibility in developing an effective air quality control program,” any adopted regulations must still be “economically reasonable so as to reduce, prevent, and control air pollution,” and “the air pollution control measures utilized [must] bear a reasonable relationship to the economic, environmental, and

energy impacts and other costs of such measures.” Colorado Air Pollution Prevention and Control Act (“State Act”), C.R.S. § 25-7-102. In reviewing the proposed Ozone Action Plan and the alternative proposals that will come before the Commission, the Commissioners must bear this in mind, taking a careful look at the estimated ozone benefits to be realized from each of the proposals in relation to the estimated costs, as well as whether the proposal(s) fall squarely within the scope of this rulemaking.

Moreover, the Commission should be mindful of the initial scope of this rulemaking as set forth in the Commission Notice of Proposed Rulemaking:

The Air Quality Control Commission will consider a proposal from the Denver Metropolitan Area’s Air Quality Council, the North Front Range Transportation & Air Quality Planning Council and the Colorado Department of Public Health and Environment Air Pollution Control Division to adopt an ozone action plan for the Denver Metropolitan and North Front Range 8-house ozone nonattainment area.

In order to evaluate the estimated ozone benefits to be realized in relation to the estimated costs, the Commission should rely on the best scientific data available to first identify the problem to be addressed by the proposed rule(s). Of course, high ozone concentrations in the non-attainment area are the overarching problem, and the first question to ask is what are the sources that actually contribute most to ozone formation in the non-attainment area? Secondly, the Commission must carefully evaluate the proposed controls to ensure that they address the core problem in a reasonably efficient and cost-effective manner. A very significant tool available to the Commission in meeting these requirements is the Ozone Source Apportionment Tool (“OSAT”) analysis derived from the CAMx photochemical modeling outputs. The OSAT results show in dramatic fashion why lower cost-per-ton controls in one sector that contributes much less to ozone formation may be less effective than higher cost-per-ton controls of sources that contribute more greatly to ozone formation. Those results are summarized and graphically displayed in a number of the Well Operators’ exhibits, identified below, and to be filed with their Final Statement.

C. Proposed Ozone Action Plan Measures Supported by the Well Operators

The Well Operators do support many of the measures proposed in the Ozone Action Plan, including:

1. Incorporating more stringent cut-points adopted last February by AQCC for the Inspection and Maintenance (“I/M”) Program in the seven-county Denver Metropolitan Area (“DMA”) into the SIP.
2. Requiring 7.8 pounds per square inch Reid Vapor Pressure (“RVP”) gasoline be sold exclusively in the entire NAA, also as a SIP requirement.
3. Requiring low-bleed control devices on all new and existing pneumatic devices for oil and gas facilities in the NAA by 2009, except where their

installation is technically infeasible or not warranted due to safety concerns.

4. Expanding current Regulation Number 7 to require the installation of reasonably available control technology on VOC stationary sources across the entire NAA, except where inconsistent with system-wide tank controls.
5. Removing current Regulation Number 3 APEN exemptions for selected small sources of VOCs, except to the extent inconsistent with system-wide tank controls.
6. Implementing a motor vehicle I/M program in the North Front Range (“NFR”), except the Well Operators support implementing that program starting January 1, 2010.
7. Continuing to implement the high-emitter pilot program in the DMA.
8. Tightening the collector car license plate requirements under state law to limit it to true collector motor vehicles thereby closing a loophole that allows high-emitting vehicles to more easily escape testing and repair.
9. Requiring the installation of auto-igniters on combustion systems controlling condensate tank emissions.

D. SIP Proposed Measures Not Supported

The Well Operators do not support the following portions of the Ozone Action Plan proposed for inclusion in the SIP on multiple grounds, one of which being that proposed changes are not supported by the State’s own data and modeling. More specifically, the Well Operators oppose:

1. Abandoning the present system-wide control approach to regulating condensate storage tanks in favor of mandatory controls for all tanks with emissions above 2 tpy, which will significantly burden operators and complicate the scheme for regulating tanks, while delivering few, if any, additional emission reduction benefits in the 2010 attainment year relative to the existing regulatory approach at an increased control percentage of 85% for tanks emitting 1 tpy or more;
2. Requiring the installation of electronic surveillance systems (“ESS”), in addition to auto-igniters, on combustion systems controlling condensate tank emissions;
3. Establishing the proposed ESS requirements by the proposed effective date for all tanks to be controlled under the Division’s proposal, because they can simply not be achieved by then; and

4. Revising the definition of a “modified” source for condensate tanks to include any well refracting or stimulation, because it is unnecessary, unprecedented and unjustified.

E. State-Only Proposed Measures Not Supported

1. RICE Controls: The Well Operators oppose the inclusion of state-wide RICE controls in the Ozone Action Plan that focus solely on existing and modified lean-burn and rich-burn natural gas fired reciprocating internal combustion engines (“ICE”) of 500 horsepower (“HP”) or greater. The Well Operators oppose these state-wide RICE controls because they exceed the scope of the notice of rulemaking, they are not tailored to doing what this Commission has intended to do in its oil and gas strategy (“keeping clean areas clean”), and the controls will not appreciably contribute to improvements in ozone as modeled by contractors for the Division and the Regional Air Quality Council (“RAQC”). Additionally, the Division has failed to accurately quantify the emission reduction benefits such a state-only rule would deliver, and will arbitrarily require the installation and operation of control devices irrespective of an engine’s ability to comply with emission limitations. Furthermore, the Division has failed to account for emission reduction benefits that are already built into two recently adopted United States EPA New Source Performance Standards (“NSPS”) applicable to ICE. Specifically, NSPS IIII and JJJJ (“Quad I” and “Quad J”) establish emission limitations for both compression ignition (“CI”), and spark ignition (“SI”) ICE. Quad I, which became effective March 2008, regulates engines as far back as June 2006 and will produce quantifiable emission reductions as early as 2009. Finally, the Division’s rush to control certain specific natural gas RICE is inconsistent with the Division’s planned comprehensive review of all or most NOx sources starting as early as the first quarter of 2009.

2. NFR Motor Vehicle I/M: Although the Well Operators fully support the implementation of a vehicle I/M program in the NFR, some or all of the Well Operators propose moving up the implementation date of the program from January 1, 2012 to January 1, 2010. This is the subject of an alternate proposal that is separately described below at Section VII of this Final Statement and contained in exhibits submitted with this Final Statement. The State’s own I/M program contractor has stated that the program can be up and running by January 1, 2010, which would allow the NAA to begin to benefit from substantial emissions reductions in the NFR during the all-important 2010 ozone season. Moreover, some or all of the Well Operators believe it would be inconsistent with the Governor’s letter directive of July 26, 2007 to delay the full implementation of this I/M program until 2013 or 2014, essentially ignoring one of the largest contributors to ozone formation in the NAA, as graphically confirmed by the state’s own OSAT results.

F. Time Needed to Present Testimony

The Well Operators have provided written testimony for nine (9) witnesses in support of their positions and alternate proposals, the full text of which is submitted with this Final Statement. At the hearing, the Well Operators’ witnesses will verbally present a brief summary of their written testimony to provide the proper context for the Commission regarding this rulemaking and further provide the opportunity for limited questions and possible cross-examination. In light of this approach, the Well Operators anticipate they will need two and one-

half (2.5) hours to present testimony and introduce exhibits, inclusive of their rebuttal testimony, and exclusive of possible cross-examination by the Division's counsel or other parties, or significant questioning by the Commission.

II. THE WELL OPERATORS' STATEMENT OF FACTUAL AND LEGAL ISSUES

A. Generalizations About Growth in Oil and Gas Industry Emissions State-Wide are not Consistent with the Hard Data on DJ Basin Gas Production and the Industry's Major Reductions in Emissions Since 2004.

The DJ Basin is a mature natural gas field. While high gas prices fuel the drilling of new wells to keep production up, new wells in the DJ Basin are "infill" wells under applicable COGCC rules, and frequently produce to existing, consolidated tank batteries that are already controlled under Regulation Number 7. Such growth in the number of wells does not translate directly into growth in emissions for the DJ Basin. The Division's simplified approach that growth in production has outpaced reductions in emissions, is therefore inaccurate and misleading with respect to the DJ Basin. *See* Well Operators' Exhibit Numbers 1 and 3, displaying DJ Basin gas production and flash emission reductions over time. Oil and gas industry emissions of VOCs have been reduced more since 2004 than they have grown as a result of increased production, especially if voluntary pneumatic device control replacement is taken into account.

B. SIP Proposed Measures

1. The Proposed Changes in the Ozone Action Plan are Inconsistent with the State's Own Data and Modeling.

Because the control measures in the Ozone Action Plan were developed before source apportionment results became available on September 4, 2008, they do not reflect the unexpectedly heavy contribution of NOx emissions to ozone formation that was identified. Indeed, the September 8, 2008 Draft Final OSAT Report describes several trends that emerged from the source apportionment results. First, more than two-thirds of ozone contribution to the NAA comes from outside the 12 km domain. Second, the largest and most significant contributors to ozone formation in the DMA are mobile and non-road mobile sources. Third, at the two Ft. Collins monitors and the Greeley monitor, the largest contributors again are mobile sources, followed by non-road mobile sources, and then oil and gas sources. *See* September 8, 2008 Draft Final OSAT Report, pp. 3-9. Nevertheless, the Ozone Action Plan is predominantly focused on controlling VOC emissions from the oil and gas industry, seeking a reduction of 109 tons per day ("tpd") and a NOx reduction of only 10 tpd. This is completely opposite to the source apportionment results, which show many times more ozone attributed to anthropogenic sources of NOx than to anthropogenic sources of VOCs. And when it comes to VOCs, source apportionment also shows that lower reactivity VOCs from oil and gas sources play a much smaller role than higher reactivity VOCs from on-road and non-road mobile sources. *See* Testimony of Bruce Macdonald, and the Well Operators' exhibits referred to therein. Thus, the Ozone Action Plan is far less effective than it would be if it contained more NOx controls than VOC controls, and did not rely so heavily, if not exclusively, on oil and gas sources of VOCs,

which are a comparatively minor contributor of VOCs that actually form ozone, according to the best available modeling results.

The OSAT analysis, employing outputs from the CAMx model, with its refined gridded data and various physical and chemical algorithms embedded in the model, represents the best approach to evaluating sources and impacts related to ozone generation currently available. The Division's "weight of evidence" ("WOE") analysis is not as technically sound as the CAMx modeling results. While the WOE may be required for USEPA evaluation, the implementation of a control strategy should focus on the CAMx OSAT analysis. The following issues are raised regarding the technical and WOE analysis:

- Comparing tons of VOCs from different source categories without regard to their photochemical reactivity is misleading, and has contributed to our almost total reliance on oil and gas VOC controls as an ozone reduction strategy;
- Back trajectory analysis employing the NOAA HYSPLIT model tells us nothing about the conversion of ozone precursors in a parcel of air as it moves around, and its use over complex terrain is not recommended; and
- The observed correlation of high ozone events and 500 millibar (pressure) heights within the atmosphere is also inconclusive, and does not provide a basis for ignoring OSAT results.

Concerns about emission inventory accuracy affecting modeling results are appropriately raised, but weigh as heavily (if not more heavily), for mobile source VOC emissions as for oil and gas VOC emissions. In fact, a prior evaluation of doubling and tripling mobile source VOCs showed better model performance. *See* the testimony of Dr. Bruce Macdonald concerning these and related issues.

2. Abandonment of the System-Wide Control Approach to Regulating Condensate Storage Tanks in Favor of Mandatory Controls for all Facilities with Emissions above an Applicability Threshold is not Warranted.

The current regulatory framework for Regulation Number 7 is based on a "system-wide" control approach that requires each company to achieve a percentage-emission reduction level during the ozone season and a slightly lower percentage-emission reduction level during the non-ozone season (to enable periodic maintenance of control devices in the "off-season"). The system-wide approach provides oil and gas operators needed flexibility to service and reposition their ECDs as production levels in the field change, and that approach was adopted by the Commission in 2004 with the strong support of the oil and gas industry. Each and every year thereafter under the system-wide approach, the oil and gas industry has met and exceeded the required emission reductions, even as that requirement increased from 37.5% in 2004 to the present 75%. And while the required emission reductions stayed at 75% in 2007-2008, the oil and gas industry continued to increase its overall reductions from 79% in 2007 to 84% in 2008, which is further evidence of the strong incentive to over-control at work in the existing regulatory approach.

The Ozone Action Plan would abandon the system-wide control approach in favor of a threshold approach. This represents a fundamental shift that is more onerous for industry and would not generate any greater environmental benefit in 2010 than the Well Operators' Alternate Proposal, which is described in detail in Section VII.A. The Ozone Action Plan mandates controls on all facilities above an applicability threshold, plus it requires controls on all tanks during the first 90 days of production. Due to the fluctuating and dynamic nature of oil and gas production, the threshold-based approach will require that operators constantly evaluate production and emission levels to determine whether the applicability threshold has been triggered for any given tank. As a result of this ongoing need to evaluate condensate production levels at all tanks and add more controls as necessary based on those changes, the Ozone Action Plan's threshold approach is more burdensome to operators than the system-wide approach. It also represents a wholesale change from the existing Regulation Number 7 requirements, after only four years since their adoption, and thus is likely to promote greater confusion and compliance uncertainty in the regulated community, especially over the next four years.

Additionally, because it appears that any burner outage or correction of condensate production data indicating the need for controls on a tank that has none may be a violation under the proposed rule, the Ozone Action Plan will: (1) require industry and the Division to devote more resources to reporting outages under the upset provisions of Regulation Number 3; and/or (2) result in multiple minor violations for companies, again requiring company and Division resources to resolve them. As an example, Noble estimates that even at a very respectable 0.27% flare downtime, a figure it has worked very hard to achieve in recent months, the Company would have on average 4.6 violations per day to report to the Division under the threshold approach. This sort of penalty exposure is arbitrary, in that it does not deter bad conduct, but merely punishes the statistically inevitable. In contrast, the system-wide approach encourages companies to over-comply, resulting in lower levels of actual emissions while reducing an operator's risk of noncompliance due to isolated burner malfunctions or production data corrections.

Under the system-wide approach, operators also have an incentive to engage in pollution prevention and/or pursue more expensive alternatives to VOC emissions control, like vapor recovery, reducing line pressure (which lowers flash emission potential) or condensate stabilization. The Ozone Action Plan removes such flexibility and incentives without producing greater environmental benefit. Instead, the Ozone Action Plan will inefficiently force industry to monitor production at thousands of unmanned remote production facilities and will likely lead to a higher focus on enforcement by the Division. Such a result is neither necessary, nor desirable, in the Well Operators' view.

This fundamental change in the regulatory approach to condensate storage tanks will not lessen the burden on operators, large or small. Operators will need to constantly reevaluate where to install controls on tanks as emissions fluctuate due to production changes. Also, this change will require enforcement for every minor flare outage even if field-wide compliance remains high. Most importantly, the proposed change will eliminate the present flexibility and incentives for operators to "over-comply" and engage in pollution prevention. Accordingly, the Well Operators have prepared and submitted with this Final Statement an Alternate Proposal that retains the system-wide control approach for condensate storage tanks, but at the higher emission control level of 85% for tanks emitting 1 tpy or more of VOCs. That Alternate Proposal is

described below at Section VII.A. of this Final Statement, and is fully documented in the Well Operators' Exhibit Numbers 43, 44, and 45.

In addition to the above factors favoring system-wide tank controls, there are important "disbenefits" associated with pushing the control of VOCs down to very low-emitting tanks, and those disbenefits have not been adequately addressed by the Division. The disbenefits concern (1) the increased carbon footprint associated with the flaring of flash emissions, relative to emitting those emissions, and consideration of these disbenefits by the Commission also weighs in favor of the Well Operators' alternate proposal for condensate tank controls, rather than putting a flare on every tank emitting as little as 2 tpy of VOCs, or even less; and (2) the increased NOx emissions associated with flare controls on very low-emitting tanks.

Examination of available data reveals that, on average, there is a 40% greater emission of greenhouse gases ("GHGs") associated with the flaring of condensate tank flash emissions, and this disbenefit is ignored or discounted by the Division. As the Commission well knows, the Colorado Climate Action Plan calls for a 20% reduction in GHG emissions by 2020, as measured against 2005 emissions. Because 2005 is the year in which tank controls were first required at 37.5% for the ozone season, the increases associated with flaring of tank emissions in the DJ Basin are quite significant in the aggregate since that baseline year. *See* the Well Operators' Exhibit Numbers ___ and ___ regarding GHG disbenefits associated with flaring tank emissions of VOCs from condensate.

Additionally, although the NOx emissions associated with flaring tank emissions are significantly lower than the tons of VOCs controlled through flaring, they are not insignificant, especially when adjusted to reflect the OSAT results that account for ozone formation potential and photoreactivity. See the written testimony of Curtis O. Rueter regarding NOx disbenefits associated with flaring tank emissions of VOCs. Moreover, the flaring of tank emission for low-emitting tanks, between 5 tpy and 2 tpy, entails the combustion of significant volumes of fuel gas to keep pilots lit between intermittent periods of "slug" production to wellhead tanks. These NOx emission increases contribute to ozone formation and therefore diminish further the asserted benefits of attempting to control the lowest emitting condensate tanks operating in the DJ Basin.

3. The Division's Proposal Requires the Installation of Both Auto-Igniters and ESS on Combustion Systems Controlling Condensate Tank Emissions.

The Well Operators believe the requirement to install both auto-igniters and ESS is burdensome, redundant and unnecessary. By design, auto-igniters should provide essentially continuous operation of burners, unless a well, tank battery and burner is shut down by operating personnel. The ESS just tracks pilot light temperature and does not provide any direct air quality benefit.

ESS will generate a staggering amount of data. As proposed, an ESS will record a temperature measurement every 15 minutes, 24 hours a day, 7 days a week. This equates to 672 data points per week for one flare. Anadarko estimates that it will need to install ESS on 2,000 control devices in 2009, and Noble estimates it will need to install 1,288 ESS in 2009, both based

upon the threshold approach proposed in the Ozone Action Plan Exhibit Numbers 23 and 24. If installed, Anadarko's ESS will produce 1,344,000 data points weekly, and Noble's will produce 865,536 data points each week. That is 2,209,536 data points *every week*, from just two operators in the DJ Basin. Once an ESS generates the data, it still has to be collected and analyzed to determine if any flare outages are indicated. Regardless of who will have to collect and/or analyze it, that much data will create a substantial burden on the operators and further strain the Division's limited resources.

In addition, the cost of purchasing and installing the ESS are quite significant. Anadarko estimates capital costs at \$3,800.00 per flare and Noble at \$3,600.00 per flare. Based upon the numbers above, Anadarko's total cost for purchasing and installing ESS would be \$7,600,000 by 2011 and Noble's would be \$4,636,000 in 2009. That is an extraordinary expense for a piece of equipment that will not provide any direct air quality benefit, and is not providing data that are dispositive of the question whether emissions are being controlled, *i.e.*, the data only indicate if the flare pilot light is on.

4. The Proposed Monitoring Requirements Simply Cannot be Achieved by the Effective Date of the Proposed Revisions.

The Ozone Action Plan would mandate controls on all new and modified tanks greater than 2 tpy by 2009, all existing tanks greater than 10 tpy by 2010, all existing tanks greater than 5 tpy by 2011, and all existing tanks greater than 2 tpy by 2012. To meet these proposed requirements, the oil and gas industry would need to install approximately 2,000 to 4,000 data loggers plus 2,000 to 4,000 auto-igniters in 2009. Moreover, an additional complement of control devices, possibly numbering in the hundreds, would be required by the Division's proposed "first 90 days" control requirement.

Based on their own actual compliance experience with the current Regulation Number 7, the Well Operators do not believe that data logger and auto-igniter manufacturers can provide enough devices and/or that industry will be able to adequately test and install such systems as well as procure and install the necessary data management systems within the timeline proposed in the Ozone Action Plan. Nor does the Ozone Action Plan provide any flexibility on the proposed deadlines should the manufacturers fail to meet demand or if complications arise from installing and testing the ESS, which have not been field-proven for conditions in the DJ Basin. Such an approach further exposes the oil and gas industry to enforcement for unavoidable circumstances, making compliance virtually impossible.

5. The Proposed Definition of a Modified Source for Condensate Tanks to Include Well Refracting.

The Well Operators believe that a well or condensate tank should only be considered a modified source if refracting results in a net increase in emissions above the originally permitted or APENed emissions level. This approach to well/tank modification protects the environment because it acknowledges that, in most cases, the original registration and/or permitting of condensate tanks will reflect their highest levels of production, when a new well is initially brought into production. It does not exempt condensate tanks from being considered "modified" if reworking a well does, in fact, result in a net emissions increase above initially permitted or

registered levels, which does occur from time to time. This approach is also consistent with other states in which oil and gas sources are significant, such as Texas and Oklahoma.

Well reworking and refracing that does not result in emissions above initially permitted or registered levels should not be considered a modification, and changing the definition of source modification in this unprecedented manner will just increase the paperwork burden on operators and the Division without providing any air quality benefits. Moreover, this unprecedented departure from the long-established definition of “modification” of a source is only necessitated by the Division’s desire to move to a threshold-based regulatory scheme from the established and effective system-wide approach followed for the last four years. Retention of the system-wide approach at a higher control percentage, as proposed by the Well Operators, will eliminate the need to tinker with this universal air quality definition and will eliminate a substantial paperwork burden for operators and regulators alike.

C. State-Only Proposed Measures

1. Proposed State-Wide RICE Controls.

The proposed adoption of state-wide engine controls should be deferred for consideration among a broad range of NOx controls in 2009. The Well Operators oppose the proposed adoption of state-wide RICE controls at this time for a variety of reasons, including:

- The ozone reduction benefits of such controls have not been properly estimated and would appear to be negligible;
- Recently adopted federal NSPSs will help “keep clean areas clean,” as intended by the AQCC, without overlap of and potential inconsistency with state engine requirements proposed by the Division;
- The Division has failed to account for the benefits of the federal engine NSPSs in making its case for state-wide RICE controls; and
- The proposed RICE controls would arbitrarily require specific engine technology regardless of emissions performance, which are not mandated under the noted NSPS.

These and other problems are addressed in greater detail below.

As proposed, the state-wide RICE controls would single out the oil and gas sector by requiring those who own or operate modified and existing stationary SI lean-burn and rich-burn natural gas-fired ICE of greater than or equal to 500 HP to control emissions from those engines and install and operate after-treatment control devices on those engines. The majority of larger natural gas-fired ICE in Colorado are in service in the oil and gas industry. The Division’s proposed rule does not impose similar requirements on SI ICE fired with other fuels (like the NSPSs), nor does it impose similar requirements on CI ICE (like the NSPSs). Even the Division’s proposed retention of a previous emission limitation for those stationary SI natural gas ICE of greater than 100 HP excludes SI ICE fired with other fuels and all CI ICE. These

shortcomings, coupled with negligible or non-existent ozone benefits, weigh heavily in favor of deferring state-wide RICE controls for further consideration by the Commission in 2009.

- a. The proposed state-wide RICE controls are outside the scope of the noticed rulemaking.

As an initial matter, the proposed state-wide RICE controls are outside the scope of the notice of the proposed OAP, in violation of the Colorado Administrative Procedure Act. Finally adopted rules must be consistent with the subject matter as set forth in the notice of proposed rule-making. C.R.S. § 24-4-103(4)(c). The OAP rulemaking notice focused specifically and exclusively on the consideration of a proposal “to adopt an ozone action plan for the *DMA and the NFR 8-hour ozone non-attainment area*.” See Commission Notice of Proposed Rulemaking. The proposed state-wide RICE control rule is just that—*state-wide*. The proposed state-wide RICE control rule does not limit its application to the DMA and NFR area, but instead extends to the far reaches of the four corners of our state. Even the RAQC modeling indicates that emission reductions from state-wide RICE controls will not appreciably improve ozone in the NAA. See Testimony of Martha Hyder. Thus, the adoption of such a state-wide rule under the proposed notice is clearly outside the scope of the rule-making and should not be considered in this rule-making.

Additionally, a related issue concerns the definition of the NAA itself, and how air quality control regions are supposed to develop a SIP to bring those regions into attainment with federal NAAQS. As the Well Operators have previously noted, the State of Colorado opposed EPA’s attempt to expand the NAA even more than it last did, and in so doing made a cogent argument about the sources contributing most significantly to ozone being primarily within a smaller NAA. See the Well Operators’ Exhibit Number 40, memo dated May 20, 2008 regarding NAA boundary designation for the Denver and NFR areas. Of course, Colorado prevailed in keeping the NAA boundary where it is today, and the Division has not proposed expanding it as part of the 8-hour ozone SIP development process. Accordingly, state-wide RICE controls should not be included in the Ozone Action Plan.

- b. The Division has failed to adequately characterize the emission benefits of its proposed state-wide RICE controls.

The Division has been unable to provide a specific estimate of the emission reductions to be delivered by several standards that are already “on the books,” including the federal NSPSs and the state’s own existing Regulation Number 7 requirements for new and relocated engines. At best, the Division has shown a “marginal” benefit from state-wide reductions in NO_x emissions from oil and gas and point sources through its sensitivity analyses. See testimony of Martha Hyder. Modeling of the Division’s state-wide control scenario, which included not only overestimated NO_x emissions reductions from engines, but also: (1) additional VOC reductions in the NAA due to condensate tank controls that will not be effective until 2011 and 2012, well after the 2010 attainment date; and (2) vehicle I/M program benefits as though fully implemented by 2010 when discontinued in 2006 showed only minor improvements in ozone in the NFR area.] *Id.* Based on the sensitivity analyses and OSAT results, such improvements are most likely due to the 2011 and 2012 condensate tank controls and/or vehicle I/M program controls rather than the state-wide RICE controls. *Id.* The modeling, in fact, showed large areas with

small ozone increases over most of the Western Slope, undoubtedly due to the additional NO_x controls in that NO_x limited region. *Id.* Finally, the OSAT modeling showed that very little of the ozone at NAA monitors can be ascribed to emissions outside of the NAA. *Id.* Thus, it is remarkably unclear as to what benefits will accrue relative to ozone formation in the NAA, if any, through the adoption of the Division's state-wide RICE control proposal.

- c. The Division requires the installation and operation of after-treatment control devices irrespective of compliance with the proposed emission limitations.

The installation and operation of after-treatment control devices on stationary lean-burn and rich-burn natural gas SI ICE with greater than 500 HP are required under the Division's proposal as of May 1, 2010, regardless of whether an engine applicable emission standards without such controls. Many of the engines in place can meet or exceed the current Regulation Number 7 emissions limitations that apply to new and relocated engines, without after-treatment control devices. *See* Testimony of Dr. Daniel B. Olsen, P.E. Requiring specific after-treatment technology for existing and modified engines is therefore arbitrary, wasteful and unwise. By mandating specific after-treatment technology, the Division is taking operational field decisions away from the owner and operator, who is in a better position to know what operational modifications or other types of control technology may be cost-effective and efficient to comply with an identified emission limitation. *Id.* For example, certain after-treatment may create additional NH₃, which will effectively neutralize any NO_x emission reduction benefits. *Id.* Moreover, other technologies are available for lean-burn engines to reduce emissions, and the installation and operation of exhaust after-treatment is expensive and imposes additional backpressure on engines, which results in efficiency loss. *Id.* If any control of existing and modified engines is warranted, it should be in the form of a performance standard, not the arbitrary imposition of a specific control technology, as prescribed by the Division's proposal.

- d. The Division did not consider or account for projected emission reductions realized through EPA's Quad I and Quad J.

Surprisingly, the Division did not factor in or account—in any way—for the emission reduction benefits that Colorado would see—both in attainment areas and its NAA—through the installation, reconstruction, modification, and operation of CI and SI ICE of various sizes and fuel types regulated under the fully-promulgated and effective NSPSs. *See* the Well Operators' Exhibit Number 33. Irrespective of the State's failure thus far to adopt Quad I and Quad J through incorporation into the AQCC's rules, owners and operators are obligated to comply with these federal regulations, and their compliance will most certainly result in significant emission reduction benefits. Any emission reduction benefits that the Division hoped to attain through the proposed state-wide RICE controls will be largely realized through the two previously promulgated and fully effective NSPS. *See* Testimony of Martha Hyder and Dr. Olsen.

EPA's NSPS JJJJ in 2009 alone is estimated to provide more than a 60,000 tpy reduction of NO_x, 29,000 tpy reduction of CO, 800 tpy of VOC, and 311 of HAP nationally. *See* Memorandum from Tanya Parise, Alpha-Gamma Technologies, Inc. to Jaime Pagan, EPA Energy Strategies Group (Dec. 18, 2007). Even assuming Colorado accounts for only five percent of the national emission reductions, the State would still realize a projected emission

reduction benefit of 3,000 tpy for NO_x, 1,450 tpy for CO, 45 tpy of VOC, and 15.5 tpy of HAPs. By 2015, EPA estimates that the two NSPSs will reduce NO_x by 115,000 tpy, CO by 63,000 tpy, VOC by 2,000 tpy, HAP by 800 tpy, PM by 3,000 tpy, NMHC by 600 tpy, and SO₂ by 9,000, nationally. *See* 71 Fed. Reg. 39154, 39168 (July 11, 2006); 73 Fed. Reg. 3568, 3586 (Jan. 18, 2008). Again, even assuming that Colorado accounts for only five percent of the national emission reductions to be realized through Quad I and Quad J, the State would realize a projected emission reduction benefit of 5,750 tpy of NO_x, 3,150 tpy of CO, 100 tpy of VOC, 40 tpy of HAP, 150 tpy of PM, 30 tpy of NMHC and 450 tpy of SO₂.

In light of the foregoing, the Division's proposed state-wide RICE controls should not be promulgated. Instead, the Division should acknowledge and consider the projected emission reduction benefits associated with NSPSs Quad I and Quad J in advance of any further sector-specific emission reduction strategies for which it cannot meaningfully articulate ozone reduction benefits. State-wide engine controls are more appropriately reserved for the Division's proposed 2009 plan to more thoughtfully consider and comprehensively review a variety of NO_x sources.

2. Implementation of the I/M program in the NFR should be moved forward to January 1, 2010.

The Ozone Action Plan proposes to expand the existing motor vehicle inspection and maintenance (I/M") program currently applicable in the seven county DMA to the AIR Program area in Larimer and Weld Counties. The Well Operators generally support this proposal and agree that the establishment of an I/M program in the NFR is an important component of any serious effort to demonstrate: (1) attainment with the 0.08 ppm ozone standard, and (2) further progress toward attaining a lowered ozone NAAQS of 0.075 ppm.

The OSAT results indicate that on-road mobile sources in the NFR are one of largest source contributors to ozone formation in that area, due to their VOC and NO_x emissions. The OSAT results further indicate that the majority of ozone formed is attributed to anthropogenic NO_x sources. These two conclusions underscore the need to reduce NO_x emissions from mobile sources in the NFR sooner rather than later.

The Well Operators assert that it is unwise to delay implementation of a reinstated I/M program in the NFR until 2012. Waiting until January 1, 2012 to begin to implement a vehicle I/M program in the NFR means that the full ozone reduction benefits of the program will not be realized until the beginning of 2014. This is hardly consistent with Governor Ritter's directive to begin to work toward attaining a lowered 8-hour ozone standard, and it flies in the face of this Commission's well-documented resolve to move quickly to address our ozone non-attainment status and protect public health. There is simply no good reason for such delay, and no more important task at hand for the Mobile Source Program of the APCD. By moving up the implementation date to 2010 as described in the Well Operators' Alternate Proposal in Section VII.B., the first half of the vehicles brought into the program will be tested in that year, and the remaining vehicles will be tested in 2011. By January 1, 2012 the program will be fully implemented.

Perhaps ironically, it is this very Commission that acted to dissolve the prior I/M program in the NFR just two years ago, over the objections of the NFRMPO and others, and that unfortunate decision most certainly contributed to our collective failure to avoid non-attainment designation via the EAC. It is well-documented that the vehicle fleet in the NFR is older and higher-emitting than in the DMA, and since dissolution of mandatory testing and repair, the NFR vehicle fleet is likely even dirtier, and not much newer. It is also well documented that a significant portion of the NFR vehicle fleet, perhaps as high as 20%, commutes into the DMA on a routine basis, and should therefore be tested under existing law, but we have failed to enforce that requirement! Delaying the reinstatement of an I/M program in the NFR under these circumstances simply can't be justified, and the state's own experience implementing the former NFR I/M program in the early nineties, and the contractor's experience here and in other states, indicates that 2010 implementation is achievable. In light of the foregoing, the Well Operators urge the Commission to reject the Division's proposed 2012 start date for an NFR I/M program and instead adopt the Well Operators' Alternate Proposal, as described in Section VII.B. to start this important program in 2010.

These factual and legal issues are the subject of written testimony, live testimony and exhibits to be presented by the Well Operators prior to and at the hearing, as summarized and listed below.

III. LIST OF ISSUES TO BE RESOLVED BY THE COMMISSION

A. SIP Proposed Measures

1. Source Apportionment Results are not Adequately Reflected in the Ozone Action Plan Controls.
2. NAA Tank Controls: System-Wide v. Threshold Approach.
3. NAA Tank Controls: Whether ESS in Addition to Auto-Igniters is Beneficial.
4. NAA Tank Controls: ESS Compliance Schedule.
5. Whether Inclusion of Well Refracting in Definition of Modified Source is Necessary or Helpful.

B. State Only Proposed Measures

1. Adoption/Deferral of State-wide RICE Controls.
2. Implementation Date of I/M program in NFR.

IV. EXHIBITS THAT WILL BE INTRODUCED AT THE HEARING

A. Oil and Gas Production Growth and Emission Reductions

1. Well Operator (“WO”) Exhibit 1: Graphic of John D. Wright, Ph.D., President, Oil & Gas Services and Chief Petroleum Engineer of Norwest Corporation, showing growth from 1999 to 2007 and projected future growth through 2012 of natural gas condensate production in Weld County, Colorado.
2. WO Exhibit 2: Graphic showing 8-Hour Denver Ozone Design Values from 1993 – 2007, based on data from the Division.
3. WO Exhibit 3: Graphic showing the levels of controlled emissions during the ozone season for the DJ Basin Operators and all operators in the DJ Basin, from 2005 - 2008.
4. WO Exhibit 4: Chart showing the expenditures to date by the DJ Basin Operators on ECDs to control condensate tank VOC emissions in the DJ Basin.
5. WO Exhibit 5: March 11, 2008 letter from Anadarko to Mr. Kenneth H. Lloyd, Executive Director of the Regional Air Quality Council, agreeing to voluntarily replace high-bleed pneumatics with low-bleed pneumatics, as well as other voluntary measures to reduce ozone impacts in the NAA.
6. WO Exhibit 6: March 11, 2008 letter from Noble to Mr. Kenneth H. Lloyd, Executive Director of the Regional Air Quality Council agreeing to voluntarily replace high-bleed pneumatics with low-bleed pneumatics, as well as other voluntary measures to reduce ozone impacts in the NAA.

B. Source Apportionment Results

1. WO Exhibit 7: Maps of the NAA and location of air monitors within the NAA.
2. WO Exhibit 8: Comments submitted to the Regional Air Quality Council on March 11, 2008, providing Guiding Principles for the Adoption of Ozone Controls.
3. WO Exhibit 9: Ozone Source Apportionment Modeling Results, Appendix C—Bar Charts demonstrating source apportionment results at each air monitor for each day modeled.
4. WO Exhibit 10: Graphic showing average contribution of O3N and O3V to Ozone formation at the Ft. Collins air monitor.

5. WO Exhibit 11: Graphic showing average contribution of O3N and O3V to Ozone formation at the Ft. Collins West air monitor.
6. WO Exhibit 12: Graphic showing average contribution of O3N and O3V to Ozone formation at the Weld County Tower air monitor.
7. WO Exhibit 13: Graphic showing average contribution of O3N and O3V to Ozone formation at the Rocky Flats North air monitor.
8. WO Exhibit 14: Graphic showing average contribution of O3N and O3V to Ozone formation at the CAMP air monitor.
9. WO Exhibit 15: Graphic showing average contribution of O3N and O3V to Ozone formation at the Chatfield Reservoir air monitor.
10. WO Exhibit 16: Graphic showing average contribution of O3N and O3V to Ozone formation in the NAA.
11. WO Exhibit 17: Chart summarizing occurrences of Design Value Days from June – July 2006 in the Ozone Modeling/OSAT Results.
12. WO Exhibit 18 & 19: Did not use.

C. System-Wide v. Threshold Tank Controls

1. WO Exhibit 20: Graphic demonstrating oil and gas operator compliance under system-wide approach from 2005 to 2008 based upon Regulation Number 7 spreadsheets.
2. WO Exhibit 21: Chart showing the requirements of the Colorado Climate Action Plan.
3. WO Exhibit 22: Graphic & charts showing the green house gas disbenefit from flaring, as opposed to venting, flash gas from condensate tanks.

D. Auto-Igniters and ESS for Tanks

1. WO Exhibit 23: Graphics/charts demonstrating the total cost and cost per ton of emissions reduced of installing and maintaining ESS as proposed under the threshold approach.
2. WO Exhibit 24: Chart demonstrating the number of data points generated every day, week and month by ESS as proposed under the threshold approach.
3. WO Exhibit 25: Charts demonstrating the estimated number of flares in non-compliance under the threshold approach on a daily basis assuming a 0.5% downtime rate.

E. Modified Source

1. WO Exhibit 26: Memorandum documenting the regulatory approach taken by several other oil and gas producing states regarding when a well or wellhead tank becomes a modified source.

F. State-Wide RICE

1. WO Exhibit 27: Graphic from OSAT results demonstrating origin of regional anthropogenic ozone precursors for an average of days with elevated ozone at Rocky Flats North monitor.
2. WO Exhibit 28: Graphic from OSAT results demonstrating origin of regional anthropogenic ozone precursors and boundary conditions for an average of days with elevated ozone at Rocky Flats North monitor.
3. WO Exhibit 29: Graphic from OSAT results demonstrating origin of regional anthropogenic ozone precursors for an average of days with elevated ozone at Fort Collins West monitor.
4. WO Exhibit 30: Graphic from OSAT results demonstrating origin of regional anthropogenic ozone precursors and boundary conditions for an average of days with elevated ozone at Fort Collins West monitor.
5. WO Exhibit 31: OSAT results Figure ES-2 showing projected 2010 8-hour ozone design values.
6. WO Exhibit 32: OSAT results Figure ES-3 showing the differences in ozone concentrations (future design values) for the two control scenarios and the 2010 base case.
7. WO Exhibit 33: November 3, 2008 APCD response to Emissions Inventory Questions.
8. WO Exhibit 34: December 18, 2007 Memorandum from Tanya Parise, Alpha-Gamma Technologies, Inc. to Jaime Pagan, EPA Energy Strategies Group.
9. WO Exhibit 35: June 20, 2005 Memorandum from Tanya Parise, Alpha-Gamma Technologies, Inc. to Sims Roy.
10. WO Exhibit 36: Regulatory Impact Analysis for the Standards of Performance for the Stationary Spark Ignition New Source Performance Standard and New Area Source NESHAP EPA-452/R-07-015 (Dec. 2007).
11. WO Exhibit 37: Regulatory Impact Analysis for the Standards of Performance for the Compression Ignition New Source Performance

Standard and New Area Source NESHAP EPA-452/R-06-003 (June 2006).

12. WO Exhibit 38: W-mail from Amnon Bar-Ilan, Ph.D, Environ International Corporation, Doug Henderer, Buys and Associates, and Kathleen Sgamma, IPAMS (Nov. 7, 2008, 13:21:36 MST).
13. WO Exhibit 39: M. DeFoort, D, Olsen, and B. Wilson, The Effect of Air-Fuel Ratio Control Strategies on Nitrogen Compound Formation in Three-Way Catalysts, International Journal of Engine Research (Aug. 6, 2003).
14. WO Exhibit 40: Comments submitted to the Regional Air Quality Council on May 20, 2008, providing comments on behalf of the DJ Basin Operators on the Role of Non-Attainment Boundaries in Ozone SIP Development.

G. Rebuttal Exhibits

1. Rebuttal exhibits will be identified in the Well Operators' Rebuttal Statement.

H. Vehicle Inspection and Maintenance Program

1. WO Exhibit 41: Graphics demonstrating that by not implementing a vehicle inspection and maintenance program in the NFR in 2010, the state is allowing mobile sources to emit 1018.35 tons of ozone precursors every year and demonstrating that VOC emissions from mobile and non-mobile sources are approximately two times more photoreactive the oil & gas VOC emissions.
2. WO Exhibit 42: Graphic demonstrating that by delaying a vehicle inspection and maintenance program in the NFR from 2010 until 2012, a total of approximately 3000 tons of ozone precursors will be released in the NAA by mobile sources.

I. Alternate Proposals

1. WO Exhibit 43: Alternate Proposal for System-Wide Tank Controls in the NAA (redline and strikeout of existing affected provisions).
2. WO Exhibit 44: Economic Impact Statement for Alternate Proposal for System-Wide Tank Controls in the NAA.
3. WO Exhibit 45: Statement of Basis and Purpose for Alternate Proposal for System-Wide Tank Controls in the NAA.
4. WO Exhibit 46: Alternate Proposal for NFR Vehicle I/M program (2010 implementation)(redline and strikeout of Division's proposal).

5. WO Exhibit 47: Economic Impact Statement for NFR Vehicle I/M program (2010 implementation).
6. WO Exhibit 48: Statement of Basis and Purpose for NFR Vehicle I/M program (2010 implementation).

V. THE WELL OPERATORS PLAN TO CALL THE FOLLOWING WITNESSES AT THE HEARING IN THIS MATTER

1. Brian Lockard, Air Quality Manager, Noble Energy, Inc.—testimony on compliance with Regulation Number 7; on the estimated costs of condensate tank controls, ESS auto-igniters required by the Ozone Action Plan; amount of data generated by ESS under the Ozone Action Plan; problems with compliance under the Ozone Action Plan; NO_x and green-house gas disbenefits of the threshold approach; benefits of the Well Operators’ Alternate Proposal; on the flexibility and incentives to over comply afforded by the Well Operators’ Alternate Proposal and its system-wide control approach; and reasons to refrac a well and any increase of emissions there from.
2. Phil Schlagel, Environmental and Regulatory Supervisor, Anadarko Petroleum Corporation—testimony on compliance with Regulation Number 7; on the estimated costs of condensate tank controls, ESS auto-igniters required by the Ozone Action Plan; amount of data generated by ESS under the Ozone Action Plan; problems with compliance under the Ozone Action Plan; benefits of the Well Operators’ Alternate Proposal; on the flexibility and incentives to “over comply” afforded by the Well Operators’ Alternate Proposal and its “system-wide control approach”; and reasons to refrac a well and any associated increase of emissions.
3. Rick Matar, Air Quality Practice Manager, Williams Production RMT Company—testimony on the costs and operational burdens of the Division’s proposed state-wide RICE controls and their comparison with the likely benefits of recently adopted federal engine standards (NSPS Quad J) in greatly reducing engine emissions from new and reconstructed engines in gas-producing basins that are undergoing rapid development within Colorado.
4. Curtis O. Rueter, P.E., Air Quality Manager for North America, Noble Energy, Inc.—testimony on NO_x and green-house gas disbenefits of the Division’s threshold approach to control of condensate tanks in the NAA, in contravention of the Colorado Climate Action Plan.
5. Dr. Bruce C. Macdonald, Regional Vice President for the Air Quality Practice Area, AECOM Environment (a subsidiary of AECOM, Inc., formerly ENSR Inc.)—testimony on ozone modeling, including results, modeling assumptions, parameters, inputs, results, and sensitivity analyses

including OSAT results, with analysis of the Division’s prior use of air mass modeling to perform “back-trajectory analyses” in connection with the Weight of Evidence analysis.

6. Martha Hyder, Wind River Environmental Group LLC—testimony on ozone modeling, including results, modeling assumptions, parameters, inputs, results, sensitivity analyses including OSAT results, and agreement and/or disagreement with ambient monitoring and meteorological data, and specific analysis of the Division’s intention to regulate state-wide RICE through limited application of controls to natural gas fired ICE and exclusion of emission reduction benefits associated with Quad I and Quad J.
7. Dr. Daniel P. Olsen, P.E.—testimony on the Division’s intention to regulate state-wide RICE through the: (1) limited application of natural gas fired ICE; (2) required installation and operation of control technology devices regardless of the ICE’s ability to meet emission limitation requirements; and (3) exclusion of emission reduction benefits associated with Quad I and Quad J.
8. Dr. Lisa A. McDonald, Senior Economist, Louis Berger Group, Inc.—testimony on the incremental costs associated with increasing pollution control requirements for flash emissions from condensate tanks as proposed by the Division and by the Well Operators’ Alternate Proposal; on the incremental costs associated with implementing the I/M program in the NFR beginning in 2010 as opposed to 2012 (the latter date proposed in the Ozone Action Plan).
9. Dr. John D. Wright, Ph.D., Norwest Questa Engineering Corp.—testimony concerning historic and projected growth in condensate production in the DJ Basin.

VI. WRITTEN TESTIMONY

The written testimony/expert reports of the Well Operators’ witnesses listed above are submitted with this Final Statement.

VII. ALTERNATE PROPOSAL

The following Alternate Proposals, along with a redline and strike-through of affected provisions of AQCC Rule a proposed Statement of Basis and Purpose and an Economic Impact Analysis for each, will be attached as exhibits to the Well Operators’ Final Statement.

A. The Well Operators’ Alternate Proposal for Condensate Tank Controls in the NAA

The Well Operators propose that condensate tank controls in the NAA under Regulation Number 7 keep the current system-wide approach, but increase the required control percentage

for all tanks emitting 1 tpy or more to 85% by May 1, 2010. The current requirement is 75% system-wide control for tanks emitting approximately 5 tpy or more. Supplemental modeling of this control scenario confirms that it produces the same or greater benefits than the proposed Ozone Action Plan in the attainment year 2010. The Well Operators have attached their proposed rule language, economic impact statement and statement of basis and purpose as exhibits to this Final Statement.

B. I/M 2010

Some or all of the Well Operators propose moving forward the commencement date of the NFR vehicle I/M program from January 1, 2012 to January 1, 2010. Under the Ozone Action Plan's proposal, vehicles in the NFR will not begin being tested until January 2012, which means that the program will not be fully implemented until January 1, 2014. Under this alternate proposal, vehicles would begin being tested in 2010 and the program would be fully implemented by January 1, 2012. To delay this control strategy until 2012, as the Ozone Action Plan proposes, is inconsistent with Governor Ritter's directive to begin working toward attaining the lowered ozone standard, and essentially ignores thousands of tons of ozone precursor emissions from one of the largest contributing sources to ozone in the NAA, the on-road mobile source category.

VIII. RESERVATIONS

The Well Operators reserve the right to present additional testimony, witnesses and exhibits for purposes of rebuttal, to use demonstrative aids at the hearing that contain information already provided in exhibits and testimony, and to address very recent changes and any future changes to the Division's proposal and any alternate proposal(s) of the Division or any other party in their rebuttal filings and at the hearing, as necessary.

IX. CONCLUSION

The Well Operators urge the Commission to consider the data and modeling results carefully in their deliberations on the proposed Ozone Action Plan and various alternative proposals, along with the testimony of fact and expert witnesses. If the Commission members do this, being mindful of the legal requirements for rulemaking by a regulatory authority, the Well Operators believe the Commission should adopt the Ozone Action Plan in part, but should defer state-wide RICE controls, and adopt the Well Operators' alternate proposals concerning tank controls and the NFR vehicle I/M program. Those alternate proposals will preserve the current system-wide approach to condensate tank controls, but at a control percentage requirement of 85% for tanks emitting 1 tpy or more, and will implement an I/M program for the NFR beginning in 2010, instead of 2012. Such a result is better supported by the CAMx modeling results and OSAT results, and more likely will make progress toward attainment of a lowered 8-hour ozone NAAQS of 0.075 ppm, consistent with Governor Ritter's directive.

Dated this 17th day of November, 2008.

Respectfully submitted,

s/ John R. Jacus

OGI Service Provider Survey

March 2016

The World's Sixth Sense™

Company A

Business Details

- 95% of service work done upstream and 5% midstream
- Trained operator, insured with many expenses (that would be involved with a company doing their own inspections) like camera, trucks, etc.

Pricing

- If per hour; \$250 per hour. This would include mileage but there would be a per diem from travel (per hour for travel) and lodging, food, etc.
- If per well site; \$300 per well pad (a basic well pad*). Add \$50 per tank above a basic well pad
 - Plus mileage
 - Often this includes an “odor complaint” inspection
 - Discounted rate if hired for companywide inspection for many pad sites
 - Sometimes has “crews” of the hiring company to fix the finds from the camera and he will rescan at no charge. If they repair and he has to revisit there is usually a charge associated.

* NOTE: a “basic well pad” is 4 tanks (3 oil and 1 water), 1 separator and/or heater, 1 combustor, 1 VRU

Scans

- Estimates 5-6 well pads to be scanned per day (about 45 minutes per site/onsite)
- Has done as many as 15 in one day

Company B

Business Details

- Trained operator, insured with many expenses (that would be involved with a company doing their own inspections) like camera, trucks, etc.
- Also has aerial survey capabilities.

Pricing

- If per well site; \$800 per well pad.
 - Plus mileage, travel, lodging, etc.
 - Discounted rate if hired for companywide inspection for many pad sites
- Aerial surveys at \$1100 per hour plus expenses.

Scans

- Estimates about 15 well pads to be scanned per day.
- Estimates about 30 minutes per well pad.

1 EXECUTIVE SUMMARY

1.1 Background

The action analyzed in this regulatory impact analysis (RIA) amends the new source performance standards (NSPS) for the oil and natural gas source category by setting standards for both methane and volatile organic compounds (VOC) for certain equipment, processes and activities across this source category. The Environmental Protection Agency (EPA) is including requirements for methane emissions in this rule because methane is a greenhouse gas (GHG), and the oil and natural gas category is the country's largest emitter of methane. In 2009, the EPA found that by causing or contributing to climate change, GHGs endanger both the public health and the public welfare of current and future generations.

The EPA is amending the NSPS to include standards for reducing methane as well as VOC emissions across the oil and natural gas source category. Specifically, we are establishing both methane and VOC standards for several emission sources not covered by the 2012 NSPS (i.e., hydraulically fractured oil well completions, fugitive emissions from well sites, compressor stations, pneumatic pumps). In addition, we are establishing methane standards for certain emission sources that are regulated for VOC under the 2012 NSPS (i.e., hydraulically fractured gas well completions, equipment leaks at natural gas processing plants). However, we do not expect any incremental benefits or costs as a result from regulating methane for VOC sources regulated under the 2012 NSPS.

With respect to certain equipment that are used across the source category, the 2012 NSPS regulates only a subset of this equipment (pneumatic controllers, centrifugal compressors, reciprocating compressors). The new amendments establish methane standards for these equipment across the source category and extend the VOC standards from the 2012 NSPS to the remaining unregulated equipment. Lastly, amendments to the 2012 NSPS are established that improve several aspects of the 2012 standards related to implementation. These improvements result from reconsideration of certain issues raised in petitions for reconsideration that were received by the Administrator on the 2012 NSPS for the oil and natural gas sector and related amendments. Except for these implementation improvements and the setting of standards for methane, these amendments do not change the requirements for operations already covered by the 2012

standards.

As part of the regulatory process, the EPA is required to develop a regulatory impact analysis (RIA) for rules that have costs or benefits that exceed \$100 million annually. The EPA estimates the final NSPS will have costs that exceed \$100 million, so the Agency has prepared an RIA. This RIA includes an economic impact analysis and an analysis of the climate, health, and welfare impacts anticipated from the final NSPS.¹ We also estimate potential impacts of the rule on national energy markets using the U.S. Energy Information Administration's National Energy Modeling System (NEMS). The engineering compliance costs are annualized using 3 and 7 percent discount rates.

This analysis estimates regulatory impacts for the analysis years of 2020 to represent the near-term impacts of the rule, and 2025 to represent impacts of the rule over a longer period. Therefore, the emissions reductions, benefits, and costs by 2020 and 2025 (i.e., including all emissions reductions, costs, and benefits in all years from 2016 to 2025) would be potentially significantly greater than the estimated emissions reductions, benefits, and costs provided within this rule. Affected facilities are facilities that are new or modified since the proposal in September 2015. In 2020, affected facilities are those that are newly established or modified in 2020, as well as those that have accumulated between 2016 and 2019. The regulatory impact estimates for 2025 include sources newly affected in 2025 as well as the accumulation of affected sources from 2016 through 2024 that are assumed to be in continued operation in 2025, thus incurring compliance costs and emissions reductions in 2025.

Several emission controls for the NSPS, such as reduced emissions completions (RECs) of hydraulically-fractured oil wells, capture methane and VOC emissions that otherwise would be vented to the atmosphere. The averted methane emissions can be directed into natural gas production streams and sold. The revenues derived from natural gas recovery are expected to offset a portion of the engineering costs of implementing the NSPS. In this RIA, we present

¹ The analysis in this RIA and the RIA that accompanied the proposal together constitute the economic assessment required by CAA section 317. In the EPA's judgment, the assessment is as extensive as practicable taking into account the EPA's time, resources, and other duties and authorities.

results that include the additional product recovery and the revenues we expect producers to gain from the additional product recovery.

The baseline used for the impacts analysis of our NSPS takes into account emissions reductions conducted pursuant to state regulations covering the relevant operations. A detailed discussion on the derivation of the baseline is presented in Section 3 of this RIA.

1.2 Market Failure

Many regulations are promulgated to correct market failures, which lead to a suboptimal allocation of resources within the free market. Air quality and pollution control regulations address “negative externalities” whereby the market does not internalize the full cost of production that is borne by society, as public goods such as air quality are unpriced.

Greenhouse Gas (GHG) and VOC emissions impose costs on society, such as negative climate, health, and welfare impacts. These impacts are not reflected in the market price of the goods produced through the polluting process and are referred to as negative externalities. For this regulatory action, the goods produced, processed, transported, or stored are crude oil, natural gas, and other hydrocarbon products. If an oil and natural gas firm pollutes the atmosphere while extracting, processing, transporting, or storing goods, this cost will not be borne by the polluting firm but by society as a whole. The market price of the products will fail to incorporate the full cost to society of the pollution related to production. All else held equal, the quantity of oil and natural gas produced in a competitive market will not be at the socially optimal level. More oil and natural gas will be produced than would occur if the oil and natural gas producers had to account for the full cost of production, including the negative externality. Consequently, absent a regulation on emissions, the marginal social cost of the last units of oil and natural gas produced will exceed its marginal social benefit.

1.3 Regulatory Options Analyzed in this RIA

In this RIA, we examine three broad regulatory options. Table 1-1 shows the emissions sources, points, and controls for the three NSPS regulatory options analyzed in this RIA, which we term Option 1, Option 2, and Option 3. Option 2 was selected for promulgation.

Table 1-1 Emissions Sources and Controls Evaluated for the NSPS

| Emissions Point | Emissions Control | Option 1 | Option 2 (final) | Option 3 |
|---|--------------------------------------|-----------------|-------------------------|-----------------|
| Well Completions and Recompletions | | | | |
| Hydraulically Fractured Development Oil Wells | REC / Combustion | X | X | X |
| Hydraulically Fractured Wildcat and Delineation Oil Wells | Combustion | X | X | X |
| Fugitive Emissions | | | | |
| Well Sites | Planning, Monitoring and Maintenance | Annual | Semiannual | Quarterly |
| Gathering and Boosting Stations | Planning, Monitoring and Maintenance | Semiannual | Quarterly | Quarterly |
| Transmission Compressor Stations | Monitoring and Maintenance | Semiannual | Quarterly | Quarterly |
| Pneumatic Pumps | | | | |
| Well Sites | Route to control | X | X | X |
| Pneumatic Controllers | | | | |
| Natural Gas Transmission and Storage | Emissions limit | X | X | X |
| Reciprocating Compressors | | | | |
| Natural Gas Transmission and Storage | Maintenance | X | X | X |
| Centrifugal Compressors | | | | |
| Natural Gas Transmission and Storage | Route to control | X | X | X |

Option 2 contains reduced emission completion (REC) and completion combustion requirements for a subset of newly completed oil wells that are hydraulically fractured or refractured. Option 2 requires fugitive emissions survey and repair programs be performed semiannually (twice per year) at the affected newly drilled or refractured oil and natural gas well sites, and quarterly at new or modified gathering and boosting stations and new or modified transmission and storage compressor stations. Option 2 also requires reductions from centrifugal compressors, reciprocating compressors, and pneumatic controllers and pumps.

Options 1 and 3 differ from the finalized Option 2 with respect to the requirements for fugitive emissions. Well site fugitive requirements under Option 1 are annual, while new or

modified gathering and boosting station and new or modified transmission and storage compressor stations require a semiannual fugitive emission survey and repair program. Less frequent survey requirements lead to lower costs as well as lower emissions reduction compared to the selected Option 2. The more stringent Option 3 requires quarterly monitoring for all sites under the fugitive emissions program. More frequent surveys result in greater emission reductions, however there are also increased costs, resulting in a net effect of lower net benefits compared to the finalized Option 2.

1.4 Summary of Results

For the final NSPS, a summary of the key results of the RIA for the final standards (Option 2) follow. Key results for Options 1 through 3 are summarized in Table 1-2 through Table 1-4, respectively. Note all dollar estimates are in 2012 dollars:

- **Emissions Analysis:** The final NSPS is anticipated to prevent significant new emissions, including 300,000 short tons of methane, 150,000 tons of VOCs and 1,900 tons of hazardous air pollutants (HAP) in 2020, increasing to 510,000 short tons of methane, 210,000 tons of VOCs, and 3,900 tons of HAP prevented in 2025.² The CO₂-equivalent (CO₂ Eq.) methane emission reductions are 6.9 million metric tons in 2020 and 11 million metric tons in 2025.
- **Benefits Analysis:** The monetized benefits in this RIA include those from reducing methane emissions, which are valued using the social cost of methane (SC-CH₄).³ The EPA estimates that, in 2020, the rule will yield monetized climate benefits of \$160 million to approximately \$950 million; the mean SC-CH₄ at the 3% discount rate results in an estimate of about \$360 million in 2020. In 2025, the EPA estimates monetized climate benefits of \$320 million to approximately \$1.8 billion; the mean SC-CH₄ at the 3% discount rate results in an estimate of about \$690 million in 2025.⁴ While we expect that the avoided emissions will result in improvements in ambient air quality and reductions in negative health effects associated with exposure to HAP, ozone, and particulate matter (PM), we have determined that quantification of those benefits cannot be accomplished for this rule.⁵ This is not to imply that there are no health benefits

² Estimates are presented in short tons.

³ The social cost of methane (SC-CH₄) is the monetary value of impacts associated with a marginal change in methane emissions in a given year.

⁴ The range of estimates reflects four SC-CH₄ estimates and are associated with different discount rates (model average at 2.5, 3 and 5 percent; 95th percentile at 3 percent). See Section 4.3 for a complete discussion.

⁵ Previous studies have estimated the monetized benefits-per-ton of reducing VOC emissions associated with the effect that those emissions have on ambient PM_{2.5} levels and the health effects associated with PM_{2.5} exposure (Fann, Fulcher, and Hubbell, 2009). While these ranges of benefit-per-ton estimates provide useful context, the geographic distribution of VOC emissions from the oil and gas sector are not consistent with emissions modeled in Fann, Fulcher, and Hubbell (2009). In addition, the benefit-per-ton estimates for VOC emission reductions in

anticipated from the final NSPS; rather, it is a reflection of the difficulties in modeling the direct and indirect impacts of the reductions in emissions for this industrial sector with the data currently available. In addition to health improvements, there will be improvements in visibility effects, ecosystem effects, as well as additional natural gas recovery. The specific control technologies for the final NSPS are anticipated to have minor secondary disbenefits.

- **Engineering Cost Analysis:** The EPA estimates the total capital cost of the final NSPS to be \$250 million for affected sources in 2020 and \$360 million for affected sources in 2025. The estimate of total annualized engineering costs of the final NSPS is \$390 million in 2020 and \$640 million in 2025 when using a 7 percent discount rate. When estimated revenues from additional natural gas are included, the annualized engineering costs of the NSPS are estimated to be \$320 million in 2020 and \$530 million in 2025, assuming a wellhead natural gas price of \$4/thousand cubic feet (Mcf). The estimated engineering compliance costs that include product recovery are sensitive to the assumption about the price of the recovered product. There is also geographic variability in wellhead prices, which can influence estimated engineering costs. For example, \$1/Mcf change in the wellhead price causes a change in estimated engineering compliance costs of about \$16 million in 2020 and \$27 million in 2025, given the EPA estimates that about 16 million Mcf in 2020 and 27 million Mcf of natural gas will be recovered by implementing the NSPS. When using a 3 percent discount rate, the estimate of total annualized engineering costs of the final NSPS is \$380 million in 2020 and \$630 million in 2025, or \$320 million in 2020 and \$520 million in 2025, when estimated revenues from additional natural gas are included.
- **Energy Markets Impacts Analysis:** The EPA used the National Energy Modeling System (NEMS) to estimate the impacts of the final rule on the United States energy markets. We estimate that natural gas and crude oil drilling levels decline slightly over the 2020 to 2025 period relative to the baseline (by about 0.17 percent for natural gas wells and about 0.02 percent for crude oil wells). Natural gas production decreases slightly over the 2020 to 2025 period under the rule relative to the baseline (by about 0.03 percent), while crude oil production does not vary appreciably. Crude oil wellhead prices for onshore lower 48 production are not estimated to change appreciably over the 2020 to 2025 period relative to the baseline. However, wellhead natural gas prices for onshore lower 48 production are estimated to increase slightly over the 2020 to 2025 period relative to the baseline (about 0.20 percent). Net imports of natural gas are estimated to increase slightly over the 2020 to 2025 period (by about 0.11 percent) relative to the baseline. Crude oil net imports are not estimated to change appreciably over the 2020 to 2025 period relative to the baseline.
- **Small Entity Analyses:** To understand the potential impact of the rule on small entities, the EPA conducted a screening analysis of the potential impacts by estimating the ratio of potential compliance costs to firm sales (i.e. a cost-to-sales test). Based on the results of this screening analysis, the EPA concluded that it is unable to certify that the final rule

that study are derived from total VOC emissions across all sectors. Larger uncertainties about the relationship between VOC emissions and PM_{2.5} coupled with the highly localized nature of air quality responses associated with VOC reductions, lead us to conclude that the available VOC benefit-per-ton estimates are not appropriate to calculate monetized benefits of these rules, even as a bounding exercise.

will not have a Significant Impact on a Substantial Number of Small Entities (SISNOSE). The EPA convened a Small Business Advisory Review panel and completed an Initial Regulatory Flexibility Analysis before proposing the rule. The EPA also completed a Final Regulatory Flexibility Analysis for the final rule.

- **Employment Impacts Analysis:** The EPA estimated the labor impacts due to the installation, operation, and maintenance of control equipment and control activities, as well as the labor associated with new reporting and recordkeeping requirements. The EPA estimated one-time and continual, annual labor requirements by estimating hours of labor required for compliance and converting this number to full-time equivalents (FTEs) by dividing by 2,080 (40 hours per week multiplied by 52 weeks). The one-time labor requirement to comply with the final NSPS is estimated at about 270 FTEs in 2020 and in 2025. The annual labor requirement to comply with the NSPS is estimated at about 1,100 FTEs in 2020 and 1,800 FTEs in 2025. The EPA notes that this type of FTE estimate cannot be used to identify the specific number of employees involved or whether new jobs are created for new employees, versus displacing jobs from other sectors of the economy.

Table 1-2 presents the summary results for Option 1, Table 1-3 presents summary results for Option 2, and Table 1-4 presents summary results for Option 3.

Table 1-2 Summary of the Monetized Benefits, Costs, and Net Benefits for Option 1 in 2020 and 2025 (2012\$)

| | 2020 | 2025 |
|---------------------------------------|---|---|
| Total Monetized Benefits ¹ | \$290 million | \$540 million |
| Total Costs ² | \$240 million | \$360 million |
| Net Benefits ³ | \$54 million | \$180 million |
| | Non-monetized climate benefits | Non-monetized climate benefits |
| Non-monetized Benefits | Health effects of PM2.5 and ozone exposure from 130,000 tons of VOC reduced | Health effects of PM2.5 and ozone exposure from 170,000 tons of VOC reduced |
| | Health effects of HAP exposure from 1,300 tons of HAP reduced | Health effects of HAP exposure from 2,700 tons of HAP reduced |
| | Health effects of ozone exposure from 250,000 tons of methane | Health effects of ozone exposure from 390,000 tons of methane |
| | Visibility impairment | Visibility impairment |
| | Vegetation effects | Vegetation effects |

¹ The benefits estimates are calculated using four different estimates of the social cost of methane (SC-CH₄) (model average at 2.5 percent discount rate, 3 percent, and 5 percent; 95th percentile at 3 percent). For purposes of this table, we show the benefits associated with the model average at a 3 percent discount rate. However, we emphasize the importance and value of considering the benefits calculated using all four SC-CH₄ estimates; the additional benefit estimates range from \$130 million to \$780 million in 2020 and \$250 million to \$1.4 billion in 2025 for Option 1, as shown in Section 4.3. The CO₂-equivalent (CO₂ Eq.) methane emission reductions are 5.6 million metric tons in 2020 and 8.9 million metric tons in 2025. Also, the specific control technologies for the NSPS are anticipated to have minor secondary disbenefits. See Section 4.7 for details.

² The engineering compliance costs are annualized using a 7 percent discount rate and include estimated revenue from additional natural gas recovery as a result of the NSPS. As can be seen in section 3.5.1 of the final RIA, the national cost estimates in for this rule are not highly sensitive to the use of a 3 percent or 7 percent discount rate in this RIA. As a result, the net benefits of the rule are not highly sensitive to choice of discount rate for annualizing capital costs.

³ Estimates may not sum due to independent rounding.

Table 1-3 Summary of the Monetized Benefits, Costs, and Net Benefits for Option 2 (Finalized Option) in 2020 and 2025 (2012\$)

| | 2020 | 2025 |
|---------------------------------------|---|---|
| Total Monetized Benefits ¹ | \$360 million | \$690 million |
| Total Costs ² | \$320 million | \$530 million |
| Net Benefits ³ | \$35 million | \$170 million |
| Non-monetized Benefits | Non-monetized climate benefits | Non-monetized climate benefits |
| | Health effects of PM2.5 and ozone exposure from 150,000 tons of VOC reduced | Health effects of PM2.5 and ozone exposure from 210,000 tons of VOC reduced |
| | Health effects of HAP exposure from 1,900 tons of HAP reduced | Health effects of HAP exposure from 3,900 tons of HAP reduced |
| | Health effects of ozone exposure from 300,000 tons of methane | Health effects of ozone exposure from 510,000 tons of methane |
| | Visibility impairment | Visibility impairment |
| | Vegetation effects | Vegetation effects |

¹ The benefits estimates are calculated using four different estimates of the social cost of methane (SC-CH₄) (model average at 2.5 percent, 3 percent, and 5 percent; 95th percentile at 3 percent). For purposes of this table, we show the benefits associated with the model average at a 3 percent discount rate. However, we emphasize the importance and value of considering the benefits calculated using all four SC-CH₄ estimates; the additional benefit estimates range from \$160 million to \$950 million in 2020 and \$320 million to \$1.8 billion in 2025 for Option 2, as shown in Section 4.3. The CO₂-equivalent (CO₂ Eq.) methane emission reductions are 6.9 million metric tons in 2020 and 11 million metric tons in 2025. Also, the specific control technologies for the NSPS are anticipated to have minor secondary disbenefits. See Section 4.7 for details.

² The engineering compliance costs are annualized using a 7 percent discount rate and include estimated revenue from additional natural gas recovery as a result of the NSPS. As can be seen in section 3.5.1 of the final RIA, the national cost estimates in for this rule are not highly sensitive to the use of a 3 percent or 7 percent discount rate in this RIA. As a result, the net benefits of the rule are not highly sensitive to choice of discount rate for annualizing capital costs.

³ Estimates may not sum due to independent rounding.

Table 1-4 Summary of the Monetized Benefits, Costs, and Net Benefits for Option 3 in 2020 and 2025 (2012\$)

| | 2020 | 2025 |
|---------------------------------------|--|---|
| Total Monetized Benefits ¹ | \$420 million | \$840 million |
| Total Costs ² | \$490 million | \$880 million |
| Net Benefits ³ | -\$75 million | -\$38 million |
| Non-monetized Benefits | Non-monetized climate benefits | Non-monetized climate benefits |
| | Health effects of PM2.5 and ozone exposure from 160,00 tons of VOC reduced | Health effects of PM2.5 and ozone exposure from 230,000 tons of VOC reduced |
| | Health effects of HAP exposure from 2,400 tons of HAP reduced | Health effects of HAP exposure from 5,000 tons of HAP reduced |
| | Health effects of ozone exposure from 350,000 tons of methane | Health effects of ozone exposure from 610,000 tons of methane |
| | Visibility impairment Vegetation effects | Visibility impairment Vegetation effects |

¹ The benefits estimates are calculated using four different estimates of the social cost of methane (SC-CH₄) (model average at 2.5 percent, 3 percent, and 5 percent; 95th percentile at 3 percent). For purposes of this table, we show the benefits associated with the model average at a 3 percent discount rate. However, we emphasize the importance and value of considering the benefits calculated using all four SC-CH₄ estimates; the additional benefit estimates range from \$190 million to \$1.1 billion in 2020 and \$390 million to \$2.2 billion in 2025 for this more stringent option, as shown in Section 4.3. The CO₂-equivalent (CO₂ Eq.) methane emission reductions are 8 million metric tons in 2020 and 14 million metric tons in 2025. Also, the specific control technologies for the NSPS are anticipated to have minor secondary disbenefits.

² The engineering compliance costs are annualized using a 7 percent discount rate and include estimated revenue from additional natural gas recovery as a result of the NSPS. As can be seen in section 3.5.1 of the final RIA, the national cost estimates in for this rule are not highly sensitive to the use of a 3 percent or 7 percent discount rate in this RIA. As a result, the net benefits of the rule are not highly sensitive to choice of discount rate for annualizing capital costs.

³ Estimates may not sum due to independent rounding.

1.5 Summary of NSPS Impacts Changes from the Proposal RIA

This section summarizes major changes from the proposal version of the RIA. These changes were a result of revised assumptions and technical factors, as well as changes in the rule itself from proposal. With respect to changes in the rule’s provisions from proposal, we focus on changes that have an effect on estimates of emissions reductions, costs, and benefits.

Changes resulting from revised assumptions and technical factors include:

- **Annual Energy Outlook and National Energy Modeling System updates:** At proposal, the Energy Information Administration (EIA) 2014 Annual Energy Outlook (AEO) was used to derive projections of oil and natural gas well drilling activities. For this RIA, we used the 2015 AEO, the latest version available at the time of the signature of the rule. Section 3.4.2 presents a brief discussion comparing the 2014 and 2105 AEOs.

The EPA also updated the version of the NEMS model from 2014 to 2015 to develop the energy markets impacts presented in Section 6.2 of this RIA.

- **EPA Greenhouse Gas Inventory updates:** The EPA updated the unit-level cost and emissions analyses where possible to reflect recent updates to the Greenhouse Gas Inventory. In particular, data from the Greenhouse Gas Reporting program and the Greenhouse Gas Inventory was used to update the equipment and component counts and potential emissions of the model plants for fugitive emissions.
- **Revised first year of regulatory program:** At proposal, 2020 was assumed to represent a single year of potential impacts. However, NSPS-affected facilities are facilities that are new or modified since the proposal in September 2015. In this final RIA, affected facilities in 2020 are those that are newly established or modified in 2020, as well as those that have accumulated between 2016 and 2019. As a result, the years of analysis in this RIA are 2020, to represent the near-term impacts of the rule, and 2025, to represent impacts of the rule over a longer period. This methodological change results in a higher estimate of the number of affected facilities than at proposal and better represents the impacts of the rule.
- **New hydraulically fractured oil well completions with insufficient pressure to implement REC required to combust completions emissions:** Using the formula estimated to identify hydraulically fractured well completions that would not have sufficient pressure to perform a REC, approximately 40 percent of oil well completions that would otherwise be required to perform a REC would be required to combust emissions rather than implement a REC. The overall proportion of completions that are assumed to be feasible to REC remains unchanged from the proposal analysis at 50 percent. More detailed discussion is presented in a technical memorandum on this subject in the docket.⁶
- **Revised unit-level emissions and cost estimates:** The EPA revised the cost of control estimates for fugitive emissions monitoring and pneumatic pumps based on information provided by commenters.
- **Revised approach to projecting affected facilities from historical activity data:** Newly constructed affected facilities are estimated based on averaging the year-to-year changes in the past 10 years of activity data in the Greenhouse Gas Inventory for compressor stations, pneumatic pumps, compressors, and controllers. At proposal, this was done by averaging the increasing years only. The approach was modified to average the number of newly constructed units in all years.

The changes in the rules requirements that affect emissions, cost, and benefit estimates include:

- **Fugitive emissions:** The EPA proposed to exclude low production well sites (e.g., well sites where the average combined oil and natural gas production is less than 15 barrels of oil equivalent (boe) per day averaged over the first 30 days of production) from the standards for the collection of fugitive emissions components at well sites. Based on

⁶ [Placeholder for title of low pressure well equation technical memo]

analysis in response to comments, the EPA is finalizing the requirement that low production well sites are regulated under a monitoring and repair standard based on semiannual monitoring. With respect to fugitive emissions at compressor stations, based on analysis in response to comments, the EPA is finalizing the requirement to implement the fugitives program at compressor stations on a quarterly basis, as opposed to the proposed semiannual (twice per year) basis.

- **Hydraulically fractured oil well completions:** For the final rule, the EPA refined requirements that require wells that are not low GOR, low pressure, or exploration/delineation wells to have a separator on site during completion flowback. Wells with low GOR (less than 300 scf/of gas per stock barrel of oil produced) are still excluded from well completion requirements, but, unlike at proposal, they are considered affected facilities and their exclusion from requirements is provided the owner or operator maintains records of the low GOR certification, and submit a claim signed by the certifying official.
- **Pneumatic pumps:** The EPA changed the definition of an affected pneumatic pump facility to include only natural gas driven pumps in order to incentivize the use of lower emitting alternatives. The EPA also exempted chemical injection pumps and portable or temporary pumps from control requirements.

1.6 Organization of this Report

The remainder of this report details the methodology and the results of the RIA. Section 2 presents the industry profile of the oil and natural gas industry. Section 3 describes the emissions and engineering cost analysis. Section 4 presents the benefits analysis. Section 5 presents a comparison of benefits and costs. Section 6 presents energy markets impact, employment impact, and small entity impact analyses.

2 INDUSTRY PROFILE

2.1 Introduction

The oil and natural gas industry includes five segments: drilling and extraction, processing, transportation, refining, and marketing. The Oil and Natural Gas NSPS require controls for the oil and natural gas products and processes of the drilling and extraction of crude oil and natural gas, natural gas processing, and natural gas transportation segments.

Most crude oil and natural gas production facilities are classified under NAICS 211: Crude Petroleum and Natural Gas Extraction (211111) and Natural Gas Liquid Extraction (211112). The drilling of oil and natural gas wells is included in NAICS 213111. Most natural gas transmission and storage facilities are classified under NAICS 486210—Pipeline Transportation of Natural Gas. While other NAICS (221210—Natural Gas Distribution, 486110—Pipeline Transportation of Crude Oil, and 541360—Geophysical Surveying and Mapping Services) are often included in the oil and natural gas sector, these are not discussed in detail in the Industry Profile because they are not directly affected by the final NSPS.

The outputs of the oil and natural gas industry are inputs for larger production processes of gas, energy, and petroleum products. As of 2014, the Energy Information Administration (EIA) estimates that about 515,000 producing natural gas wells are operating in the U.S. The latest available information from EIA indicates that there were about 536,000 producing oil wells in the U.S. as of 2011. Domestic dry natural gas production was 25.7 trillion cubic feet (tcf) in 2014, the highest annual production level in U.S. history. The leading five natural gas producing states in 2014 were Texas, Pennsylvania, Oklahoma, Louisiana and Wyoming. Domestic crude oil production in 2014 was 3,200 million barrels (bbl), the highest annual level in the U.S. since 1991. The leading five crude oil producing states in 2014 were Texas, North Dakota, California, Alaska, and Oklahoma.

The Industry Profile provides a brief introduction to the components of the oil and natural gas industry that are relevant to the NSPS. The purpose is to give the reader a general understanding of the geophysical, engineering, and economic aspects of the industry that are addressed in subsequent economic analyses in this RIA. The Industry Profile relies heavily on background material from the EPA's "Economic Analysis of Air Pollution Regulations: Oil and

Natural Gas Production” (1996), the EPA’s “Sector Notebook Project: Profile of the Oil and Gas Extraction Industry” (2000), and the EPA’s “Regulatory Impact Analysis: Final New Source Performance Standards and Amendments to the National Emissions Standards for Hazardous Air Pollutants for the Oil and Natural Gas Industry” (2012).

2.2 Products of the Crude Oil and Natural Gas Industry

Each producing crude oil and natural gas field has its own unique properties. The composition of the crude oil and the natural gas as well as the reservoir characteristics are likely to be different across all reservoirs.

2.2.1 Crude Oil

Crude oil can be broadly classified as paraffinic, naphthenic (or asphalt-based), or intermediate. Generally, paraffinic crudes are used in the manufacture of lube oils and kerosene. Paraffinic crudes have a high concentration of straight chain hydrocarbons and are relatively low in sulfur compounds. Naphthenic crudes are generally used in the manufacture of gasolines and asphalt and have a high concentration of olefin and aromatic hydrocarbons. Naphthenic crudes may contain a high concentration of sulfur compounds. Intermediate crudes are those that are not classified in either of the above categories.

Another method to classify hydrocarbons, including crude oil, is through the measurement of API gravity. API gravity is a weight per-unit of volume measure of a hydrocarbon liquid as determined by a method recommended by the American Petroleum Institute (API). A heavy or paraffinic crude oil is typically one with an API gravity of 20° or less, while a light or naphthenic crude oil, which typically flows freely at atmospheric conditions, usually has an API gravity in the range of the high 30's to the low 40's.

Crude oils recovered in the production phase may be referred to as live crudes. Live crudes contain entrained or dissolved gases that may be released during processing or storage. Dead crudes are those that have gone through various separation and storage phases and contain little, if any, entrained or dissolved gases.

2.2.2 *Natural Gas*

Natural gas is a mixture of hydrocarbons and varying quantities of non-hydrocarbons that exist in a gaseous phase or in a solution with crude oil or other hydrocarbon liquids in natural underground reservoirs. Natural gas may contain contaminants, such as hydrogen sulfide (H₂S), CO₂, mercaptans, and entrained solids.

Natural gas may be classified as a wet gas or dry gas. Wet gas is unprocessed or partially processed natural gas produced from a reservoir that contains condensable hydrocarbons. Dry gas is either natural gas whose water content has been reduced through dehydration or natural gas that contains little or no recoverable liquid hydrocarbons.

Natural gas is classified as acid, sour or sweet. Acid gas contains CO₂ and/or H₂S, where the concentration of H₂S is below the threshold to be classified as sour. Acid gas may contain other contaminants. Natural gas is classified as sour when it contains an H₂S concentration of greater than 0.25 grains per 100 standard cubic feet. Sour gas may also contain other contaminants. Concentrations of H₂S and CO₂, along with organic sulfur compounds, vary widely among sour gases. The process by which these two contaminants are removed from the natural gas stream is called sweetening, most commonly performed through amine treating. A majority of total onshore natural gas production and nearly all offshore natural gas production is classified as sweet.

2.2.3 *Condensates*

Condensates are hydrocarbons in a gaseous state under reservoir conditions, but become liquid in either the wellbore or the production process. Condensates, including volatile oils, typically have an API gravity of 40° or more. In addition, condensates may include hydrocarbon liquids recovered from gaseous streams from various oil and natural gas production or natural gas transmission and storage processes and operations.

2.2.4 *Other Recovered Hydrocarbons*

Various hydrocarbons may be recovered through the processing of the extracted hydrocarbon streams. These hydrocarbons include mixed natural gas liquids (NGL), natural gasoline, propane, butane, and liquefied petroleum gas (LPG).

2.2.5 *Produced Water*

Produced water is the water recovered from a production well. Produced water is separated from the extracted hydrocarbon streams in various production processes and operations.

2.3 Oil and Natural Gas Production Processes

2.3.1 *Exploration and Drilling*

Exploration involves the search for rock formations associated with oil or natural gas deposits and involves geophysical prospecting and/or exploratory drilling. Well development occurs after exploration has located an economically recoverable field and involves the construction of one or more wells from the beginning (called spudding) to either well completion if hydrocarbons are found in sufficient quantities, or to abandonment otherwise.

After the site of a well has been located, drilling commences. A well bore is created by using a rotary drill to drill into the ground. As the well bore gets deeper, sections of drill pipe are added. A mix of fluids called drilling mud are released down into the drill pipe, which then push up the walls of the well bore, removing drill cuttings by taking them to the surface. The weight of the mud prevents high-pressure reservoir fluids from pushing their way out (“blowing out”). The well bore is cased in with telescoping steel piping during drilling to avoid its collapse, to prevent water infiltration into the well and to prevent crude oil and natural gas from contaminating the water table. The steel pipe is cemented by filling the gap between the steel casing and the wellbore with cement.

Horizontal drilling technology has been available since the 1950s. Horizontal drilling facilitates the construction of horizontal wells by allowing for the well bore to run horizontally underground, increasing the surface area of contact between the reservoir and the well bore

allowing more oil or natural gas to move into the well. Horizontal wells are particularly useful in unconventional gas extraction where the gas is not concentrated in a reservoir. Recent advances have made it possible to steer the drill in different directions (directional drilling) from the surface without stopping the drill to switch directions and allowing for a more controlled and precise drilling trajectory.

Hydraulic fracturing (also referred to as “fracking”) has been performed since the 1940s (U.S. DOE, 2013). Hydraulic fracturing involves pumping fluids into the well under very high pressures in order to fracture the formation containing the resource. Proppant, a mixture of sand and other materials, is pumped down to hold the fractures open to secure gas flow from the formation (U.S. EPA, 2004).

2.3.2 Production

Production is the process of extracting the hydrocarbons and separating the mixture of liquid hydrocarbons, gas, water, and solids, removing the constituents that are non-saleable, and selling the liquid hydrocarbons and gas. The major activities of crude oil and natural gas production are bringing the fluid to the surface, separating the liquid and gas components, and removing impurities.

Oil and natural gas are found in the pores of rocks and sand (Hyne, 2001). In a conventional source, the oil and natural gas have been pushed out of these pores by water and moved until an impermeable surface had been reached. Because the oil and natural gas can travel no further, the liquids and gases accumulate in a reservoir. Where oil and gas are associated, a gas cap forms above the oil. Natural gas is extracted from a well either because it is associated with oil in an oil well or from a pure natural gas reservoir. Once a well has been drilled to reach the reservoir, the oil and gas can be extracted in different ways depending on the well pressure (Hyne, 2001).

Frequently, oil and natural gas are produced from the same reservoir. As wells deplete the reservoirs into which they are drilled, the gas to oil ratio increases (as does the ratio of water to hydrocarbons). This increase of gas over oil occurs because the well is usually drilled into the bottom, oil-heavy portion of a formation to recover most of the liquid first, with the natural gas

cap sitting on top. Production sites often handle crude oil and natural gas from more than one well (Hyne, 2001).

Well pressure is required to move the resource up from the well to the surface. During **primary extraction**, pressure from the well itself drives the resource out of the well directly. Well pressure depletes during this process. Typically, about 30 to 35 percent of the resource in the reservoir is extracted this way (Hyne, 2001). The amount extracted depends on the specific well characteristics (such as permeability and oil viscosity). When the well lacks enough pressure itself to drive the resource to the surface, gas or water is injected into the well to increase the well pressure and force the resource out (**secondary** or **improved oil recovery**). Finally, **in tertiary extraction** or **enhanced recovery**, gas, chemicals or steam are injected into the well. This can result in recovering up to 60 percent of the original amount of oil in the reservoir (Hyne, 2001).

In contrast to conventional sources, unconventional oil and gas are trapped in rock, sand or, in the case of oil, are found in rock as a chemical substance that requires a further chemical transformation to become oil (U.S. DOE, 2013). Therefore, the resource does not move into a reservoir as in the case with a conventional source. Mining, induced pressure, or heat is required to release the resource. The specific type of extraction method needed depends on the type of formation where the resource is located. Unconventional oil and natural gas resource types relevant for this rule include:

- **Shale Oil and Natural Gas:** Shale natural gas comes from sediments of clay mixed with organic matter. These sediments form low permeability shale rock formations that do not allow the gas to move. To release the gas, the rock must be fragmented, making the extraction process more complex than it is for conventional gas extraction. Shale gas can be extracted by drilling either vertically or horizontally, and breaking the rock using hydraulic fracturing (U.S. DOE, 2013).
- **Tight Sands Natural Gas:** Reservoirs are composed of low-porosity sandstones and carbonate into which natural gas has migrated from other sources. Extraction of the natural gas from tight gas reservoirs is often performed using horizontal wells. Hydraulic fracturing is often used in tight sands (U.S. DOE, 2013).
- **Coalbed Methane:** Natural gas is present in a coal bed due to the activity of microbes in the coal or from alterations of the coal through temperature changes. Horizontal drilling is used but given that coalbed methane reservoirs are frequently associated with underground water reservoirs, hydraulic fracturing is often restricted (Andrews, 2009).

2.3.3 *Natural Gas Processing*

As natural gas is separated from the liquid components, it may contain impurities that pose potential hazards or other problems. Natural gas conditioning is the process of removing impurities from the gas stream so it is of sufficient quality to pass through transportation systems and to be used by final consumers. Conditioning is not always required. Natural gas from some formations emerges from the well sufficiently pure that it can be sent directly to the pipeline.

One concern in natural gas processing is posed by water vapor. At high pressures, water can react with components in the gas to form gas hydrates, which are solids that can clog pipes, valves, and gauges, especially at cold temperatures (Manning and Thompson, 1991). Nitrogen and other gases may also be mixed with the natural gas in the subsurface. These other gases must be separated from the methane prior to sale. High vapor pressure hydrocarbons that are liquid at surface temperature and pressure (benzene, toluene, ethylbenzene, and xylene, or BTEX) are removed and processed separately.

Dehydration removes water from the gas stream. Three main approaches toward dehydration are the use of a liquid desiccant, a solid desiccant, or refrigeration. When using a liquid desiccant, the gas is exposed to a glycol that absorbs the water. The water can be evaporated from the glycol by a process called heat regeneration and the glycol can then be reused. Solid desiccants, often materials called molecular sieves, are crystals with high surface areas that attract water molecules. The solids can be regenerated by heating them above the boiling point of water and then be reused as well. Finally, particularly for gas extracted from deep, hot wells, simply cooling the gas to a temperature below the condensation point of water can remove enough water to transport the gas. Of the three approaches mentioned above, glycol dehydration is the most common when processing at or near the well.

The most significant impurity in natural gas is H_2S , which may or may not be contained in natural gas. H_2S is toxic and potentially fatal, at certain concentrations, to humans and it is corrosive to pipes. It is therefore desirable to remove H_2S as soon as possible in the conditioning process.

Sweetening, the procedure in which H_2S and sometimes CO_2 are removed from the gas stream, is most commonly performed using amine treatment. In this process, the gas stream is

exposed to an amine solution, which will react with H₂S and separate it from the natural gas. The contaminant gas solution is then heated, thereby separating the gases and regenerating the amine. The sulfur gas may be disposed of by flaring, incinerating, or when a market exists, sending it to a sulfur-recovery facility to generate elemental sulfur as a salable product.

2.3.4 *Natural Gas Transmission and Distribution*

After processing, natural gas enters a network of compressor stations, high-pressure transmission pipelines, and often-underground storage sites. Compressor stations are any facility which supplies energy to increase pressure to improve the movement of natural gas through transmission pipelines or into underground storage. Typically, compressor stations are located at intervals along a transmission pipeline to maintain desired pressure for natural gas transport. These stations will use either large internal combustion engines or gas turbines as prime movers to provide the necessary horsepower to maintain system pressure. Underground storage facilities are subsurface facilities utilized for storing natural gas which has been transferred from its original location for the primary purpose of load balancing, which is the process of equalizing the receipt and delivery of natural gas. Processes and operations that may be located at underground storage facilities include compression and dehydration.

2.4 Reserves and Markets

Crude oil and natural gas have historically served two separate and distinct markets. Oil is an international commodity, transported and consumed throughout the world. Natural gas, on the other hand, has historically been consumed close to where it is produced. However, as pipeline infrastructure and LNG trade expand, natural gas is increasingly a national and international commodity. The following subsections provide historical and forecast data on the U.S. reserves, production, consumption, and foreign trade of crude oil and natural gas.

2.4.1 Domestic Proved Reserves

Table 2-1 shows crude oil and dry natural gas proved reserves, unproved reserves, and total technically recoverable resources as of 2009. The EIA⁷ defines these concepts as:

- **Proved reserves:** estimated quantities of energy sources that analysis of geologic and engineering data demonstrates with reasonable certainty are recoverable under existing economic and operating conditions.
- **Unproved resources:** additional volumes estimated to be technically recoverable without consideration of economics or operating conditions, based on the application of current technology.
- **Total technically recoverable resources:** resources that are producible using current technology without reference to the economic viability of production.

According to the EIA, dry natural gas is consumer-grade natural gas. The dry natural gas volumes reported in Table 2-1 reflect the amount of gas remaining after the liquefiable portion and any non-hydrocarbon gases that render it unmarketable have been removed from the natural gas. The sum of proved reserves and unproved reserves equal the total technically recoverable resources. As seen in Table 2-1, as of 2009, proved domestic crude oil reserves accounted for about 10 percent of the total technically recoverable crude oil resources.

Total proved natural gas reserves, accounted for about 12 percent of the total technically recoverable natural gas resources. Significant proportions of these reserves exist in Alaska and in offshore areas. While dry natural gas proved reserves were estimated at 272.5 tcf in 2009, wet natural gas reserves were estimated at 283.9 tcf. Of the 283.9 tcf, 250.5 tcf (about 88 percent) were considered to be wet non-associated natural gas, while 33.3 tcf (about 12 percent) were considered to be wet associated-dissolved natural gas. Associated-dissolved natural gas, according to EIA, is natural gas that occurs in crude oil reservoirs as free natural gas or in solution with crude oil.

Table 2-1 Technically Recoverable Crude Oil and Natural Gas Resource Estimates, 2009

| Region | Proved Reserves | Unproved Resources | Total Technically Recoverable Resources |
|--|-----------------|--------------------|---|
| Crude Oil and Lease Condensate (billion barrels) | | | |
| 48 States Onshore | 14.2 | 112.6 | 126.7 |
| 48 States Offshore | 4.6 | 50.3 | 54.8 |
| Alaska | 3.6 | 35.0 | 38.6 |
| Total U.S. | 22.3 | 197.9 | 220.2 |
| Dry Natural Gas (trillion cubic feet) | | | |
| Conventionally Reservoired Fields | 105.5 | 904.0 | 1,009.5 |
| 48 States Onshore ¹ | 81.4 | 369.7 | 451.1 |
| 48 States Offshore | 15.0 | 262.6 | 277.6 |
| Alaska | 9.1 | 271.7 | 280.8 |
| Tight Gas, Shale Gas and Coalbed Methane | 167.1 | 1,026.7 | 1,193.8 |
| Total U.S. | 272.5 | 1,930.7 | 2,203.3 |

Source: U.S. Energy Information Administration, **Annual Energy Review 2012**. Totals may not sum due to independent rounding.

¹ Includes associated-dissolved natural gas that occurs in crude oil reservoirs either as free gas (associated) or as gas in solution with crude oil (dissolved gas).

Table 2-2 and Figure 2-1 show trends in crude oil and natural gas production and reserves from 1990 to 2014. In Table 2-2, proved ultimate recovery equals the sum of cumulative production and proved reserves. Cumulative production is the accumulated crude oil or dry natural gas that has been produced over time. While crude oil and natural gas are nonrenewable resources, the table shows that proved ultimate recovery rises over time as new discoveries become economically accessible. Reserves growth and decline is also partly a function of exploration activities, which are correlated with oil and natural gas prices. For example, when oil prices are high there is more of an incentive to use secondary and tertiary recovery, as well as to develop unconventional sources. Annual production (the difference in cumulative production over one year) as a percentage of proved reserves has declined over time for both crude oil and natural gas from around 11 percent in the early 1990s to between 8 and 10 percent over the period from 2006 to 2014 for crude oil and from about 10 percent during the early 1990s to between 7 and 9 percent from 2006 to 2014 for natural gas.

Table 2-2 Crude Oil and Natural Gas Cumulative Domestic Production, Proved Reserves, and Proved Ultimate Recovery, 1990-2014

| | Crude Oil and Lease Condensate (million barrels) | | | Dry Natural Gas (Billion Cubic Feet or bcf) | | |
|------|---|--------------------|-------------------------|--|--------------------|-------------------------|

Table 2-3 presents the U.S. proved reserves of crude oil and natural gas by state or producing area as of 2014. Five areas currently account for 79 percent of total proved reserves of crude oil in the U.S., led by Texas and followed by North Dakota, U.S. Federal Offshore, Alaska, and California. The top five states in terms of proved reserves of natural gas, Texas,

Pennsylvania, Oklahoma, West Virginia, and Wyoming, account for about 67 percent of the U.S. total proved natural gas reserves.

Table 2-3 Crude Oil and Dry Natural Gas Proved Reserves by State, 2013

| State/Region | Crude Oil (million bbls) | Dry Natural Gas (bcf) | Crude Oil (% of total) | Dry Natural Gas (% of total) |
|------------------------------|-------------------------------------|----------------------------------|-----------------------------------|---|
| Alabama | 66 | 2,036 | 0.2 | 0.6 |
| Alaska | 2,855 | 6,745 | 7.8 | 1.8 |

Total may not sum due to independent rounding.

* New York crude oil reserves are included in miscellaneous states

**Miscellaneous for crude oil includes Arizona, Idaho, Missouri, Nevada, New York, South Dakota, Tennessee & Virginia as well as Illinois, Indiana, and Nebraska.

**Miscellaneous for dry natural gas includes Arizona, Idaho, Illinois, Indiana, Maryland, Missouri, Nebraska, Oregon, South Dakota & Tennessee as well as Virginia.

2.4.2 Domestic Production

Domestic oil production was in a state of decline that began in 1970 and continued to a low point in 2008. As of 2014, domestic oil production has recovered to the highest levels since 1991. Table 2-4 shows U.S. production in 2014 at 3,179 million bbl per year.

Note: First purchase price represents the average price at the lease or wellhead at which domestic crude is purchased. Prices adjusted using GDP Implicit Price Deflator.

Note: Total Production includes Crude Oil plus Lease Condensate Production.

Average well productivity has also generally decreased since 1990 (Table 2-4 and Figure 2-2), though there are signs of a slight rebounding starting around 2008. These overall production and productivity decreases are in spite of the fact that average first purchase prices have generally shown an increasing trend with some decline in 2014.

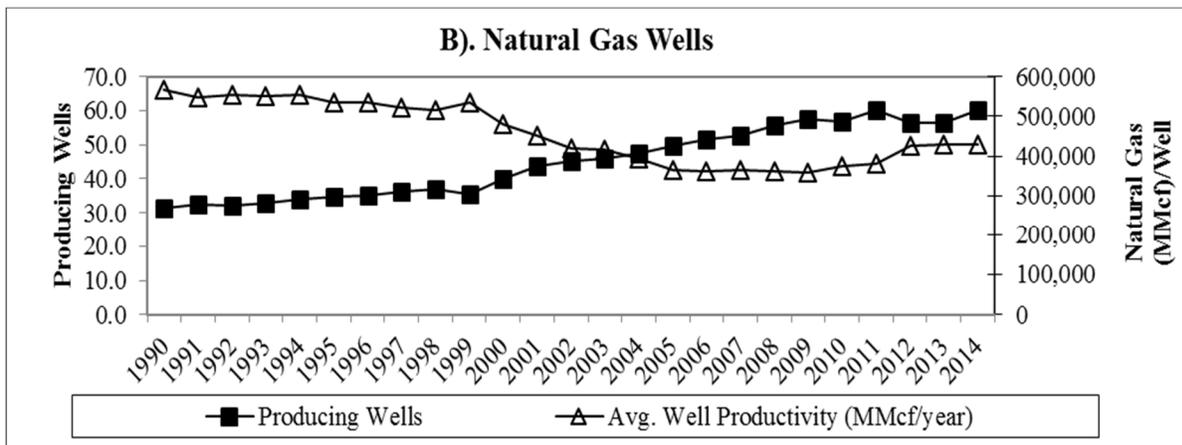

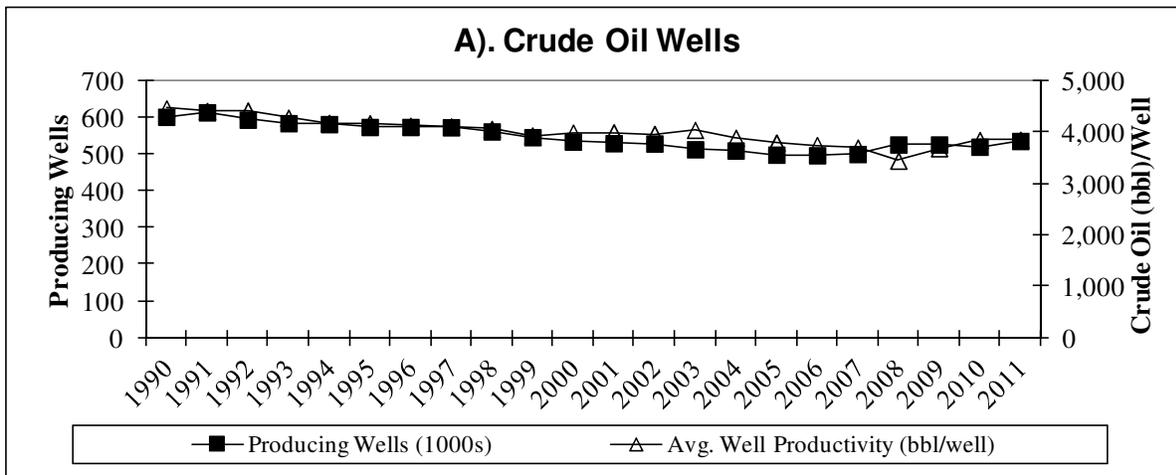

Figure 2-2 A) Total Producing Crude Oil Wells and Average Well Productivity, 1990-2011. B) Total Producing Natural Gas Wells and Average Well Productivity, 1990-2014.
 Source: U.S. Energy Information Administration (U.S. EIA). 2014. Natural Gas Annual 2014. <<http://www.eia.gov/naturalgas/annual/pdf/nga14.pdf>>. Accessed January 22, 2016.

Annual production of natural gas from natural gas wells has increased more than 8000 bcf from the 1990 to 2014 (Table 2-5). The number of wells producing natural gas has nearly doubled between 1990 and 2014 (Figure 2-2B). While the number of producing wells has increased overall, average well productivity has declined, despite improvements in exploration and gas well stimulation technologies. Average well productivity has shown slight improvements since 2009.

¹ Dry gas production is gas production after accounting for gas used repressurizing wells, the removal of nonhydrocarbon gases, vented and flared gas, and gas used as fuel during the production process.

Domestic exploration and development for oil has continued during the last two decades. From 2002 to 2010, crude oil well drilling showed significant increases, although the 1992-2004 period showed relatively low levels of crude drilling activity compared to periods before and after (Table 2-6). The drop in 2009 showed a departure from the increasing trend, likely due to the recession experienced in the U.S.

Meanwhile, natural gas drilling has increased significantly during the 1990-2010 period. Like crude oil drilling, 2009 and 2010 saw a relatively low level of natural gas drillings. The

success rate of wells (producing wells versus dry wells) has also increased gradually over time from 75 percent in 1990, to 86 percent in 2000, to a peak of 90 percent in 2009 (Table 2-6). The increasing success rate reflects improvements in exploration technology, as well as technological improvements in well drilling and completion. Similarly, average well depth has increased by an estimated 1,227 feet during this period (Table 2-6).

Table 2-6 Crude Oil and Natural Gas Exploratory and Development Wells and Average Depth, 1990-2010

* Average Depth values for 2009-2010 are estimates.

Produced water is an important byproduct of the oil and natural gas industry, as management, including reuse and recycling, of produced water can be costly and challenging. Texas, California, Wyoming, Oklahoma, and Kansas were the top five states in terms of produced water volumes in 2007 (Table 2-7). These estimates do not include estimates of

flowback water from hydraulic fracturing activities (ANL 2009). As can be seen in Table 2-7, the amount of water produced is not necessarily correlated with the ratio of water produced to the volume of oil or natural gas produced. Texas, Alaska and Wyoming were the three largest producers in barrels of oil equivalent (boe) terms, but had relatively low produced water to oil ratios compared to states like Illinois, Florida, Missouri, Indiana and Kansas.

Table 2-7 U.S. Onshore and Offshore Oil, Gas, and Produced Water Generation, 2007

Source: Argonne National Laboratory and Department of Energy (2009). Natural gas production converted to barrels oil equivalent to facilitate comparison using the conversion of 0.178 barrels of crude oil equals 1000 cubic feet natural gas. Totals may not sum due to independent rounding.

Figure 2-3 shows the distribution of produced water management practices in 2007. More than half of the water produced (51 percent) was re-injected to enhance resource recovery through maintaining reservoir pressure or hydraulically pushing oil from the reservoir. About one third (34 percent) was injected, typically into wells whose primary purpose is to sequester produced water. A small percentage (three percent) was discharged into surface water when it met water quality criteria. The destination of the remaining produced water (11 percent, the difference between the total managed and total generated) is uncertain (ANL, 2009).

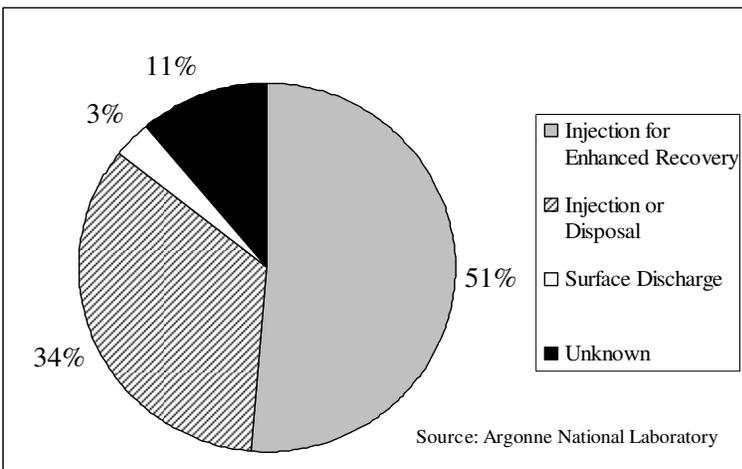

Figure 2-3 U.S. Produced Water Volume by Management Practice, 2007

The movement of crude oil and natural gas primarily takes place via pipelines. Total crude oil pipeline mileage decreased during the 1990-2010 period, appearing to follow the downward supply trend shown in Table 2-4. Since 2010, total crude oil pipeline mileage has increased by over 12,000 miles (Table 2-8).

Table 2-8 splits natural gas pipelines into four types: distribution mains, distribution service, transmission pipelines, and gathering lines. Gathering lines are low-volume pipelines that gather natural gas from production sites and deliver it directly to gas processing plants or compression stations which connect numerous gathering lines to transport gas primarily to processing plants. Transmission pipelines move large volumes of gas to or from processing plants and distribution points. From these distribution points, the gas enters a distribution system that delivers the gas to final consumers. Mileage on the distribution side, distribution mains and

distribution service, has increased while transmission pipeline and gathering line mileage has decreased. Since 2010, total natural gas pipeline has increased by over 61,000 miles.

Table 2-8 U.S. Oil and Natural Gas Pipeline Mileage, 2010-2014

| | Natural Gas Pipelines (miles) | | | | | Crude Oil Pipelines (miles) |

2.4.3 Domestic Consumption

Historical crude oil sector-level consumption trends for 1990 through 2012 are shown in Table 2-9 and Figure 2-4. Total consumption rose gradually until 2008, when total consumption basically leveled off as a result of the economic recession. The share of residential, commercial, industrial, and electric power on a percentage basis declined during this period, while the percentage of the share of total consumption by the transportation sector rose from 64 percent in 1990 to 71 percent in 2012.

Table 2-9 Crude Oil Consumption by Sector, 1990-2012

| | Total (million barrels) | Percent of Total | | | |

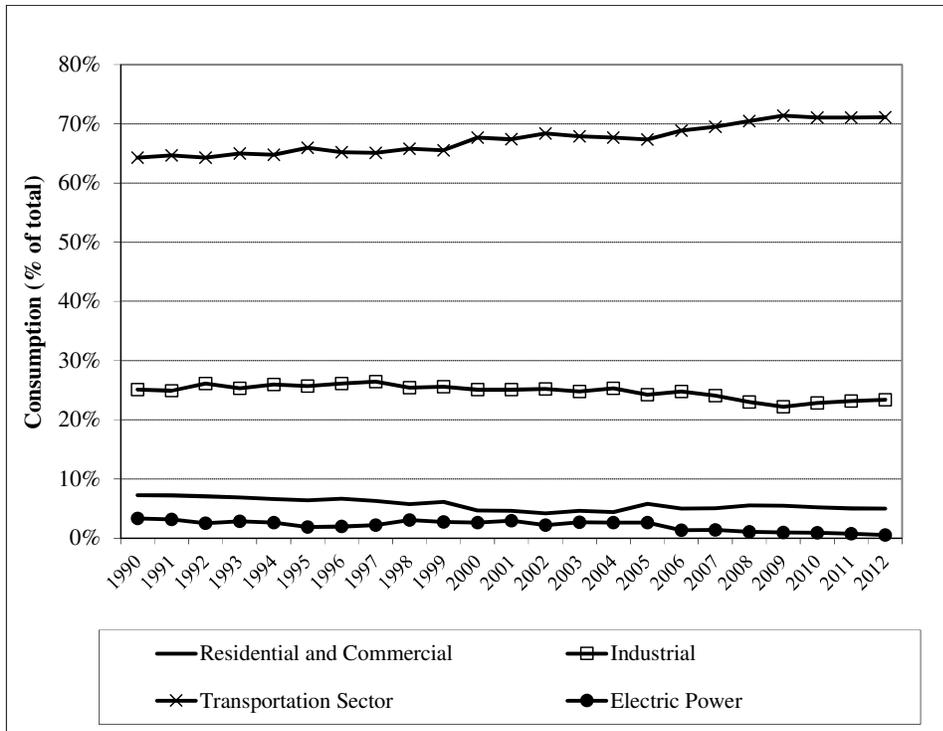

Figure 2-4 Crude Oil Consumption by Sector (Percent of Total Consumption), 1990-2012

Natural gas consumption has increased over the last twenty years. From 1990 to 2014, total U.S. consumption increased by an average of about 1.6 percent per year (Table 2-10 and Figure 2-5). Over this period, the percentage of natural gas consumed by the industrial sector declined, whereas the percent of total natural gas used for electric power generation increased dramatically, an important trend in the industry as many utilities increasingly use natural gas for peak generation or switch from coal-based to natural gas-based electricity generation. The residential sector demand has bounced around between about 23 and 19 percent, where the lower percentage of total demand falls mainly in the years post 2008 with slightly larger dip in 2012. Commercial sector demand hovered around 13 and 14 percent, also with a slight dip in 2012. The transportation sector has maintained a fairly constant consumption level of right around 3 percent between 1990 and 2014.

Table 2-10 Natural Gas Consumption by Sector, 1990-2014

| | Percent of Total | | | | | |
|------|------------------|-------------|------------|------------|----------------|----------------|
| | Total (tcf) | Residential | Commercial | Industrial | Electric Power | Transportation |

2.4.4 International Trade

Until 2006, net trade of crude oil and refined petroleum products increased, showing increased substitution of imports for domestic production, as well as imports satisfying growing consumer demand in the U.S. (Table 2-11). Since then, however, imports have been declining while exports have been rising, leading to significant declines in net trade or crude oil and petroleum products.

Table 2-11 Total Crude Oil and Petroleum Products Trade (Million Bbl), 1990-2014

| | Imports | | | Exports | | | Net Imports | | |
|------|-----------|--------------------|-------|-----------|--------------------|-------|-------------|--------------------|-------|
| | Crude Oil | Petroleum Products | Total | Crude Oil | Petroleum Products | Total | Crude Oil | Petroleum Products | Total |

From 1990 to 2007, natural gas imports have increased steadily in both volume and percentage terms (Table 2-12). Imported natural gas constituted a lower percentage of domestic natural gas consumption from 2007 through 2014 compared to earlier years. Until recent years, industry analysts have forecasted that LNG imports would continue to grow as a percentage of U.S. consumption. However, it is possible that increasingly accessible domestic unconventional gas resources, such as shale gas and coalbed methane, is reducing the need for the U.S. to import natural gas, either via pipeline or shipped LNG.

2.4.5 Forecasts

In this section, we provide forecasts of well drilling activity and crude oil and natural gas domestic production, imports, and prices. The forecasts are from the most current forecast information available from the EIA, the 2014 and 2015 Annual Energy Outlook. The 2014 and 2015 Annual Energy Outlook was produced using the National Energy Modeling System (NEMS), which the EPA uses to analyze the impacts of the final NSPS on the national economy as is discussed in detail in Section 7.

Table 2-13 present forecasts of successful wells drilled in the U.S. from 2010 to 2040. Crude oil well forecasts for the lower 48 states show a rise up to the year 2025 then a gradual

decline until 2040. Meanwhile, the forecast shows an increase in natural gas drilling in the lower 48 states from the present to 2040, more than doubling during this 25-year period.

Table 2-13 Forecast of Total Successful Wells Drilled, Lower 48 States, 2010-2040

| Year | Totals | |
|------|-----------|-------------|
| | Crude Oil | Natural Gas |
| 2010 | 19,316 | 19,056 |
| 2011 | 23,048 | 14,355 |
| 2012 | 26,749 | 11,011 |
| 2013 | 25,248 | 11,507 |
| 2014 | 22,274 | 14,099 |
| 2015 | 22,706 | 14,076 |
| 2016 | 22,552 | 15,004 |
| 2017 | 22,355 | 15,773 |
| 2018 | 22,421 | 18,340 |

Table 2-14 presents forecasts of domestic crude oil production, reserves, imports and Figure 2-6 depicts these trends graphically. Table 2-14 also shows forecasts of proved reserves in the lower 48 states. The reserves forecast shows steady growth from 2012 to 2040, with an increase of 49 percent overall. This increment is smaller than the forecast increase in production from the lower 48 states during this period, 52 percent, showing production is forecast to grow

more rapidly than reserves. In addition, Table 2-14 shows average wellhead prices increasing more than 41 percent from 2012 to 2040, from \$96.38 per barrel to \$136.13 per barrel in 2013 dollar terms.

Table 2-14 Forecast of Crude Oil Supply, Reserves, and Wellhead Prices, 2012-2040

| | Domestic Production (million bbls) | | | | | | | Lower 48 End of Year Reserves (million bbls) | Lower 48 Average Wellhead Price (2013 dollars per barrel) |

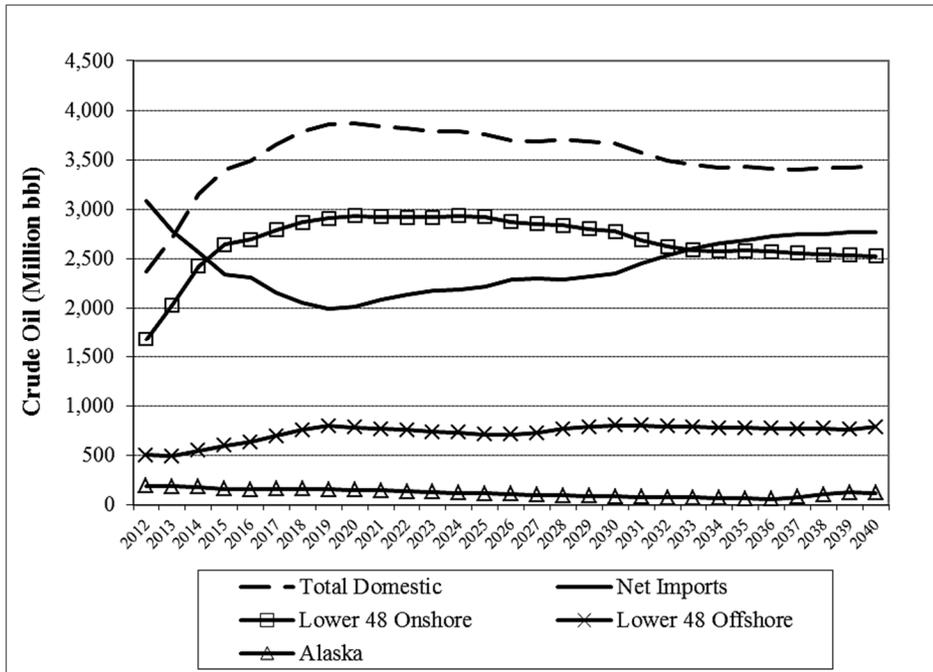

Figure 2-6 Forecast of Domestic Crude Oil Production and Net Imports, 2010-2040
 Source: U.S. Energy Information Administration (U.S. EIA). April 2015. Annual Energy Outlook 2015 with Projections to 2040. < [http://www.eia.gov/forecasts/aeo/pdf/0383\(2015\).pdf](http://www.eia.gov/forecasts/aeo/pdf/0383(2015).pdf)>. Accessed January 25, 2016.

Table 2-15 shows domestic natural gas production is forecast to increase until 2040. Meanwhile, imports of natural gas via pipeline are eliminated during the forecast period, from 1.37 tcf in 2012 to -2.33 tcf in 2040. Imports of LNG are also expected to be eliminated during the forecast period, from 0.15 tcf in 2012 to -3.29 tcf in 2040. Dry Gas Production increases about 47 percent, from 24.06 tcf in 2012 to 35.45 in 2040. Total supply increases about 17 percent, from 25.64 tcf in 2012 to 29.90 tcf in 2040.

2.5 Industry Costs

2.5.1 Finding Costs

Real costs of drilling oil and natural gas wells have increased significantly over the past two decades, particularly in recent years. Cost per well has increased by an annual average of about 15 percent, and cost per foot has increased on average of about 13 percent per year (Figure 2-7).

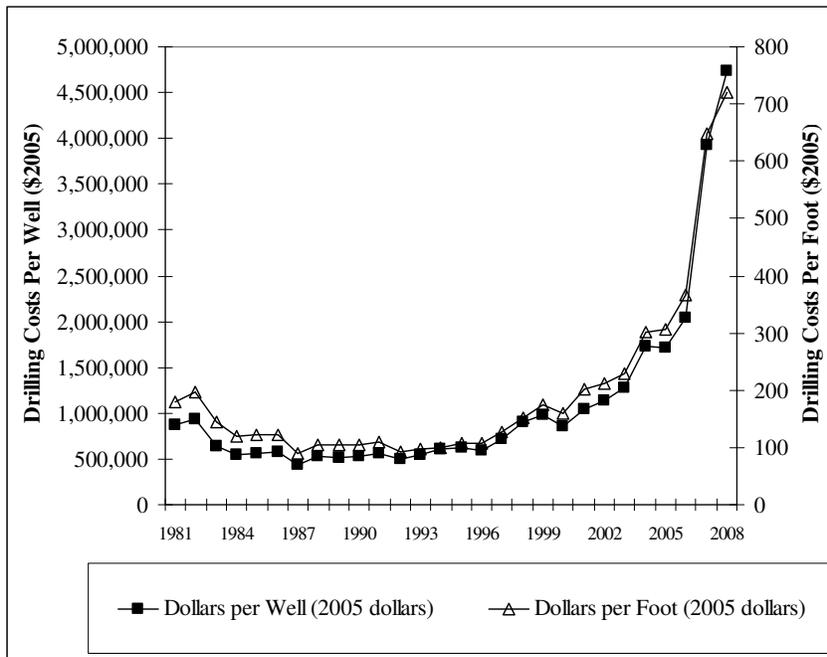

Figure 2-7 Costs of Crude Oil and Natural Gas Wells Drilled, 1981-2008

The average finding costs compiled and published by the EIA add an additional level of detail to drilling costs, in that finding costs incorporate the broader costs associated with adding proved reserves of crude oil and natural gas. These costs include exploration and development costs, as well as costs associated with the purchase or leasing of real property. The EIA publishes finding costs as running three-year averages, in order to better compare these costs, which occur over several years, with annual average lifting costs. Figure 2-8 shows average domestic onshore, offshore and foreign finding costs for the sample of U.S. firms in the EIA's Financial Reporting System (FRS) database from 1981 to 2009. The costs are reported in 2009 dollars on a barrel of oil equivalent basis for crude oil and natural gas combined. The average domestic

finding costs dropped from 1981 until the mid-1990s. Interestingly, in the mid-1990s, domestic onshore, offshore and foreign finding costs converged for a few years. After this period, offshore finding costs rose faster than domestic onshore and foreign costs.

After 2000, average finding costs rose sharply, with the finding costs for domestic onshore, offshore and foreign proved reserves diverging onto different trajectories. Note the drilling costs in Figure 2-7 and finding costs in Figure 2-8 present similar trends overall.

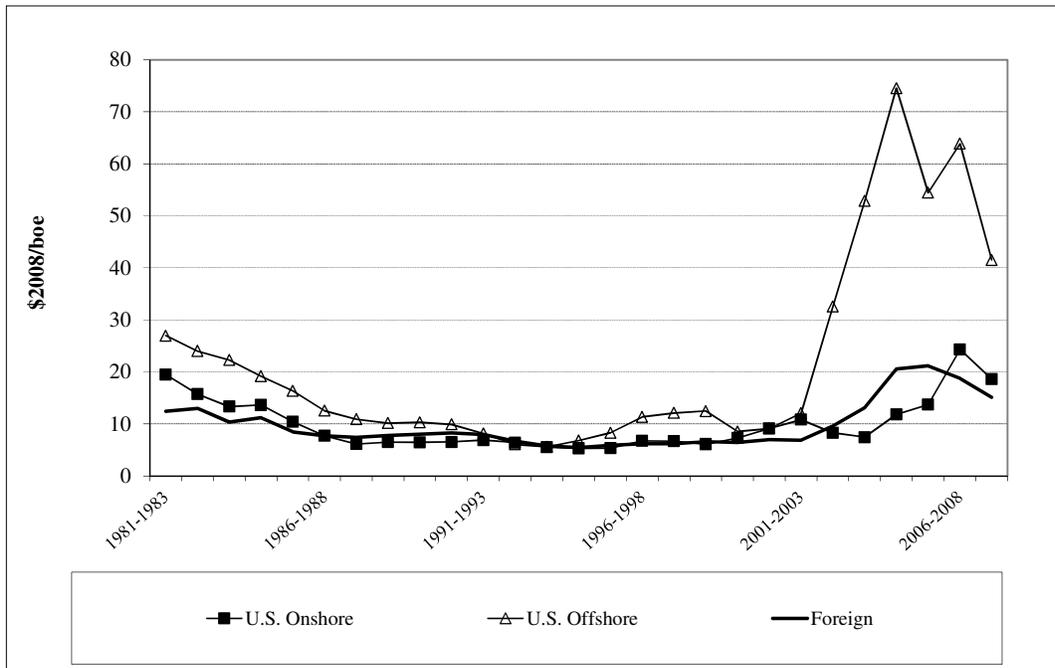

Figure 2-8 Finding Costs for FRS Companies, 1981-2009

Source: U.S. Energy Information Administration (U.S. EIA). February 2011. Performance Profiles of Major Energy Producers, 2009. Figure 17 data. <http://www.eia.gov/finance/performanceprofiles/oil_gas.cfm>. Accessed January 19, 2016.

2.5.2 Lifting Costs

Lifting costs are the costs to produce crude oil or natural gas once the resource has been found and accessed. The EIA's definition of lifting costs includes costs of operating and maintaining wells and associated production equipment. Direct lifting costs exclude production taxes or royalties, while total lifting costs includes taxes and royalties. Like finding costs, the EIA reports average lifting costs for FRS firms in 2009 dollars on a barrel of oil equivalent basis.

Total lifting costs are the sum of direct lifting costs and production taxes. Figure 2-9 depicts direct lifting cost trends from 1981 to 2009 for domestic and foreign production.

Direct lifting costs (excludes taxes and royalties) for domestic production rose a little more than \$2 per barrel of oil equivalent between 1981 and 1985, then declined almost \$5 per barrel of oil equivalent by 2000. From 2000 to 2009, domestic lifting costs increased sharply, just over \$8 per barrel of oil equivalent. Foreign lifting costs diverged from domestic lifting costs from 1981 to 1991, with foreign lifting costs lower than domestic costs during this period. After 1991, foreign and domestic lifting costs followed a similar track until they again diverged in 2004, with domestic lifting again becoming more expensive. Combined with finding costs, the total finding and lifting costs rose significantly in from 2000 to 2009.

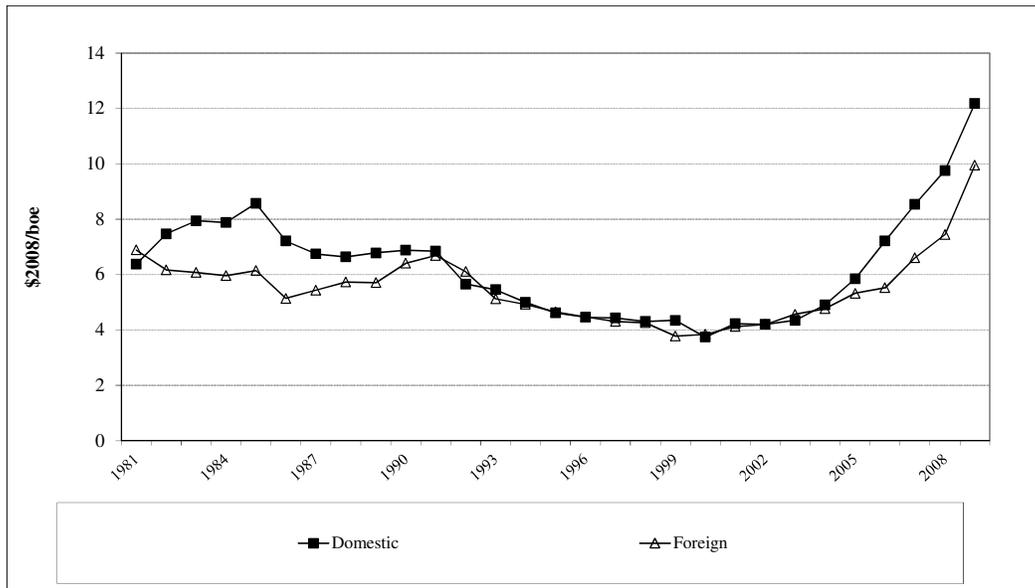

Figure 2-9 Direct Oil and Natural Gas Lifting Costs for FRS Companies, 1981-2009 (3-year Running Average)

Source: U.S. Energy Information Administration (U.S. EIA). February 2011. Performance Profiles of Major Energy Producers, 2009. Figure 15 data. <http://www.eia.gov/finance/performanceprofiles/oil_gas.cfm>. Accessed January 19, 2016.

2.5.3 *Operating and Equipment Costs*

The EIA report, “Oil and Gas Lease Equipment and Operating Costs 1994 through 2009”⁸, contains indices and estimated costs for domestic oil and natural gas equipment and production operations. The indices and cost trends track costs for representative operations in six regions (California, Mid-Continent, South Louisiana, South Texas, West Texas, and Rocky Mountains) with producing depths ranging from 2000 to 16,000 feet and low to high production rates (for example, 50,000 to 1 million cubic feet per day for natural gas).

Figure 2-10 depicts crude oil operating costs and equipment costs indices for 1976 to 2009, as well as the crude oil price in 1976 dollars. The indices show that crude oil operating and equipment costs track the price of oil over this time period, but operating costs have risen more quickly than equipment costs. Operating and equipment costs and oil prices rose steeply in the late 1970s, but generally decreased from about 1980 until the late 1990s. Oil costs and prices again generally rose between 2000 and 2009, with a peak in 2008. The 2009 index values for crude oil operating and equipment costs are 154 and 107, respectively.

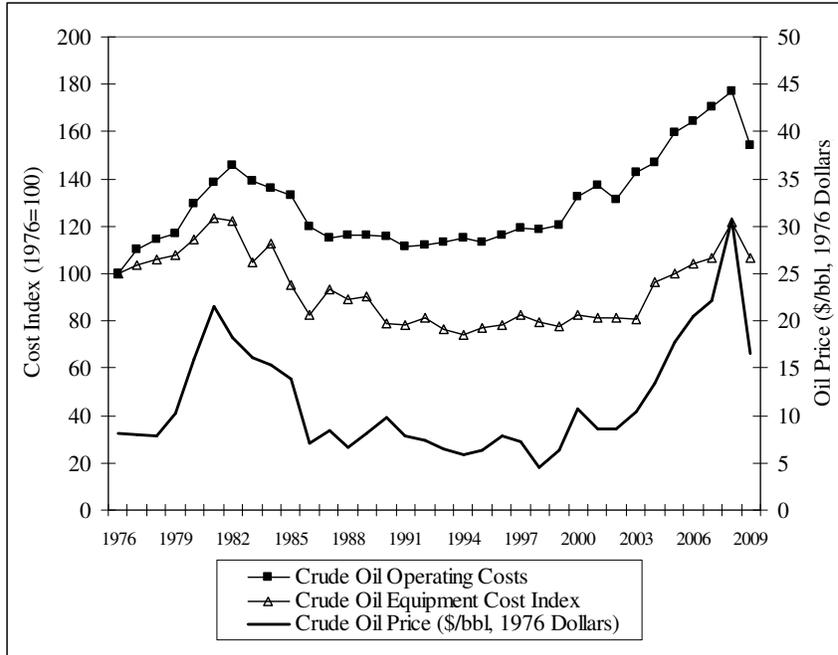

Figure 2-10 Crude Oil Operating Costs and Equipment Costs Indices (1976=100) and Crude Oil Price (in 1976 dollars), 1976-2009⁹

Source: U.S. Energy Information Administration. "Oil and Gas Lease Equipment and Operating Costs 1994 through 2009." September 28, 2010.

<http://www.eia.doe.gov/pub/oil_gas/natural_gas/data_publications/cost_indices_equipment_production/current/coststudy.html> Accessed February 2, 2011.

Figure 2-11 depicts natural gas operating and equipment costs indices, as well as natural gas prices. Similar to the cost trends for crude oil, natural gas operating and equipment costs track the price of natural gas over this time period, while operating costs have risen more quickly than equipment costs. Operating and equipment costs and gas prices also rose steeply in the late 1970s, but generally decreased from about 1980 until the mid-1990s. The 2009 index values for natural gas operating and equipment costs are 137 and 112, respectively.

⁹ The last release date for the EIA's *Oil and Gas Lease Equipment and Operating Costs* analysis was September 2010. Updates have been discontinued.

2.6 Firm Characteristics

A regulatory action to reduce pollutant discharges from facilities producing crude oil and natural gas will potentially affect the business entities that own the regulated facilities. In the oil and natural gas production industry, facilities comprise those sites where plants and equipment extract, process, and transport extracted streams recovered from the raw crude oil and natural gas resources. Companies that own these facilities are legal business entities that have the capacity to conduct business transactions and make business decisions that affect the facility.

2.6.1 Ownership

Enterprises in the oil and natural gas industry may be divided into different groups that include producers, transporters, and distributors. The producer segment may be further divided between major and independent producers. Major producers include large oil and gas companies that are involved in each of the five industry segments: drilling and exploration, production,

transportation, refining, and marketing. Independent producers include smaller firms that are involved in some but not all of the five activities.

According to the Independent Petroleum Association of America (IPAA), independent companies produce approximately 54 percent of domestic crude oil, 85 percent of domestic natural gas, and drill almost 95 percent of the wells in the U.S (IPAA, 2012-13). Through the mid-1980s, natural gas was a secondary fuel for many producers. However, now it is of primary importance to many producers. IPAA reports that about 50 percent of its members' spending in 2007 was directed toward natural gas production, largely toward production of unconventional gas (IPAA, 2009). Meanwhile, transporters are comprised of the pipeline companies, while distributors are comprised of the local distribution companies.

2.6.2 Size Distribution of Firms in Affected NAICS

As of 2012, there were 6,679 firms within the 211111 and 211112 NAICS codes, of which 6,551 (98 percent) were considered small entities (Table 2-16). Within NAICS 211111 and 211112, large firms compose about 2 percent of the firms, but account for almost 61 percent of employment listed under these NAICS. The small and large firms within NAICS 21311 are similarly distributed, with large firms accounting for about 2 percent of firms, but 56 percent of employment. Within NAICS 486210, large firms compose about 43 percent of total firms and about 95 percent of employment.

Table 2-16 SBA Size Standards and Size Distribution of Oil and Natural Gas Firms

| NAICS | NAICS Description | SBA Size Standard** (Employees or Annual Receipts) | *Small Firms | *Large Firms | *Total Firms |
|--------------------------------------|---|---|--------------|--------------|--------------|
| Number of Firms by Firm Size | | | | | |
| 211111 | Crude Petroleum and Natural Gas Extraction | 500 ¹ | 6,444 | 92 | 6,536 |
| 211112 | Natural Gas Liquid Extraction | 500 ² | 107 | 36 | 143 |
| 213111 | Drilling Oil and Gas Wells | 500 ³ | 2,085 | 59 | 2,144 |
| 213112 | Support Activities for Oil and Gas Operations | \$38.5 million | 8,750 | 127 | 8,877 |
| 486210 | Pipeline Transportation of Natural Gas | \$27.5 million | 92 | 46 | 138 |
| Total Employment by Firm Size | | | | | |
| 211111 | Crude Petroleum and Natural Gas Extraction | 500 | 47,528 | 66,996 | 114,524 |
| 211112 | Natural Gas Liquid Extraction | 500 | 1,709 | 8,768 | 10,477 |
| 213111 | Drilling Oil and Gas Wells | 500 | 39,628 | 66,740 | 106,368 |
| 213112 | Support Activities for Oil and Gas Operations | \$38.5 million | 126,523 | 145,834 | 272,357 |
| 486210 | Pipeline Transportation of Natural Gas | \$27.5 million | 1,503 | 31,823 | 33,326 |

**The SBA size standards for some of the NAICS were updated in February, 2016.

1. Updated to 1,250 employees
2. Updated to 750 employees
3. Updated to 1,000 employees.

2.6.3 Trends in National Employment and Wages

As well as producing much of the U.S. energy supply, the oil and natural gas industry directly employs a significant number of people. Table 2-17 shows employment in oil and natural gas-related NAICS codes from 1990 to 2014. The overall trend shows a decline in total industry employment throughout the 1990s, hitting a low of about 314,000 in 1999, but rebounding to a 2014 peak of about 660,000. Crude Petroleum and Natural Gas Extraction (NAICS 211111) and Support Activities for Oil and Gas Operations (NAICS 213112) employ the majority of workers in the industry.

Table 2-17 Oil and Natural Gas Industry Employment by NAICS, 1990-2014

| | Crude Petroleum and Natural Gas Extraction (NAICS 211111) | Natural Gas Liquid Extraction (NAICS 211112) | Drilling of Oil and Natural Gas Wells (NAICS 213111) | Support Activities for Oil and Gas Ops. (NAICS 213112) | Pipeline Trans. of Crude Oil (NAICS 486110) | Pipeline Trans. of Natural Gas (NAICS 486210) | Total |
|------|--|---|---|---|--|--|--------------|
| 1990 | 182,848 | 8,260 | 52,365 | 109,497 | 11,112 | 47,533 | 411,615 |
| 1991 | 177,803 | 8,443 | 46,466 | 116,170 | 11,822 | 48,643 | 409,347 |

From 1990 to 2014, average wages for the oil and natural gas industry have increased. Table 2-18 shows real wages (in 2012 dollars) from 1990 to 2014 for the NAICS codes associated with the oil and natural gas industry. Employees in the NAICS 211 codes earn the highest average wages in the oil and natural gas industry, while employees in the NAICS 213 codes have relatively lower wages. Average wages in natural gas pipeline transportation show the highest variation.

Table 2-18 Oil and Natural Gas Industry Average Wages by NAICS, 1990-2014 (2012 dollars)

| | Crude Petroleum and Natural Gas Extraction (211111) | Natural Gas Liquid Extraction (211112) | Drilling of Oil and Natural Gas Wells (213111) | Support Activities for Oil and Gas Ops. (213112) | Pipeline Trans. of Crude Oil (486110) | Pipeline Trans. of Natural Gas (486210) | Total |
|------|--|---|---|---|--|--|--------------|

2.6.4 Horizontal and Vertical Integration

Because of the existence of major companies, the industry possesses a wide dispersion of vertical and horizontal integration. The vertical aspects of a firm's size reflect the extent to which goods and services that can be bought from outside are produced in house, while the horizontal aspect of a firm's size refers to the scale of production in a single-product firm or its scope in a multiproduct one. Vertical integration is a potentially important dimension in analyzing firm-level impacts because the regulation could affect a vertically integrated firm on more than one

level. The regulation may affect companies for whom oil and natural gas production is only one of several processes in which the firm is involved. For example, a company that owns oil and natural gas production facilities may ultimately produce final petroleum products, such as motor gasoline, jet fuel, or kerosene. This firm would be considered vertically integrated because it is involved in more than one level of requiring crude oil and natural gas and finished petroleum products. A regulation that increases the cost of oil and natural gas production will ultimately affect the cost of producing final petroleum products.

Horizontal integration is also a potentially important dimension in firm-level analyses for any of the following reasons. A horizontally integrated firm may own many facilities of which only some are directly affected by the regulation. Additionally, a horizontally integrated firm may own facilities in unaffected industries. This type of diversification would help mitigate the financial impacts of the regulation. A horizontally integrated firm could also be indirectly as well as directly affected by the regulation.

In addition to the vertical and horizontal integration that exists among the large firms in the industry, many major producers often diversify within the energy industry and produce a wide array of products unrelated to oil and gas production. As a result, some of the effects of regulation of oil and gas production can be mitigated if demand for other energy sources moves inversely compared to petroleum product demand.

In the natural gas sector of the industry, vertical integration is less predominant than in the oil sector. Transmission and local distribution of natural gas usually occur at individual firms, although processing is increasingly performed by the integrated major companies. Several natural gas firms operate multiple facilities. However, natural gas wells are not exclusive to natural gas firms. Typically, wells produce both oil and gas and can be owned by a natural gas firm or an oil company.

Unlike the large integrated firms that have several profit centers such as refining, marketing, and transportation, most independent firms have to rely solely on profits generated at the wellhead from the sale of oil and natural gas or the provision of oil and gas production-related engineering or financial services. Overall, independent producers typically sell their output to refineries or natural gas pipeline companies and are not vertically integrated.

Independents may also own relatively few facilities, indicating limited horizontal integration.

2.6.5 Firm-level Information

The annual *Oil and Gas Journal* (OGJ) survey, the OGJ150, reports financial and operating results for public oil and natural gas companies with domestic reserves and headquarters in the U.S. In the past, the survey reported information on the top 300 companies, though now it has been reduced to the top 150. In 2014, 143 public companies are listed; in 2013 there were 139 firms.¹⁰ The 2012 list contains four companies that were not on the list in the previous year. Table 2-19 lists selected statistics for the top 20 companies in 2014. The results presented in the table reflect a decline in U.S. oil prices.

Net income for the top 134 companies fell about 17.5% between 2013 and 2014 to about \$74 billion. Revenues for these companies increased by about \$6 billion from 2013 to 2014, reaching \$920.5 billion. Even though net revenue decreased in 2014, companies continued to invest. Capital and exploratory spending for the companies in 2014 totaled \$226.4 billion, up 9.3% from 2013.

The total worldwide liquids production for the 143 firms increased 8.41 percent 3.32 billion bbl, while total worldwide gas production increased 0.54 percent to a total of 17 tcf (*Oil and Gas Journal*, September 7, 2015). Meanwhile, the firms increased both oil and natural gas production and reserves from 2013 to 2014. Domestic production of liquids increased about 16.73 percent from 2013 to 1.97 billion bbl, and domestic natural gas production was up about 3.95 percent to 12.4 tcf in 2014. US liquids reserves from the OGJ150 firms increased by 9.85% up to 25.53 billion bbl, and US natural gas reserves increased by 8.56% to 172.92 tcf. For context, the OGJ150 domestic crude production represents about 62 percent of total domestic production (3.18 billion bbl, according to EIA) in 2014. The OGJ150 natural gas production represents about 48 percent of total domestic production (31.3 tcf, according to EIA) in 2014.

Source: Oil and Gas Journal. "OGJ150" September 7, 2015. The annual *Oil and Gas Journal* (OGJ) survey, the OGJ150, reports financial and operating results for public oil and natural gas companies with domestic reserves and headquarters in the U.S.

Notes: The source for employment figures is Hoovers, a D&B Company. (Data accessed on January 20, 2016. Employee numbers are for 2014)

The OGJ also releases a period report entitled “Worldwide Gas Processing Survey”, which provides a wide range of information on existing processing facilities. We used a recent list of U.S. gas processing facilities (*Oil and Gas Journal*, June 7, 2010) and other resources, such as the American Business Directory and company websites, to best identify the parent company of the facilities. As of 2009, there are 579 gas processing facilities in the U.S., with a processing capacity of 73,767 million cubic feet per day and throughput of 45,472 million cubic feet per day (Table 2-20). The overall trend in U.S. gas processing capacity is showing fewer, but larger facilities. For example, in 1995, there were 727 facilities with a capacity of 60,533 million cubic feet per day (U.S. DOE, 2006).

Trends in gas processing facility ownership are also showing a degree of concentration, with large firms owning multiple facilities, which also tend to be relatively large (Table 2-20). While we estimate 142 companies own the 579 facilities, the top 20 companies (in terms of total throughput) own 264, or 46 percent, of the facilities. That larger companies tend to own larger facilities is indicated by these top 20 firms owning 86 percent of the total capacity and 88 percent of actual throughput.

Table 2-20 Top 20 Natural Gas Processing Firms (Based on Throughput), 2009

| Rank | Company | Processing Plants (No.) | Natural Gas Capacity (MMcf/day) | Natural Gas Throughput (MMcf/day) |

| TOTAL FOR ALL COMPANIES | | 579 | 73,767 | 45,472 |

Source: *Oil and Gas Journal*. “Special Report: Worldwide Gas Processing: New Plants, Data Push Global Gas Processing Capacity Ahead in 2009.” June 7, 2010, with additional analysis to determine ultimate ownership of plants.

The OGJ also issues a periodic report on the economics of the U.S. pipeline industry. This report examines the economic status of all major and non-major natural gas pipeline companies, which amounts to 165 companies in 2014 (*Oil and Gas Journal*, September 7, 2015, “Gas Pipeline Table,” pp. 126-128). Table 2-21 presents the pipeline mileage, volumes of natural gas transported, operating revenue, and net income for the top 20 U.S. natural gas pipeline companies in 2014. Ownership of gas pipelines is mostly independent from ownership of oil and gas production companies, as is seen from the lack of overlap between the OGJ list of Top 20 pipeline companies and the Top 20 firms from the OGJ150. This observation shows that the pipeline industry is still largely based upon firms serving regional markets.

The top 20 companies maintain about 58 percent of the total pipeline mileage and transport about 52 percent of the total volume of the industry (Table 2-21). Operating revenues

of the top 20 companies equaled \$13.2 billion, representing 54 percent of the total operating revenues for major and non-major companies. The top 20 companies also account for 69 percent of the net income of the industry.

Table 2-21 Performance of Top 20 Gas Pipeline Companies (Based on Net Income), 2014

| Rank | Company | Transmission (miles) | Vol. trans for others (MMcf) | Operating Revenue (\$000s) | Net Income (\$000s) |

2.6.6 Financial Performance and Condition

From a broad industry perspective, the EIA Financial Reporting System (FRS) collects financial and operating information from a subset of the major U.S. energy producers and reports summary information in the publication "The Performance Profiles of Major Energy Producers".¹¹ This information is used in annual report to Congress, and is released to the public in aggregate form. While the companies that report information to the FRS each year changes,

¹¹ The "Performance Profiles of Major Energy Producers 2009" released on February 25, 2011 is the most recent release of this report.

the EIA makes an effort to retain sufficient consistency to reliably evaluate trends. For 2009, 30 companies in the FRS¹² accounted for 43 percent of total U.S. crude oil and NGL production, 43 percent of natural gas production, 78 percent of U.S. refining capacity, and 0.3 percent of U.S. electricity net generation (U.S. EIA, 2011). Table 2-22 aggregates a series of financial trends selected from the FRS firms' financial statements presented in 2008 dollars. The table shows operating revenues and expenses rising significantly from 1990 to 2008, with operating income (the difference between operating revenues and expenses) rising as well, followed by all three financial factors dropping off significantly in 2009. Interest expenses remained relatively flat during this period. Meanwhile, recent years have shown that other income and income taxes have played a more significant role for the industry. Net income has risen as well, though the decrease in net income spans both 2008 and 2009 mainly as a factor of oil and natural gas prices declining significantly during the latter half of 2008.

¹² Alenco, Alon USA, Anadarko Petroleum Corporation, Apache Corporation, BP America, Inc., Chalmette, Chesapeake Energy Corporation, Chevron Corporation, CITGO Petroleum Corporation, ConocoPhillips, Devon Energy Corporation, El Paso Corporation, EOG Resources, Inc., Equitable Resources, Inc., Exxon Mobil Corporation, Hess Corporation, Hovensa, Lyondell Chemical Corporation, Marathon Oil Corporation, Motiva Enterprises, L.L.C., Occidental Petroleum Corporation, Shell Oil Company, Sunoco, Inc., Tesoro Petroleum Corporation, The Williams Companies, Inc., Total Holdings USA, Inc., Valero Energy Corp., Western Refining, WRB Refining LLC, and XTO Energy, Inc.

Table 2-22 Selected Financial Items from Income Statements (Billion 2008 Dollars)

| Year | Operating Revenues | Operating Expenses | Operating Income | Interest Expense | Other Income* | Income Taxes | Net Income |
|------|--------------------|--------------------|------------------|------------------|---------------|--------------|------------|
| 1990 | 766.9 | 706.4 | 60.5 | 16.8 | 13.6 | 24.8 | 32.5 |
| 1991 | 673.4 | 635.7 | 37.7 | 14.4 | 13.4 | 15.4 | 21.3 |
| 1992 | 670.2 | 637.2 | 33.0 | 12.7 | -5.6 | 12.2 | 2.5 |
| 1993 | 621.4 | 586.6 | 34.8 | 11.0 | 10.3 | 12.7 | 21.5 |
| 1994 | 606.5 | 565.6 | 40.9 | 10.8 | 6.8 | 14.4 | 22.5 |
| 1995 | 640.8 | 597.5 | 43.3 | 11.1 | 12.9 | 17.0 | 28.1 |
| 1996 | 706.8 | 643.3 | 63.6 | 9.1 | 13.4 | 26.1 | 41.8 |
| 1997 | 673.6 | 613.8 | 59.9 | 8.2 | 13.4 | 23.9 | 41.2 |
| 1998 | 614.2 | 594.1 | 20.1 | 9.2 | 11.0 | 6.0 | 15.9 |

* Other Income includes other revenue and expenses (excluding interest expense), discontinued operations, extraordinary items, and accounting changes. Totals may not sum due to independent rounding.

Table 2-23 shows the estimated return on investments in percentage terms for a variety of business lines in 1998, 2003, 2008, and 2009 for FRS companies. For U.S. petroleum-related business activities, oil and natural gas production was the most profitable line of business relative to refining/marketing and pipelines, sustaining a return on investment greater than 10 percent in 1998, 2003, and 2008, with a significant decrease in 2009. Returns to foreign oil and natural gas production rose above domestic production in 2008 and 2009. Electric power generation and sales emerged as a highly profitable line of business in 2008 for the FRS companies quickly followed by a significant decline in 2009.

Table 2-23 Return on Investment for Lines of Business (all FRS), for 1998, 2003, 2008, and 2009 (percent)

| Line of Business | 1998 | 2003 | 2008 | 2009 |
|--------------------------------|-------------|-------------|-------------|-------------|
| Petroleum | 10.8 | 13.4 | 11.9 | 4.5 |
| U.S. Petroleum | 10 | 13.7 | 8.1 | 0.4 |
| Oil and Natural Gas Production | 12.5 | 16.5 | 10.7 | 3.5 |
| Refining/Marketing | 6.6 | 9.3 | 2.4 | -6.6 |
| Pipelines | 6.7 | 11.5 | 2.4 | 4.7 |
| Foreign Petroleum | 11.9 | 13.0 | 17.8 | 10.3 |
| Oil and Natural Gas Production | 12.5 | 14.2 | 16.3 | 11 |
| Refining/Marketing | 10.6 | 8.0 | 26.2 | 5.8 |
| Downstream Natural Gas* | - | 8.8 | 5.1 | 9.6 |
| Electric Power | - | 5.2 | 181.4 | -32 |
| Other Energy | 7.1 | 2.8 | -2.1 | 5.1 |
| Non-energy | 10.9 | 2.4 | -5.3 | 2.8 |

Source: Energy Information Administration, Form EIA-28 (Financial Reporting System).

Note: Return on investment measured as contribution to net income/net investment in place.

* The downstream natural gas and electric power lines of business were added to the EIA-28 survey form beginning with the 2003 reporting year.

The oil and natural gas industry also produces significant tax revenues for local, state, and federal authorities. Table 2-24 shows income and production tax trends from 1990 to 2009 for FRS companies. The column with U.S. federal, state, and local taxes paid or accrued includes deductions for the U.S. Federal Investment Tax Credit (\$198 million in 2008)¹³ and the effect of the Alternative Minimum Tax (\$34 million in 2008). Income taxes paid to state and local authorities were \$3,060 million in 2008¹³, about 13 percent of the total paid to U.S. authorities.

The difference between total current taxes and U.S. federal, state, and local taxes includes taxes and royalties paid to foreign countries. As can be seen in Table 2-24 foreign taxes paid far exceeds domestic taxes paid. Other non-income production taxes paid, which have risen almost three-fold between 1990 and 2008, include windfall profit and severance taxes, as well as other production-related taxes.

¹³ Data was withheld in 2009 to avoid disclosure.

Table 2-24 Income and Production Taxes, 1990-2009 (Million 2008 Dollars)

| Year | US Federal, State, and Local Taxes Paid or Accrued | Total Current | Total Deferred | Total Income Tax Expense | Other Production Taxes Paid |
|-------|--|---------------|-------------------|-----------------------------|-----------------------------------|
| 1990 | 9,568 | 25,056 | -230 | 24,826 | 4,341 |

3 EMISSIONS AND ENGINEERING COSTS

3.1 Introduction

This chapter describes the emissions and engineering cost analysis for the final NSPS. The first section discusses the emissions points and control options. The following section describes each step in the emissions and engineering cost analysis and presents an overview of results. Detailed tables describing the impacts for each source and option can be found at the end of the chapter. We provide reference to the detailed Technical Support Document (TSD) prepared by the EPA for the reader interested in a greater level of detail.¹⁴

3.2 Sector Emissions Overview

This section provides estimates of overall emissions from the crude oil and natural gas industry to provide context for estimated reductions as a result of the rule. Crude oil and natural gas production sector VOC emissions are approximately 2.8 million tons, according to the 2011 EPA National Emissions Inventory (NEI). The Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2014 (to be published April 15, 2016) estimates 2014 methane emissions from Petroleum and Natural Gas Systems (not including petroleum refineries and petroleum transportation) to be 232 MMt CO₂ Eq. In 2014, total methane emissions from the oil and gas industry represented 32 percent of the total methane emissions from all sources and account for about 3 percent of all CO₂ Eq. emissions in the U.S., with the combined petroleum and natural gas systems being the largest contributor to U.S. anthropogenic methane emissions (U.S. EPA, 2016).

For the analysis supporting this final action, including this RIA, we used the methane 100-year global warming potential (GWP) of 25 to be consistent with and comparable to key Agency emission quantification programs such as the Inventory of Greenhouse Gas Emissions and Sinks (GHG Inventory) and the Greenhouse Gas Reporting Program (GHGRP).¹⁵ The use of

¹⁴ U.S. EPA. 2016. Oil and Natural Gas Sector: Standards of Performance for Crude Oil and Natural Gas Production, Transmission and Distribution. Background Technical Support Document for the Proposed Amendments to the New Source Performance Standards.

¹⁵ See, for example Table A-1 to subpart A of 40 C.F.R. part 98.

the 100-year GWP of 25 for methane value is currently required by the UNFCCC for reporting of national inventories, such as the GHG Inventory. Updated estimates for methane GWP have been developed by IPCC (2013).¹⁶ The most recent 100-year GWP estimates for methane, which are presented in the IPCC Fifth Assessment Report (AR5, 2013), range from 28-36. In discussing the science and impacts of methane emissions generally, we use the GWP range of 28-36. When presenting emissions estimates, we use the GWP of 25 for consistency and comparability with other emissions estimates in the U.S. and internationally.

3.3 Emissions Points and Pollution Controls assessed in the RIA

A series of emissions controls were evaluated as part of the NSPS review. This section provides a basic description of emissions sources and the controls evaluated for each source to facilitate the reader's understanding of the economic impact and benefit analyses. Additional technical details on the engineering and cost basis of the analysis is presented in the TSD.

Completions of Hydraulically Fractured and Re-fractured Oil Wells: Well completion activities include multiple steps after the well bore hole has reached the target depth. The highest emissions are from venting of natural gas to the atmosphere during flowback. Flowback emissions are short-term in nature and occur as a specific event during completion of a new well or during activities that involve re-drilling or re-fracturing an existing well. The TSD separately considers developmental wells and exploratory wells. Developmental wells are wells drilled within known boundaries of a proven oil or gas field, while exploratory or "wildcat" wells are wells drilled in areas of new or unknown potential.

The EPA considered techniques that have been proven to reduce emissions from well completions: reduced emissions completions (RECs) and completion combustion, as well as re-injecting the natural gas back into the well or another well, using the gas as an on-site fuel source, or use for another beneficial purpose. The use of a REC not only reduces emissions but delivers natural gas product that would typically be vented to the sales meter. Completion combustion destroys the organic compounds. Technical barriers to the operation of a separator

¹⁶ IPCC, 2013: Climate Change 2013: The Physical Science Basis. Contribution of Working Group I to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change [Stocker, T.F., D. Qin, G.-K. Plattner, M. Tignor, S.K. Allen, J. Boschung, A. Nauels, Y. Xia, V. Bex and P.M. Midgley (eds.)]. Cambridge University Press, Cambridge, United Kingdom and New York, NY, USA, 1535 pp.

such as well pressure and flowback composition can limit the feasibility of RECs in some situations. Other barriers, such as proximity of pipelines, may prevent recovered gas from being routed to a sales line, but do not necessarily prevent reinjection or on-site use.

Fugitive Emissions: There are several potential sources of fugitive emissions throughout the oil and natural gas sector. Fugitive emissions occur when connection points are not fitted properly or when seals and gaskets start to deteriorate. Changes in pressure and pressure or mechanical stresses can also cause components or equipment to leak. Potential sources of fugitive emissions include valves, connectors, pressure relief devices, open-ended lines, flanges, closed vent systems, and thief hatches or other openings on a controlled storage unit. These fugitive emissions do not include devices that vent as part of normal operations.

The TSD considers fugitive emissions from production wellsites and compressor stations. The EPA considered two options for reducing methane and VOC emissions from leaking components: a leak monitoring program based on individual component monitoring using EPA Method 21 for leak detection combined with a leak correction, and a leak monitoring program based on the use of OGI leak detection combined with leak correction. In addition, alternative frequencies for fugitive emissions surveys were considered: annual, semiannual, and quarterly.

Pneumatic Controllers: Pneumatic controllers are automated instruments used for maintaining a process condition such as liquid level, pressure, pressure differential, and temperature. In many situations across all segments of the oil and natural gas industry, pneumatic controllers make use of the available high-pressure natural gas to operate or control a valve. In these “gas-driven” pneumatic controllers, natural gas may be released with every valve movement and/or continuously from the valve control pilot. Not all pneumatic controllers are gas driven. These “non-gas driven” pneumatic controllers use sources of power other than pressurized natural gas. Examples include solar, electric, and instrument air. At oil and gas locations with electrical service, non-gas-driven controllers are typically used. Continuous bleed pneumatic controllers can be classified into two types based on their emissions rates: (1) high-bleed controllers and (2) low-bleed controllers. The EPA evaluated the impact of replacing high-bleed controllers with low-bleed controllers.

Pneumatic Pumps: Pneumatic pumps are devices that use gas pressure to drive a fluid

by raising or reducing the pressure of the fluid by means of a positive displacement, a piston or a set of rotating impellers. Gas powered pneumatic pumps are generally used at oil and natural gas production sites where electricity is not readily available (GRI/EPA, 1996) and can be a significant source of methane and VOC emissions. Pneumatic chemical and methanol injection pumps are generally used to pump small volumes of chemicals or methanol into well bores, surface equipment, and pipelines. Typically, these pumps include plunger pumps with a diaphragm or large piston on the gas end and a smaller piston on the liquid end to enable a high discharge pressure with a varied but much lower pneumatic supply gas pressure. They are typically used semi-continuously with some seasonal variation. Pneumatic diaphragm pumps are used widely in the onshore oil and gas sector to move larger volumes of liquids per unit of time at lower discharge pressures than chemical and methanol injection pumps. The usage of these pumps is episodic including transferring bulk liquids such as motor oil, pumping out sumps, and circulation of heat trace medium at wellsites in cold climates during winter months.

For both of these types of pumps, emissions occur when the gas used in the pump stroke is exhausted to enable liquid filling of the liquid chamber side of the diaphragm. Emissions are a function of the amount of fluid pumped, the pressure of the pneumatic supply gas, the number of pressure ratio's between the pneumatic supply gas pressure and the fluid discharge pressure, and the mechanical inefficiency of the pump. As discussed in the white papers, several options for reducing methane and VOC emissions were identified: replace a natural gas-assisted pump with an instrument air pump, replace a natural gas-assisted pump with a solar-charged direct current pump (solar pumps), replace a natural gas-assisted pump with an electric pump, and route pneumatic pump emissions to a control device. The EPA evaluated the impact of routing pump emissions to a pre-existing on-site control device.

Centrifugal and Reciprocating Compressors: Compressors are mechanical devices that increase the pressure of natural gas and allow the natural gas to be transported from the production site, through the supply chain, and to the consumer. The types of compressors that are used by the oil and gas industry as prime movers are reciprocating and centrifugal compressors. Centrifugal compressors use either wet or dry seals.

Emissions from compressors occur when natural gas leaks around moving parts in the

compressor. In a reciprocating compressor, emissions occur when natural gas leaks around the piston rod when pressurized natural gas is in the cylinder. Over time, during operation of the compressor, the rod packing system becomes worn and will need to be replaced to prevent excessive leaking from the compression cylinder. The control options reviewed for reducing emissions from reciprocating compressors include control techniques that limit the leaking of natural gas past the piston rod packing. This includes replacement of the compressor rod packing, replacement of the piston rod, and the refitting or realignment of the piston rod.

Emissions from centrifugal compressors depend on the type of seal used: either “wet”, which use oil circulated at high pressure, or “dry”, which use a thin gap of high pressure gas. The use of dry gas seals substantially reduces emissions. In addition, they significantly reduce operating costs and enhance compressor efficiency. Limiting or reducing the emission from the rotating shaft of a centrifugal compressor using a mechanical dry seal system was evaluated. For centrifugal compressors equipped with wet seals, a flare was evaluated as an option for reducing emissions from centrifugal compressors.

3.4 Engineering Cost Analysis

In this section, we provide an overview of the engineering cost analysis used to estimate the additional private expenditures industry may make to comply with the NSPS. A detailed discussion of the methodology used to estimate cost impacts is presented in the TSD.

The following sections describe each step in the engineering cost analysis. First, representative facilities are established for each source category, including baseline emissions and control options. Second, the number of incrementally affected facilities for each type of equipment or facility are projected. National emissions reductions and cost estimates are calculated by multiplying representative factors, from the first step, by the estimated number of affected facilities in each projection year, from the second step. In addition to emissions reductions, some control options result in natural gas recovery, which can then be combusted for useful processes or sold. The national cost estimates include estimated revenue from product recovery where applicable.

3.4.1 Regulatory Options

For each emissions source, point, and control option, the TSD develops a representative facility. The characteristics of this facility include typical equipment, operating characteristics, and representative factors including baseline emissions and the costs, emissions reductions, and product recovery resulting from each control option. In this RIA, we examine three broad regulatory options. Table 3-1 shows the emissions sources, points, and controls for the three NSPS regulatory options analyzed in this RIA, which we term Option 1, Option 2, and Option 3. Option 2 was selected for promulgation.

Table 3-1 Emissions Sources and Controls Evaluated for the NSPS

| Emissions Point | Emissions Control | Option 1 | Option 2 (final) | Option 3 |
|---|--------------------------------------|-------------------|-----------------------------|------------------|
| Well Completions and Recompletions | | | | |
| Hydraulically Fractured Development Oil Wells | REC / Combustion | X | X | X |
| Hydraulically Fractured Wildcat and Delineation Oil Wells | Combustion | X | X | X |
| Fugitive Emissions | | | | |
| Well Sites | Planning, Monitoring and Maintenance | Annual | Semiannual | Quarterly |
| Gathering and Boosting Stations | Planning, Monitoring and Maintenance | Semiannual | Quarterly | Quarterly |
| Transmission Compressor Stations | Monitoring and Maintenance | Semiannual | Quarterly | Quarterly |
| Pneumatic Pumps | | | | |
| Well Sites | Route to control | X | X | X |
| Pneumatic Controllers | | | | |
| Natural Gas Transmission and Storage | Emissions limit | X | X | X |
| Reciprocating Compressors | | | | |
| Natural Gas Transmission and Storage | Maintenance | X | X | X |
| Centrifugal Compressors | | | | |
| Natural Gas Transmission and Storage | Route to control | X | X | X |

The selected Option 2 contains reduced emission completion (REC) and completion combustion requirements for a subset of newly completed oil wells that are hydraulically fractured or refractured. Option 2 requires fugitive emissions survey and repair programs be semiannually (twice per year) at the affected newly drilled or refractured oil and natural gas well sites, and quarterly at new or modified gathering and boosting stations and new or modified transmission and storage compressor stations. Option 2 also requires reductions from centrifugal compressors, reciprocating compressors, and pneumatic controllers throughout the oil and natural gas source category.

The unselected Options 1 and 3 differ from the selected Option 2 with respect to the requirements for fugitive emissions. Option 1 requires fugitive emissions survey and repair

programs be performed annually at the affected newly drilled or refractured oil and natural gas well sites, and semiannually at new or modified gathering and boosting stations and new or modified transmission and storage compressor stations. Fewer surveys being performed leads to lower costs and emissions reductions than under the selected Option 2. Finally, the more stringent Option 3 requires quarterly monitoring for all sites under the fugitive emissions program. More frequent surveys result in higher costs and higher emissions reductions than Option 2.

3.4.2 Projection of Incrementally Affected Facilities

The second step in estimating national costs and emissions impacts of the final rule is projecting the number of incrementally affected facilities. Incrementally affected facilities are facilities that would be expected to change their emissions control activities as a result of the NSPS. Facilities in states with similar state-level requirements and facilities with only recordkeeping requirements are not included within incrementally affected facilities.

The years of analysis are 2020, to represent the near-term impacts of the rule, and 2025, to represent impacts of the rule over a longer period. Therefore, the emissions reductions, benefits, and costs by 2020 and 2025 (i.e., including all emissions reductions, costs, and benefits in all years from 2016 to 2025) would be potentially significantly greater than the estimated emissions reductions, benefits, and costs provided within this rule. Affected facilities are facilities that are new or modified since the proposal in September 2015. In 2020, affected facilities are those that are newly established or modified in 2020, as well as those that have accumulated between 2016 and 2019. Over time, more facilities are newly established or modified in each year, and to the extent the facilities remain in operation in future years, the total number of facilities subject to the NSPS accumulates. In 2025, affected facilities include facilities newly established or modified in 2025, and also facilities which were newly established or modified from 2016 through 2024 and are still operating in 2025. The analysis has assumed that all new equipment and facilities established from 2016 through 2024 are still in operation in 2025. This approach differs from the way affected facilities were estimated in the proposal RIA. At proposal, 2020 was assumed to represent a single year of potential impacts, and 2025 included newly established or modified facilities from 2020 through 2024. This methodological

change results in a higher estimate of the number of affected facilities than at proposal and better represents the impacts of the rule.

The EPA has projected affected facilities using a combination of historical data from the U.S. GHG Inventory, and projected activity levels taken from the Energy Information Administration (EIA) Annual Energy Outlook (AEO). The EPA derived typical counts for new compressors, pneumatic controllers, and pneumatic pumps by averaging the year-to-year changes over the past ten years in the GHG Inventory. New and modified hydraulically fractured oil well completions and wellsites are based on projections and growth rates consistent with the drilling activity in the Annual Energy Outlook. For the final RIA, the projections have been updated to reflect the projections in the 2015 Annual Energy Outlook. In addition, while the projections used in the proposal RIA were based on the long-term growth trajectory from 2012 to 2025, the current analysis is based on the full times series in the 2015 AEO reference scenario.

The 2015 Annual Energy Outlook was the most recent projection available at the time the analysis underlying this RIA was being prepared. The 2015 AEO includes the growth in U.S. crude oil production over the last two years, along with the late-2014 drop in global crude oil prices, and reflects how these factors have altered the economics of the oil market. In comparison to the 2014 AEO reference case, the 2015 AEO reference case shows higher crude oil production (18 percent higher for 2025 in the 2015 AEO), slightly lower natural gas production (about 4 percent lower for 2025 in the 2015 AEO), lower Brent spot and West Texas Intermediate crude oil prices, and lower total wells drilled in the lower 48 states (about 20 percent lower for 2025 in the 2015 AEO).

While it is desirable to analyze impacts beyond 2025 in this RIA, the EPA has chosen not to largely because of the limited information available on the turnover rate of emissions sources and controls. For this RIA, we have used the U.S. EIA's National Energy Modelling System (NEMS) to generate a limited set of future year projections to inform impact estimates for subset of affected sources. We also used the model to estimate key market impacts of the rules, based upon EPA's parameterization of regulatory costs and natural gas capture in the model. While NEMS produces highly regarded projections of production and well drilling, and is useful to estimate market impacts of the NSPS, it is not a compliance model and does not directly model

affected units. In addition, in a dynamic industry like oil and natural gas, technological progress in control technology is also likely to be dynamic. These factors make it reasonable to use 2025 as the latest year of analysis as extending the analysis beyond 2025 would introduce substantial and increasing uncertainties in projected impacts of the NSPS.

We also reviewed state regulations and permitting requirements which require mitigation measures for many emission sources in the oil and natural gas sector. State regulations in Colorado and Wyoming both require RECs for hydraulically fractured oil and gas wells, and North Dakota requires combustion of completion emissions. Sources in Colorado, Wyoming, Utah, and Ohio are subject to fugitive emissions requirements. Applicable facilities in these states are not included in the estimates of incrementally affected facilities presented in the RIA, as sources in those states are already subject to similar requirements to the federal standards. This means that any additional costs and benefits incurred by facilities in these states to comply with the federal standards beyond the state requirements (e.g., to comply with the on-site separator requirement) are not reflected in this RIA. A more detailed discussion on the derivation of the baseline for this rule is presented for each emissions source in the TSD. In section 4.3.1 of the TSD, Table 4-3 provides a detailed breakout of affected oil well completions.

Table 3-2 Incrementally Affected Sources under Final NSPS, 2016 to 2025 on an Annual Basis

| Emissions Sources | Incrementally Affected Sources ¹ | | | | | | | | | |
|--|---|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| | 2016 | 2017 | 2018 | 2019 | 2020 | 2021 | 2022 | 2023 | 2024 | 2025 |
| Oil Well Completions and Recompletions | 13,000 | 13,000 | 13,000 | 13,000 | 13,000 | 13,000 | 13,000 | 13,000 | 14,000 | 14,000 |
| Fugitive Emissions | 19,000 | 19,000 | 19,000 | 19,000 | 19,000 | 19,000 | 19,000 | 20,000 | 20,000 | 21,000 |
| Pneumatic Pumps | 790 | 790 | 790 | 790 | 790 | 790 | 790 | 790 | 790 | 790 |
| Compressors | 33 | 33 | 33 | 33 | 33 | 33 | 33 | 33 | 33 | 33 |
| Pneumatic Controllers | 96 | 96 | 96 | 96 | 96 | 96 | 96 | 96 | 96 | 96 |
| Total | 32,000 | 32,000 | 33,000 | 33,000 | 33,000 | 33,000 | 33,000 | 34,000 | 35,000 | 35,000 |

¹ Incrementally affected sources includes sources that have to change their control activity as a result of the rule. The table does not include estimate counts of a) affected facilities in states with similar state-level requirements to the NSPS, b) facilities with only recordkeeping requirements, or c) replacement or modification of existing sources except in the case of oil well completions and fugitive emissions at wellsites.

Table 3-2 presents the number of affected sources for each year of analysis after generally accounting for state regulations. In addition to the caveats regarding facilities affected by state regulations described above, facilities with only recordkeeping requirements are also not

included within incrementally affected facilities (e.g., wells with low GOR are not included in the estimate of facilities affected by the oil well completion requirements).

Table 3-3 Total Number of Affected Sources for the NSPS in 2020 and 2025

| Emissions Sources | Affected Sources ¹ | |
|---|-------------------------------|---------------------|
| | 2020 | 2025 |
| Hydraulically Fractured and Re-fractured Oil Well Completions | 13,000 ³ | 14,000 ³ |
| Fugitive Emissions | 94,000 | 190,000 |
| Pneumatic Pumps | 3,900 | 7,900 |
| Compressors | 170 | 330 |
| Pneumatic Controllers | 480 | 960 |
| Total ² | 110,000 | 220,000 |

¹ In addition to newly affected sources in 2020, total affected sources in 2020 include sources that become affected in the 2016-2019 period and are assumed to be in continued operation in 2020. Similarly, affected sources in 2025 reflect sources newly constructed or modified from 2016 to 2025, assumed to still be in operation in 2025. The table does not include estimate counts of: a) affected facilities in states already regulating those sources, b) facilities with only recordkeeping requirements, or c) replacement or modification of existing sources except for oil well completions and fugitive emissions at wellsites. Estimates are rounded to two significant digits.

² Totals may not sum due to independent rounding.

³ Affected oil well completions include a mix of RECs and flaring based on subcategory and technical infeasibility criteria. Exploratory and delineation wells are required to combust emissions. Of development oil well completions, 50% are estimated to be feasible to perform a REC; the remainder would combust emissions (either because they are unable to implement a REC due to low pressure or other technical infeasibility reasons). See section 4.3.1 of the TSD for a detailed breakout of affected oil well completions

Table 3-3 presents estimates of the total number of affected sources for this final rule. Note that hydraulically fractured and re-fractured oil well completions do not grow significantly from 2020 to 2025, while other sources do. This is a result of completions being a one-time activity in a given year, while other sources are affected and remain affected as they continue to operate, thus these sources accumulate over time. The estimates for hydraulically fractured and re-fractured oil well completions and fugitive emissions at wellsites (a large fraction of the incrementally affected sources under the fugitive emissions provisions) include both new and modified sources.

The estimates for other sources are based upon projections of new sources alone, and do not include replacement or modification of existing sources. While some of these sources are unlikely to be modified, particularly pneumatic pumps and controllers, the impact estimates may be under-estimated due to the focus on new sources. In the proposal, the EPA solicited comments on these projection methods as well as solicits information that would improve our

estimate of the turnover rates or rates of modification of relevant sources, as well as the number of wells on wellsites. While the EPA received comments on the projection methods used in the proposal RIA, we did not receive comments with sufficient information to further incorporate modification and turnover in the projection methodologies. The EPA has modified its methodology for using historical inventory information to estimate new sources reflecting comments received, resulting in lower estimates of the number of new compressor stations, pumps, compressors, and pneumatic controllers constructed each year. Newly constructed affected facilities are estimated based on averaging the year-to-year changes in the past 10 years of activity data in the Greenhouse Gas Inventory for compressor stations, pneumatic pumps, compressors, and pneumatic controllers. At proposal, this was done by averaging the increasing years only. The approach was modified to average the number of newly constructed units in all years. In years when the total count of equipment decreased, there were assumed to be no newly constructed units.

3.4.3 Emissions Reductions

Table 3-4 summarizes the national emissions reductions for the evaluated NSPS emissions sources and points for 2020 and 2025. These reductions are estimated by multiplying the unit-level emissions reductions associated with each applicable control and facility type by the number of incrementally affected sources. The detailed description of emissions controls is provided in the TSD. Please note that all results have been rounded to two significant digits.

Table 3-4 Emissions Reductions for Final NSPS Option 2, 2020 and 2025

| Source/Emissions Point | Emissions Reductions, 2020 | | | |
|--|----------------------------|------------------|------------------|---|
| | Methane (short tons) | VOC (short tons) | HAP (short tons) | Methane (metric tons CO ₂ Eq.) |
| Oil Well Completions and Recompletions | 120,000 | 97,000 | 12 | 2,600,000 |
| Fugitive Emissions | 170,000 | 46,000 | 1,700 | 3,800,000 |
| Pneumatic Pumps | 13,000 | 3,600 | 140 | 290,000 |
| Compressors | 4,000 | 110 | 3 | 92,000 |
| Pneumatic Controllers | 1,300 | 37 | 1 | 30,000 |
| Total | 300,000 | 150,000 | 1,900 | 6,900,000 |
| Source/Emissions Point | Emissions Reductions, 2025 | | | |
| | Methane (short tons) | VOC (short tons) | HAP (short tons) | Methane (metric tons CO ₂ Eq.) |
| Oil Well Completions and Recompletions | 120,000 | 100,000 | 12 | 2,800,000 |
| Fugitive Emissions | 350,000 | 94,000 | 3,600 | 7,900,000 |
| Pneumatic Pumps | 26,000 | 7,200 | 270 | 590,000 |
| Compressors | 8,100 | 220 | 7 | 180,000 |
| Pneumatic Controllers | 2,700 | 74 | 2 | 61,000 |
| Total | 510,000 | 210,000 | 3,900 | 11,000,000 |

3.4.4 Product Recovery

The annualized cost estimates presented below include revenue from additional natural gas recovery. Several emission controls for the NSPS capture methane and VOC emissions that would otherwise be vented to the atmosphere. A large proportion of the averted methane emissions can be directed into natural gas production streams and sold. For the environmental controls that avert the emission of saleable natural gas, we base the estimated revenues from

averted natural gas emissions on an estimate of the amount of natural gas that would not be emitted during one year.

The controls that result in natural gas recovery are: RECs at hydraulically fractured oil wells, fugitive emissions monitoring and repair, rod packing replacement in reciprocating compressors, and the use of low-bleed pneumatic devices. The requirements for completions at exploration and delineation wells, pneumatic pumps, and centrifugal compressors do not result in natural gas recovery. In some of these cases, alternative control strategies do result in natural gas recovery, but these alternative controls were not assumed as part of this analysis. For example, alternatives to routing pneumatic pump emissions to a control device include substituting a solar or electric pump where a gas-driven pump would have otherwise been used.

Table 3-5 summarizes natural gas recovery and revenue included in annualized cost calculations. When including the additional natural gas recovery in the cost analysis, we assume that producers are paid \$4 per thousand cubic feet (Mcf) for the recovered gas at the wellhead. The EIA's 2015 Annual Energy Outlook reference case projects Henry Hub natural gas prices to be \$4.88/MMBtu in 2020 and \$5.46/MMBtu in 2025 in 2013 dollars.¹⁷ After adjusting to \$/Mcf (using the conversion of 1 MMBtu = 1.028 Mcf) in 2012 dollars (using the GDP-Implicit Price Deflator), these prices are \$4.94/Mcf in 2020 and \$5.52 in 2025. When including the additional natural gas recovery in the main cost analysis, we assume that producers are paid \$4 per thousand cubic feet (Mcf) for the recovered gas at the wellhead. The \$4/Mcf price assumed in this RIA is intended to reflect the AEO estimate but simultaneously be conservatively low and also account for markup on the natural gas between the wellhead and the Henry Hub for processing and transportation.¹⁸

Operators in the gathering and boosting, and transmission and storage parts of the industry do not typically own the natural gas they transport; rather, the operators receive payment for the transportation service they provide. As a result, the unit-level cost and emission reduction analyses supporting BSER decisions in the preamble (and presented in Volume 1 of

¹⁷ Available at: http://www.eia.gov/forecasts/aeo/tables_ref.cfm.

¹⁸ An EIA study indicated that the Henry Hub price is, on average, about 11 percent higher than the wellhead price. See <http://www.eia.gov/oiaf/analysispaper/henryhub/>.

the TSD) do not include estimates of revenue from natural gas recovery as offsets to compliance costs. From a social perspective, however, the increased financial returns from natural gas recovery accrues to entities somewhere along the natural gas supply chain and should be accounted for in the national impacts analysis. An economic argument can be made that, in the long run, no single entity is going to bear the entire burden of the compliance costs or fully receive the financial gain of the additional revenues associated with natural gas recovery. The change in economic surplus resulting from natural gas recovery is going to be spread out amongst different agents via price mechanisms. Therefore, the most simple and transparent option for allocating these revenues would be to keep the compliance costs and associated revenues together in a given source category and not add assumptions regarding the allocation of these revenues across agents. This is the approach followed in Volume 2 of the TSD, as well as in the RIA.

Table 3-5 Estimated Natural Gas Recovery (Mcf) for selected Option 2 in 2020 and 2025

| Source/Emissions Point | 2020 | | 2025 | |
|--|--------------------|-------------------|--------------------|-------------------|
| | Gas recovery (Mcf) | Value of recovery | Gas recovery (Mcf) | Value of recovery |
| Oil Well Completions and Recompletions | 5,700,000 | \$23,000,000 | 6,100,000 | \$24,000,000 |
| Fugitive Emissions | 9,800,000 | \$39,000,000 | 20,000,000 | \$80,000,000 |
| Pneumatic Pumps | 0 | \$0 | 0 | \$0 |
| Compressors | 180,000 | \$720,000 | 360,000 | \$1,400,000 |
| Pneumatic Controllers | 69,000 | \$280,000 | 140,000 | \$550,000 |
| Total | 16,000,000 | \$63,000,000 | 27,000,000 | \$110,000,000 |

As natural gas prices can increase or decrease rapidly, the estimated engineering compliance costs can vary when revenue from additional natural gas recovery is included. In addition, there is geographic variability in wellhead prices, which can also influence estimated engineering costs. For Option 2, a \$1/Mcf change in the wellhead price causes a change in estimated engineering compliance costs of about 5 percent. Section 3.5.2 further examines the sensitivity of national compliance costs to natural gas prices.

3.4.5 Engineering Compliance Costs

Table 3-6 summarizes the capital and annualized costs and revenue from product recovery for the evaluated emissions sources and points. The capital costs represent total capital cost expenditures associated with affected units in 2020 and 2025, including capital cost expenditures made prior to the analysis year. The detailed description of cost estimates is provided in TSD. To estimate total annualized engineering compliance costs, we added the annualized costs of each item without accounting for different expected lifetimes. This approach is mathematically equivalent to establishing an overall, representative project time horizon and annualizing costs after consideration of control options that would need to be replaced periodically within the given time horizon.

Table 3-6 Engineering Compliance Cost Estimates for Final NSPS Option 2 in 2020 and 2025 (millions 2012\$)

| Source/Emissions Point | Compliance Costs, 2020 | | | |
|--|----------------------------|------------------------------------|-------------------------------|---|
| | Capital Costs ¹ | Annualized Costs (without savings) | Revenue from Product Recovery | Nationwide Annualized Costs with Addl. Revenue (2012\$) |
| Oil Well Completions and Recompletions | \$150 | \$150 | \$23 | \$130 |
| Fugitive Emissions | \$77 | \$230 | \$39 | \$190 |
| Pneumatic Pumps | \$21 | \$3 | \$0 | \$3.1 |
| Compressors | \$1.4 | \$0.9 | \$0.7 | \$0.2 |
| Pneumatic Controllers | \$0.1 | \$0.0 | \$0.3 | -\$0.27 |
| Reporting and Recordkeeping | \$0 | \$6.3 | \$0 | \$6.3 |
| Total | \$250 | \$390 | \$63 | \$320 |

| Source/Emissions Point | Compliance Costs, 2025 | | | |
|--|----------------------------|------------------------------------|-------------------------------|---|
| | Capital Costs ¹ | Annualized Costs (without savings) | Revenue from Product Recovery | Nationwide Annualized Costs with Addl. Revenue (2012\$) |
| Oil Well Completions and Recompletions | \$160 | \$160 | \$24 | \$130 |
| Fugitive Emissions | \$160 | \$460 | \$80 | \$380 |
| Pneumatic Pumps | \$43 | \$6 | \$0 | \$6 |
| Compressors | \$2.9 | \$1.8 | \$1.4 | \$0.3 |
| Pneumatic Controllers | \$0.2 | \$0.0 | \$0.6 | -\$0.5 |
| Reporting and Recordkeeping | \$0.0 | \$6.3 | \$0 | \$6.3 |
| Total | \$360 | \$640 | \$110 | \$530 |

¹ Capital costs represent total capital costs associated with control of affected sources in 2020 and 2025, including expenditures made in previous years. Sums may not total due to independent rounding.

Engineering capital costs were annualized using a 7 percent interest rate. Section 3.4

provides a comparison to using a 3 percent interest rate. Different emissions control options were annualized using expected lifetimes that were determined to be most appropriate for individual options. For control options evaluated for the NSPS, the following lifetimes were used to annualize capital costs of emissions controls:

- Reduced emissions completions and combustion devices: 1 year
- Fugitive emissions monitoring program design: 8 years
- Reciprocating compressors rod packing: 3.8 – 4.4 years
- Centrifugal compressors and pneumatic pumps: 10 years
- Pneumatic controllers: 15 years

Note the large majority of capital costs are required for the completions fugitive emissions requirements. Alternative assumptions of the lifetimes of these expenditures are most likely influence estimates of total compliance costs, where alternative assumptions for compressors, pumps, and controllers would likely to have relatively small effects.

Reporting and recordkeeping costs were drawn from the information collection requirements (ICR) in this final rule that have been submitted for approval to the Office of Management and Budget (OMB) under the Paperwork Reduction Act (see Preamble for more detail). The 2020 and 2025 reporting and recordkeeping costs in this RIA are assumed to be equal to the third year cost reporting in the ICR cost estimates (\$6.3 million). These recordkeeping and recordkeeping costs are estimated for the selected Option 2 for all new and modified facilities regardless of whether they implement additional controls as a result of the NSPS. While these costs may differ across regulatory options as a result of the varying frequency of the fugitives program across the options, we do not have the information to estimate the ICR burden for the unselected Option 1 and 3. As a result, we assume all options have the same recordkeeping and reporting cost burden. Note also that reporting and recordkeeping costs are included for all affected entities, regardless of whether they are in states with regulatory requirements similar to the final NSPS.

3.4.6 Comparison of Regulatory Alternatives

Table 3-7 presents a comparison of the regulatory alternatives through each step of the emissions analysis in 2020 and 2025. The requirements between the options vary with respect to the fugitive emissions requirements. The less stringent Option 1 requires annual monitoring for well sites under the fugitive emissions program and semi-annual for compressor stations. The more stringent Option 3 requires quarterly monitoring for all sites under the fugitive emissions program. Annual, semi-annual, and quarterly fugitive emissions surveys are assumed to result in reductions in emissions of 40 percent, 60 percent and 80 percent, respectively.¹⁹ For more information on these assumptions, please see Section 4.3.2.2 of the TSD. Natural gas recovery also varies as a result of survey frequency. Variation in natural gas recovery, capital and annualized costs reflect these differences in the number of affected facilities and frequency of fugitive emissions surveys. In addition, the ratio between national compliance costs and national emissions reductions is presented using both the single pollutant and multipollutant approach.

Table 3-7 Comparison of Regulatory Alternatives

| | Regulatory Alternative | | |
|---|------------------------|---------------------|---------------|
| | Option 1 | Option 2 (final) | Option 3 |
| Impacts in 2020 | | | |
| Affected Sources | 110,000 | 110,000 | 110,000 |
| Emissions Reductions | | | |
| Methane Emissions Reduction (short tons/year) | 250,000 | 300,000 | 350,000 |
| VOC Emissions Reduction (short tons/year) | 130,000 | 150,000 | 160,000 |
| Natural Gas Recovery (Mcf) | 13,000,000 | 16,000,000 | 19,000,000 |
| Compliance Costs | | | |
| Capital Costs (2012\$) | \$240,000,000 | \$250,000,000 | \$260,000,000 |
| Annualized Costs Without Addl. Revenue (2012\$) | \$290,000,000 | \$390,000,000 | \$570,000,000 |
| Annualized Costs With Addl. Revenue (2012\$) | \$240,000,000 | \$320,000,000 | \$490,000,000 |
| Impacts in 2025 | | | |
| Affected Sources | 220,000 | 220,000 | 220,000 |
| Emissions Reductions | | | |
| Methane Emissions Reduction (short tons/year) | 390,000 | 510,000 | 610,000 |
| VOC Emissions Reduction (short tons/year) | 170,000 | 210,000 | 230,000 |

¹⁹ The EPA performed a sensitivity analysis based on the midpoints of the Method 21 emission reduction efficiency percentages, which were determined to be 55, 65, and 75 percent for annual, semiannual and quarterly monitoring, respectively. Even based on this conservative analysis, the EPA finds that the chosen monitoring frequencies are the BSER for these sources. The EPA additionally concluded that the 40, 60, and 80 percent emission reduction efficiency percentages are reasonable and accurate. See section 4.3.2.2 of the final TSD for further information.

| | | | |
|---|---------------|---------------|-----------------|
| Natural Gas Recovery (Mcf) | 20,000,000 | 27,000,000 | 33,000,000 |
| Compliance Costs | | | |
| Capital Costs (2012\$) | \$350,000,000 | \$360,000,000 | \$380,000,000 |
| Annualized Costs Without Addl. Revenue (2012\$) | \$440,000,000 | \$640,000,000 | \$1,000,000,000 |
| Annualized Costs With Addl. Revenue (2012\$) | \$360,000,000 | \$530,000,000 | \$880,000,000 |

3.5 Engineering Cost Sensitivity Analysis

This section illustrates the sensitivity of engineering cost and emissions analysis results of Option 2 to choice of discount rate and natural gas prices.

3.5.1 Compliance Costs Estimated Using 3 and 7 Percent Discount Rates

Table 3-8 shows that the choice of discount rate has minor effects on the nationwide annualized costs of the final rule.

Table 3-8 Annualized Costs using 3 and 7 Percent Discount Rates for Final NSPS Option 2 in 2020 and 2025 (millions 2012\$)

| | Nationwide Annualized Costs, 2020 | | Nationwide Annualized Costs, 2025 | |
|---|-----------------------------------|--------------|-----------------------------------|--------------|
| | 7 percent | 3 percent | 7 percent | 3 percent |
| Oil Well Completions and Re Completions | \$130 | \$130 | \$130 | \$130 |
| Fugitive Emissions | \$190 | \$190 | \$380 | \$380 |
| Pneumatic Pumps | \$3.1 | \$2.5 | \$6.1 | \$5 |
| Compressors | \$0.16 | \$0.12 | \$0.31 | \$0.24 |
| Pneumatic Controllers | -\$0.27 | -\$0.27 | -\$0.53 | -\$0.54 |
| Reporting and Recordkeeping | \$6.3 | \$6.3 | \$6.3 | \$6.3 |
| Total | \$320 | \$320 | \$530 | \$520 |

The choice of discount rate has a small effect on nationwide annualized costs. Discount rate generally affects estimates of annualized costs for controls with high capital costs relative to annual costs. The compliance costs related to oil well completions and fugitive emissions surveys occur in each year, so the interest rate has little impact on annualized costs for these sources. The annualized costs for pneumatic pumps, compressors, and pneumatic controllers are

sensitive to interest rate, but these constitute a relatively small part of the total compliance cost estimates for the rule.

3.5.2 Sensitivity of Compliance Costs to Natural Gas Prices

The annualized compliance cost estimates presented in this RIA include revenue from additional natural gas recovery, and therefore national compliance costs depend the price of natural gas. This section examines the sensitivity of national compliance costs to varying natural gas prices. When including the additional natural gas recovery in the main cost analysis, we assume that producers are paid \$4 per thousand cubic feet (Mcf) for the recovered gas at the wellhead. As discussed earlier, the \$4/Mcf price assumed in this RIA is intended to reflect the AEO estimate but simultaneously be conservatively low and also account for markup on the natural gas between the wellhead and the Henry Hub for processing and transportation.

EPA recognizes that current natural gas prices are below \$4/Mcf. In 2015, the Henry Hub Natural Gas Spot Price ranged between about \$2 and \$3 dollars per MMBtu (about \$1.94/Mcf and \$2.91/Mcf, respectively).²⁰ The models used to forecast natural gas prices in the Annual Energy Outlook are deterministic. A deterministic model does not incorporate potential stochastic influences and will therefore produces the same result for each model run using all else equal. While the Annual Energy Outlook is a commonly referenced publication that provides mid-term forecasts, the U.S. EIA also produces the Short-Term Energy Outlook (STEO), which provides confidence intervals for some energy prices over a shorter time frame based on the prices paid for financial derivatives (e.g., options) based on natural gas. To better understand the uncertainty associated with the 2020 and 2025 natural gas price assumed in this analysis, EPA reviewed the March 2016 STEO, which includes monthly forecasted natural gas prices through 2017.²¹ While the STEO analysis only extends to the end of 2017, the published

²⁰ Assuming the average heat context of natural gas is 1,028 Btu per cubic foot, 1 Mcf = 1.028 MMBtu. Based on this assumption, to convert natural gas prices denominated in MMBtu to Mcf, the \$/MMBtu is multiplied by 1/1.028 or 0.973.

²¹ U.S. Energy Information Administration (U.S. EIA). 2016. Short-Term Energy Outlook, March 8, 2016. <<http://www.eia.gov/forecasts/steo/report/natgas.cfm>> March 8, 2016.

confidence intervals for future natural gas prices can provide some basis for understanding the potential uncertainty around slightly longer-term forecasts.

In the STEO, forecasted prices are traded futures contracts. Based on this information the STEO also presents a 95% confidence interval for the price of natural gas through 2017. However, that the probability analysis uses the Henry Hub spot price, rather than the wellhead price paid to producer. The EIA analysis projects an expected December 2017 Henry Hub price of \$3.31 per MMBtu (\$3.22/Mcf) with a 95 percent confidence interval of \$1.45 to \$5.25 per MMBtu (\$1.41/Mcf to \$5.10/Mcf). While this confidence interval is not for wellhead natural gas prices, it is relevant for understating the challenges associated with precisely predicting future natural gas prices.

To analyze the sensitivity of the engineering costs of the rule to assumed natural gas prices, Table 3-12 presents nationwide annualized costs for each source category assuming natural gas prices of \$2, \$3, \$4, and \$5 per Mcf.

Table 3-9 Annualized Costs Using Natural Gas Prices from \$2 to \$5 per Mcf

| Source/Emissions Point | Nationwide Annualized Costs (million 2012\$), 2020 | | | | Nationwide Annualized Costs (million 2012\$), 2025 | | | |
|--|--|--------------|--------------|--------------|--|--------------|--------------|--------------|
| | \$2/Mcf | \$3/Mcf | \$4/Mcf | \$5/Mcf | \$2/Mcf | \$3/Mcf | \$4/Mcf | \$5/Mcf |
| Oil Well Completions and Recompletions | \$140 | \$130 | \$130 | \$120 | \$150 | \$140 | \$130 | \$130 |
| Fugitive Emissions | \$210 | \$200 | \$190 | \$180 | \$420 | \$400 | \$380 | \$360 |
| Pneumatic Pumps | \$3.1 | \$3.1 | \$3.1 | \$3.1 | \$6.1 | \$6.1 | \$6.1 | \$6.1 |
| Compressors | \$0.52 | \$0.34 | \$0.16 | -\$0.023 | \$1 | \$0.68 | \$0.31 | -\$0.046 |
| Pneumatic Controllers | -\$0.13 | -\$0.20 | -\$0.27 | -\$0.33 | -\$0.25 | -\$0.39 | -\$0.53 | -\$0.67 |
| Reporting and Recordkeeping | \$6.3 | \$6.3 | \$6.3 | \$6.3 | \$6.3 | \$6.3 | \$6.3 | \$6.3 |
| Total | \$350 | \$340 | \$320 | \$310 | \$580 | \$560 | \$530 | \$500 |

Note that all figures are rounded to two significant digits. Annualized costs are estimated using a 7 percent discount rate. Totals may not sum due to independent rounding.

For Option 2, a \$1/Mcf change in the wellhead price causes a change in estimated engineering compliance costs of about \$16 million in 2020 and \$27 million in 2025, in 2012 dollars. In percentage terms, a \$1/Mcf reduction in the wellhead price causes about a 5 percent increase in national compliance costs in either 2020 or 2025. These amounts include revenue from product recovery in all segments. As described above, this approach differs with respect to

the gathering and boosting and transmission segments between the unit-level cost and emissions reduction analysis supporting BSER decisions (which is focused on control costs borne by regulated sources) and this RIA (which is focused on societal costs). Operators in the gathering and boosting and transmission and storage segments may not own the natural gas they transport, and so may not be able to offset compliance costs with revenue from product recovery in the short term. Changes in costs are affected for the oil well completions, fugitive emissions sources, reciprocating compressors, and pneumatic controllers because control of these sources results in product recovery. Costs for pumps and centrifugal compressors are not affected because routing emissions to a control does not result in product recovery. Valued at \$4/Mcf, estimated national gas recovery as a result of the NSPS in the gathering and boosting segment would be about \$3 million in 2020 and \$6 million in 2025 and in the transmission and storage segment would be about \$2 million in 2020 and \$4 million in 2025.

3.6 Detailed Impacts Tables

The following tables show the full details of the costs and emissions reductions by emissions sources for each regulatory option in 2020 and 2025.

Table 3-10 Incrementally Affected Units, Emissions Reductions and Costs, Option 1, 2020

| Source/Emissions Point | Projected No. of Affected Units For Which Federal Regulations Require Further Action | Nationwide Emissions Reductions | | | | National Costs | |
|---|--|---------------------------------|-----------------------|-----------------------|----------------------------|----------------------|--------------------------------------|
| | | Methane (short tons/year) | VOC (short tons/year) | HAP (short tons/year) | Methane (metric tons CO2e) | Capital Costs | Annualized Costs With Addl. Revenues |
| Well Completions and Recompletions | | | | | | | |
| Hydraulically Fractured Development Oil Wells | 12,000 | 110,000 | 89,000 | 11 | 2,400,000 | \$140,000,000 | \$120,000,000 |

4 BENEFITS OF EMISSIONS REDUCTIONS

4.1 Introduction

The final NSPS is designed to prevent new emissions from the oil and gas sector. For the NSPS, we predict that there will be climate and ozone benefits from methane reductions, ozone and PM_{2.5} health benefits from VOC reductions, and HAP “co-benefits”. These co-benefits would occur because the control techniques to meet the standards simultaneously reduce methane, VOC, and HAP emissions. The NSPS is anticipated to prevent 300,000 tons of methane, 150,000 tons of VOC, and 1,900 tons of HAP from new sources in 2020. In 2025, the NSPS is estimated to prevent 510,000 tons of methane, 210,000 tons of VOC, and 3,900 tons of HAP. The CO₂-equivalent (CO₂ Eq.) methane emission reductions are estimated to be 6.9 million metric tons in 2020 and 11 million metric tons in 2025. As described in the subsequent sections, these pollutants are associated with substantial climate, health, and welfare effects. The only benefits monetized in this RIA are methane-related climate benefits. The methane-related climate effects are estimated to be \$360 million and \$690 million using a 3 percent discount rate in 2020 and 2025, respectively.²² The specific control techniques for the NSPS are anticipated to have minor emissions disbenefits (e.g., increases in emissions of carbon dioxide (CO₂), nitrogen oxides (NO_x), PM, carbon monoxide (CO), and total hydrocarbons (THC)) and emission changes associated with the energy markets impacts.

While we expect that the avoided VOC emissions will also result in improvements in air quality and reduce health and welfare effects associated with exposure to ozone, fine particulate matter (PM_{2.5}), and HAP, we have determined that quantification of the VOC-related health benefits cannot be accomplished for this rule in a defensible way. This is not to imply that these benefits do not exist; rather, it is a reflection of the difficulties in modeling the direct and indirect impacts of the reductions in emissions for this industrial sector with the data currently available. With the data available, we are not able to provide credible health benefits estimates for this rule, due to the differences in the locations of oil and natural gas emission points relative to existing information and the highly localized nature of air quality responses associated with HAP and

²² Table 4-3 presents the methane-related climate effects based on SC-CH₄ at discount rates of 2.5, 3, and 5 percent.

VOC reductions.²³ In this chapter, we provide a qualitative assessment of the health benefits associated with reducing exposure to these pollutants, as well as visibility impairment and ecosystem benefits. Table 4-1 summarizes the quantified and unquantified benefits in this analysis.

Table 4-1 Climate and Human Health Effects of Emission Reductions from this Rule

| Category | Specific Effect | Effect Has Been Quantified | Effect Has Been Monetized | More Information | |

| Strokes and cerebrovascular disease (age 50-79) | | — | — | PM ISA ³ | |
| Other cardiovascular effects (e.g., other ages) | | — | — | PM ISA ² | |
| Other respiratory effects (e.g., pulmonary function, non-asthma ER visits, non-bronchitis chronic diseases, other ages and populations) | — | — | PM ISA ² | | |

²³ Previous studies have estimated the monetized benefits-per-ton of reducing VOC emissions associated with the effect those emissions have on ambient PM_{2.5} levels and the health effects associated with PM_{2.5} exposure (Fann, Fulcher, and Hubbell, 2009). While these ranges of benefit-per-ton estimates provide useful context, the geographic distribution of VOC emissions from the oil and gas sector are not consistent with emissions modeled in Fann, Fulcher, and Hubbell (2009). In addition, the benefit-per-ton estimates for VOC emission reductions in that study are derived from total VOC emissions across all sectors. Coupled with the larger uncertainties about the relationship between VOC emissions and PM_{2.5} and the highly localized nature of air quality responses associated with VOC reductions, these factors lead us to conclude that the available VOC benefit-per-ton estimates are not appropriate to calculate monetized benefits of these rules, even as a bounding exercise.

| Category | Specific Effect | Effect Has Been Quantified | Effect Has Been Monetized | More Information |

¹ The global climate and related impacts of CO₂ and CH₄ emissions changes, such as sea level rise, are estimated within each integrated assessment model as part of the calculation of the SC-CO₂ and SC-CH₄. The resulting monetized damages, which are relevant for conducting the benefit-cost analysis, are used in this RIA to estimate the welfare effects of quantified changes in CO₂ emissions.

² We assess these benefits qualitatively because we do not have sufficient confidence in available data or methods.

³ We assess these benefits qualitatively due to data limitations for this analysis, but we have quantified them in other analyses.

⁴ We assess these benefits qualitatively because current evidence is only suggestive of causality or there are other significant concerns over the strength of the association.

4.2 Emission Reductions from the Final NSPS

As described in Section 2 of this RIA, oil and natural gas operations in the U.S. include a variety of emission points for methane, VOC, and HAP, including wells, wellsites, processing plants, compressor stations, storage equipment, and transmission and distribution lines. These emission points are located throughout much of the country with significant concentrations in particular regions. For example, wells and processing plants are largely concentrated in the South Central, Midwest, and Southern California regions of the U.S., whereas gas compression stations are located all over the country. Distribution lines to customers are frequently located within areas of high population density.

In implementing this rule, emission controls may lead to reductions in ambient PM_{2.5} and ozone below the National Ambient Air Quality Standards (NAAQS) in some areas and assist other areas with attaining the NAAQS. Due to the high degree of variability in the responsiveness of ozone and PM_{2.5} formation to VOC emission reductions, we are unable to determine how this rule might affect attainment status without air quality modeling data.²⁴ Because the NAAQS RIAs also calculate ozone and PM benefits, there are important differences worth noting in the design and analytical objectives of each RIA. The NAAQS RIAs illustrate the potential costs and benefits of attaining a new air quality standard nationwide based on an array of emission control strategies for different sources.²⁵ By contrast, the emission reductions for implementation rules, including this rule, are generally from a specific class of well-characterized sources. In general, the EPA is more confident in the magnitude and location of the emission reductions for implementation rules rather than illustrative NAAQS analyses. Emission reductions achieved under these and other promulgated rules will ultimately be reflected in the baseline of future NAAQS analyses, which would reduce the incremental costs and benefits associated with attaining future NAAQS.

²⁴ The responsiveness of ozone and PM_{2.5} formation is discussed in greater detail in sections 4.4.1 and 4.5.1 of this RIA.

²⁵ NAAQS RIAs hypothesize, but do not predict, the control strategies States may choose to enact when implementing a NAAQS. The setting of a NAAQS does not directly result in costs or benefits, and as such, the NAAQS RIAs are merely illustrative and are not intended to be added to the costs and benefits of other regulations that result in specific costs of control and emission reductions. However, some costs and benefits estimated in this RIA may account for the same air quality improvements as estimated in an illustrative NAAQS RIA.

Table 4-2 shows the direct emissions reductions anticipated for this rule, across the regulatory options examined. It is important to note that these benefits accrue at different spatial scales. HAP emission reductions reduce exposure to carcinogens and other toxic pollutants primarily near the emission source. VOC emissions are precursors to secondary formation of PM_{2.5} and ozone and reducing these emissions would reduce exposure to these secondary pollutants on a regional scale. Climate effects associated with long-lived greenhouse gases like methane generally do not depend on the location of the emission of the gas, and have global impacts. Methane is also a precursor to global background concentrations of ozone.

Table 4-2 Direct Emission Reductions across NSPS Regulatory Options in 2020 and 2025

| Pollutant | Option 1 | Option 2 (Final) | Option 3 |
|---|----------|---------------------|----------|
| | | 2020 | |
| Methane (short tons/year) | 250,000 | 300,000 | 350,000 |
| VOC (short tons/year) | 130,000 | 150,000 | 160,000 |
| HAP (short tons/year) | 1,300 | 1,900 | 2,400 |
| Methane (metric tons) | 230,000 | 280,000 | 320,000 |
| Methane (million metric tons CO ₂ Eq.) | 5.6 | 6.9 | 8.0 |
| | | 2025 | |
| Methane (short tons/year) | 390,000 | 510,000 | 610,000 |
| VOC (short tons/year) | 170,000 | 210,000 | 230,000 |
| HAP (short tons/year) | 2,700 | 3,900 | 5,000 |
| Methane (metric tons) | 360,000 | 460,000 | 550,000 |
| Methane (million metric tons CO ₂ Eq.) | 8.9 | 11 | 14 |

4.3 Methane Climate Effects and Valuation

Methane is the principal component of natural gas. Methane is also a potent greenhouse gas (GHG) that, once emitted into the atmosphere, absorbs terrestrial infrared radiation, which in turn contributes to increased global warming and continuing climate change. Methane reacts in the atmosphere to form ozone, which also impacts global temperatures. Methane, in addition to other GHG emissions, contributes to warming of the atmosphere, which over time leads to increased air and ocean temperatures, changes in precipitation patterns, melting and thawing of global glaciers and ice, increasingly severe weather events, such as hurricanes of greater intensity, and sea level rise, among other impacts.

According to the Intergovernmental Panel on Climate Change (IPCC) Fifth Assessment Report (AR5, 2013), changes in methane concentrations since 1750 contributed 0.48 W/m² of forcing, which is about 17 percent of all global forcing due to increases in anthropogenic GHG concentrations, and which makes methane the second leading long-lived climate forcer after CO₂. However, after accounting for changes in other greenhouse substances such as ozone and stratospheric water vapor due to chemical reactions of methane in the atmosphere, historical methane emissions were estimated to have contributed to 0.97 W/m² of forcing today, which is about 30 percent of the contemporaneous forcing due to historical greenhouse gas emissions.

The oil and gas category emits significant amounts of methane. The public Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2014 (to be published April 15, 2016) estimates 2014 methane emissions from Petroleum and Natural Gas Systems (not including petroleum refineries and petroleum transportation) to be 232 MMt CO₂ Eq. In 2014, total methane emissions from the oil and gas industry represented 32 percent of the total methane emissions from all sources and account for about 3 percent of all CO₂ Eq. emissions in the U.S., with the combined petroleum and natural gas systems being the largest contributor to U.S. anthropogenic methane emissions (U.S. EPA, 2016c).

Actions taken to comply with the NSPS are anticipated to significantly decrease methane emissions from the oil and natural gas sector in the United States. The final standards are expected to reduce methane emissions annually by about 6.9 million metric tons CO₂ Eq. in 2020 and by about 12 million metric tons CO₂ Eq. in 2025. It is important to note that the emission reductions are based upon predicted activities in 2020 and 2025; however, the EPA did not forecast sector-level emissions in 2020 and 2025 for this rulemaking. To give a sense of the magnitude of the reductions, the methane reductions estimated for 2020 are equivalent to about 2.8 percent of the methane emissions for this sector reported in the U.S. GHG Inventory for 2014 (about 232 million metric tons CO₂ Eq. are from petroleum and natural gas production and gas processing, transmission, and storage). Expected reductions in 2025 are equivalent to around 4.7 percent of 2014 emissions. As it is expected that emissions from this sector would increase over time, the estimates compared against the 2014 emissions would likely overestimate the percent of reductions from total emissions in 2020 and 2025.

We calculated the global social benefits of methane emissions reductions expected from the NSPS using estimates of the social cost of methane (SC-CH₄), a metric that estimates the monetary value of impacts associated with marginal changes in methane emissions in a given year. It includes a wide range of anticipated climate impacts, such as net changes in agricultural productivity and human health, property damage from increased flood risk, and changes in energy system costs, such as reduced costs for heating and increased costs for air conditioning. The SC-CH₄ estimates applied in this analysis were developed by Marten *et al.* (2014) and are discussed in greater detail below.

A similar metric, the social cost of CO₂ (SC-CO₂), provides important context for understanding the Marten *et al.* SC-CH₄ estimates. Estimates of the SC-CO₂ have been used by the EPA and other federal agencies to value the impacts of CO₂ emissions changes in benefit cost analysis for GHG-related rulemakings since 2008. The SC-CO₂ is a metric that estimates the monetary value of impacts associated with marginal changes in CO₂ emissions in a given year. Similar the SC-CH₄ includes a wide range of anticipated climate impacts, such as net changes in agricultural productivity, property damage from increased flood risk, and changes in energy system costs, such as reduced costs for heating and increased costs for air conditioning.

The SC-CO₂ estimates were developed over many years, using the best science available, and with input from the public. Specifically, an interagency working group (IWG) that included the EPA and other executive branch agencies and offices used three integrated assessment models (IAMs) to develop the SC-CO₂ estimates and recommended four global values for use in regulatory analyses. The SC-CO₂ estimates were first released in February 2010 and updated in 2013 using new versions of each IAM. The 2013 update did not revisit the 2010 modeling decisions with regards to the discount rate, reference case socioeconomic and emission scenarios, and equilibrium climate sensitivity distribution. Rather, improvements in the way damages are modeled are confined to those that have been incorporated into the latest versions of the models by the developers themselves and published in the peer-reviewed literature. The 2010 SC-CO₂ Technical Support Document (2010 SC-CO₂ TSD) provides a complete discussion of the

methods used to develop these estimates and the current SC-CO₂ TSD presents and discusses the 2013 update (including recent minor technical corrections to the estimates).²⁶

One key methodological aspect discussed in the SC-CO₂ TSDs is the global scope of the estimates. The SC-CO₂ estimates represent global measures because of the distinctive nature of the climate change, which is highly unusual in at least three respects. First, emissions of most GHGs contribute to damages around the world independent of the country in which they are emitted. The SC-CO₂ must therefore incorporate the full (global) damages caused by GHG emissions to address the global nature of the problem. Second, the U.S. operates in a global and highly interconnected economy, such that impacts on the other side of the world can affect our economy. This means that the true costs of climate change to the U.S. are larger than the direct impacts that simply occur within the U.S. Third, climate change represents a classic public goods problem because each country's reductions benefit everyone else and no country can be excluded from enjoying the benefits of other countries' reductions, even if it provides no reductions itself. In this situation, the only way to achieve an economically efficient level of emissions reductions is for countries to cooperate in providing mutually beneficial reductions beyond the level that would be justified only by their own domestic benefits. In reference to the public good nature of mitigation and its role in foreign relations, thirteen prominent academics noted that these "are compelling reasons to focus on a global SCC" (Pizer et al., 2014). In addition, the IWG recently noted that there is no bright line between domestic and global damages. Adverse impacts on other countries can have spillover effects on the United States, particularly in the areas of national security, international trade, public health and humanitarian concerns.²⁷

The 2010 SC-CO₂ TSD also noted a number of limitations to the SC-CO₂ analysis, including the incomplete way in which the IAMs capture catastrophic and non-catastrophic impacts, their incomplete treatment of adaptation and technological change, uncertainty in the extrapolation of damages to high temperatures, and assumptions regarding risk aversion. Currently IAMs do not assign value to all of the important physical, ecological, and economic

²⁶ Both the 2010 SC-CO₂ TSD and the current SC-CO₂ TSD are available at:
<<https://www.whitehouse.gov/omb/oira/social-cost-of-carbon>>

²⁷ See Response to Comments: Social Cost of Carbon For Regulatory Impact Analysis Under Executive Order 12866, July 2015, page 31, at <<https://www.whitehouse.gov/sites/default/files/omb/inforeg/scc-response-to-comments-final-july-2015.pdf>>

impacts of climate change recognized in the climate change literature due to a lack of precise information on the nature of damages and because the science incorporated into these models understandably lags behind the most recent research.²⁸ The limited amount of research linking climate impacts to economic damages makes the modeling exercise even more difficult. These individual limitations do not all work in the same direction in terms of their influence on the SC-CO₂ estimates, though taken together they suggest that the SC-CO₂ estimates are likely conservative. In particular, the IPCC Fourth Assessment Report (2007), which was the most current IPCC assessment available at the time of the IWG’s 2009-2010 review, concluded that “It is very likely that [SC-CO₂ estimates] underestimate the damage costs because they cannot include many non-quantifiable impacts.” Since then, the peer-reviewed literature has continued to support this conclusion. For example, the IPCC Fifth Assessment report (2014) observed that SC-CO₂ estimates continue to omit various impacts, such as “the effects of the loss of biodiversity among pollinators and wild crops on agriculture.”²⁹ Nonetheless, these estimates and the discussion of their limitations represent the best available information about the social benefits of CO₂ reductions to inform benefit-cost analysis. The new versions of the models offer some improvements in these areas, although further work is warranted.

Accordingly, the EPA and other agencies continue to engage in research on modeling and valuation of climate impacts with the goal to improve these estimates. The EPA and other agencies also continue to consider feedback on the SC-CO₂ estimates from stakeholders through a range of channels, including public comments on Agency rulemakings that use the SC-CO₂ in supporting analyses and through regular interactions with stakeholders and research analysts implementing the SC-CO₂ methodology used by the IWG. In addition, OMB sought public

²⁸ Climate change impacts and social cost of greenhouse gases modeling is an area of active research. For example, see: (1) Howard, Peter, “Omitted Damages: What’s Missing from the Social Cost of Carbon.” March 13, 2014, http://costofcarbon.org/files/Omitted_Damages_Whats_Missing_From_the_Social_Cost_of_Carbon.pdf; and (2) Electric Power Research Institute, “Understanding the Social Cost of carbon: A Technical Assessment,” October 2014, www.epri.com.

comment on the approach used to develop the SC-CO₂ estimates through a separate comment period and published a response to those comments in 2015.³⁰

After careful evaluation of the full range of comments submitted to OMB, the IWG continues to recommend the use of the SC-CO₂ estimates in regulatory impact analysis. With the release of the response to comments, the IWG announced plans in July 2015 to obtain expert independent advice from the National Academies of Sciences, Engineering and Medicine to ensure that the SC-CO₂ estimates continue to reflect the best available scientific and economic information on climate change.³¹ The Academies then convened a committee, “Assessing Approaches to Updating the Social Cost of Carbon,” (Committee) that is reviewing the state of the science on estimating the SC-CO₂, and will provide expert, independent advice on the merits of different technical approaches for modeling and highlight research priorities going forward. While the Committee’s review focuses on the SC-CO₂ methodology, recommendations on how to update many of the underlying modeling assumptions will also likely pertain to the SC-CH₄ estimates. EPA will evaluate its approach based upon any feedback received from the Academies’ panel.

To date, the Committee has released an interim report, which recommended against doing a near term update of the SC-CO₂ estimates. For future revisions, the Committee recommended the IWG move efforts towards a broader update of the climate system module consistent with the most recent, best available science, and also offered recommendations for how to enhance the discussion and presentation of uncertainty in the SC-CO₂ estimates. Specifically, the Committee recommended that “the IWG provide guidance in their technical support documents about how [SC-CO₂] uncertainty should be represented and discussed in individual regulatory impact analyses that use the [SC-CO₂]” and that the technical support document for each update of the estimates present a section discussing the uncertainty in the overall approach, in the models used, and uncertainty that may not be included in the estimates.³² At the time of this writing, the IWG

is reviewing the interim report and considering the recommendations. EPA looks forward to working with the IWG to respond to the recommendations and will continue to follow IWG guidance on SC-CO₂.

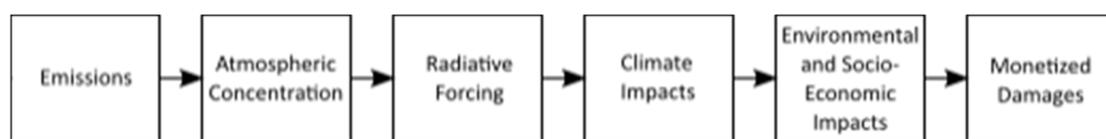

The four SC-CO₂ estimates are: \$13, \$45, \$67, and \$130 per metric ton of CO₂ emissions in the year 2020 (2012 dollars).³³ The first three values are based on the average SC-CO₂ from the three IAMs, at discount rates of 5, 3, and 2.5 percent, respectively. Estimates of the SC-CO₂ for several discount rates are included because the literature shows that the SC-CO₂ is sensitive to assumptions about the discount rate, and because no consensus exists on the appropriate rate to use in an intergenerational context (where costs and benefits are incurred by different generations). The fourth value is the 95th percentile of the SC-CO₂ across all three models at a 3 percent discount rate. It is included to represent lower probability but higher -impact outcomes from climate change, which are captured further out in the tail of the SC-CO₂ distribution, and while less likely than those reflected by the average SC-CO₂ estimates, would be much more harmful to society and therefore, are relevant to policy makers. The SC-CO₂ increases over time because future emissions are expected to produce larger incremental damages as economies grow and physical and economic systems become more stressed in response to greater climate change.

A challenge particularly relevant to this analysis is that the IWG did not estimate the social costs of non-CO₂ GHG emissions at the time the SC-CO₂ estimates were developed. One alternative approach to value methane impacts is to use the global warming potential (GWP) to convert the emissions to CO₂ equivalents which are then valued using the SC-CO₂ estimates.

The GWP measures the cumulative radiative forcing from a perturbation of a non-CO₂ GHG relative to a perturbation of CO₂ over a fixed time horizon, often 100 years. The GWP mainly reflects differences in the radiative efficiency of gases and differences in their atmospheric lifetimes. While the GWP is a simple, transparent, and well-established metric for

³³ The current version of the SC-CO₂ TSD is available at: <<https://www.whitehouse.gov/sites/default/files/omb/inforeg/scc-td-final-july-2015.pdf>>. The TSDs present SC-CO₂ in \$2007. The estimates were adjusted to 2012\$ using the GDP Implicit Price Deflator (1.0804). Also available at: <http://www.bea.gov/iTable/index_nipa.cfm>. The SC-CO₂ values have been rounded to two significant digits. Unrounded numbers from the 2013 SCC TSD were adjusted to 2012\$ and used to calculate the CO₂ benefits.

assessing the relative impacts of non-CO₂ emissions compared to CO₂ on a purely physical basis, there are several well-documented limitations in using it to value non-CO₂ GHG benefits, as discussed in the 2010 SC-CO₂ TSD and previous rulemakings (e.g., U.S. EPA 2012b, 2012d).³⁴ In particular, several recent studies found that GWP-weighted benefit estimates for methane are likely to be lower than the estimates derived using directly modeled social cost estimates for these gases (Marten and Newbold, 2012; Marten et al. 2014; and Waldhoff et al. 2014). Gas comparison metrics, such as the GWP, are designed to measure the impact of non-CO₂ GHG emissions relative to CO₂ at a specific point along the pathway from emissions to monetized damages (depicted in Figure 4-1), and this point may differ across measures.

Source: Marten *et al.* 2014

Figure 4-1 Path from GHG Emissions to Monetized Damages

The GWP is not ideally suited for use in benefit-cost analyses to approximate the social cost of non-CO₂ GHGs because it ignores important nonlinear relationships beyond radiative forcing in the chain between emissions and damages. These can become relevant because gases have different lifetimes and the SC-CO₂ takes into account the fact that marginal damages from an increase in temperature are a function of existing temperature levels. Another limitation of gas comparison metrics for this purpose is that some environmental and socioeconomic impacts are not linked to all of the gases under consideration, or radiative forcing for that matter, and will therefore be incorrectly allocated. For example, the economic impacts associated with increased agricultural productivity due to higher atmospheric CO₂ concentrations included in the SC-CO₂ would be incorrectly allocated to methane emissions with the GWP-based valuation approach.

Also of concern is the fact that the assumptions made in estimating the GWP are not consistent with the assumptions underlying SC-CO₂ estimates in general, and the SC-CO₂ estimates developed by the IWG more specifically. For example, the 100-year time horizon usually used in estimating the GWP is less than the approximately 300-year horizon the IWG

³⁴ See also Reilly and Richards, 1993; Schmalensee, 1993; Fankhauser, 1994; Marten and Newbold, 2012.

used in developing the SC-CO₂ estimates. The GWP approach also treats all impacts within the time horizon equally, independent of the time at which they occur. This is inconsistent with the role of discounting in economic analysis, which accounts for a basic preference for earlier over later gains in utility and expectations regarding future levels of economic growth. In the case of methane, which has a relatively short lifetime compared to CO₂, the temporal independence of the GWP could lead the GWP approach to underestimate the SC-CH₄ with a larger downward bias under higher discount rates (Marten and Newbold, 2012).³⁵

The EPA sought public comments on the valuation of non-CO₂ GHG impacts in previous rulemakings (e.g., U.S. EPA 2012b, 2012d). In general, the commenters strongly encouraged the EPA to incorporate the monetized value of non-CO₂ GHG impacts into the benefit cost analysis, however they noted the challenges associated with the GWP-approach, as discussed above, and encouraged the use of directly-modeled estimates of the SC-CH₄ to overcome those challenges.

The EPA had cited several researchers that had directly estimated the social cost of non-CO₂ emissions using IAMs but noted that the number of such estimates was small compared to the large number of SC-CO₂ estimates available in the literature. The EPA found considerable variation among these published estimates in terms of the models and input assumptions they employ (U.S. EPA, 2012d)³⁶. These studies differed in the emissions perturbation year, employed a wide range of constant and variable discount rate specifications, and considered a range of baseline socioeconomic and emissions scenarios that have been developed over the last 20 years. Furthermore, at the time, none of the other published estimates of the social cost of non-CO₂ GHG were consistent with the SC-CO₂ estimates developed by the IWG, and most were likely underestimates due to changes in the underlying science since their publication.

Therefore, the EPA concluded in those rulemaking analyses that the GWP approach would serve as an interim method of analysis until directly modeled social cost estimates for non-CO₂ GHGs, consistent with the SC-CO₂ estimates developed by the IWG, were developed.

³⁵ We note that the truncation of the time period in the GWP calculation could lead to an overestimate of SC-CH₄ for near term perturbation years when the SC-CO₂ is based on a sufficiently low or steeply declining discount rate.

³⁶ The researchers cited U.S. EPA 2012d include: Fankhauser (1994); Kandlikar (1995); Hammitt et al. (1996); Tol et al. (2003); Tol (2004); and Hope and Newberry (2006).

The EPA presented GWP-weighted estimates in sensitivity analyses rather than the main benefit-cost analyses.³⁷

Since then, a paper by Marten *et al.* (2014) provided the first set of published SC-CH₄ estimates in the peer-reviewed literature that are consistent with the modeling assumptions underlying the SC-CO₂ estimates.³⁸ Specifically, the estimation approach Marten *et al.* used incorporated the same set of three IAMs, five socioeconomic and emissions scenarios, equilibrium climate sensitivity distribution, three constant discount rates, and aggregation approach used by the IWG to develop the SC-CO₂ estimates. The aggregation method involved distilling the 45 distributions of the SC-CH₄ produced for each emissions year into four estimates: the mean across all models and scenarios using a 2.5 percent, 3 percent, and 5 percent discount rate, and the 95th percentile of the pooled estimates from all models and scenarios using a 3 percent discount rate. Marten *et al.* also used the same rationale as the IWG to develop global estimates of the SC-CH₄, given that methane is a global pollutant.

In addition, the atmospheric lifetime and radiative efficacy of methane used by Marten *et al.* is based on the estimates reported by the IPCC in their Fourth Assessment Report (AR4, 2007), including an adjustment in the radiative efficacy of methane to account for its role as a precursor for tropospheric ozone and stratospheric water. These values represent the same ones used by the IPCC in AR4 for calculating GWPs. At the time Marten *et al.* developed their estimates of the SC-CH₄, AR4 was the latest assessment report by the IPCC. The IPCC updates GWP estimates with each new assessment, and in the most recent assessment, AR5, the latest estimate of the methane GWP ranged from 28-36, compared to a GWP of 25 in AR4. The updated values reflect a number of changes: changes in the lifetime and radiative efficiency estimates for CO₂, changes in the lifetime estimate for methane, and changes in the correction

³⁷ For example, the 2012 New Source Performance Standards and Amendments to the National Emissions Standards for Hazardous Air Pollutants for the Oil and Natural Gas Industry are expected to reduce methane emissions by 900,000 metric tons annually, see <<http://www.gpo.gov/fdsys/pkg/FR-2012-08-16/pdf/2012-16806.pdf>>. Additionally, the 2017-2025 Light-duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, promulgated jointly with the National Highway Traffic Safety Administration, is expected to reduce methane emissions by over 100,000 metric tons in 2025 increasing to nearly 500,000 metric tons in 2050, see <<http://www.gpo.gov/fdsys/pkg/FR-2012-10-15/pdf/2012-21972.pdf>>.

³⁸ Marten *et al.* (2014) also provided the first set of SC-N₂O estimates that are consistent with the assumptions underlying the SC-CO₂ estimates.

factor applied to methane's GWP to reflect the effect of methane emissions on other climatically important substances such as tropospheric ozone and stratospheric water vapor. In addition, the range presented in the latest IPCC report reflects different choices regarding whether to account for climate feedbacks on the carbon cycle for both methane and CO₂ (rather than just for CO₂ as was done in AR4).^{39,40}

Marten *et al.* (2014) discuss these estimates, (SC-CH₄ estimates presented below in Table 4-3), and compare them with other recent estimates in the literature.⁴¹ The authors noted that a direct comparison of their estimates with all of the other published estimates is difficult, given the differences in the models and socioeconomic and emissions scenarios, but results from three relatively recent studies offer a better basis for comparison (see Hope (2006), Marten and Newbold (2012), Waldhoff *et al.* (2014)). Marten *et al.* found that, in general, the SC-CH₄ estimates from their 2014 paper are higher than previous estimates. The higher SC-CH₄ estimates are partially driven by the higher effective radiative forcing due to the inclusion of indirect effects from methane emissions in their modeling. Marten *et al.*, similar to other recent studies, also find that their directly modeled SC-CH₄ estimates are higher than the GWP-weighted estimates. More detailed discussion of the SC-CH₄ estimation methodology, results and a comparison to other published estimates can be found in Marten *et al.*

³⁹ *Climate Change 2013: The Physical Science Basis. Contribution of Working Group I to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change* [Stocker, T.F., D. Qin, G.-K. Plattner, M. Tignor, S.K. Allen, J. Boschung, A. Nauels, Y. Xia, V. Bex and P.M. Midgley (eds.)]. Cambridge University Press, Cambridge, United Kingdom and New York, NY, USA.

⁴⁰ Note that this analysis uses a GWP value for methane of 25 for CO₂ equivalency calculations, consistent with the GHG emissions inventories and the IPCC Fourth Assessment Report (AR4).

⁴¹ Marten *et al.* (2014) estimates are presented in 2007 dollars. These estimates were adjusted for inflation using National Income and Product Accounts Tables, Table 1.1.9, Implicit Price Deflators for Gross Domestic Product (US Department of Commerce, Bureau of Economic Analysis), <http://www.bea.gov/iTable/index_nipa.cfm> (1.0804) Accessed 3/3/15.

**Table 4-3 Social Cost of Methane (SC-CH₄), 2012 – 2050^a [in 2012\$ per metric ton]
(Source: Marten *et al.*, 2014^b)**

| Year | SC-CH ₄ | | | |
|------|--------------------|-------------------|---------------------|---------------------------|
| | 5 Percent Average | 3 Percent Average | 2.5 Percent Average | 3 Percent 95th percentile |
| 2012 | \$430 | \$1,000 | \$1,400 | \$2,800 |
| 2015 | \$490 | \$1,100 | \$1,500 | \$3,000 |
| 2020 | \$580 | \$1,300 | \$1,700 | \$3,500 |
| 2025 | \$700 | \$1,500 | \$1,900 | \$4,000 |
| 2030 | \$820 | \$1,700 | \$2,200 | \$4,500 |
| 2035 | \$970 | \$1,900 | \$2,500 | \$5,300 |
| 2040 | \$1,100 | \$2,200 | \$2,800 | \$5,900 |
| 2045 | \$1,300 | \$2,500 | \$3,000 | \$6,600 |
| 2050 | \$1,400 | \$2,700 | \$3,300 | \$7,200 |

^a The values are emissions-year specific and are defined in real terms, i.e., adjusted for inflation using the GDP implicit price deflator.

^b The estimates in this table have been adjusted to reflect the minor technical corrections to the SC-CO₂ estimates described above. See Corrigendum to Marten *et al.* (2014) for more details
<<http://www.tandfonline.com/doi/abs/10.1080/14693062.2015.1070550>>.

The application of directly modeled estimates from Marten *et al.* (2014) to benefit-cost analysis of a regulatory action is analogous to the use of the SC-CO₂ estimates. Specifically, the SC-CH₄ estimates in Table 4-3 are used to monetize the benefits of reductions in methane emissions expected as a result of the rulemaking. Forecasted changes in methane emissions in a given year, expected as a result of the regulatory action, are multiplied by the SC-CH₄ estimate for that year. To obtain a present value estimate, the monetized stream of future non-CO₂ benefits are discounted back to the analysis year using the same discount rate used to estimate the social cost of the non-CO₂ GHG emission changes. In addition, the limitations for the SC-CO₂ estimates discussed above likewise apply to the SC-CH₄ estimates, given the consistency in the methodology.

In early 2015, the EPA conducted a peer review of the application of the Marten *et al.* (2014) non-CO₂ social cost estimates in regulatory analysis and received responses that supported this application.⁴² Three reviewers considered seven charge questions that covered

⁴² For a copy of the peer review responses, see Docket ID EPA-HQ-OAR-2010-0505-5016. Also available at <https://cfpub.epa.gov/si/si_public_pra_view.cfm?dirEntryID=291976> (see “SCCH4 EPA PEER REVIEW FILES.PDF”).

issues such as the EPA's interpretation of the Marten *et al.* estimates, the consistency of the estimates with the SC-CO₂ estimates, the EPA's characterization of the limits of the GWP-approach to value non-CO₂ GHG impacts, and the appropriateness of using the Marten *et al.* estimates in regulatory impact analyses. The reviewers agreed with the EPA's interpretation of Marten *et al.*'s estimates, generally found the estimates to be consistent with the SC-CO₂ estimates, and concurred with the limitations of the GWP approach, finding directly modeled estimates to be more appropriate. While outside of the scope of the review, the reviewers briefly considered the limitations in the SC-CO₂ methodology (e.g., those discussed earlier in this section) and noted that because the SC-CO₂ and SC-CH₄ methodologies are similar, the limitations also apply to the resulting SC-CH₄ estimates. Two of the reviewers concluded that use of the SC-CH₄ estimates developed by Marten *et al.* and published in the peer-reviewed literature is appropriate in RIAs, provided that the Agency discuss the limitations, similar to the discussion provided for SC-CO₂ and other economic analyses. All three reviewers encouraged continued improvements in the SC-CO₂ estimates and suggested that as those improvements are realized they should also be reflected in the SC-CH₄ estimates, with one reviewer suggesting the SC-CH₄ estimates lag this process. The EPA supports continued improvement in the SC-CO₂ estimates developed by the U.S. government and agrees that improvements in the SC-CO₂ estimates should also be reflected in the SC-CH₄ estimates. The fact that the reviewers agree that the SC-CH₄ estimates are generally consistent with the SC-CO₂ estimates that are recommended by OMB's guidance on valuing CO₂ emissions reductions, leads the EPA to conclude that use of the SC-CH₄ estimates is an analytical improvement over excluding methane emissions from the monetized portion of the benefit cost analysis.

The EPA also carefully considered the full range of public comments and associated technical issues on the Marten *et al.* SC-CH₄ estimates received through this rulemaking and determined that it would continue to use the estimates in the final rulemaking analysis. Based on the evaluation of the public comments on this rulemaking, the favorable peer review of the Marten *et al.* application, and past comments urging the EPA to value non-CO₂ GHG impacts in its rulemakings, the EPA concluded that the estimates represent the best scientific information on the impacts of climate change available in a form appropriate for incorporating the damages from incremental methane emissions changes into regulatory analysis. The Agency has valued the methane benefits expected from this rulemaking using the Marten *et al.* (2014) SC-CH₄ estimates

and has included those benefits in the main benefits analysis. Please see the Response to Comments document, section XIII-H-4, for EPA’s detailed responses to the comments on methane valuation.

The estimated methane benefits are presented in Table 4-4 below for years 2020 and 2025 across regulatory options. Applying this approach to the methane reductions estimated for the final NSPS option (Option 2), the 2020 methane benefits vary by discount rate and range from about \$160 million to approximately \$950 million; the mean SC-CH₄ at the 3 percent discount rate results in an estimate of about \$360 million in 2020. The methane benefits increase for Option 2 in 2025 and likewise vary by discount rate, ranging from about \$320 million to approximately \$1.8 billion in that year; the mean SC-CH₄ at the 3-percent discount rate results in an estimate of about \$690 million in 2025.

Table 4-4 Estimated Global Benefits of Methane Reductions* (in millions, 2012\$)

| Discount rate and statistic | Option 1 | | Option 2 (final) | | Option 3 | |
|--|----------|---------|------------------|---------|----------|---------|
| | 2020 | 2025 | 2020 | 2025 | 2020 | 2025 |
| Million metric tonnes of methane reduced | 0.23 | 0.36 | 0.28 | 0.46 | 0.32 | 0.55 |
| Million metric tonnes of CO ₂ Eq. | 5.6 | 8.9 | 6.9 | 11 | 8.0 | 14 |
| 5% (average) | \$130 | \$250 | \$160 | \$320 | \$190 | \$390 |
| 3% (average) | \$290 | \$540 | \$360 | \$690 | \$420 | \$840 |
| 2.5% (average) | \$390 | \$690 | \$480 | \$890 | \$560 | \$1,100 |
| 3% (95 th percentile) | \$780 | \$1,400 | \$950 | \$1,800 | \$1,100 | \$2,200 |

*The SC-CH₄ values are dollar-year and emissions-year specific. SC-CH₄ values represent only a partial accounting of climate impacts.

The vast majority of this rule’s climate-related benefits are associated with methane reductions, but some climate-related impacts are expected from the rule’s secondary air impacts. The secondary impacts are discussed in Section 4.7.

Methane is also a precursor to ozone. In remote areas, methane is a dominant precursor to tropospheric ozone formation (U.S. EPA, 2013). Approximately 40 percent of the global annual mean ozone increase since preindustrial times is believed to be due to anthropogenic methane (HTAP, 2010). Projections of future emissions also indicate that methane is likely to be a key contributor to ozone concentrations in the future (HTAP, 2010). Unlike NO_x and VOCs, which affect ozone concentrations regionally and at time scales of hours to days, methane emissions

affect ozone concentrations globally and on decadal time scales given methane's relatively long atmospheric lifetime (HTAP, 2010). Reducing methane emissions, therefore, can reduce global background ozone concentrations, human exposure to ozone, and the incidence of ozone-related health effects (West *et al.*, 2006, Anenberg *et al.*, 2009). These benefits are global and occur in both urban and rural areas. Reductions in background ozone concentrations can also have benefits for agriculture and ecosystems (UNEP/WMO, 2011). Studies show that controlling methane emissions can reduce global ozone concentrations and climate change simultaneously. But, controlling other shorter-lived ozone precursors such as NO_x, carbon monoxide, or non-methane VOCs have larger local health benefits from greater reductions in local ozone concentrations (West and Fiore, 2005; West *et al.*, 2006; Fiore *et al.*, 2008; Dentener *et al.*, 2005; Shindell *et al.*, 2005, 2012; UNEP/WMO, 2011). The health, welfare, and climate effects associated with ozone are described in the preceding sections.

A paper was published in the peer-reviewed scientific literature that presented a range of estimates of the monetized ozone-related mortality benefits of reducing methane emissions (Sarofim *et al.* 2015). For example, under their base case assumptions using a 3% discount rate, Sarofim *et al.* find global ozone-related mortality benefits of methane emissions reductions to be \$790 per tonne of methane in 2020, with 10.6%, or \$80, of this amount resulting from mortality reductions in the United States. The methodology used in this study is consistent in some (but not all) aspects with the modeling underlying the SC-CO₂ and SC-CH₄ estimates discussed above, and required a number of additional assumptions such as baseline mortality rates and mortality response to ozone concentrations. The proposal requested comment on the application of the Sarofim *et al.* (2015) for this benefits analysis as an approach to estimating the ozone related mortality benefits resulting from the methane reductions expected from this rulemaking. Some commenters objected to the inclusion of these benefits because they argue that methane is not a VOC, whereas one commenter agreed that there is a connection between methane emissions, higher ozone levels, and therefore human mortality. While the EPA does consider the methane impacts on ozone to be important, there remain unresolved questions regarding several methodological choices involved in applying the Sarofim *et al.* (2015) approach in the context of an EPA benefits analysis, and therefore the EPA is not including a quantitative analysis of this effect in this rule at this time.

4.4 VOC as a PM_{2.5} Precursor

This rulemaking would reduce emissions of VOC, which are a precursor to PM_{2.5}. Most VOC emitted are oxidized to CO₂ rather than to PM, but a portion of VOC emission contributes to ambient PM_{2.5} levels as organic carbon aerosols (U.S. EPA, 2009a). Therefore, reducing these emissions would reduce PM_{2.5} formation, human exposure to PM_{2.5}, and the incidence of PM_{2.5}-related health effects. However, we have not quantified the PM_{2.5}-related benefits in this analysis. Analysis of organic carbon measurements suggest only a fraction of secondarily formed organic carbon aerosols are of anthropogenic origin. The current state of the science of secondary organic carbon aerosol formation indicates that anthropogenic VOC contribution to secondary organic carbon aerosol is often lower than the biogenic (natural) contribution. Given that a fraction of secondarily formed organic carbon aerosols is from anthropogenic VOC emissions and the extremely small amount of VOC emissions from this sector relative to the entire VOC inventory, it is unlikely this sector has a large contribution to ambient secondary organic carbon aerosols. Photochemical models typically estimate secondary organic carbon from anthropogenic VOC emissions to be less than 0.1 µg/m³.

Due to data limitations regarding potential locations of new and modified sources affected by this rulemaking, we did not perform the air quality modeling needed to quantify PM_{2.5} benefits associated with reducing VOC emissions for this rule. Due to the high degree of variability in the responsiveness of PM_{2.5} formation to VOC emission reductions, we are unable to estimate the effect that reducing VOC will have on ambient PM_{2.5} levels without air quality modeling. However, we provide the discussion below for context regarding findings from previous modeling.

4.4.1 PM_{2.5} Health Effects and Valuation

Reducing VOC emissions would reduce PM_{2.5} formation, human exposure, and the incidence of PM_{2.5}-related health effects. Reducing exposure to PM_{2.5} is associated with significant human health benefits, including avoiding mortality and respiratory morbidity. Researchers have associated PM_{2.5}- exposure with adverse health effects in numerous toxicological, clinical and epidemiological studies (U.S. EPA, 2009a). When adequate data and resources are available, the EPA generally quantifies several health effects associated with

exposure to PM_{2.5} (e.g., U.S. EPA (2011g)). These health effects include premature mortality for adults and infants; cardiovascular morbidity, such as heart attacks; respiratory morbidity, such as asthma attacks and acute and chronic bronchitis; which result in hospital and ER visits, lost work days, restricted activity days, and respiratory symptoms. Although the EPA has not quantified these effects in previous benefits analyses, the scientific literature suggests that exposure to PM_{2.5} is also associated with adverse effects on birth weight, pre-term births, pulmonary function, other cardiovascular effects, and other respiratory effects (U.S. EPA, 2009a).

When the EPA quantifies PM_{2.5}-related benefits, the agency assumes that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because the scientific evidence is not yet sufficient to allow differentiation of effect estimates by particle type (U.S. EPA, 2009a). Based on our review of the current body of scientific literature, the EPA estimates PM-related premature mortality without applying an assumed concentration threshold. This decision is supported by the data, which are quite consistent in showing effects down to the lowest measured levels of PM_{2.5} in the underlying epidemiology studies.

Fann, Fulcher, and Hubbell (2009) examined how the monetized benefit-per-ton estimates of reducing ambient PM_{2.5} varies by the location of the emission reduction, the type of source emitting the precursor, and the specific precursor controlled. This study employed a reduced form air quality model to estimate changes in ambient PM_{2.5} from reducing 12 different combinations of precursor emissions and emission sources, including reducing directly emitted carbonaceous particles, nitrogen oxides, sulfur oxides, ammonia, and VOCs for nine urban areas and nationwide. For each precursor/source combination in each location, the study authors then estimated the total monetized health benefits associated with the PM_{2.5} change and divided these benefits by the corresponding emissions changes to generate benefit-per-ton estimates. The estimates from this study can provide general context for the unquantified VOC benefits in this rulemaking. Specifically, Fann, Fulcher, and Hubbell (2009) found that the monetized benefit-per-ton of reducing VOC emissions ranged from \$560 in Seattle, WA to \$5,700 in San Joaquin, CA, with a national average of \$2,400. These estimates assume a 50 percent reduction in VOC, from the Laden *et al.* (2006) mortality function (based on the Harvard Six Cities study, a large cohort epidemiology study in the Eastern U.S., an analysis year of 2015, a 3 percent discount

rate, and 2006\$). Additional benefit-per-ton estimates are available from this dataset using alternate assumptions regarding the relationship between PM_{2.5} exposure and premature mortality from empirical studies and those supplied by experts (e.g., Pope *et al.*, 2002; Laden *et al.*, 2006; Roman *et al.*, 2008). The EPA generally presents a range of benefits estimates derived from the American Cancer Society cohort (e.g., Pope *et al.*, 2002; Krewski *et al.*, 2009) to the Harvard Six Cities cohort (e.g., Laden *et al.*, 2006; Lepuele *et al.*, 2012) because the studies are both well-designed and extensively peer reviewed. The EPA provides the benefit estimates derived from expert opinions in Roman *et al.* (2008) as a characterization of uncertainty. As shown in Table 4-5, the range of VOC benefits that reflect the range of epidemiology studies and the range of the urban areas is \$300 to \$7,500 per ton of VOC reduced (2012\$).⁴³ Since these estimates were presented in the 2012 Oil and Gas NSPS RIA (U.S. EPA, 2012b), we updated our methods to apply more recent epidemiological studies for these cohorts (i.e., Krewski *et al.*, 2009; Lepuele *et al.*, 2012) as well as additional updates to the morbidity studies and population data.⁴⁴ Because these updates would not lead to significant changes in the benefit-per-ton estimates for VOC, we have not updated them here.

While these ranges of benefit-per-ton estimates provide general context, the geographic distribution of VOC emissions from the oil and gas sector are not consistent with emissions modeled in Fann, Fulcher, and Hubbell (2009). In addition, the benefit-per-ton estimates for VOC emission reductions in that study are derived from total VOC emissions across all sectors. Coupled with the larger uncertainties about the relationship between VOC emissions and PM_{2.5}, these factors lead the EPA to conclude that the available VOC benefit per ton estimates are not appropriate to calculate monetized benefits of this rule, even as a bounding exercise.

⁴³ We also converted the estimates from Fann, Fulcher, and Hubbell (2009) to 2012\$ and applied EPA's current value of a statistical life (VSL) estimate. For more information regarding EPA's current VSL estimate, please see Section 5.6.5.1 of the RIA for the PM NAAQS RIA (U.S. EPA, 2012c). EPA continues to work to update its guidance on valuing mortality risk reductions.

⁴⁴ For more information regarding these updates, please see Section 5.3 of the RIA for the final PM NAAQS (U.S. EPA, 2012c).

* The estimates in this table provide general context regarding the potential magnitude of monetized benefits from reducing VOC emissions, but these urban areas were not chosen based on the locations of VOC emissions from the oil and gas sector. Coupled with other uncertainties, these VOC benefit-per-ton estimates are not appropriate to calculate monetized benefits of this rule. These estimates assumed a 50 percent reduction in VOC emissions, an analysis year of 2015, and a 3 percent discount rate. All estimates are rounded to two significant digits. These estimates have been adjusted from Fann, Fulcher, and Hubbell (2009) to reflect a more recent currency year and the EPA's current VSL estimate. However, these estimates have not been updated to reflect recent epidemiological studies for mortality studies, morbidity studies, or population data. Using a discount rate of 7 percent, the benefit-per-ton estimates would be approximately 9 percent lower. Assuming a 75 percent reduction in VOC emissions would increase the VOC benefit-per-ton estimates by approximately 13 percent. Assuming a 25 percent reduction in VOC emissions would decrease the VOC benefit-per-ton estimates by 13 percent. The EPA generally presents a range of benefits estimates derived from the expert functions from Roman *et al.* (2008) as a characterization of uncertainty.

4.4.2 *Organic PM Welfare Effects*

According to the previous residual risk assessment for this sector (U.S. EPA, 2012a), persistent and bioaccumulative HAP reported as emissions from oil and gas operations include polycyclic organic matter (POM). POM defines a broad class of compounds that includes polycyclic aromatic hydrocarbon compounds (PAHs). Several significant ecological effects are associated with deposition of organic particles, including persistent organic pollutants, and PAHs (U.S. EPA, 2009a). This summary is from section 6.6.1 of the 2012 PM NAAQS RIA (U.S. EPA, 2012c).

PAHs can accumulate in sediments and bioaccumulate in freshwater, flora, and fauna. The uptake of organics depends on the plant species, site of deposition, physical and chemical properties of the organic compound and prevailing environmental conditions (U.S. EPA, 2009a). PAHs can accumulate to high enough concentrations in some coastal environments to pose an environmental health threat that includes cancer in fish populations, toxicity to organisms living in the sediment and risks to those (e.g., migratory birds) that consume these organisms. Atmospheric deposition of particles is thought to be the major source of PAHs to the sediments of coastal areas of the U.S. Deposition of PM to surfaces in urban settings increases the metal and organic component of storm water runoff. This atmospherically-associated pollutant burden can then be toxic to aquatic biota. The contribution of atmospherically deposited PAHs to aquatic food webs was demonstrated in high elevation mountain lakes with no other anthropogenic contaminant sources.

The Western Airborne Contaminants Assessment Project (WACAP) is the most comprehensive database on contaminant transport and PM depositional effects on sensitive ecosystems in the Western U.S. (Landers *et al.*, 2008). In this project, the transport, fate, and ecological impacts of anthropogenic contaminants from atmospheric sources were assessed from 2002 to 2007 in seven ecosystem components (air, snow, water, sediment, lichen, conifer needles, and fish) in eight core national parks. The study concluded that bioaccumulation of semi-volatile organic compounds occurred throughout park ecosystems, an elevational gradient in PM deposition exists with greater accumulation in higher altitude areas, and contaminants accumulate in proximity to individual agriculture and industry sources, which is counter to the

original working hypothesis that most of the contaminants would originate from Eastern Europe and Asia.

4.4.3 *Visibility Effects*

Reducing secondary formation of PM_{2.5} from VOC emissions would improve visibility throughout the U.S. Fine particles with significant light-extinction efficiencies include sulfates, nitrates, organic carbon, elemental carbon, and soil (Sisler, 1996). Suspended particles and gases degrade visibility by scattering and absorbing light. Higher visibility impairment levels in the East are due to generally higher concentrations of fine particles, particularly sulfates, and higher average relative humidity levels. Visibility has direct significance to people's enjoyment of daily activities and their overall sense of wellbeing. Good visibility increases the quality of life where individuals live and work, and where they engage in recreational activities. Previous analyses (U.S. EPA, 2006b; U.S. EPA, 2011a; U.S. EPA, 2011g; U.S. EPA, 2012c) show that visibility benefits are a significant welfare benefit category. Without air quality modeling, we are unable to estimate visibility related benefits, nor are we able to determine whether VOC emission reductions would be likely to have a significant impact on visibility in urban areas or Class I areas.

4.5 VOC as an Ozone Precursor

This rulemaking would reduce emissions of VOC, which are also precursors to secondary formation of ozone. Ozone is not emitted directly into the air, but is created when its two primary components, volatile organic compounds (VOC) and oxides of nitrogen (NO_x), react in the presence of sunlight. In urban areas, compounds representing all classes of VOC are important for ozone formation, but biogenic VOC emitted from vegetation tend to be more important compounds in non-urban vegetated areas (U.S. EPA, 2013). Therefore, reducing these emissions would reduce ozone formation, human exposure to ozone, and the incidence of ozone-related health effects. However, we have not quantified the ozone-related benefits in this analysis for several reasons. First, previous rules have shown that the monetized benefits associated with reducing ozone exposure are generally smaller than PM-related benefits, even when ozone is the pollutant targeted for control (U.S. EPA, 2010a, 2014b). Second, the complex non-linear chemistry of ozone formation introduces uncertainty to the development and application of a

benefit-per-ton estimate, particularly for sectors with substantial new growth. Third, the impact of reducing VOC emissions is spatially heterogeneous depending on local air chemistry. Urban areas with a high population concentration are often VOC-limited, which means that ozone is most effectively reduced by lowering VOC. Rural areas and downwind suburban areas are often NO_x-limited, which means that ozone concentrations are most effectively reduced by lowering NO_x emissions, rather than lowering emissions of VOC. Between these areas, ozone is relatively insensitive to marginal changes in both NO_x and VOC.

Due to data limitations regarding potential locations of new and modified sources affected by this rulemaking, we did not perform air quality modeling for this rule needed to quantify the ozone benefits associated with reducing VOC emissions. Due to the high degree of variability in the responsiveness of ozone formation to VOC emission reductions and data limitations regarding the location of new and modified wellsites, we are unable to estimate the effect that reducing VOC will have on ambient ozone concentrations without air quality modeling.

4.5.1 Ozone Health Effects and Valuation

Reducing ambient ozone concentrations is associated with significant human health benefits, including mortality and respiratory morbidity (U.S. EPA, 2010a). Researchers have associated ozone exposure with adverse health effects in numerous toxicological, clinical and epidemiological studies (U.S. EPA, 2013). When adequate data and resources are available, EPA generally quantifies several health effects associated with exposure to ozone (e.g., U.S. EPA, 2010a; U.S. EPA, 2011a). These health effects include respiratory morbidity such as asthma attacks, hospital and emergency department visits, school loss days, as well as premature mortality. The scientific literature is also suggestive that exposure to ozone is also associated with chronic respiratory damage and premature aging of the lungs.

In a recent EPA analysis, EPA estimated that reducing 15,000 tons of VOC from industrial boilers resulted in \$3.6 to \$15 million (2008\$) of monetized benefits from reduced ozone exposure (U.S. EPA, 2011b).⁴⁵ After updating the currency year to 2012\$, this implies a

⁴⁵ While EPA has estimated the ozone benefits for many scenarios, most of these scenarios also reduce NO_x emissions, which make it difficult to isolate the benefits attributable to VOC reductions.

benefit-per-ton for ozone of \$260 to \$1,100 per ton of VOC reduced. Since EPA conducted the analysis of industrial boilers, EPA published the *Integrated Science Assessment for Ozone* (U.S. EPA, 2013), the *Health Risk and Exposure Assessment for Ozone* (U.S. EPA, 2014a), and the RIA for the proposed Ozone NAAQS (U.S. EPA, 2014b). Therefore, the ozone mortality studies applied in the boiler analysis, while current at that time, do not reflect the most updated literature available. The selection of ozone mortality studies used to estimate benefits in RIAs was revisited in the RIA for the proposed Ozone NAAQS. Applying the more recent studies would lead to benefit-per-ton estimates for ozone within the range shown here. While these ranges of benefit-per-ton estimates provide useful context, the geographic distribution of VOC emissions from the oil and gas sector are not consistent with emissions modeled in the boiler analysis. Therefore, we do not believe that those estimates to provide useful estimates of the monetized benefits of this rule, even as a bounding exercise.

4.5.2 Ozone Vegetation Effects

Exposure to ozone has been associated with a wide array of vegetation and ecosystem effects in the published literature (U.S. EPA, 2013). Sensitivity to ozone is highly variable across species, with over 66 vegetation species identified as “ozone-sensitive”, many of which occur in state and national parks and forests. These effects include those that damage or impair the intended use of the plant or ecosystem. Such effects are considered adverse to the public welfare and can include reduced growth and/or biomass production in sensitive trees, reduced yield and quality of crops, visible foliar injury, species composition shift, and changes in ecosystems and associated ecosystem services.

4.5.3 Ozone Climate Effects

Ozone is a well-known short-lived climate forcing greenhouse gas (GHG) (U.S. EPA, 2013). Stratospheric ozone (the upper ozone layer) is beneficial because it protects life on Earth from the sun’s harmful ultraviolet (UV) radiation. In contrast, tropospheric ozone (ozone in the lower atmosphere) is a harmful air pollutant that adversely affects human health and the environment and contributes significantly to regional and global climate change. Due to its short atmospheric lifetime, tropospheric ozone concentrations exhibit large spatial and temporal variability (U.S. EPA, 2009b). The IPCC AR5 estimated that the contribution to current warming

levels of increased tropospheric ozone concentrations resulting from human methane, NO_x, and VOC emissions was 0.5 W/m², or about 30 percent as large a warming influence as elevated CO₂ concentrations. This quantifiable influence of ground level ozone on climate leads to increases in global surface temperature and changes in hydrological cycles.

4.6 Hazardous Air Pollutant (HAP) Benefits

When looking at exposures from all air toxic sources of outdoor origin across the U.S., we see that emissions declined by approximately 60 percent since 1990. However, despite this decline, the 2011 National-Scale Air Toxics Assessment (NATA) predicts that most Americans are exposed to ambient concentrations of air toxics at levels that have the potential to cause adverse health effects (U.S. EPA, 2015).⁴⁶ The levels of air toxics to which people are exposed vary depending on where they live and work and the kinds of activities in which they engage. In order to identify and prioritize air toxics, emission source types and locations that are of greatest potential concern, the EPA conducts the NATA.⁴⁷ The most recent NATA was conducted for calendar year 2011 and was released in December 2015. NATA includes four steps:

- 1) Compiling a national emissions inventory of air toxics emissions from outdoor sources
- 2) Estimating ambient concentrations of air toxics across the U.S. utilizing dispersion models
- 3) Estimating population exposures across the U.S. utilizing exposure models
- 4) Characterizing potential public health risk due to inhalation of air toxics including both cancer and noncancer effects

Based on the 2011 NATA, the EPA estimates that less than 1 percent of census tracts nationwide have increased cancer risks greater than 100 in a million. The average national cancer risk is about 40 in a million. Nationwide, the key pollutants that contribute most to the overall

⁴⁶ The 2011 NATA is available on the Internet at <http://www.epa.gov/national-air-toxics-assessment/2011-national-air-toxics-assessment>.

⁴⁷ The NATA modeling framework has a number of limitations that prevent its use as the sole basis for setting regulatory standards. These limitations and uncertainties are discussed on the 2011 NATA website. Even so, this modeling framework is very useful in identifying air toxic pollutants and sources of greatest concern, setting regulatory priorities, and informing the decision making process. U.S. EPA. (2015) 2011 National-Scale Air Toxics Assessment. <<http://www.epa.gov/national-air-toxics-assessment/2011-national-air-toxics-assessment>>.

cancer risks are formaldehyde and benzene.^{48,49} Secondary formation (e.g., formaldehyde forming from other emitted pollutants) was the largest contributor to cancer risks, while stationary, mobile, biogenics, and background sources contribute lesser amounts to the remaining cancer risk.

Noncancer health effects can result from chronic,⁵⁰ subchronic,⁵¹ or acute⁵² inhalation exposure to air toxics, and include neurological, cardiovascular, liver, kidney, and respiratory effects as well as effects on the immune and reproductive systems. According to the 2011 NATA, about 80 percent of the U.S. population was exposed to an average chronic concentration of air toxics that has the potential for adverse noncancer respiratory health effects. Results from the 2011 NATA indicate that acrolein is the primary driver for noncancer respiratory risk.

Figure 4-2 and Figure 4-3 depict the 2011 NATA estimated census tract-level carcinogenic risk and noncancer respiratory hazard from the assessment. It is important to note that large reductions in HAP emissions may not necessarily translate into significant reductions in health risk because toxicity varies by pollutant, and exposures may or may not exceed levels of concern. For example, acetaldehyde mass emissions were more than seventeen times acrolein emissions on a national basis in the EPA's 2011 National Emissions Inventory (NEI). However, the Integrated Risk Information System (IRIS) reference concentration (RfC) for acrolein is considerably lower than that for acetaldehyde, this results in 2011 NATA estimates of nationwide chronic respiratory noncancer risks from acrolein being over three times that of

⁴⁸ Details on EPA's approach to characterization of cancer risks and uncertainties associated with the 2011 NATA risk estimates can be found at <<http://www.epa.gov/national-air-toxics-assessment/nata-limitations>>.

⁴⁹ Details about the overall confidence of certainty ranking of the individual pieces of NATA assessments including both quantitative (e.g., model-to-monitor ratios) and qualitative (e.g., quality of data, review of emission inventories) judgments can be found at <<http://www.epa.gov/national-air-toxics-assessment/nata-limitations>>.

⁵⁰ Chronic exposure is defined in the glossary of the Integrated Risk Information System (IRIS) database (<<http://www.epa.gov/iris>>) as repeated exposure by the oral, dermal, or inhalation route for more than approximately 10 of the life span in humans (more than approximately 90 days to 2 years in typically used laboratory animal species).

⁵¹ Defined in the IRIS database as repeated exposure by the oral, dermal, or inhalation route for more than 30 days, up to approximately 10 of the life span in humans (more than 30 days up to approximately 90 days in typically used laboratory animal species).

⁵² Defined in the IRIS database as exposure by the oral, dermal, or inhalation route for 24 hours or less.

acetaldehyde.⁵³ Thus, it is important to account for the toxicity and exposure, as well as the mass of the targeted emissions.

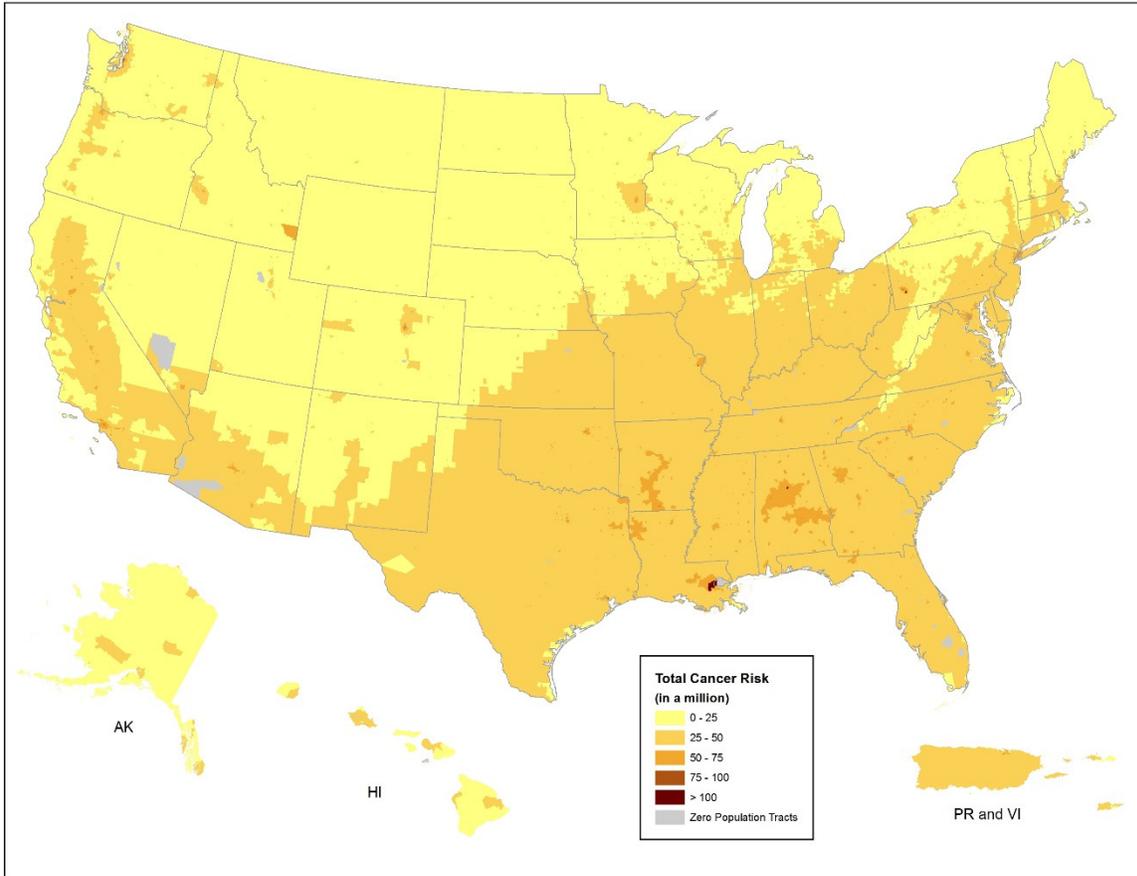

Figure 4-2 2011 NATA Model Estimated Census Tract Carcinogenic Risk from HAP Exposure from All Outdoor Sources based on the 2011 National Emissions Inventory

⁵³ Details on the derivation of IRIS values and available supporting documentation for individual chemicals (as well as chemical values comparisons) can be found at <<http://www.epa.gov/iris>>.

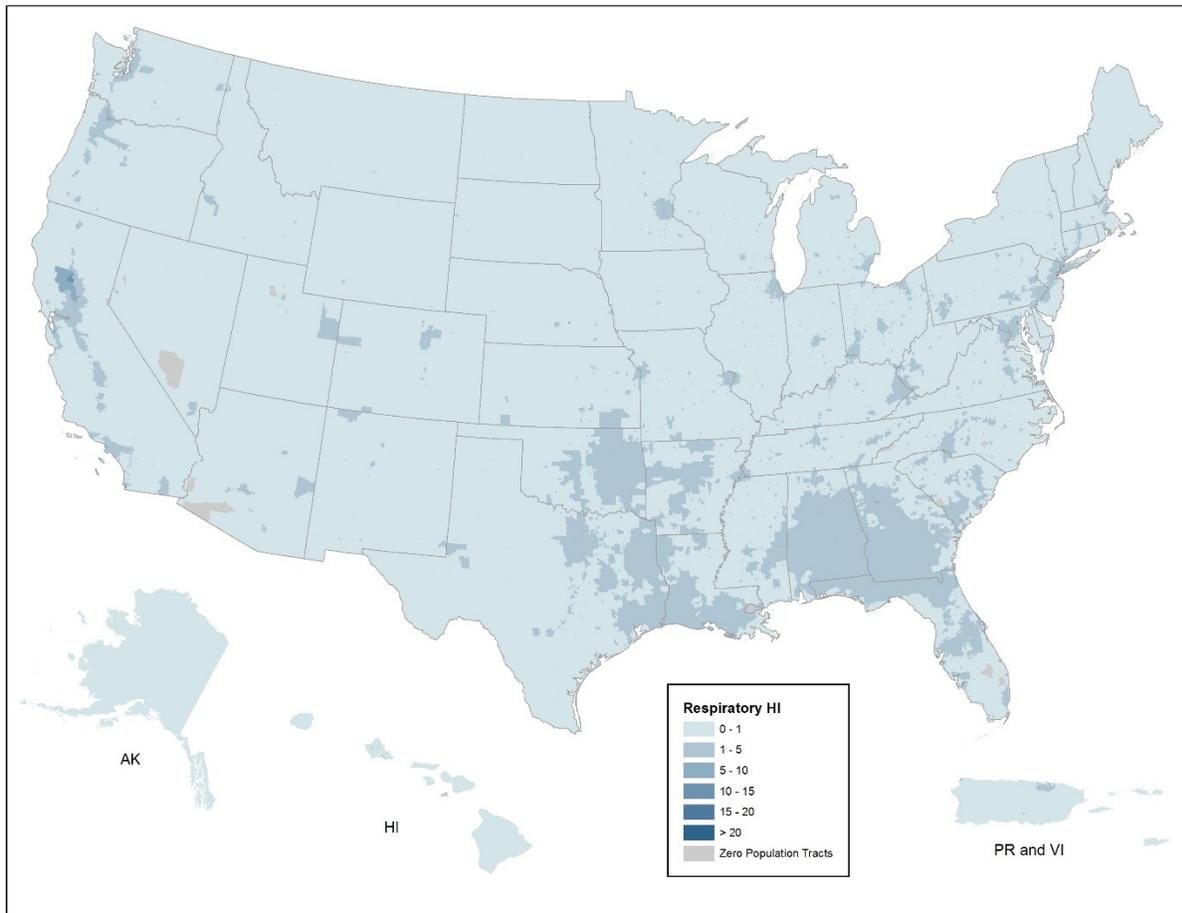

Figure 4-3 2011 NATA Model Estimated Census Tract Noncancer (Respiratory) Risk from HAP Exposure from All Outdoor Sources based on the 2011 National Emissions Inventory

Due to methodology and data limitations, we were unable to estimate the benefits associated with the hazardous air pollutants that would be reduced as a result of this rule. In a few previous analyses of the benefits of reductions in HAP, EPA has quantified the benefits of potential reductions in the incidences of cancer and noncancer risk (e.g., U.S. EPA, 1995). In those analyses, EPA relied on unit risk factors (URF) and reference concentrations (RfC) developed through risk assessment procedures. The URF is a quantitative estimate of the carcinogenic potency of a pollutant, often expressed as the probability of contracting cancer from a 70-year lifetime continuous exposure to a concentration of one $\mu\text{g}/\text{m}^3$ of a pollutant. These URFs are designed to be conservative, and as such, are more likely to represent the high end of

the distribution of risk rather than a best or most likely estimate of risk. An RfC is an estimate (with uncertainty spanning perhaps an order of magnitude) of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious noncancer health effects during a lifetime. As the purpose of a benefit analysis is to describe the benefits most likely to occur from a reduction in pollution, use of high-end, conservative risk estimates would overestimate the benefits of the regulation. While we used high-end risk estimates in past analyses, advice from the EPA's Science Advisory Board (SAB) recommended that we avoid using high-end estimates in benefit analyses (U.S. EPA-SAB, 2002). Since this time, EPA has continued to develop better methods for analyzing the benefits of reductions in HAP.

As part of the second prospective analysis of the benefits and costs of the Clean Air Act (U.S. EPA, 2011a), EPA conducted a case study analysis of the health effects associated with reducing exposure to benzene in Houston from implementation of the Clean Air Act (IEc, 2009). While reviewing the draft report, EPA's Advisory Council on Clean Air Compliance Analysis concluded that "the challenges for assessing progress in health improvement as a result of reductions in emissions of hazardous air pollutants (HAP) are daunting...due to a lack of exposure-response functions, uncertainties in emissions inventories and background levels, the difficulty of extrapolating risk estimates to low doses and the challenges of tracking health progress for diseases, such as cancer, that have long latency periods" (U.S. EPA-SAB, 2008).

In 2009, EPA convened a workshop to address the inherent complexities, limitations, and uncertainties in current methods to quantify the benefits of reducing HAP. Recommendations from this workshop included identifying research priorities, focusing on susceptible and vulnerable populations, and improving dose-response relationships (Gwinn *et al.*, 2011).

In summary, monetization of the benefits of reductions in cancer incidences requires several important inputs, including central estimates of cancer risks, estimates of exposure to carcinogenic HAP, and estimates of the value of an avoided case of cancer (fatal and non-fatal). Due to methodology and data limitations, we did not attempt to monetize the health benefits of reductions in HAP in this analysis. Instead, we provide a qualitative analysis of the health effects associated with the HAP anticipated to be reduced by this rule. EPA remains committed to

improving methods for estimating HAP benefits by continuing to explore additional concepts of benefits, including changes in the distribution of risk.

Available emissions data show that several different HAP are emitted from oil and natural gas operations, either from equipment leaks, processing, compressing, transmission and distribution, or storage tanks. Emissions of eight HAP make up a large percentage of the total HAP emissions by mass from the oil and gas sector: toluene, hexane, benzene, xylenes (mixed), ethylene glycol, methanol, ethyl benzene, and 2,2,4-trimethylpentane (U.S. EPA, 2012a). In the subsequent sections, we describe the health effects associated with the main HAP of concern from the oil and natural gas sector: benzene, toluene, carbonyl sulfide, ethyl benzene, mixed xylenes, and n-hexane. This rule is anticipated to avoid or reduce 3,400 tons of HAP in 2025. With the data available, it was not possible to estimate the tons of each individual HAP that would be reduced.

4.6.1 Benzene

The EPA's IRIS database lists benzene as a known human carcinogen (causing leukemia) by all routes of exposure, and concludes that exposure is associated with additional health effects, including genetic changes in both humans and animals and increased proliferation of bone marrow cells in mice.^{54,55,56} EPA states in its IRIS database that data indicate a causal relationship between benzene exposure and acute lymphocytic leukemia and suggest a relationship between benzene exposure and chronic non-lymphocytic leukemia and chronic lymphocytic leukemia. The International Agency for Research on Carcinogens (IARC) has determined that benzene is a human carcinogen and the U.S. Department of Health and Human

Services has characterized benzene as a known human carcinogen.^{57,58} A number of adverse noncancer health effects including blood disorders, such as preleukemia and aplastic anemia, have also been associated with long-term exposure to benzene.^{59,60}

4.6.2 Toluene⁶¹

Under the 2005 Guidelines for Carcinogen Risk Assessment, there is inadequate information to assess the carcinogenic potential of toluene because studies of humans chronically exposed to toluene are inconclusive, toluene was not carcinogenic in adequate inhalation cancer bioassays of rats and mice exposed for life, and increased incidences of mammary cancer and leukemia were reported in a lifetime rat oral bioassay.

The central nervous system (CNS) is the primary target for toluene toxicity in both humans and animals for acute and chronic exposures. CNS dysfunction (which is often reversible) and narcosis have been frequently observed in humans acutely exposed to low or moderate levels of toluene by inhalation: symptoms include fatigue, sleepiness, headaches, and nausea. Central nervous system depression has been reported to occur in chronic abusers exposed to high levels of toluene. Symptoms include ataxia, tremors, cerebral atrophy, nystagmus (involuntary eye movements), and impaired speech, hearing, and vision. Chronic inhalation exposure of humans to toluene also causes irritation of the upper respiratory tract, eye irritation, dizziness, headaches, and difficulty with sleep.

Human studies have also reported developmental effects, such as CNS dysfunction, attention deficits, and minor craniofacial and limb anomalies, in the children of women who abused toluene during pregnancy. A substantial database examining the effects of toluene in

subchronic and chronic occupationally exposed humans exists. The weight of evidence from these studies indicates neurological effects (i.e., impaired color vision, impaired hearing, decreased performance in neurobehavioral analysis, changes in motor and sensory nerve conduction velocity, headache, and dizziness) as the most sensitive endpoint.

4.6.3 Carbonyl Sulfide

Limited information is available on the health effects of carbonyl sulfide. Acute (short-term) inhalation of high concentrations of carbonyl sulfide may cause narcotic effects and irritate the eyes and skin in humans.⁶² No information is available on the chronic (long-term), reproductive, developmental, or carcinogenic effects of carbonyl sulfide in humans. Carbonyl sulfide has not undergone a complete evaluation and determination under U.S. EPA's IRIS program for evidence of human carcinogenic potential.⁶³

4.6.4 Ethylbenzene

Ethylbenzene is a major industrial chemical produced by alkylation of benzene. The pure chemical is used almost exclusively for styrene production. It is also a constituent of crude petroleum and is found in gasoline and diesel fuels. Acute (short-term) exposure to ethylbenzene in humans results in respiratory effects such as throat irritation and chest constriction, and irritation of the eyes, and neurological effects such as dizziness. Chronic (long-term) exposure of humans to ethylbenzene may cause eye and lung irritation, with possible adverse effects on the blood. Animal studies have reported effects on the blood, liver, and kidneys and endocrine system from chronic inhalation exposure to ethylbenzene. No information is available on the developmental or reproductive effects of ethylbenzene in humans, but animal studies have reported developmental effects, including birth defects in animals exposed via inhalation. Studies in rodents reported increases in the percentage of animals with tumors of the nasal and oral

cavities in male and female rats exposed to ethylbenzene via the oral route.^{64,65} The reports of these studies lacked detailed information on the incidence of specific tumors, statistical analysis, survival data, and information on historical controls, thus the results of these studies were considered inconclusive by the International Agency for Research on Cancer (IARC, 2000) and the National Toxicology Program (NTP).^{66,67} The NTP (1999) carried out a chronic inhalation bioassay in mice and rats and found clear evidence of carcinogenic activity in male rats and some evidence in female rats, based on increased incidences of renal tubule adenoma or carcinoma in male rats and renal tubule adenoma in females. NTP (1999) also noted increases in the incidence of testicular adenoma in male rats. Increased incidences of lung alveolar/bronchiolar adenoma or carcinoma were observed in male mice and liver hepatocellular adenoma or carcinoma in female mice, which provided some evidence of carcinogenic activity in male and female mice (NTP, 1999). IARC (2000) classified ethylbenzene as Group 2B, possibly carcinogenic to humans, based on the NTP studies.

4.6.5 Mixed Xylenes

Short-term inhalation of mixed xylenes (a mixture of three closely-related compounds) in humans may cause irritation of the nose and throat, nausea, vomiting, gastric irritation, mild transient eye irritation, and neurological effects.⁶⁸ Other reported effects include labored breathing, heart palpitation, impaired function of the lungs, and possible effects in the liver and kidneys.⁶⁹ Long-term inhalation exposure to xylenes in humans has been associated with a

number of effects in the nervous system including headaches, dizziness, fatigue, tremors, and impaired motor coordination.⁷⁰ EPA has classified mixed xylenes in Category D, not classifiable with respect to human carcinogenicity.

4.6.6 *n*-Hexane

The studies available in both humans and animals indicate that the nervous system is the primary target of toxicity upon exposure of *n*-hexane via inhalation. There are no data in humans and very limited information in animals about the potential effects of *n*-hexane via the oral route. Acute (short-term) inhalation exposure of humans to high levels of hexane causes mild central nervous system effects, including dizziness, giddiness, slight nausea, and headache. Chronic (long-term) exposure to hexane in air causes numbness in the extremities, muscular weakness, blurred vision, headache, and fatigue. Inhalation studies in rodents have reported behavioral effects, neurophysiological changes and neuropathological effects upon inhalation exposure to *n*-hexane. Under the Guidelines for Carcinogen Risk Assessment (U.S. EPA, 2005), the database for *n*-hexane is considered inadequate to assess human carcinogenic potential, therefore the EPA has classified hexane in Group D, not classifiable as to human carcinogenicity.⁷¹

4.6.7 *Other Air Toxics*

In addition to the compounds described above, other toxic compounds might be affected by this rule, including hydrogen sulfide (H₂S). Information regarding the health effects of those compounds can be found in EPA's IRIS database.⁷²

4.7 Secondary Air Emissions Impacts

The control techniques to meet the standards are associated with several types of secondary emissions impacts, which may partially offset the direct benefits of this rule. Table 4-6 shows the estimated secondary emissions associated with combustion of emissions as a result of the rule. In

⁷⁰ Agency for Toxic Substances and Disease Registry (ATSDR), 2007. The Toxicological Profile for xylene is available electronically at <<http://www.atsdr.cdc.gov/ToxProfiles/TP.asp?id=296&tid=53>>.

⁷² U.S. EPA Integrated Risk Information System (IRIS) database is available at: <www.epa.gov/iris>.

particular, combustion-related emissions result from the control of oil well completions (i.e., exploratory and delineation wells and development wells where RECs are infeasible and pneumatic pumps and centrifugal compressors (because the requirement for these sources is to route to control). More details on the estimation of secondary impacts for each emissions category are presented in the TSD. Relative to the direct emission reductions anticipated from this rule, the magnitude of these secondary air pollutant increases is small.

Table 4-6 Increases in Secondary Air Pollutant Emissions (short tons per year)

| Emissions Category | 2020 | | | | |
|---|------------------|-----------------|----------------|----------------|----------------|
| | CO ₂ | NO _x | PM | CO | THC |
| Total Hydraulically Fractured and Re-fractured Oil Well Completions | 890,000 | 460 | 17 | 2,500 | 940 |
| Fugitive Emissions | <i>minimal</i> | <i>minimal</i> | <i>minimal</i> | <i>minimal</i> | <i>minimal</i> |
| Pneumatic Pumps | 100,000 | 52 | 2 | 290 | 110 |
| Pneumatic Controllers | 3,900 | 2 | 0 | 11 | 4 |
| Compressors | 0 | 0 | 0 | 0 | 0 |
| Total 2020 | 1,000,000 | 510 | 19 | 2,800 | 1,100 |

| Emissions Category | 2025 | | | | |
|---|------------------|-----------------|----------------|----------------|----------------|
| | CO ₂ | NO _x | PM | CO | THC |
| Total Hydraulically Fractured and Re-fractured Oil Well Completions | 950,000 | 490 | 18 | 2,700 | 1,000 |
| Fugitive Emissions | <i>minimal</i> | <i>minimal</i> | <i>minimal</i> | <i>minimal</i> | <i>minimal</i> |
| Pneumatic Pumps | 200,000 | 100 | 4 | 570 | 220 |
| Pneumatic Controllers | 7,800 | 4 | 0 | 22 | 8 |
| Compressors | 0 | 0 | 0 | 0 | 0 |
| Total in 2025 | 1,200,000 | 600 | 22 | 3,200 | 1,200 |

The secondary emission impacts for regulatory options are equal across the options. This result holds because the only requirements varied across the options is the frequency of survey and repair requirements. Moving from Option 1 to Option 3 increases the frequency of survey and repair under the fugitive emissions requirement, and secondary emissions from the fugitive emissions requirements are expected to be minimal.

The CO₂ impacts in Table 4-6 are the emissions that are expected to occur from natural gas emissions that are captured by emissions controls and combusted. However, because of the atmospheric chemistry associated with the natural gas emissions, most of the carbon in the VOCs

and CH₄ emissions expected in the absence of combustion-related emissions controls would have eventually oxidized forming CO₂ in the atmosphere and led to approximately the same long-run CO₂ concentrations as with controls.⁷³ Therefore, most of the impact of these CO₂ contribution to atmospheric concentrations from the flaring of CH₄ and VOC versus future oxidization is not additional to the impacts that otherwise would have occurred through the oxidation process. However, there is a shift in the timing of the contribution of atmospheric CO₂ concentration under the policy case (in which case natural gas emissions that are captured by emissions controls are combusted). In the case of VOCs, the oxidization time in the atmosphere is relatively short, on the order of hours to months, so from a climate perspective the difference between emitting the carbon immediately as CO₂ during combustion or as VOCs is expected to be negligible. In the case of CH₄, the oxidization time is on the order of a decade, so the timing of the contribution to atmospheric CO₂ concentration will differ between the baseline and policy case. Because the growth rate of the SC-CO₂ estimates are lower than their associated discount rates, the estimated impact of CO₂ produced in the future via oxidized methane from these fossil-based emissions may be less than the estimated impact of CO₂ released immediately from combusting emissions, which would imply a small disbenefit associated with the earlier release of CO₂ during combustion of the CH₄ emissions.

In the proposal RIA, the EPA solicited comment on the appropriateness of monetizing the impact of the earlier release of CO₂ due to combusting methane and VOC emissions from oil and gas sites and a new potential approach for approximating this value using the SC-CO₂. This illustrative analysis provides a method for evaluating the estimated emissions outcomes associated with destroying one metric ton of methane by combusting fossil-based emissions at oil and gas sites (flaring) and releasing the CO₂ emissions immediately versus releasing them in the future via the methane oxidation process. This illustrative analysis as provided in the proposal demonstrated that the potential disbenefits of flaring—i.e., an earlier contribution of CO₂ emissions to atmospheric concentrations—are minor compared to the benefits of flaring—i.e., avoiding the release of and associated climate impacts from CH₄ emissions. EPA did not receive any comments regarding the appropriate methodology for conducting such an analysis,

⁷³ The social cost of methane (SC-CH₄) used previously in this chapter to monetize the benefits of the CH₄ emissions reductions does not include the impact of the carbon in CH₄ emissions after it oxidizes to CO₂.

but did receive one comment letter that voiced general support for monetizing the secondary impacts.

In consideration of this comment while recognizing the challenges and uncertainties related to estimation of these secondary emissions impacts for this rulemaking, EPA has continued to examine this issue in the context of this regulatory analysis—i.e, the combusting of fossil-based CH₄ at oil and gas sites—and explored ways to improve this illustrative analysis. Specifically, EPA has modified the illustrative analysis by updating the oxidization process of CH₄ to be dynamic and consistent with the modeling that underlies the SC-CH₄ estimates. Also for this illustrative analysis, EPA assumed an average methane oxidation period of 12 years, consistent with the perturbation lifetime-folding time used in IPCC AR4. The estimated disbenefits associated with destroying one metric ton of methane through combustion of emissions at oil and gas sites and releasing the CO₂ emissions in 2020 instead of being released in the future via the methane oxidation process are found to be small relative to the benefits of flaring. Specifically, the disbenefit is estimated to be about \$15 per metric ton CH₄ (based on average SC-CO₂ at 3 percent) or roughly one percent of the SC-CH₄ estimate per metric ton for 2020. The analogous estimate for 2025 is \$18 per metric ton CH₄ or about one percent of the SC-CH₄ estimates per metric ton for 2025.^{74,75}

⁷⁴ To calculate the CO₂ related impacts associated the complete destruction of a ton of CH₄ emissions through flaring for this illustrative application, EPA took the difference between the SC-CO₂ at the time of the flaring and the discounted value of the CO₂ impacts assuming a geometric decay of CH₄ via the oxidation process with a 12 year e-folding time using the same discount rate as used to estimate the SC-CO₂. This value was then scaled by 44/16 to account for the relative mass of carbon contained in a ton of CH₄ versus a ton of CO₂. More specifically, the impacts of shifting the CO₂ impacts are calculated as

$$(44/16) \left[SC-CO_2_\tau - \sum_{t=\tau}^T e^{-1/12(t-\tau)} (1 - e^{-1/12}) \left(\frac{1}{1+r} \right)^{t-\tau} SC-CO_2_t \right],$$

where τ is the year the CH₄ is destroyed, r is the discount rate, and T is the time horizon of the analysis. Ideally the time horizon, T, would be sufficiently long to capture the period in which nearly all of the CH₄ is expected to have been oxidized. In this analysis we use the 2100 as the time horizon, making the assumption that the SC-CO₂ remains constant after 2050, the last year for which the IWG provides estimates. This methodology improves upon the one presented at proposal by updating the oxidization process of CH₄ to be dynamic and consistent with the modeling that underlies the SC-CH₄ estimates.

⁷⁵ The EPA also calculated these estimates using additional SC-CO₂ values, specifically the average SC-CO₂ at discount rates of 5 and 2.5 percent and the 95th percentile at 3 percent. Applying these values, the estimates of the disbenefit of releasing CO₂ emissions in 2020 instead of in the future via methane oxidation ranges from \$7 to \$40 per metric ton CH₄. The corresponding estimates for 2025 range from \$9 to \$51 per metric ton CH₄.

It is important to note that there are challenges and uncertainties related to this illustrative method and estimates, which was developed to analyze secondary fossil-based emissions from combustion. For example, these dollar per ton CH₄ estimates cannot readily be applied to the total CH₄ emissions reductions presented in section 3 without additional information about the downstream outcomes associated with the recovered gas that is not flared – e.g., whether some of that captured gas going to be burned or leaked somewhere down the line.

The EPA will continue to study this issue and assess the complexities involved in estimating the net emissions effects associated with secondary fossil-based emissions, including differences in the timing of contributions to atmospheric CO₂ concentrations. Given the uncertainties related to estimating net secondary emissions effects and that the EPA has not yet received appropriate input and review on some aspects of these calculations, the EPA is not including monetized estimates of the impacts of small changes in the timing of atmospheric CO₂ concentration increases in the final benefits estimates in this RIA. The EPA will continue to follow the scientific literature on this topic and update its methodologies as warranted.

Table 4-7 provides a summary of the direct and secondary emissions changes. Based on the summary and analysis above, the net impact of both the direct and secondary impacts of this final rule would be an improvement in ambient air quality, which would reduce potency of greenhouse gas emissions, reduce exposure to various harmful pollutants, improve visibility impairment, and reduce vegetation damage.

Table 4-7 Summary of Emissions Changes (short tons per year, except where noted)

| | Pollutant | Option 1 | | Option 2 (final) | | Option 3 | |
|-----------------------------------|-----------------|-----------|-----------|------------------|-----------|-----------|-----------|
| | | 2020 | 2025 | 2020 | 2025 | 2020 | 2025 |
| Change in Direct Emissions | Methane | -250,000 | -390,000 | -300,000 | -510,000 | -350,000 | -610,000 |
| | VOC | -130,000 | -170,000 | -150,000 | -210,000 | -160,000 | -230,000 |
| | HAP | -1,300 | -2,700 | -1,900 | -3,900 | -2,400 | -5,000 |
| Secondary Emissions | CO ₂ | 1,000,000 | 1,200,000 | 1,000,000 | 1,200,000 | 1,000,000 | 1,200,000 |
| | NO _x | 510 | 600 | 510 | 600 | 510 | 600 |
| | PM | 19 | 22 | 19 | 22 | 19 | 22 |
| | CO | 2,800 | 3,200 | 2,800 | 3,200 | 2,800 | 3,200 |
| | THC | 1,100 | 1,200 | 1,100 | 1,200 | 1,100 | 1,200 |

5 COMPARISON OF BENEFITS AND COSTS

5.1 Comparison of Benefits and Costs across Regulatory Options

Tables 5-1 through Table 5-3 present the summary of the benefits, costs, and net benefits for the NSPS across regulatory options. Table 5-4 provides a summary of the direct and secondary emissions changes for each regulatory option.

Table 5-1 Summary of the Monetized Benefits, Costs, and Net Benefits for Option 1 in 2020 and 2025 (2012\$)

| | 2020 | 2025 |
|---------------------------------------|---|---|
| Total Monetized Benefits ¹ | \$290 million | \$540 million |
| Total Costs ² | \$240 million | \$360 million |
| Net Benefits ³ | \$54 million | \$180 million |
| | Non-monetized climate benefits | Non-monetized climate benefits |
| Non-monetized Benefits | Health effects of PM2.5 and ozone exposure from 130,000 tons of VOC reduced | Health effects of PM2.5 and ozone exposure from 170,000 tons of VOC reduced |
| | Health effects of HAP exposure from 1,300 tons of HAP reduced | Health effects of HAP exposure from 2,700 tons of HAP reduced |
| | Health effects of ozone exposure from 250,000 tons of methane | Health effects of ozone exposure from 390,000 tons of methane |
| | Visibility impairment | Visibility impairment |
| | Vegetation effects | Vegetation effects |

¹ The benefits estimates are calculated using four different estimates of the social cost of methane (SC-CH₄) (model average at 2.5 percent discount rate, 3 percent, and 5 percent; 95th percentile at 3 percent). For purposes of this table, we show the benefits associated with the model average at a 3 percent discount rate. However, we emphasize the importance and value of considering the benefits calculated using all four SC-CH₄ estimates; the additional benefit estimates range from \$130 million to \$780 million in 2020 and \$250 million to \$1.4 billion in 2025 for Option 1, as shown in Section 4.3. The CO₂-equivalent (CO₂ Eq.) methane emission reductions are 5.6 million metric tons in 2020 and 8.9 million metric tons in 2025. Also, the specific control technologies for the NSPS are anticipated to have minor secondary disbenefits. See Section 4.7 for details.

² The engineering compliance costs are annualized using a 7 percent discount rate and include estimated revenue from additional natural gas recovery as a result of the NSPS. As can be seen in section 3.5.1 of the final RIA, the national cost estimates in for this rule are not highly sensitive to the use of a 3 percent or 7 percent discount rate in this RIA. As a result, the net benefits of the rule are not highly sensitive to choice of discount rate for annualizing capital costs.

³ Estimates may not sum due to independent rounding.

Table 5-2 Summary of the Monetized Benefits, Costs, and Net Benefits for Selected Option 2 in 2020 and 2025 (2012\$)

| | 2020 | 2025 |
|---------------------------------------|---|---|
| Total Monetized Benefits ¹ | \$360 million | \$690 million |
| Total Costs ² | \$320 million | \$530 million |
| Net Benefits ³ | \$35 million | \$170 million |
| Non-monetized Benefits | Non-monetized climate benefits | Non-monetized climate benefits |
| | Health effects of PM2.5 and ozone exposure from 150,000 tons of VOC reduced | Health effects of PM2.5 and ozone exposure from 210,000 tons of VOC reduced |
| | Health effects of HAP exposure from 1,900 tons of HAP reduced | Health effects of HAP exposure from 3,900 tons of HAP reduced |
| | Health effects of ozone exposure from 300,000 tons of methane | Health effects of ozone exposure from 510,000 tons of methane |
| | Visibility impairment | Visibility impairment |
| | Vegetation effects | Vegetation effects |

¹ The benefits estimates are calculated using four different estimates of the social cost of methane (SC-CH₄) (model average at 2.5 percent, 3 percent, and 5 percent; 95th percentile at 3 percent). For purposes of this table, we show the benefits associated with the model average at a 3 percent discount rate. However, we emphasize the importance and value of considering the benefits calculated using all four SC-CH₄ estimates; the additional benefit estimates range from \$160 million to \$950 million in 2020 and \$320 million to \$1.8 billion in 2025 for Option 2, as shown in Section 4.3. The CO₂-equivalent (CO₂ Eq.) methane emission reductions are 6.9 million metric tons in 2020 and 11 million metric tons in 2025. Also, the specific control technologies for the NSPS are anticipated to have minor secondary disbenefits. See Section 4.7 for details.

² The engineering compliance costs are annualized using a 7 percent discount rate and include estimated revenue from additional natural gas recovery as a result of the NSPS. As can be seen in section 3.5.1 of the final RIA, the national cost estimates in for this rule are not highly sensitive to the use of a 3 percent or 7 percent discount rate in this RIA. As a result, the net benefits of the rule are not highly sensitive to choice of discount rate for annualizing capital costs.

³ Estimates may not sum due to independent rounding.

Table 5-3 Summary of the Monetized Benefits, Costs, and Net Benefits for Option 3 in 2020 and 2025 (2012\$)

| | 2020 | 2025 |
|---------------------------------------|---|--|
| Total Monetized Benefits ¹ | \$420 million | \$840 million |
| Total Costs ² | \$490 million | \$880 million |
| Net Benefits ³ | -\$75 million | -\$38 million |
| Non-monetized Benefits | Non-monetized climate benefits Health effects of PM2.5 and ozone exposure from 160,00 tons of VOC reduced Health effects of HAP exposure from 2,400 tons of HAP reduced Health effects of ozone exposure from 350,000 tons of methane Visibility impairment Vegetation effects | Non-monetized climate benefits Health effects of PM2.5 and ozone exposure from 230,000 tons of VOC reduced Health effects of HAP exposure from 5,000 tons of HAP reduced Health effects of ozone exposure from 610,000 tons of methane Visibility impairment Vegetation effects |

¹ The benefits estimates are calculated using four different estimates of the social cost of methane (SC-CH₄) (model average at 2.5 percent, 3 percent, and 5 percent; 95th percentile at 3 percent). For purposes of this table, we show the benefits associated with the model average at a 3 percent discount rate. However, we emphasize the importance and value of considering the benefits calculated using all four SC-CH₄ estimates; the additional benefit estimates range from \$190 million to \$1.1 billion in 2020 and \$390 million to \$2.2 billion in 2025 for this more stringent option, as shown in Section 4.3. The CO₂-equivalent (CO₂ Eq.) methane emission reductions are 8 million metric tons in 2020 and 14 million metric tons in 2025. Also, the specific control technologies for the NSPS are anticipated to have minor secondary disbenefits.

² The engineering compliance costs are annualized using a 7 percent discount rate and include estimated revenue from additional natural gas recovery as a result of the NSPS. As can be seen in section 3.5.1 of the final RIA, the national cost estimates in for this rule are not highly sensitive to the use of a 3 percent or 7 percent discount rate in this RIA. As a result, the net benefits of the rule are not highly sensitive to choice of discount rate for annualizing capital costs.

³ Estimates may not sum due to independent rounding.

A break-even analysis answers the question: “What would the benefits need to be for the benefits to exceed the costs?” While a break-even approach is not equivalent to a benefits analysis or even a net benefits analysis, we feel the results are illustrative, particularly in the context of previously modeled benefits. For Options 1 and 2 (final selected option), the monetized climate benefits from methane emission reductions already exceed the costs, which renders a break-even analysis for these options unnecessary. For Option 3, the monetized net benefits are estimated to be -\$73 million and -\$37 million and the estimated VOC emission reductions are 160,000 and 230,000 tons for 2020 and 2025, respectively. Thus, a break-even analysis suggests that the VOC emissions would need to be valued at \$460 per ton in 2020 and \$160 per ton in 2025 for the total monetized benefits of Option 3 to exceed costs, assuming that

the health benefits from HAP emission reductions and the ozone health benefits from methane emission reductions are zero. Previous assessments have shown that the PM_{2.5} health benefits associated with reducing VOC emissions were valued at \$300 to \$7,500 per ton of VOC emissions reduced in specific urban areas and ozone health benefits from reducing VOC emissions were valued at \$260 to \$1,100 per ton of VOC emissions reduced. These break-even estimates assume that all other pollutants have zero value. Of course, it is inappropriate to assume that the value of reducing any of these pollutants is zero. Thus, the real break-even point is actually lower than the estimates provided above because the other pollutants each have non-zero benefits that should be considered. Furthermore, a single pollutant can have multiple effects (e.g., VOCs contribute to both ozone and PM_{2.5} formation that each have health and welfare effects) that would need to be summed in order to develop a comprehensive estimate of the monetized benefits associated with reducing that pollutant.

Table 5-4 Summary of Emissions Changes across Options for the NSPS in 2020 and 2025 (short tons per year, unless otherwise noted)

| | Pollutant | Option 1 | | Option 2 (final) | | Option 3 | |
|--------------------------------------|-----------------|-----------|-----------|------------------|-----------|-----------|-----------|
| | | 2020 | 2025 | 2020 | 2025 | 2020 | 2025 |
| Reduction in Direct Emissions | Methane | -250,000 | -390,000 | -300,000 | -510,000 | -350,000 | -610,000 |
| | VOC | -130,000 | -170,000 | -150,000 | -210,000 | -160,000 | -230,000 |
| | HAP | -1,300 | -2,700 | -1,900 | -3,900 | -2,400 | -5,000 |
| Secondary Emissions | CO ₂ | 1,000,000 | 1,200,000 | 1,000,000 | 1,200,000 | 1,000,000 | 1,200,000 |
| | NO _x | 510 | 600 | 510 | 600 | 510 | 600 |
| | PM | 19 | 22 | 19 | 22 | 19 | 22 |
| | CO | 2,800 | 3,200 | 2,800 | 3,200 | 2,800 | 3,200 |
| | THC | 1,100 | 1,200 | 1,100 | 1,200 | 1,100 | 1,200 |

5.2 Uncertainties and Limitations

Throughout the RIA, we considered a number of sources of uncertainty, both quantitatively and qualitatively, regarding emissions reductions, benefits, and costs of the rule. We summarize the key elements of our discussions of uncertainty here:

- **Projection methods and assumptions:** As discussed in Section 3.4.2, over time, more facilities are newly established or modified in each year, and to the extent the facilities remain in operation in future years, the total number of facilities subject to the NSPS

accumulates. The large majority of impacts of the rule (completion requirements at hydraulically fractured oil well completions and fugitive emissions requirements at wellsites) are based on projections and growth rates consistent with the drilling activity in the 2015 Annual Energy Outlook. To the extent actual drilling activities diverge from the Annual Energy Outlook projections, the projected regulatory impacts estimated in this document will diverge.

- **Years of analysis:** The years of analysis are 2020, to represent the near-term impacts of the rule, and 2025, to represent impacts of the rule over a longer period, as discussed in Section 3.4.2. While it is desirable to analyze impacts beyond 2025 in this RIA, the EPA has chosen not to do this largely because of the limited information available on the turnover rate of emissions sources and controls. Extending the analysis beyond 2025 would introduce substantial and increasing uncertainties in projected impacts of the NSPS.
- **State regulations in baseline:** In preparing the impacts analysis, the EPA reviewed state regulations and permitting requirements, as discussed in Section 3.4.2. Applicable facilities in these states with similar requirements to the final NSPS are not included in the estimates of incrementally affected facilities presented in the RIA. This means that any additional costs and benefits incurred by facilities in these states to comply with the federal standards beyond the state requirements are not reflected in this RIA.
- **Wellhead natural gas prices used to estimate revenues from natural gas recovery:** The annualized compliance cost estimates presented in this RIA include revenue from natural gas recovery resulting from emissions reductions. As a result, national compliance costs depend the price of natural gas. The sensitivity of national compliance costs to assumptions about wellhead natural gas prices are examined in Section 3.5.2.
- **Monetized methane-related climate benefits:** The EPA considered the uncertainty associated with the social cost of methane (SC-CH₄) estimates, which were used to calculate the global social benefits of methane emissions reductions expected from the NSPS. The modeling underlying the development of the SC-CH₄ estimates, which is consistent with the modeling assumptions underlying the interagency working group's SC-CO₂ estimates, addressed uncertainty in several ways. For example, the analysis addressed uncertainty in following areas: differences in model structure through an

ensemble of three integrated assessment models; sensitivity of the SC-CH₄ estimates to key exogenous projections by using five different socioeconomic and emissions forecasts; and three discount rates to reflect some uncertainty about how interest rates may change over time and the possibility that climate damages are positively correlated with uncertain future economic activity. The application of four point estimates also helps reflect uncertainty. Chapter 4 of this RIA provides a comprehensive discussion about the methodology and application of the SC-CH₄ as well as consideration of several types of secondary emissions impacts, which may partially offset the direct benefits of this rule.

- **Non-monetized benefits:** Numerous categories of health, welfare, and climate benefits are not quantified and monetized in this RIA. These unquantified benefits, including benefits from reducing emissions of methane, VOCs and HAP, are described in detail in Chapter 4.

6 ECONOMIC IMPACT ANALYSIS AND DISTRIBUTIONAL ASSESSMENTS

6.1 Introduction

This section includes three sets of analyses for the final NSPS:

- Energy Markets Impacts
- Final Regulatory Flexibility Analysis
- Employment Impacts

6.2 Energy Markets Impacts Analysis

We use the National Energy Modeling System (NEMS) to estimate the impacts of the final NSPS on U.S. energy markets. The impacts we estimate include changes in drilling activity, price and quantity changes in the production and consumption of crude oil and natural gas, and changes in international trade of crude oil and natural gas.

A brief conceptual discussion about our energy markets impacts modeling approach is necessary before going into detail on NEMS, how we implemented the regulatory impacts, and presenting results. Economically, it is possible to view the recovered natural gas as an explicit output or as contributing to an efficiency gain in production at the producer level for a given cost. For example, the analysis for the rule shows that performing reduced emissions completions on hydraulically-fractured oil wells would account for about 36 percent of the natural gas captured by emissions controls in 2020 and about 23 percent of captured natural gas in 2025. The fugitive emissions program at well sites is expected to account for about 62 percent of the natural gas captured by emissions controls in 2020 and about 75 percent of captured natural gas in 2025. The assumed \$4/Mcf price for natural gas is the price paid to producers at the wellhead. In the natural gas industry, production is metered at or very near to the wellhead, and producers are paid based upon this metered production.

In the engineering cost analysis, it is necessary to estimate the expected costs and revenues from implementing emissions controls at the unit level. Because of this, we estimate the net costs as expected costs minus expected revenues for representative units. On the other hand, NEMS models the profit maximizing behavior of representative project developers at a drilling project level. The net costs of the regulation alter the expected discounted cash flow of drilling and implementing oil and gas projects, and the behavior of the representative drillers adjusts

accordingly. While in the regulatory case natural gas drilling has become more efficient because of the gas recovery, project developers still interact with markets for which supply and demand are simultaneously adjusting. Consequently, project development adjusts to a new equilibrium. While we believe the cost savings as measured by revenues from selling recovered gas (engineering costs) and measured by cost savings from averted production through efficiency gains (energy economic modeling) are approximately the same, it is important to note that the engineering cost analysis and the national-level cost estimates do not incorporate economic feedbacks such as supply and demand adjustments.

6.2.1 Description of the Department of Energy National Energy Modeling System

NEMS is a model of the U.S. energy economy developed and maintained by the Energy Information Administration of the U.S. Department of Energy (DOE). NEMS is used to produce the Annual Energy Outlook, a reference publication that provides detailed forecasts of the energy economy from the current year to 2040. DOE first developed NEMS in the 1980s, and the model has undergone frequent updates and significant expansion since. DOE uses the modeling system extensively to produce issue reports, legislative analyses, and respond to Congressional inquiries.

The EIA is legally required to make the NEMS system source code available and fully documented for the public. The source code and accompanying documentation is released annually when a new Annual Energy Outlook is produced. Because of the availability of the NEMS model, numerous agencies, national laboratories, research institutes, and academic and private sector researchers have used NEMS to analyze a variety of issues.

NEMS models the dynamics of energy markets and their interactions with the broader U.S. economy. The system projects the production of energy resources such as oil, natural gas, coal, and renewable fuels, the conversion of resources through processes such as refining and electricity generation, and the quantity and prices for final consumption across sectors and regions. The dynamics of the energy system are governed by assumptions about energy and environmental policies, technological developments, resource supplies, demography, and macroeconomic conditions. An overview of the model and complete documentation of NEMS can be found at the website: <http://www.eia.gov/forecasts/aeo/>.

NEMS is a large-scale, deterministic mathematical programming model. NEMS iteratively solves multiple models, linear and non-linear, using nonlinear Gauss-Seidel methods (Gabriel *et al.* 2001). What this means is that NEMS solves a single module, holding all else constant at provisional solutions, then moves to the next module after establishing an updated provisional solution.

NEMS provides what EIA refers to as “mid-term” projections to the year 2040. For this RIA, we draw upon the same assumptions and model used in the Annual Energy Outlook 2015.⁷⁶ The RIA baseline is consistent with that of the Annual Energy Outlook 2015, which is used extensively in Section 2 in the Industry Profile.

6.2.2 *Inputs to National Energy Modeling System*

To model potential impacts associated with the final rule, we modified oil and gas production costs within the Oil and Gas Supply Module (OGSM) of NEMS and domestic and Canadian natural gas production within the Natural Gas Transmission and Distribution Module (NGTDM). The OGSM projects domestic oil and gas production from onshore, offshore and Alaskan wells, as well as having a smaller-scale treatment of Canadian oil and gas production (U.S. EIA, 2014). The treatment of oil and gas resources is detailed in that oil, shale oil, conventional gas, shale gas, tight sands gas, and coalbed methane (CBM) are explicitly modeled. New exploration and development is pursued in the OGSM if the expected net present value of extracted resources exceeds expected costs, including costs associated with capital, exploration, development, production, and taxes. Detailed technology and reservoir-level production economics govern findings and success rates and costs.

The structure of the OGSM is amenable to analyzing potential impacts of the NSPS. We are able to target additional expenditures for environmental controls required by the NSPS on new exploratory and developmental oil and gas production activities. We model the impacts of additional environmental costs, as well as the impacts of additional product recovery. We explicitly model the additional natural gas recovered when implementing the rule.

⁷⁶ Assumptions for the 2015 Annual Energy Outlook can be found at <http://www.eia.gov/forecasts/aeo/assumptions/>.

While the oil production simulated by the OGSM is sent to the refining module (the Liquid Fuels Market Module), simulated natural gas production is sent to a transmission and distribution network captured in the NGTDM. The NGTDM balances gas supplies and prices and “negotiates” supply and consumption to determine a regional equilibrium between supply, demand and prices, including imports and exports via pipeline or LNG. Natural gas is transported through a simplified arc-node representation of pipeline infrastructure based upon pipeline economics.

6.2.2.1 Compliance Costs for Oil and Gas Exploration and Production

As the NSPS affects new emissions sources, we chose to estimate impacts on new exploration and development projects by adding costs of environmental regulation to the algorithm that evaluates the profitability of new projects. Regulatory costs associated with reduced emission completions for hydraulically fractured oil well completions are added to the drilling and completion costs of oil wells in the OGSM. Other regulatory costs are operations and maintenance-type costs and are added to fixed operation and maintenance (O&M) expenses associated with new projects. The additional expenses are estimated and entered on a per well basis, depending on whether the costs would apply to oil wells or natural gas wells. We base the per well cost estimates on the engineering costs. Because we model natural gas recovery, we do not include revenues from additional product recovery in these costs. This approach is appropriate given the structure of the NEMS algorithm that estimates the net present value of drilling projects.

In general, the cost of capital in the model will implicitly capture potential barriers to obtaining additional capital financing for the industry on average. However, the model may not fully capture heterogeneity in the cost of capital across the industry, and therefore, may not fully capture distributional impacts across the industry as a result of firm specific characteristics that cause them to have varying access to additional capital. An additional caveat to this analysis is that the modeling does not attempt to represent potential constraints on the supply of specific capital equipment, which may or may not be binding in practice.

Table 6-1 shows the incremental compliance that accrue to new drilling projects as a result of producers having to comply with the NSPS, across sources anticipated in 2020 and

2025. We estimate those costs as a function of new wells anticipated to be drilled in a representative year. To arrive at estimates of the per well costs, we first identify whether costs will apply primarily to crude oil wells, to natural gas wells, or to both crude oil and natural gas wells.

We divide the estimated compliance costs for the given emissions point by the appropriate number of expected new crude oil and natural gas wells in the year of analysis. The result yields an approximation of per well compliance costs. We assume this approximation is representative of the incremental cost faced by a producer when evaluating a prospective drilling project.

Hydraulically fractured oil well completions and fugitives at oil and natural gas well sites differ slightly from this approach. Drilling and completion costs of new hydraulically fractured oil wells are incremented by the weighted average of the cost of performing a REC with completion combustion and completion combustion alone. The resulting cost is itself weighted by the proportion of new hydraulically fractured oil wells estimated to be affected by the regulation. Meanwhile, assuming there is an average of two wells per wells site (see TSD for more details), new oil and gas wells face an increased annual cost of one-half of implementing the well site fugitive emission requirements.

Table 6-1 Per Well Costs for Environmental Controls Entered into NEMS (2012\$)

| Emissions Sources/Points | Wells Applied To in NEMS | Annualized Cost per Unit (2012\$) | Per Well Costs Applied in NEMS (2012\$) | Natural Gas Recovery per Unit (Mcf) | Per Well Natural Gas Recovery Applied in NEMS (Mcf) |
|--|---------------------------------------|--|--|--|--|
| Well Completions | | | | | |
| Hydraulically Fractured Oil Well Completions | New Hydraulically Fractured Oil Wells | Varies ^a | \$4,590 | 0 | 0 |
| Fugitive Emissions | | | | | |
| Oil Production Well Sites | New Oil Wells | \$2,285 | \$905 | 191 ^c | 38 |
| Natural Gas Production Well Sites | New Gas Wells | \$2,285 | \$1,101 | 73 | 18 |
| Gathering and Boosting Stations | New Gas Wells | \$25,050 | \$284 | 1,629 | 18 |
| Transmission Stations | New Gas Wells | \$27,370 | \$13 | 1,673 | 1 |
| Storage Facilities | New Gas Wells | \$42,093 | \$25 | 5,899 | 3 |
| Reciprocating Compressors | | | | | |
| Transmission Stations | New Gas Wells | \$1,748 | \$3 | 1,122 | 2 |
| Storage Facilities | New Gas Wells | \$2,077 | \$4 | 1,130 | 2 |
| Centrifugal Compressors | | | | | |
| Storage Facilities | New Gas Wells | \$114,146 | \$0 | 0 | 0 |
| Pneumatic Controllers - | | | | | |
| Transmission and Storage Stations | New Gas Wells | \$25 | \$0 | 144 | 2 |
| Pneumatic Pumps | | | | | |
| Well Sites | New Wells | \$774 | \$15 | 0 | 0 |
| Reporting and Recordkeeping | New Wells | \$6,200,000 ^b | \$154 | 0 | 0 |

^a Since compliance costs vary across hydraulically fractured oil well completions, this table uses the weighted average costs by completion cost type.

^b Reporting and recordkeeping costs are assumed to be equally allocated across all new wells.

^c Natural gas recovery at oil well sites is the weighted average of the recovery expected from oil well sites and oil well (associated gas) sites. See TSD for detailed description of these model well sites.

6.2.2.2 Adding Averted Methane Emissions into Natural Gas Production

A result of controlling methane and VOC emissions from oil and natural gas production is that methane that would otherwise be lost to the atmosphere can be directed into the natural gas production stream. We chose to model methane capture in NEMS as an increase in natural gas industry productivity, ensuring that, within the model, natural gas reservoirs are not decremented by production gains from methane capture. We add estimates of the quantities of methane captured (or otherwise not vented or combusted) to the base quantities that the OGSM model supplies to the NGTDM model. We subdivide the estimates of commercially valuable averted emissions by region and well type in order to more accurately portray the economics of

implementing the environmental technology. Adding the averted methane emissions in this manner has the effect of moving the natural gas supply curve to the right in an increment consistent with the technically achievable emissions transferred into the production stream as a result of the final NSPS. We enter the increased natural gas recovery into NEMS on a per-well basis for new wells, following an estimation procedure similar to that of entering compliance costs into NEMS on a per-well basis for new wells (Table 6-1).

6.2.3 *Energy Markets Impacts*

We estimate impacts to drilling activity, price and quantity changes in the production of crude oil and natural gas, and changes in international trade of crude oil and natural gas. In each of these estimates, we present estimates for the baseline years of 2020 and 2025 and predicted results for 2020 and 2025 under the final rule. We also present impacts over the 2020 to 2025 period. For context, we provide estimates of production activities in 2012. With the exception of examining crude oil and natural gas trade, we focus the analysis on onshore oil and natural gas production activities in the continental (lower 48) U.S. We do this because offshore production is not affected by the NSPS and the bulk of the rule's impacts are expected to be in the continental U.S.

We first report estimates of impacts on crude oil and natural gas drilling activities and production. Table 6-2 presents estimates of successful onshore natural gas and crude oil wells drilled in the continental U.S.

Table 6-2 Successful Oil and Gas Wells Drilled (Onshore, Lower 48 States)

| | 2012 | Projection, 2020 | | Projection, 2025 | | Projection, 2020-25 | |
|---|---------------|------------------|---------------|------------------|---------------|---------------------|----------------|
| | | Baseline | NSPS | Baseline | NSPS | Baseline | NSPS |
| Successful Wells Drilled | | | | | | | |
| Natural Gas | 10,490 | 10,501 | 10,481 | 12,200 | 12,145 | 65,896 | 65,785 |
| Crude Oil | 28,496 | 27,455 | 27,463 | 29,244 | 29,231 | 168,768 | 168,736 |
| Total | 38,986 | 37,956 | 37,944 | 41,444 | 41,376 | 234,664 | 234,521 |
| % Change in Successful Wells Drilled from Baseline | | | | | | | |
| Natural Gas | | | 0.19% | | -0.45% | | -0.17% |
| Crude Oil | | | 0.03% | | -0.04% | | -0.02% |
| Total | | | 0.03% | | -0.16% | | -0.06% |

Results show that the final NSPS will have a relatively small impact on onshore well drilling in the lower 48 states. Drilling remains essentially unchanged in 2020, with very slight increases both oil and natural gas wells, relative to the baseline. Meanwhile, drilling of both natural gas and crude oil wells decreases slightly in 2025, relative to the baseline. The small increase in drilling in 2020 is somewhat counter-intuitive as production costs have been increased under the proposed NSPS. However, given NEMS is a dynamic, multi-period model, it is important to examine changes over multiple periods. Crude oil drilling over the 2020 to 2025 period decreases overall but by about 30 wells total, or about 0.02 percent, relative to the baseline. Natural gas drilling, over the same period remains declines by about 110 wells total, or about 0.17 percent, relative to the baseline.

Table 6-3 shows estimates of the changes in the domestic production of natural gas and crude oil under the NSPS.

Table 6-3 Domestic Natural Gas and Crude Oil Production (Onshore, Lower 48 States)

| | 2012 | Projection, 2020 | | Projection, 2025 | | Projection, 2020-25 | |
|---|--------|------------------|--------|------------------|--------|---------------------|---------|
| | | Baseline | NSPS | Baseline | NSPS | Baseline | NSPS |
| Domestic Production | | | | | | | |
| Natural Gas (trillion cubic feet) | 22.158 | 26.544 | 26.537 | 28.172 | 28.163 | 164.130 | 164.086 |
| Crude Oil (million bbls/day) | 4.597 | 8.031 | 8.031 | 8.027 | 8.028 | 48.084 | 48.086 |
| % Change in Domestic Natural Gas and Crude Oil Production (Onshore, Lower 48 States) | | | | | | | |
| Natural Gas | | | -0.03% | | -0.03% | | -0.03% |
| Crude Oil | | | 0.00% | | 0.01% | | 0.00% |

As indicated by the estimated change in the new well drilling activities, the analysis shows that the proposed NSPS will have a relatively small impact on onshore natural gas and crude oil production in the lower 48 states. Crude oil production remains essentially unchanged in 2020 and 2025 (with changes around or less than 0.01 percent in both years), relative to the baseline. While slightly increasing over the time horizon, the overall change in crude oil production is less than 0.01 percent, relative to the baseline. Natural gas production is estimated to decrease slightly during the 2020-25 period, by around 0.03 percent, relative to the baseline.

Note this analysis estimates very little change in domestic natural gas production, despite some environmental controls anticipated in response to the rule capture natural gas that would otherwise be emitted (about 16 bcf in 2020 and 27 bcf in 2025). NEMS models the adjustment of energy markets to the new slightly more costly natural gas and crude oil productive activities. At the new post-rule equilibrium, producers implementing emissions controls are still anticipated to capture and sell the captured natural gas, and this natural gas might offset other production, but not so much as to make overall production increase from the baseline projections.

Table 6-4 presents estimates of national average wellhead natural gas and crude oil prices for onshore production in the lower 48 states.

Table 6-4 Average Natural Gas and Crude Oil Wellhead Price (Onshore, Lower 48 States, 2012\$)

| | 2012 | Projection, 2020 | | Projection, 2025 | | Projection, 2020-25 | |
|--|--------|------------------|--------|------------------|--------|---------------------|--------|
| | | Baseline | NSPS | Baseline | NSPS | Baseline | NSPS |
| Lower 48 Average Wellhead Price | | | | | | | |
| Natural Gas (2012\$ per Mcf) | 2.566 | 4.428 | 4.441 | 5.184 | 5.190 | 4.880 | 4.890 |
| Crude Oil (2012\$ per barrel) | 94.835 | 73.920 | 73.918 | 85.219 | 85.218 | 79.530 | 79.527 |
| % Change in Lower 48 Average Wellhead Price from Baseline | | | | | | | |
| Natural Gas | | | 0.29% | | 0.12% | | 0.20% |
| Crude Oil | | | 0.00% | | 0.00% | | -0.01% |

Wellhead crude oil prices for onshore lower 48 production are not estimated to change meaningfully in 2020 or 2025, or over the 2020-25 period, relative to the baseline. The production-weighted average price for wellhead crude oil over the 2020 to 2025 period is not estimated to change more than 0.01 percent, relative to the baseline. Meanwhile, wellhead natural gas prices for onshore lower 48 production are estimated to increase slightly in response

to the rule in 2020 by about 0.29 percent and by about 0.12 percent in 2025, relative to the baseline. The production-weighted average price for wellhead natural gas over the 2020 to 2025 period is estimated to increase by around 0.2 percent, relative to the baseline.

Table 6-5 Net Imports of Natural Gas and Crude Oil

| | 2012 | Projection, 2020 | | Projection, 2025 | | Projection, 2020-25 | |
|-----------------------------------|-------|------------------|--------|------------------|--------|---------------------|---------|
| | | Baseline | NSPS | Baseline | NSPS | Baseline | NSPS |
| Net Imports | | | | | | | |
| Natural Gas (trillion cubic feet) | 1.519 | -2.557 | -2.554 | -3.502 | -3.498 | -18.959 | -18.939 |
| Crude Oil (million barrels/day) | 8.459 | 5.513 | 5.513 | 6.073 | 6.072 | 5.857 | 5.857 |
| % Change in Net Imports | | | | | | | |
| Natural Gas | | | 0.12% | | 0.11% | | 0.11% |
| Crude Oil | | | 0.00% | | -0.02% | | 0.00% |

Meanwhile, as shown in Table 6-5, net imports of natural gas are estimated to increase slightly in 2020 and 2025 relative to the baseline (by about 0.12 percent and 0.11 percent, respectively) relative to the baseline. Net imports of natural gas are also expected to increase by about 0.11 percent across the 2020 to 2025 period under the rule. Crude oil imports are not estimated to change in 2020 and to decrease slightly in 2025 by about 0.02 percent relative to the baseline. Over the 2020 to 2025 period, net imports of crude oil are not estimated to change in response to the rule.

6.3 Final Regulatory Flexibility Analysis

The Regulatory Flexibility Act (RFA; 5 U.S.C. §601 et seq.), as amended by the Small Business Regulatory Enforcement Fairness Act (Public Law No. 104121), provides that whenever an agency publishes a final rule after a general notice of proposed rulemaking is made, it must prepare and make available a final regulatory flexibility analysis (FRFA), unless it certifies that the rule, if promulgated, will not have a significant economic impact on a substantial number of small entities (5 U.S.C. §605[b]). Small entities include small businesses, small organizations, and small governmental jurisdictions. A FRFA describes the economic impact of the rule on small entities and any significant alternatives to the rule that would accomplish the objectives of the rule while minimizing significant economic impacts on small entities. Pursuant to section 604 of the RFA, the EPA prepared a final regulatory flexibility

analysis (FRFA) that examines the impact of the final rule on small entities along with regulatory alternatives that could minimize that impact.

Prior to publication of the proposed rule, the EPA prepared an initial regulatory flexibility analysis (IRFA) and convened a Small Business Advocacy Review (SBAR) Panel consisting of the Director of the Sector Policies & Programs Division of the EPA Office of Air Quality Planning & Standards, the Administrator of the Office of Information and Regulatory Affairs within the Office of Management and Budget, and the Chief Counsel for Advocacy of the Small Business Administration. The IRFA and Final SBAR Panel Report can be found in the docket to this rulemaking at EPA-HQ-OAR-2010-0505.

6.3.1 Reasons why the Action is Being Considered

The EPA is finalizing amendments to subpart OOOO due to reconsideration of certain issues raised in petitions for reconsideration that were received by the Administrator, which include implementation improvements. The EPA is also finalizing a new subpart, 40 CFR 60, subpart OOOOa, which includes: standards for greenhouse gas (GHG) emissions (in the form of limitations on methane) from certain facilities that are covered by current VOC standards in the oil and natural gas source category, and standards for GHG and VOC emissions from facilities across the source category that are currently unregulated, including hydraulically fractured oil well completions; fugitive emissions from well sites and compressor stations; pneumatic pumps; and centrifugal compressors, reciprocating compressors and pneumatic controllers in the transmission and storage segment. The EPA is including requirements for methane emissions in subpart OOOOa because methane is a GHG, and the oil and natural gas category is currently one of the country's largest emitters of methane. In 2009, the EPA found that by causing or contributing to climate change, GHGs endanger both the public health and the public welfare of current and future generations.⁷⁷

6.3.2 Significant Issues Raised

The EPA received comments on the proposed standards related to the potential impacts on small entities and requests for comments that were included based on the SBAR Panel

⁷⁷ “Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act,” 74 FR 66496 (Dec. 15, 2009) (“2009 Endangerment Finding”).

Recommendations. See sections VI and VIII of the preamble to the final rule and the RTC Document in Docket ID EPA-HQ-OAR-2010-0505 for more detailed responses.

Low production wells: Several commenters supported the proposed exemption of low production well sites from the fugitive monitoring requirements. Commenters noted that marginal wells generate relatively low revenue and these wells are often drilled and operated by small companies.

Response: While these commenters did provide support for the proposed low production well exemption, other commenters indicated that low production well sites have the potential to emit substantial amounts of fugitive emissions, and that a significant number of wells would be excluded from fugitive emissions monitoring based on this exemption. We did not receive data showing that low production well sites have lower emissions than non-low production well sites. In fact, the data that were provided indicated that the potential emissions from these well sites could be as significant as the emissions from non-low production well sites since the type of equipment and the well pressures are more than likely the same. In discussions with stakeholders, they indicated that well site fugitive emissions are not based on production, but rather on the number of pieces of equipment and components. Therefore, we believe that the emissions from low production and non-low production well sites are comparable and we did not finalize the proposed exclusion of low production well sites from fugitive emissions monitoring.

REC costs: Commenters stated that small operators have higher well completion costs, and typically conduct completions less frequently. Generally, small operators lack the purchasing power to get the discounted prices service companies offer to larger operators. However, commenters did not provide specific cost information.

Response: The BSER analysis is based on the averages of nationwide data. It is possible for a small operator to have higher than the nationwide average completion costs, however, the daily completion cost provided by the commenters is not significantly different than the EPA's estimate. Therefore, we do not believe that the cost of RECs disfavor small businesses.

Phase-in period for RECs: Commenters stated that the EPA should create a compliance phase-in period of at least 6 months for the REC requirements, to accommodate small operators. Commenters stated that REC equipment is in short supply, and this will drive up REC costs.

Commenters stated that small entities lack the purchasing power of larger operators, which makes it difficult to obtain the needed equipment before the compliance period begins.

Response: We agree that compliance with the REC requirements in the final rule could be burdensome for some in the near term due to the unavailability of REC equipment. As discussed in section VI of the preamble, the final rule provides a phase-in approach that would allow a quick build-up of the REC supplied in the near term.

Alternatives to OGI technology: Several commenters indicated that the EPA should allow alternatives to OGI technology as the cost is excessive for small operators.

Response: In the final rule, the EPA is allowing Method 21 with a repair threshold of 500 ppm as an alternative to OGI. We believe this alternative will alleviate some of the burden on small entities.

Basing monitoring frequency on the percentage of leaking components: Commenters indicated that using a percentage of components, rather than a set number of components, to determine the frequency of surveys is also unfair to small entities since a small site will have fewer fugitive emission components than a larger site. Commenters stated that smaller entities are much more likely to operate these smaller sites, and thus are more likely to have a higher frequency survey requirements under the percentage-based system.

Response: The EPA agrees that imposing a performance based monitoring schedule would require operators to develop a program that would require extensive administration to ensure compliance. We believe that the potential for a performance-based approach to encourage greater compliance is outweighed in this case by these additional burdens and the complexity it would add. Therefore, the EPA is finalizing a fixed monitoring frequency instead of performance based monitoring.

Timing of initial fugitive monitoring periods: Commenters stated that the requirement to conduct surveys for affected facilities using OGI technology within 30 days of the well completion or within 30 days of modification is overly restrictive. Additionally, commenters stated that small operators may not be able to find vendors available to survey a small number of

wells within the required timeframe. One commenter stated that contractors will be in high demand and may give scheduling preference to larger clients versus small business entities.

Response: EPA considered these and other comments and concluded that the proposed time of 30 days within a well completion or modification is not enough time to complete the necessary preparations for the initial monitoring survey. In addition, other commenters pointed out that first date of production should be the trigger, rather than the date of well completion. Therefore, for the collection of fugitive emissions components at a new or modified well site, we are finalizing that the initial monitoring survey must take place within **[insert date 1 year after publication of the final rule in the Federal Register]** or within 60 days of the startup of production, whichever is later. We believe this extended timeframe for compliance will alleviate some of the burden on smaller operators.

Third party compliance: Commenters believe that requiring third party compliance audits will be a significant burden on small entities. One commenter said that a third-party audit requirement will dramatically increase the costs of the program and have a negative competitive impact on smaller, less funded operators.

Response: While the EPA continues to believe that independent third party verification can furnish more, and sometimes better, data about regulatory compliance, we have explored alternatives to the independent third party verification. Specifically, the “qualified professional engineer” model was assessed to focus on the element of engineering design. The final rule requires a professional engineer certification of technical infeasibility of connecting a pneumatic pump to an existing control device, and a professional engineer design of closed vent systems. These certifications will ensure that the owner or operator has effectively assessed appropriate factors before making a claim of infeasibility and that the closed vent system is properly designed to verify that all emissions from the unit being controlled in fact reach the control device and allow for proper control. We believe this simplified approach will reduce the burden imposed on all affected facilities, including those owned by small businesses.

6.3.3 *Small Business Administration Comments*

The Chief Counsel for Advocacy of the Small Business Administration (SBA) did not file any comments in response to the proposed rule.

6.3.4 *Description and Estimate of Affected Small Entities*

The industry sectors covered by the final rule were identified during the development of the engineering cost analysis. The EPA conducted this regulatory flexibility analysis at the ultimate (i.e., highest) level of ownership, evaluating parent entities.⁷⁸ The EPA identified the size of ultimate parent entities by using the SBA size threshold guidelines.⁷⁹ The criteria for size determination vary by the organization/operation category of the ultimate parent entity, as can be seen in Table 6-6.

Table 6-6 SBA Size Standards by NAICS Code

| NAICS Codes | NAICS Industry Description | Size Standards (in millions of dollars) | Size Standards (in no. of employees) |
|-------------|---|--|---|
| 211111 | Crude Petroleum and Natural Gas Extraction | - | 1,250 |
| 211112 | Natural Gas Liquid Extraction | - | 750 |
| 213111 | Drilling Oil and Gas Wells | - | 1,000 |
| 213112 | Support Activities for Oil and Gas Operations | \$38.5 | - |
| 486110 | Pipeline Transportation of Crude Oil | - | 1,500 |
| 486210 | Pipeline Transportation of Natural Gas | \$27.5 | - |

Sources: U.S. Census Bureau, Statistics of U.S. Businesses, 2012. <<http://www.census.gov/econ/subb/>>. SBA Size Standards, 13 CFR 121. 201

We have projections of future potentially affected activities at an aggregate level, but identifying impacts on specific entities is challenging because of the difficulty of predicting potentially affected new or modified sources at the firm level. Because of these limitations, we based the analysis in this FRFA on impacts estimates for the final requirements for hydraulically fractured and re-fractured oil well completions and well site fugitive emissions. We are able to do this because the base year activity counts for the impacts estimates (as described in the TSD)

⁷⁸ See Section 2.6 of this RIA for more information on oil and natural gas industry firm characteristics and a breakdown of firms by size at the national level.

⁷⁹ U.S. Small Business Administration (SBA). 2016. Small Business Size Standards. Effective as of February 26, 2016. See: <https://www.sba.gov/sites/default/files/files/Size_Standards_Table.pdf>.

for this rule were based on detailed information for 2012 in a dataset of U.S. wells. The proprietary DrillingInfo dataset contains a variety of information including oil, condensate, and natural gas production levels, geographic locations, as well as basin and formation information, and information about owners/operators of wells, among other data fields.⁸⁰ As described in the TSD sections on hydraulically fractured and re-fractured oil well completions and fugitive emissions, we used the DrillingInfo dataset to identify and estimate all wells that were completed in 2012, as well as completions of hydraulically fracture or re-fractured oil wells.⁸¹ We used the field called “common operator” to identify the owner/operator of all wells in this set of new or modified 2012 wells.

While the FRFA does not incorporate potential impacts from other provisions of the final NSPS, the completions and fugitive emissions provisions represent about 98 percent of the estimated compliance costs of the final NSPS in 2020 and 2025 (Table 6-7). Not incorporating impacts from other provisions in this analysis is a limitation, but the EPA believes that detailed analysis of the two provisions impacts on small entities is illustrative of impacts on small entities from the rule in its entirety.

Table 6-7 Distribution of Estimated Compliance Costs Across Sources

| | Annualized Costs (With Product Recovery, 2012\$) | | | |
|---|--|----------|---------------|----------|
| | 2020 | 2020 (%) | 2025 | 2025 (%) |
| Hydraulically-fractured and Re-fractured Oil Well Completions and Recompletions | \$130,000,000 | 39% | \$130,000,000 | 25% |
| Fugitive Emissions at Well Sites | \$190,000,000 | 59% | \$380,000,000 | 73% |
| Other Sources | \$8,000,000 | 2% | \$11,000,000 | 2% |
| Total Annualized Costs of Proposed NSPS | \$320,000,000 | 100% | \$530,000,000 | 100% |

Note: sums may not total due to independent rounding.

To identify potentially affected entities under the NSPS, the EPA combined ownership information from the DrillingInfo dataset with information drawn from the Hoover’s Inc. online

⁸⁰ DrillingInfo is a private company that provides information and analysis to the energy sector. More information is available at: <http://info.drillinginfo.com>.

⁸¹ The TSD for this proposed rule provides information on this dataset of U.S. wells. Additional details on the development of this dataset can also be found in the following docketed memo: Memorandum to Mark de Figueiredo, EPA, from Casey MacQueen and Jessica Gray, ERG. “DrillingInfo Processing Methodology”. August 27, 2014.

platform, which includes information about companies, such as NAICS codes, employee counts, and sales information.⁸² Note that this analysis assumes that the firms performing potentially affected activities are also the firms performing activities in the future under the NSPS. While likely true for many firms, this will not be the case for all firms.

The EPA matched owner/operators from the DrillingInfo dataset to companies in a database developed from a download of oil and gas companies in Hoover’s online database. The EPA matched as many records as possible. In the instances where the DrillingInfo owner/operator was not the highest level or company ownership, we recorded the highest level of owner as was identifiable in Hoovers. Linking these two datasets yields information on the NAICS, employee levels, and revenues of the owner/operators shown in the DrillingInfo dataset to have new or modified wells in 2012.

The EPA then used the NAICS codes associated with the matched owner/operators to determine which owner/operators should be considered to be small entities for this analysis, based on the SBA size standards above. That said, many DrillingInfo owner/operators had no match in Hoovers. Additionally, some Hoovers records lacked the information (employees or revenues, depending on the NAICS) needed to make a size determination. We initially classified these as an “unknown” size. See Table 6-8 for a summary of results of this matching exercise.

Table 6-8 No. of Completions in 2012 by Preliminary Firm Size

| Firm Size Performing | Well Completions | No. of Firms | Number of Completions, 2012 | |
|----------------------|------------------|--------------|---|-----------------|
| | | | Hydraulically Fractured or Re-fractured Oil Wells | All Completions |
| Small | | 951 | 2,998 | 10,360 |
| Not Small | | 150 | 10,674 | 22,866 |
| Unknown | | 1,118 | 676 | 5,762 |
| Total | | 2,219 | 14,348 | 38,988 |

Note: consistent with the cost and emissions analysis, these 2012 completion counts do not include completions in states where there are state rules with similar requirements as the proposed rules. Counts are slightly lower than totals included in the impacts analysis base year estimates as some completions have no owner/operator recorded in the dataset. Sums may not total due to independent rounding.

⁸² The Hoover’s Inc. online platform includes company records that can contain NAICS codes, number of employees, revenues, and assets. For more information, see: <<http://www.hoovers.com>>.

Upon analysis of the firms of unknown size, the EPA observed that, on average, the firms of unknown size perform fewer well completions. For this reason, we made the observation that the firms of unknown size are more likely to be small than not small. To proceed with the analysis, we reclassified these firms as small, resulting in the distribution presented in the first two columns of Table 6-9.

Table 6-9 No. of Completions in 2012 by Firm Size

| Firm Size Performing Well Completions | | No. of Completions, 2012 | |
|---------------------------------------|--------------|---|-----------------|
| | | Hydraulically Fractured or Re-fractured Oil Wells | All Completions |
| Small | 2,069 | 3,674 | 16,122 |
| Not Small | 150 | 10,674 | 22,866 |
| Total | 2,219 | 14,348 | 38,988 |

Note: consistent with the cost and emissions analysis, these 2012 completion counts do not include completions in states where there are state rules with similar requirements as the proposed rules. Counts are slightly lower than totals included in the impacts analysis base year estimates as some completions have no owner/operator recorded in the dataset. Sums may not total due to independent rounding.

6.3.5 Projected Reporting, Recordkeeping and Other Compliance Requirements

The information to be collected for the NSPS is based on notification, performance tests, recordkeeping and reporting requirements which will be mandatory for all operators subject to the final standards. Recordkeeping and reporting requirements are specifically authorized by section 114 of the CAA (42 U.S.C. 7414). The information will be used by the delegated authority (state agency, or Regional Administrator if there is no delegated state agency) to ensure that the standards and other requirements are being achieved. Based on review of the recorded information at the site and the reported information, the delegated permitting authority can identify facilities that may not be in compliance and decide which facilities, records, or processes may need inspection. All information submitted to the EPA pursuant to the recordkeeping and reporting requirements for which a claim of confidentiality is made is safeguarded according to Agency policies set forth in 40 CFR part 2, subpart B.

Potential respondents under subpart OOOOa are owners or operators of new, modified or reconstructed oil and natural gas affected facilities as defined under the rule. None of the facilities in the United States are owned or operated by **state, local, tribal or the Federal** government. All facilities are privately owned for-profit businesses. The requirements in this

action result in an industry recording keeping and reporting burden associated with review of the requirements for all affected entities, gathering relevant information, performing initial performance tests and repeat performance tests if necessary, writing and submitting the notifications and reports, developing systems for the purpose of processing and maintaining information, and training personnel to be able to respond to the collection of information. The estimated average annual burden (averaged over the first 3 years after the effective date of the standards) for the recordkeeping and reporting requirements in subpart OOOOa for the 2,554 owners and operators that are subject to the rule is 98,438 labor hours, with an annual average cost of \$3,361,074. The annual public reporting and recordkeeping burden for this collection of information is estimated to average 20 hours per response. Respondents must monitor all specified criteria at each affected facility and maintain these records for 5 years. Burden is defined at 5 CFR 1320.3(b).

6.3.5.1 Methodology for Estimating Compliance Cost Impacts on Small Entities

This section describes how we project the 2012 base year estimates of incrementally affected facilities to 2020 and 2025 levels, how we estimate costs at the firm level from these activity estimates, and how we estimated sales for small entities when available data on sales are incomplete.

New and modified hydraulically fractured oil well completions and well sites in this FRFA are based on the same growth rates used to project future activities as described in the TSD and are consistent with other analyses in this RIA. These growth rates are consistent with the drilling activity in the 2015 Annual Energy Outlook. These growth rates are applied to the 2012 base year estimates for each firm in the database.

Table 6-10 presents future year estimates of incrementally affected new and modified sources.

Table 6-10 No. of Incrementally Affected Sources in 2020 and 2025 by Firm Size

| Firm Size Performing Well Completions | No. of Incrementally Affected Sources, 2020 | | | No. of Incrementally Affected Sources, 2025 | | |
|---------------------------------------|---|----------------|----------------|---|----------------|----------------|
| | Hydraulically Fractured or Re-fractured Oil Wells | Gas Well Sites | Oil Well Sites | Hydraulically Fractured or Re-fractured Oil Wells | Gas Well Sites | Oil Well Sites |
| Small | 3,500 | 5,600 | 33,000 | 3,800 | 11,000 | 68,000 |
| Not Small | 10,000 | 11,000 | 44,000 | 11,000 | 24,000 | 86,000 |
| Total | 14,000 | 17,000 | 77,000 | 15,000 | 35,000 | 160,000 |

Note: Sums may not total due to independent rounding. Assumes well sites have two wells apiece.

This approach assumes that no other firms perform potentially affected activities and firms performing these activities in 2012 will continue to do so in 2020 and 2025. Again, the analysis in this FRFA is meant to be illustrative of impacts on small entities. Exact predictions of future activities at the firm level is not possible.

Once the future year activities were estimated we allocated compliance costs across small entities based upon the costs estimated in the TSD and consistently with other analyses in this RIA. These cost estimates include estimates of revenue from natural gas recovery at the assumed value of \$4/Mcf in 2012 dollars, again consistent with other analyses in this RIA. For hydraulically fractured and re-fractured oil well completions, we assumed each small entity is required to perform RECs and combustion in the same proportions assumed in the TSD and RIA. We also assumed the same proportion would be exploratory or delineation wells as the TSD and RIA. Table 6-11 shows the distribution of compliance costs estimates across firm size and year.

Table 6-11 Distribution of Estimated Compliance Costs¹ across Firm Size Classes

| Firm Size | Annualized Compliance Costs (2012\$) | | |
|--------------|--------------------------------------|--------------------|--------------------|
| | No. of Firms | 2020 | 2025 |
| Small | 2,069 | 110,000,000 | 190,000,000 |
| Not Small | 150 | 200,000,000 | 320,000,000 |
| Total | 2,219 | 310,000,000 | 510,000,000 |

¹ Compliance cost estimates here include only costs of requirements for hydraulically fractured or re-fractured oil well completions and well-site fugitive emissions. As described in Section 6.1.3, these provisions account for the large majority of the rule's potential impact in 2020 and 2025.

Note: sums may not total due to independent rounding.

In order to estimate the cost-to-sales ratio, we again combined information from Hoovers and the DrillingInfo databases. The Hoovers database has sales information for some, but not all, small entities estimated in this FRFA analysis to have impacts. To supplement the sales information, we estimated 2012 sales by multiplying 2012 oil and natural gas production levels reported in the DrillingInfo database by assumed oil and natural gas prices at the wellhead. For natural gas, we assumed the same \$4/Mcf for natural gas.⁸³ For oil prices, we estimated revenues using two alternative prices, \$70/bbl and \$50/bbl. In the results, we call the case using \$70/bbl the “primary scenario” and the case using the \$50/bbl as the “low oil price scenario”.⁸⁴ In the instances where the 2012 production-derived revenues exceeded the Hoovers revenues, we replaced the Hoovers estimate with the production-derived estimate as more likely to be an accurate estimate of sales for 2012.

6.3.5.2 *Compliance Cost Impact Estimate Results*

This section presents results of the cost-to-sales ratio analysis for both the primary scenario and the low oil price scenario. The percent of small entities with cost-to-sales ratios exceeding 1 percent and 3 percent in 2020 and 2025 are greater under the low oil price scenario, as would be expected due to lower estimated sales revenues from a lower oil price. Also, as expected, the entities with cost-to-sales ratios greater than 1 percent and greater than 3 percent increase from 2020 to 2025 in both the main case and the low oil price scenario as affected sources accumulate under the NSPS.

⁸³ The U.S. Energy Information Administration’s 2015 Annual Energy Outlook projects 2020 Henry Hub natural gas prices to be \$4.88/MMBtu in its reference case and \$4.30/MMBtu in its “low oil” price case in 2013 dollars. Available at: <<http://www.eia.gov/beta/aeo/#/?id=14-AEO2015>>. After adjusting to \$/Mcf (using the conversion of 1 MMBtu = 1.208 Mcf) in 2012 dollars (using the GDP-Implicit Price Deflator), these prices are \$4.80/Mcf in the reference case and \$4.323/Mcf in the low oil price case. Rounding down to \$4/Mcf likely under-estimates sales.

⁸⁴ The 2015 Annual Energy Outlook projects wellhead oil prices to be \$75.16/bbl in its reference case and \$54.10/bbl in its “low oil” price case in 2013 dollars. Available at: <<http://www.eia.gov/beta/aeo/#/?id=14-AEO2015>>. After adjusting to 2012 dollars (using the GDP-Implicit Price Deflator), these prices are \$74.00/bbl in the reference case and \$53.27/bbl in the low oil price case.

Table 6-12 Compliance Costs-to-Sales¹ Ratios across Firm Size Classes for Primary Scenario and Low Oil Price Scenario²

| | 2020 (Main Case) | | 2020 (Low Oil Price Case) | |
|------------------------|-----------------------|---------------------|---------------------------|---------------------|
| | No. of Small Entities | % of Small Entities | No. of Small Entities | % of Small Entities |
| No. of Small Entities | 2,031 | - | 2,043 | - |
| Greater than 1 percent | 564 | 28% | 648 | 32% |
| Greater than 3 percent | 289 | 14% | 344 | 17% |

| | 2025 (Main Case) | | 2025 (Low Oil Price Case) | |
|------------------------|-----------------------|---------------------|---------------------------|---------------------|
| | No. of Small Entities | % of Small Entities | No. of Small Entities | % of Small Entities |
| No. of Small Entities | 2,031 | - | 2,043 | - |
| Greater than 1 percent | 824 | 41% | 924 | 45% |
| Greater than 3 percent | 419 | 21% | 502 | 25% |

¹ Compliance cost estimates here include only costs of requirements for hydraulically fractured or re-fractured oil well completions and well-site fugitive emissions. These provisions account for the large majority of the rule's potential impact in 2020 and 2025.

² In the main case, the wellhead prices are assumed to be \$4/Mcf for natural gas and \$70/bbl for crude oil. In the low oil price case, the wellhead prices are assumed to be \$4/Mcf for natural gas and \$50/bbl for crude oil.

6.3.5.3 Caveats and Limitations

The analysis above is subject to a number of caveats and limitations, many of which we discussed in the presentation of methods and results. It is useful, however, to present a complete list of the caveats and limitations here.

- Because of data limitations, the analysis presented in the FRFA only examines impacts on requirements for hydraulically fractured and re-fractured oil well completions and well site fugitive emissions. While impacts from these requirements constitute a large proportion of the estimated impacts from the final NSPS, the omission of the estimated costs of other requirements leads to a relative under-estimation of the impacts on small entities. Also, the impacts from other requirements may affect firms that are not drilling wells, such as pipeline transmission firms.
- Not all owner/operators listed in the DrillingInfo database could be identified in the Hoovers database. These owner/operators tend to have developed relatively few new or modified wells in 2012. As a result, we assumed these were small entities, whereas these entities may actually be subsidiaries of larger enterprises. While the impacts estimates are not affected in the aggregate by this assumption, the assumption likely leads to an over-estimate of the impact on small entities for the provisions examined.
- The analysis assumes the same population of entities completing wells in 2012 are also completing wells in 2020 and 2025, according to growth rates developed for the entire

sector. In the future, many of these firms will complete fewer or more wells, and other firms will complete wells. All of these firms combined may complete new or modified wells at higher or lower rates depending on economics and technological factors that are largely unpredictable.

- The approach used to estimate sales for the cost-to-sales ratio might over-estimate or under-estimate sales depending upon the accuracy of the information in the underlying databases and the market prices ultimately faced in 2020 and 2025.

6.3.6 *Regulatory Flexibility Alternatives*

The EPA considered three major options for this final rule. The option EPA is finalizing contains reduced emission completion (REC) and completion combustion requirements for a subset of newly completed oil wells that are hydraulically fractured or refractured. This option requires fugitive emissions survey and repair programs be performed semiannually (twice per year) at the affected newly drilled or refractured oil and natural gas well sites, and quarterly at new or modified gathering and boosting stations and new or modified transmission and storage compressor stations. Additionally this option requires reductions from centrifugal compressors, reciprocating compressors, pneumatic controllers, and pneumatic pumps throughout the oil and natural gas source category.

The other options considered differ from the finalized option with respect to the requirements for fugitive emissions. One option exempted low production well sites from the well site fugitive requirements. This less stringent option was analyzed as an alternative to reduce burden on small entities. However, it was rejected because we believe that low production well sites have the same type of equipment and components as production well sites with production greater than 15 boe per day. Since we did not receive additional data on equipment or component counts for low production wells, we believe that a low production well model plant would have the same equipment and component counts as a non-low production well site. This would indicate that the emissions from low production well sites could be similar to that of non-low production well sites. Additionally, we did not receive data showing that low production well sites have lower methane or VOC emissions than well sites. In fact, the data that were provided indicated that the potential emissions from these well sites could be as significant as the emissions from non-low production well sites since the type of equipment and the well pressures are more than likely the same. In discussions with industry stakeholders, they indicated that well site fugitive emissions are not based on production, but rather on the number of pieces of

equipment and components. Therefore, we believe that the emissions from low production and non-low production well sites are comparable, and low production well sites were included in the selected option.

Lastly, the more stringent option required quarterly monitoring for all sites under the fugitive emissions program. This option lead to greater emission reductions, however it was not selected because it increased costs, resulting in a net effect of lower net benefits compared to the finalized option.

In addition, the EPA is preparing a Small Entity Compliance Guide to help small entities comply with this rule. The guide will be available on the World Wide Web approximately 60 days after promulgation of the rule, at <https://www3.epa.gov/airquality/oilandgas/implement.html>.

The EPA notes that the IRFA includes numerous recommendations made by the SBAR Panel⁸⁵. The EPA considered these recommendations during the development of the proposal and final rule. The rationale for the EPA's acceptance or rejection of each recommendation can be found in the relevant discussion of each emission source throughout the preamble to the proposal, final rule, and RTC. Though all comments were seriously considered, the EPA is unable to incorporate all suggestions without compromising the effectiveness of the final regulation. Changes to the rule from proposal that may benefit small entities due to comments received include allowing both OGI and Method 21 as acceptable monitoring technology, replacing a performance based monitoring schedule with a fixed frequency, lengthening the time of initial fugitive monitoring from within 30 days to the later of either **[insert date 1 year after publication of the final rule in the Federal Register]** or with 60 days of the startup of production, and simplified the third party verification of technical infeasibility requirements. Though these are not monetized, we believe the flexibility and simplifications these changes have added to the rule result in a reduced burden on small entities.

⁸⁵ The final SBAR Panel report is found at <<https://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2010-0505-4959>>.

6.4 Employment Impact Analysis

In addition to addressing the costs and benefits of the final rule, the EPA has analyzed the impacts of this rulemaking on employment, which are presented in this section.⁸⁶ While a standalone analysis of employment impacts is not included in a standard cost-benefit analysis, such an analysis is of particular concern in the current economic climate given continued interest in the employment impact of regulations such as this final rule. Executive Order 13563, states, “Our regulatory system must protect public health, welfare, safety, and our environment while promoting economic growth, innovation, competitiveness, and job creation.”⁸⁷ A discussion of compliance costs, including reporting and recordkeeping requirements, is included in Section 3 of this RIA. This analysis uses detailed engineering information on labor requirements for each of the control strategies identified in this final rule in order to estimate partial employment impacts for affected entities in the oil and gas industry. These bottom-up, engineering-based estimates represent only one portion of potential employment impacts within the regulated industry, and do not represent estimates of the *net* employment impacts of this rule. First, this section presents an overview of the various ways that environmental regulation can affect employment. The EPA continues to explore the relevant theoretical and empirical literature and to seek public comments in order to ensure that the way the EPA characterizes the employment effects of its regulations is valid and informative. The section concludes with partial employment impact estimates that rely on engineering-based information for labor requirements for each of the control strategies identified by the rule.

6.4.1 Employment Impacts of Environmental Regulation

From an economic perspective labor is an input into producing goods and services; if a regulation requires that more labor be used to produce a given amount of output, that additional labor is reflected in an increase in the cost of production. Moreover, when the economy is at full employment, we would not expect an environmental regulation to have a net impact on overall employment because labor is being shifted from one sector to another. On the other hand, in

⁸⁶ The employment analysis in this RIA is part of the EPA’s ongoing effort to “conduct continuing evaluations of potential loss or shifts of employment which may result from the administration or enforcement of [the Act]” pursuant to CAA section 321(a).

⁸⁷ Executive Order 13563 (January 21, 2011). *Improving Regulation and Regulatory Review. Section 1. General Principles of Regulation*, Federal Register, Vol. 76, Nr. 14, p. 3821.

periods of high unemployment, net employment effects (both positive and negative) are possible.

For example, an increase in labor demand due to regulation may result in a short-term net increase in overall employment as workers are hired by the regulated sector to help meet new requirements (e.g., to install new equipment) or by the environmental protection sector to produce new abatement capital resulting in hiring previously unemployed workers. When significant numbers of workers are unemployed, the opportunity costs associated with displacing jobs in other sectors are likely to be higher. And, in general, if a regulation imposes high costs and does not increase the demand for labor, it may lead to a decrease in employment. The responsiveness of industry labor demand depends on how these forces all interact. Economic theory indicates that the responsiveness of industry labor demand depends on a number of factors: price elasticity of demand for the product, substitutability of other factors of production, elasticity of supply of other factors of production, and labor's share of total production costs. Berman and Bui (2001) put this theory in the context of environmental regulation, and suggest that, for example, if all firms in the industry are faced with the same compliance costs of regulation and product demand is inelastic, then industry output may not change much at all.

Regulations set in motion new orders for pollution control equipment and services. New categories of employment have been created in the process of implementing environmental regulations. When a regulation is promulgated, one typical response of industry is to order pollution control equipment and services in order to comply with the regulation when it becomes effective. On the other hand, the closure of plants that choose not to comply – and any changes in production levels at plants choosing to comply and remain in operation - occur after the compliance date, or earlier in anticipation of the compliance obligation. Environmental regulation may increase revenue and employment in the environmental technology industry. While these increases represent gains for that industry, they translate into costs to the regulated industries required to install the equipment.

Environmental regulations support employment in many basic industries. Regulated firms either hire workers to design and build pollution controls directly or purchase pollution control devices from a third party for installation. Once the equipment is installed, regulated firms hire workers to operate and maintain the pollution control equipment—much like they hire workers to produce more output. In addition to the increase in employment in the environmental

protection industry (via increased orders for pollution control equipment), environmental regulations also support employment in industries that provide intermediate goods to the environmental protection industry. The equipment manufacturers, in turn, order steel, tanks, vessels, blowers, pumps, and chemicals to manufacture and install the equipment.

Berman and Bui (2001) demonstrate using standard neoclassical microeconomics that environmental regulations have an ambiguous effect on employment in the regulated sector. The theoretical results imply that the effect of environmental regulation on employment in the regulated sector is an empirical question. Berman and Bui (2001) developed an innovative approach to examine how an increase in local air quality regulation that reduces nitrogen oxides (NO_x) emissions affects manufacturing employment in the South Coast Air Quality Management District (SCAQMD), which incorporates Los Angeles and its suburbs. During the time frame of their study, 1979 to 1992, the SCAQMD enacted some of the country's most stringent air quality regulations. Using SCAQMD's local air quality regulations, Berman and Bui identify the effect of environmental regulations on net employment in the regulated industries.⁸⁸ The authors find that "while regulations do impose large costs, they have a limited effect on employment" (Berman and Bui, 2001, p. 269). Their conclusion is that local air quality regulation "probably increased labor demand slightly" but that "the employment effects of both compliance and increased stringency are fairly precisely estimated zeros, even when exit and dissuaded entry effects are included" (Berman and Bui, 2001, p. 269).⁸⁹

While there is an extensive empirical, peer-reviewed literature analyzing the effect of environmental regulations on various economic outcomes including productivity, investment, competitiveness as well as environmental performance, there are only a few papers that examine the impact of environmental regulation on employment, but this area of the literature has been growing. As stated previously in this RIA section, empirical results from Berman and Bui (2001) suggest that new or more stringent environmental regulations do not have a substantial impact on net employment (either negative or positive) in the regulated sector. Similarly, Ferris, Shadbegian, and Wolverton (2014) also find that regulation-induced net employment impacts are

⁸⁸ Berman and Bui include over 40 4-digit SIC industries in their sample.

⁸⁹ Including the employment effect of exiting plants and plants dissuaded from opening will increase the estimated impact of regulation on employment.

close to zero in the regulated sector. Furthermore, Gray et al (2014) find that pulp mills that had to comply with both the air and water regulations in the EPA's 1998 "Cluster Rule" experienced relatively small and not always statistically significant, decreases in employment. Nevertheless, other empirical research suggests that more highly regulated counties may generate fewer jobs than less regulated ones (Greenstone 2002, Walker 2011). However, the methodology used in these two studies cannot estimate whether aggregate employment is lower or higher due to more stringent environmental regulation, it can only imply that relative employment growth in some sectors differs between more and less regulated areas. List *et al.* (2003) find some evidence that this type of geographic relocation, from more regulated areas to less regulated areas may be occurring. Overall, the peer-reviewed literature does not contain evidence that environmental regulation has a large impact on net employment (either negative or positive) in the long run across the whole economy.

While the theoretical framework laid out by Berman and Bui (2001) still holds for the industries affected under these emission guidelines, important differences in the markets and regulatory settings analyzed in their study and the setting presented here lead us to conclude that it is inappropriate to utilize their quantitative estimates to estimate the net employment impacts from this final regulation. In particular, the industries used in these two studies as well as the timeframe (late 1970's to early 1990's) are quite different than those in this final NSPS. Furthermore, the control strategies analyzed for this RIA include implementing RECs, reducing fugitive emissions, and reducing emissions from pneumatic controllers, pumps, and reciprocating and centrifugal compressors, which are very different than the control strategies examined by Berman and Bui.⁹⁰ For these reasons we conclude there are too many uncertainties as to the transferability of the quantitative estimates from Berman and Bui to apply their estimates to quantify the net employment impacts within the regulated sectors for this regulation, though these studies have usefulness for qualitative assessment of employment impacts.

The preceding sections have outlined the challenges associated with estimating net employment effects in the regulated sector and in the environmental protection sector. These challenges make it very difficult to accurately produce net employment estimates for the whole

⁹⁰ More detail on how emission reductions expected from compliance with this rule can be found in Section 3 of this RIA.

economy that would appropriately capture the way in which costs, compliance spending, and environmental benefits propagate through the macro-economy. Given the difficulty with estimating national impacts of regulations, the EPA has not generally estimated economy-wide employment impacts of its regulations in its benefit-cost analyses. However, in its continuing effort to advance the evaluation of costs, benefits, and economic impacts associated with environmental regulation, the EPA has formed a panel of experts as part of the EPA's Science Advisory Board (SAB) to advise the EPA on the technical merits and challenges of using economy-wide economic models to evaluate the impacts of its regulations, including the impact on net national employment.⁹¹ Once the EPA receives guidance from this panel it will carefully consider this input and then decide if and how to proceed on economy-wide modeling of net employment impacts of its regulations.

6.4.2 Labor Estimates Associated with Final Requirements

Section 2 of the RIA, in Table 2-17 and Table 2-18, presents background information on employment and wages in the oil and natural gas industry. As well as producing much of the U.S. energy supply, the oil and natural gas industry directly employs a significant number of people. Table 2-17 shows employment in six oil and natural gas-related NAICS codes from 1990 to 2014.⁹² The overall trend shows a decline in total industry employment throughout the 1990s, hitting a low of 314,000 in 1999, but rebounding to a 2014 peak of about 660,000. Crude Petroleum and Natural Gas Extraction (NAICS 211111) and Support Activities for Oil and Gas Operations (NAICS 213112) employ the majority of workers in the industry. From 1990 to 2014, average wages for the oil and natural gas industry increased. Table 2-18 shows real wages (in 2012 dollars) from 1990 to 2014 for the NAICS codes associated with the oil and natural gas industry.

The focus of this part of the analysis is on labor requirements related to the compliance actions for the final rule of the affected entities within the oil and natural gas sector. We do not estimate any potential changes in labor outside of the affected sector, and due to data and

⁹¹ For further information see:

<http://yosemite.epa.gov/sab/sabproduct.nsf/0/07E67CF77B54734285257BB0004F87ED?OpenDocument>

⁹² NAICS 211111, 21112, 213111, 213112, 486110, and 486210.

methodology limitations we do not estimate net employment impacts for the affected sector, apart from the partial estimate of the labor requirements related to control strategies. This analysis estimates the labor required to the install, operate, and maintain control equipment and activities, as well as to perform new reporting and recordkeeping requirements.

It is important to highlight that, unlike the typical case where a firm often has to reduce production in order to reduce output of negative production externalities (i.e., emissions), many of the emission controls required by the final NSPS will simultaneously increase production and reduce negative externalities. That is, these controls jointly produce environmental improvements and increase output in the regulated sector. Therefore, new labor associated with implementing these controls to comply with the new regulations can also be viewed as additional labor increasing output while reducing undesirable emissions. However, these rules may require unprofitable investments for some operators, and there is a possibility that these producers decrease output in response and create downward pressure on labor demand, both in the regulated sector and on those sectors using natural gas as an input. This RIA does not include quantified estimates of these potential adverse effects on the labor market due to data limitations and theoretical challenges, as described above.

No estimates of the labor used to manufacture or assemble pollution control equipment or to supply the materials for manufacture or assembly are included because the EPA does not currently have this information. The labor requirements analysis uses a bottom-up engineering-based methodology to estimate employment impacts. The engineering cost analysis summarized in Chapter 3 of this RIA includes estimates of the labor requirements associated with implementing the regulations. Each of these labor changes may be required as part of an initial effort to comply with the new regulation or required as a continuous or annual effort to maintain compliance. We estimate up-front and continual annual labor requirements by estimating hours of labor required and converting this number to full-time equivalents (FTEs) by dividing by 2,080 (40 hours per week multiplied by 52 weeks). We note that this type of FTE estimate cannot be used to make assumptions about the specific number of employees involved or whether new jobs are created for new employees.

The results of this employment analysis of the NSPS are presented in Table 6-13 through

Table 6-16 for 2020 and 2025 for individual sources regulated under this rule. Table 6-17 presents summary-level labor impacts for all sources. The tables break down the installation, operation, and maintenance estimates by type of pollution control evaluated in the RIA and present both the estimated hours required and the conversion of this estimate to FTE. The labor information is based upon the cost analysis presented in the TSD that supports this rule, based upon analysis presented in the RIA developed for the 2012 NSPS and NESHAP Amendments for the Oil and Natural Gas Sector (U.S. EPA, 2012). In addition, for the final NSPS, reporting and recordkeeping requirements were estimated for the entire rule rather than by anticipated control requirements. The reporting and recordkeeping estimates are consistent with estimates the EPA submitted as part of its Information Collection Request (ICR), the estimated costs which are included in the cost estimates presented in Chapter 3.

Table 6-13 presents estimates of labor requirements for hydraulically fractured oil well completions. The REC and completion combustion requirements are associated with certain new and existing oil well completions. While individual well completions take place over a short period of time (days to a few weeks), the overall industry completes new wells and re-completes some existing wells every year. Because of the continuing nature of new and existing well completions, annually, at the industry level, we report the REC-related labor requirements in annual units.

The per-unit estimates of one-time labor requirements associated with implementing RECs and completion combustion are drawn from the labor requirements estimated for implementing RECs on hydraulically fractured well completions in EPA (2012). However, the labor requirements in that report were based upon a completion that is assumed to last seven days (218 hours per completion for a REC or 22 hours labor per completion for completion combustion). In this analysis, completion events for hydraulically fractured oil wells are assumed to last three days, so we multiply the seven-day requirements by $3/7$ (93 hours per completion for a REC or 9 hours labor per completion for completion combustion).

Table 6-13 Estimates of Labor Required to Comply with NSPS for Hydraulically Fractured Oil Well Completions, 2020 and 2025

| Emissions Source/Control | Projected No. of Incrementally Affected Units (2020) | Per Unit One-time Labor Estimate (hours) | Per Unit Annual Labor Estimate (hours) | Total One-Time Labor Estimate (hours) | Total Annual Labor Estimate (hours) | One-time FTE | Annual FTE |
|---|---|---|---|--|--|---------------------|-------------------|
| 2020 | | | | | | | |
| Hydraulically Fractured Oil Well Completions and Recompletions | | | | | | | |
| Completions where REC and completion combustion is required | 7,500 | 0 | 93 | 0 | 700,000 | 0 | 340 |
| Completions where completion combustion is required | 5,600 | 0 | 9 | 0 | 53,000 | 0 | 25 |
| Total | 13,000 | N/A | N/A | 0 | 760,000 | 0 | 360 |
| 2025 | | | | | | | |
| Hydraulically Fractured Oil Well Completions and Recompletions | | | | | | | |
| Completions where REC and completion combustion is required | 8,000 | 0 | 93 | 0 | 750,000 | 0 | 360 |
| Completions where completion combustion is required | 6,000 | 0 | 9 | 0 | 57,000 | 0 | 27 |
| Total | 14,000 | N/A | N/A | 0 | 800,000 | 0 | 390 |

Note: Full-time equivalents (FTE) are estimated by first multiplying the projected number of affected units by the per-unit labor requirements and then multiplying by 2,080 (40 hours multiplied by 52 weeks). Totals may not sum due to independent rounding.

Table 6-14 presents estimates of labor requirements for fugitive emissions. Consistent with the cost estimates for fugitive emissions presented in Section 5 of the TSD, we estimate labor associated with company-level activities and activities at field sites. Company-level activities include one-time activities such as planning the company’s fugitive emissions program and annual requirements such as reporting and recordkeeping. Field-level activities include semiannual inspection and repair of leaks. It is important to note, however, that the compliance costs estimates for leak inspection were based upon an estimate of the costs to hire a contractor to provide the inspection service, but the source providing this information does not have a breakdown of the labor component of the rental cost. As a result, the labor requirements for the fugitives program remain uncertain.

Table 6-14 Estimates of Labor Required to Comply with NSPS for Fugitive Emissions, 2020 and 2025

| Emissions Source | Emissions Control | Projected No. of Incrementally Affected Units (2020) | Per Unit One-time Labor Estimate (hours) | Per Unit Annual Labor Estimate (hours) | Total One-Time Labor Estimate (hours) | Total Annual Labor Estimate (hours) | One-time FTE | Annual FTE |

| Site-level | Monitoring and Maintenance | 50 | 0.0 | 210 | 0 | 11,000 | 0 | 5 |
| Total | | 190,000 | N/A | N/A | 560,000 | 2,800,000 | 270 | 1,400 |

Note: Full-time equivalents (FTE) are estimated by first multiplying the projected number of affected units by the per unit labor requirements and then multiplying by 2,080 (40 hours multiplied by 52 weeks). Totals may not sum due to independent rounding.

Most labor required for fugitive emissions is needed at well sites in the field, which number in the thousands. Note that the labor requirements estimates increase from 2020 to 2025 as the number of sites regulated under the final NSPS accumulates.

Table 6-15 presents labor requirement estimates for monitoring and maintenance requirements for reciprocating compressors and routing emissions to a control device for centrifugal compressors. Like the estimates for completions, the per unit labor estimates were based on EPA (2012). As relatively little labor is required for reciprocating compressors and relatively few affected centrifugal compressors are expected in the future, the estimates of both one-time and on-going labor requirements for compressor requirements are minimal.

Table 6-15 Estimates of Labor Required to Comply with NSPS for Reciprocating and Centrifugal Compressors, 2020 and 2025

| Emissions Source | Emissions Control | Projected No. of Incr. Affected Units | Per-unit | Per-unit | Total | Total | One-time FTE | Annual FTE |
|--------------------|----------------------------|---------------------------------------|---------------------------|-------------------------|-------------------------------|-----------------------------|--------------|------------|
| | | | One-time Labor Est. (hrs) | Annual Labor Est. (hrs) | One-Time Labor Estimate (hrs) | Annual Labor Estimate (hrs) | | |
| 2020 | | | | | | | | |
| Compressors | | | | | | | | |
| Reciprocating | Monitoring and Maintenance | 160 | 1 | 1 | 160 | 160 | 0 | 0 |
| Centrifugal | Route to Control | 5 | 360 | 0 | 1,800 | 0 | 1 | 0 |
| Total | | 170 | N/A | N/A | 2,000 | 160 | 1 | 0 |
| 2025 | | | | | | | | |
| Compressors | | | | | | | | |
| Reciprocating | Monitoring and Maintenance | 320 | 1 | 1 | 160 | 320 | 0 | 0 |
| Centrifugal | Route to Control | 10 | 360 | 0 | 1,800 | 0 | 1 | 0 |
| Total | | 330 | N/A | N/A | 2,000 | 320 | 1 | 0 |

Note: Full-time equivalents (FTE) are estimated by first multiplying the projected number of affected units by the per unit labor requirements and then multiplying by 2,080 (40 hours multiplied by 52 weeks). Totals may not sum due to independent rounding.

Table 6-16 presents the labor requirement estimates for requirements applying to pneumatic controllers and pneumatic pumps. Note that pneumatic controllers have no one-time or continuing labor requirements. While the controls do require labor for installation, operation,

and maintenance, the required labor is less than that of the controllers that would be used absent the regulation (U.S. EPA, 2012). In this instance, we assume the incremental labor requirements are zero. Meanwhile, we are currently unable to estimate the labor associated with pneumatic pump control activities.

Table 6-16 Estimates of Labor Required to Comply with NSPS for Pneumatic Controllers and Pumps, 2020 and 2025

| Emissions Source | Emissions Control | Projected No. of Incr. Affected Units | Per-unit One-time Labor Est. (hrs) | Per-unit Annual Labor Est. (hrs) | Total One-Time Labor Estimate (hrs) | Total Annual Labor Estimate (hrs) | One-time FTE | Annual FTE |
|-----------------------|-------------------|---------------------------------------|------------------------------------|----------------------------------|-------------------------------------|-----------------------------------|--------------|------------|
| 2020 | | | | | | | | |
| Pneumatic Controllers | Emissions Limit | 480 | 0 | 0 | 0 | 0 | 0 | 0 |
| Pneumatic Pumps | Route to Control | 3,900 | N/A | N/A | N/A | N/A | N/A | N/A |
| 2025 | | | | | | | | |
| Pneumatic Controllers | Emissions Limit | 960 | 0 | 0 | 0 | 0 | 0 | 0 |
| Pneumatic Pumps | Route to Control | 7,900 | N/A | N/A | N/A | N/A | N/A | N/A |

Note: Full-time equivalents (FTE) are estimated by first multiplying the projected number of affected units by the per unit labor requirements and then multiplying by 2,080 (40 hours multiplied by 52 weeks). Totals may not sum due to independent rounding.

Table 6-17 presents the labor estimates across all emissions sources. Two main categories contain the majority of the labor requirements for the final NSPS: implementing reduced emissions completions (REC) at hydraulically fracture oil well completions and fugitive emissions detection and repair at well sites. The up-front labor requirement to comply with the final NSPS is estimated at 270 FTEs in 2020 and in 2025. The annual labor requirement to comply with final NSPS is estimated at about 1,100 FTEs in 2020 and 1,800 FTEs in 2025. We note that this type of FTE estimate cannot be used to identify the specific number of employees involved or whether new jobs are created for new employees, versus displacing jobs from other sectors of the economy.

Table 6-17 Estimates of Labor Required to Comply with NSPS, 2020 and 2025

| Emissions Source | Projected No. of Incrementally Affected Units (2020) | Total One-Time Labor Estimate (hours) | Total Annual Labor Estimate (hours) | One-time FTE | Annual FTE |
|---|--|---------------------------------------|-------------------------------------|--------------|--------------|
| 2020 | | | | | |
| Hydraulically Fractured and Re-fractured Oil Well Completions | 13,000 | 0 | 760,000 | 0 | 360 |
| Fugitive Emissions | 94,000 | 560,000 | 1,400,000 | 270 | 660 |
| Pneumatic Controllers | 480 | 0 | 0 | 0 | 0 |
| Pneumatic Pumps | 3,900 | N/A | N/A | N/A | N/A |
| Reciprocating Compressors | 160 | 160 | 160 | 0 | 0 |
| Centrifugal Compressors | 5 | 1,800 | 0 | 1 | 0 |
| Reporting and Recordkeeping Requirements | All | 0 | 180,000 | 0 | 88 |
| Total | 110,000 | 570,000 | 2,300,000 | 270 | 1,100 |
| 2025 | | | | | |
| Hydraulically Fractured and Re-fractured Oil Well Completions | 14,000 | 0 | 800,000 | 0 | 390 |
| Fugitive Emissions | 190,000 | 560,000 | 2,800,000 | 270 | 1,400 |
| Pneumatic Controllers | 960 | 0 | 0 | 0 | 0 |
| Pneumatic Pumps | 7,900 | N/A | N/A | N/A | N/A |
| Reciprocating Compressors | 320 | 160 | 320 | 0 | 0 |
| Centrifugal Compressors | 10 | 1,800 | 0 | 1 | 0 |
| Reporting and Recordkeeping Requirements | All | 0 | 180,000 | 0 | 88 |
| Total | 220,000 | 570,000 | 3,800,000 | 270 | 1,800 |

Note: Full-time equivalents (FTE) are estimated by first multiplying the projected number of affected units by the per unit labor requirements and then multiplying by 2,080 (40 hours multiplied by 52 weeks). Rounded to two significant digits. Totals may not sum due to independent rounding.

COST-BENEFIT ANALYSIS
SUBMITTED PER § 24-4-103(2.5), C.R.S.

For proposed revisions to
Colorado Air Quality Control Commission
Regulation Number 3 (5 CCR 1001-5) and
Regulation Number 7 (5 CCR 1001-9)

I. INTRODUCTION

The Colorado Air Pollution Control Division (Division) submits the following Cost-Benefit Analysis in conjunction with its proposed revisions to Colorado Air Quality Control Commission (AQCC) Regulation Number 3 (5 CCR 1001-5) and Regulation Number 7 (5 CCR 1001-9).

The proposed revisions collectively expand the air emission control requirements on oil and gas facilities in Colorado. They were developed after an extensive, year-long stakeholder process including input from diverse industry, environmental and governmental stakeholders. The proposal has received the support of several industry and environmental leaders. The Division estimates that the proposed strategies will result in substantial reductions of hydrocarbon emissions from the oil and gas industry. More specifically, the Division estimates the proposed strategies will reduce volatile organic compound (VOC) emissions by 93,500 tons per year, and methane/ethane emissions by 64,000 tons per year. The Division conservatively estimates that the annual net costs to industry of the Division's proposal will be \$42.4 million per year. This translates to approximately \$453 per ton of VOC reduced, which is very reasonable when compared to other air pollution reduction strategies adopted by the Colorado AQCC and the U.S. Environmental Protection Agency (EPA). In prehearing submittals to the AQCC, the supporters of the proposal have concluded that the Division's costs estimates are reasonable. Some opponents of the proposal have asserted that the costs may be much higher. The AQCC will consider the Division's proposal and any alternate proposals at the rulemaking hearing commencing February 19, 2014.

The proposed changes to Regulation Number 3 simplify certain air quality reporting and permitting requirements. They remove the requirements for sources with emissions below state reporting and permitting thresholds but subject to either a federal New Source Performance Standard ("NSPS") or National Emission Standard for Hazardous Air Pollutant ("NESHAP") to file an Air Pollutant Emission Notice ("APEN") and obtain a minor source permit ("catch-all provisions"). The Regulation Number 3 revisions also simplify reporting requirements for non-criteria reportable pollutant sources, and remove the permitting exemption for crude oil storage tanks.

The Regulation Number 7 rulemaking package proposes revisions that expand existing oil and gas control requirements and establish additional monitoring, recordkeeping and reporting requirements. These proposed revisions consist of the following:

- 1) Enhancing the existing control program for petroleum storage tanks by:

- a. Lowering the control requirement threshold for condensate storage tanks from 20 to 6 tons per year of uncontrolled actual volatile organic compound (VOC) emissions;
 - b. Requiring controls for crude oil and produced water storage tanks with uncontrolled actual VOC emissions that are equal or greater than 6 tons per year; and
 - c. Expanding non-attainment area requirements for tank controls during the first 90 days of production to the rest of the state;
- 2) Establishing requirements to ensure that emissions from controlled storage tanks are captured and routed to the control device;
 - 3) Establishing leak detection and repair requirements for compressor stations and well production facilities, including requirements to reduce emissions from compressor seals and open ended lines consistent with current federal requirements;
 - 4) Expanding the existing non-attainment area requirements for auto-igniters on flare devices to the rest of the state;
 - 5) Expanding the existing ozone non-attainment area requirements for low bleed pneumatic devices to the rest of the state, and where feasible requiring no-bleed pneumatic devices; and
 - 6) Requiring that the gas stream at newly constructed well production facilities either be connected to a pipeline or routed to a control device from the date of first production.
 - 7) Lowering the existing control requirement threshold for existing glycol dehydrators to 6 tons per year of uncontrolled actual VOC emissions and 2 tons per year of uncontrolled actual VOC emissions for dehydrators located within 1,320 feet of a building, and establishing a 2 ton per year control threshold for all new glycol dehydrators; and
 - 8) Establishing requirements for the use of best management practices both to minimize the need for downhole well maintenance and liquids unloading and to minimize emissions during well maintenance and liquids unloading events.

If adopted, these proposed revisions will result in substantial reduction of hydrocarbon emissions including volatile organic compounds (VOCs) and methane.

In addition to the Division's proposal, various parties to the rulemaking have submitted 6 different alternative proposals for the AQCC to consider. Some of these proposals request that the AQCC adopt additional requirements that go beyond the Division's proposal, while other alternatives request that the AQCC limit aspects of the Division's proposed revisions. Copies of each of these proposals along with any economic impact analysis that the parties submitted identifying the projected costs and benefits of their particular proposals are attached to this Cost-Benefit Analysis as exhibits.

As set forth in § 24-4-103(2.5), C.R.S. this Cost-Benefit analysis shall include the following:

- (I) The reason for the rule or amendment;

Cost Benefit Analysis for Proposed Revisions to AQCC Regulations No. 3 and 7

- (II) The anticipated economic benefits of the rule or amendment, which shall include economic growth, the creation of new jobs, and increased economic competitiveness;
- (III) The anticipated costs of the rule or amendment, which shall include the direct costs to the government to administer the rule or amendment and the direct and indirect costs to businesses and other entities required to comply with the rule or amendment;
- (IV) Any adverse effects on the economy, consumers, private markets, small businesses, job creation, and economic competitiveness; and
- (V) At least two alternatives to the proposed rule or amendment that can be identified by the submitting agency or member of the public, including the costs and benefits of pursuing each of the alternatives identified.

In connection with this Cost- Benefit Analysis, the Division has assessed the costs and benefits associated with each of the proposed strategies based on the reasonably available data. In collecting this data, the Division has sought input from various stakeholders in an effort to generate the most complete and accurate assessment of the costs and benefits of the proposed strategies. Where data was not reasonably available, the Division utilized assumptions that are set forth in this analysis.

II. THE REASON FOR THE RULE OR AMENDMENT

The Division is proposing revisions to AQCC Regulation Number 3 in order to improve the efficiency of Colorado's air quality reporting and permitting system. Under current regulation, when Colorado adopts certain federal air quality standards, all sources that are subject to these standards must report their emissions to the Division and obtain a permit. This requirement can result in the imposition of reporting and permitting burdens for very small sources of emissions. The proposed change would allow the state to adopt these federal requirements, but only require reporting and permitting for sources with emissions above established de minimis levels. The proposed revisions would also simplify reporting of non-criteria reportable pollutants, and provide that crude oil tanks must be permitted if their emissions are over the established de minimis levels. It appears that all parties to the AQCC rulemaking support the proposed revisions to Regulation Number 3.

The Division is proposing revisions to AQCC Regulation Number 7 in an effort to enhance the effectiveness of Colorado's air quality requirements for the oil and gas exploration and production sector. During the past ten years, Colorado has been a leader in developing and implementing requirements to reduce air emissions from the oil and gas sector. As a result of these efforts, Colorado now has in place a series of cost-effective requirements that significantly reduce air emissions from Colorado oil and gas facilities. Despite this success, however, the tremendous growth of oil and gas production in Colorado continues to threaten the air quality gains that we have achieved. Since 2004 gas production in Colorado has increased by 50% while oil production has more than doubled. While this growth has provided important economic benefits for Colorado, increased air emissions can have a negative impact on Colorado's public health and environment.

Specifically, VOC emissions contribute to the formation of ground level ozone. Ozone (O₃) is photochemical oxidant and known respiratory irritant. Ground level ozone is a secondary pollutant produced through the reaction of VOCs, nitrogen oxides and sunlight. Elevated levels of ground level ozone have been linked to a variety of adverse health effects including decreased lung function, increased respiratory symptoms, serious indicators of respiratory morbidity including emergency visits and hospital admissions, as well as total non-accidental and cardio-respiratory mortality. The U.S. EPA has set the current National Ambient Air Quality Standards for ground level ozone at 75 parts per billion (ppb) averaged over an 8-hour period. Based on a review of the then current health literature the Clean Air Scientific Advisory Committee concluded in 2008 that the 75 ppb standard was not sufficiently protective of public health, and recommended that the standard be set at between 60 ppb and 70 ppb. EPA is in the process of considering whether to lower the ozone standard.

Currently, the Denver Metro/North Front Range area is out of attainment with federal health-based ground level ozone standards. This includes much of the Denver/Julesberg oil field. Other areas of the state have also experienced elevated ozone levels recently, with one monitor in Western Colorado showing concentrations above 75 ppb and a number of other monitors showing levels between 60 ppb and 75 ppb.

Addressing oil and gas emissions is a critical component of Colorado's efforts to lower ozone levels since this sector represents the largest source of VOC emissions in the state. Based on the most recent inventory (2011), 54% of the anthropogenic VOC emissions in the state come from the oil and gas sector, which is roughly triple the amount of emissions from the next largest source. Moreover, because of the ongoing growth in the oil and gas industry and the projected decline in VOC emissions from other sectors, the share of VOC emissions attributable to the oil and gas sector will likely increase over the foreseeable future. The proposed emission reduction strategies will further enhance existing public health and environment protections on both a local and regional scale.

In addition to VOC emissions, oil and gas operations are a large source of methane. Methane is a potent greenhouse gas, which contributes to global climate change. In addition to reducing VOCs that contribute to regional ozone pollution, the Division's proposed strategies will reduce methane, and thereby play a role in Colorado's overall efforts to reduce greenhouse gas emissions. Methane is also a valuable natural resource (natural gas), and reducing leaks will benefit Colorado's environment and economy.

III. ANTICIPATED ECONOMIC BENEFITS

The proposed changes to Regulation Number 7 are projected to result in substantial reductions of hydrocarbon emissions (including both VOCs and methane/ethane) from the oil and gas industry. For VOCs, the Division has calculated that based on 2013 emissions, the proposed strategies will reduce VOC emissions from the oil and gas sector by approximately 93,500 tons per year or 257 tons per day. To put this in context, 257 tons per day represents approximately 45% of the total oil and gas related VOC emissions in 2011 and nearly 25% of the total 2011 VOC emissions

from all anthropogenic sources in Colorado. Additionally, the proposed strategies are projected to reduce methane/ethane emissions by approximately 64,000 tons per year.

These VOC reductions will aid Colorado's efforts to bring the Denver Metro/North Front Range area (DMA/NFR) into compliance with the current ozone NAAQS, as well as serve as a proactive step in addressing future lower ozone standards. As noted above, ground level ozone contributes to a number of health conditions, up to and including premature mortality from cardio-respiratory mortality. According to EPA, attaining the current ozone standard throughout the nation will result in between \$6.9 billion and \$18 billion in annual health benefits. For lower standards the health benefits are even greater. For example, EPA projects that achieving a 70 ppb standard will result in between \$13 billion and \$37 billion in annual health benefits, and for a 65 ppb standard the benefits will increase to between \$22 billion and \$61 billion per year. EPA does not report these health benefits by state, but since the population of the DMA/NFR accounts for approximately 2.5% of the total national population living in areas that are in violation of the current NAAQS, the health benefits attributable to Colorado are likely to be substantial.

In addition to impacting human health, elevated levels of ozone can have a negative impact on crop production. For example, EPA's analysis indicates that reducing ozone levels to 70 ppb will increase winter wheat yields in a number of Front Range counties, including an increase of between 1% and 2% in Weld County.

Separate from the beneficial impacts of reducing ozone, the proposed rules will also produce substantial benefits associated with reducing greenhouse gases. As part of this rulemaking the Environmental Defense Fund (EDF) has engaged an expert to estimate the benefits of the rulemaking based on the social cost of carbon. Based on this analysis, EDF projects that the total annual benefit from the projected methane reductions is between \$104 million and \$318 million in 2016 and between \$132 million and \$404 million in 2025.¹

In addition to the benefits associated with reductions of VOCs and methane, the proposed rules will produce additional economic benefits in the form of increased product capture and the creation of new jobs associated with the implementation of the new requirements. As discussed more fully in Section IV below, the proposed rules are expected to result in the capture of approximately \$16.8 million dollars worth of natural gas each year that would otherwise be lost to the atmosphere. Additionally, a significant portion of the overall costs associated with the proposed rules is for additional inspections of oil and gas facilities by company employees or contractors. Based on the total calculated inspection time, the proposed requirements will necessitate the hiring of approximately 150 additional employees or contractors to conduct inspections. The remaining costs of the proposal are associated with the purchase, installation and maintenance of equipment along with supervisory oversight and required recordkeeping and reporting. These expenditures will likely result in additional job creation, but the actual number of these jobs has not been calculated.

IV. ANTICIPATED COSTS

¹ A copy of the analysis is attached hereto as Exhibit O.

As set forth below, the Division has assessed the direct and indirect costs to the regulated community for each of the proposed strategies in Regulation Number 7. These costs are set forth in Sections A through H below and include equipment costs, labor costs, maintenance costs, supervision costs, travel costs, and costs associated with recordkeeping and reporting. Section I discusses the costs to government associated with administering the proposed Regulation Number 7 revisions. Finally, Section J details the costs to the regulated community and government administration costs associated with the proposed revisions to Regulation Number 3.

As detailed below, the Division estimates that the total annual costs to the regulated community as a result of the proposed strategies will be approximately \$59.2 million. In addition, as discussed in Section III above, the proposed strategies are expected to result in the capture of additional product worth approximately \$16.8 million, for a total net cost of \$42.4 million per year. In addition to these direct costs, implementation of the proposed strategies could potentially result in the shut-in of a few marginally producing wells, resulting in indirect costs in the form of lost revenues to oil and gas companies, loss of jobs associated with these facilities, lost royalty payments, and lost severance taxes. Based on available information the Division cannot reasonably calculate the amount of oil and gas that could be shut-in due to the proposed rules, but believes that the amount is likely to be very small due to the low costs attributable to small, marginally producing facilities.² An analysis by an economist hired by certain industry parties has suggested that these indirect costs could be quite large.³ This information will be considered by the AQCC as part of the rulemaking hearing.

A. Control Requirements for Petroleum Storage Tanks

Commencing in 2004 the AQCC has adopted a series of requirements aimed at reducing emissions from petroleum storage tanks at well production facilities, compressor stations and gas processing plants. Currently, condensate tanks with uncontrolled actual emissions of 20 tons per year or greater of VOC must be equipped with a control device that has a control efficiency of at least 95%. Additionally, with certain exceptions, operators in the non-attainment area must achieve a 90% system-wide reduction of VOC emissions from condensate tanks during the period from May 1 through September 30, and 70% during the period from October 1 through April 30. These current requirements only apply to tanks that store condensate, which is defined in the AQCC's Common Provisions regulation as "hydrocarbon liquids . . . with an API gravity of 40 degrees or greater." While most of the petroleum liquid produced in Colorado qualifies as condensate, there are heavier hydrocarbon liquids, typically referred to as crude oil, with an API gravity below 40 degrees that are not subject to the current control requirements. Additionally, there are a number of high volume produced water tanks that have VOC emissions above 6 tons per year that are not currently regulated under the existing requirements.

While Colorado has achieved considerable success in controlling emissions from condensate tanks since 2004, petroleum storage tanks at oil and gas production and midstream facilities

² See discussion in Section V below.

³ See Attached Exhibit B.

continue to be the most significant source of VOC emissions from this sector. To address this emission source the Division is proposing the following strategies: 1) reducing the control threshold from 20 tons per year VOC to 6 tons per year; 2) eliminating the distinction between condensate and other liquids and requiring controls strictly based on emission levels; and 3) extending the current requirement that all condensate tanks in the non-attainment area be controlled during the first 90 days of production to storage tanks throughout the state. In order to meet each of these three strategies, the Division assumes that owners and operators will equip tanks with enclosed flares, as is the typical practice under the existing tank control requirements. The estimated costs associated with installing and maintaining an enclosed flare are set forth in subsection 1 below. Utilizing the calculated flare costs, the estimated costs and benefits for each of the three tank control strategies are discussed in subsections 2-4 below.

1. General Cost Estimates for Flares

The estimated cost for a flare control device is based on identified costs from a 2008 oil and gas cost study⁴ adjusted for inflation. Based on this data, the estimated annualized cost of a flare control device with auto-igniter⁵ is about \$6,287.⁶

Table 1: Flare Control Device with Auto Igniter – Annualized Cost Analysis*

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |
|---------------------|--------------------------|--------------------------------|-----------------------|------------------------|
| Flare | \$18,169 | | | |
| Freight/Engineering | | \$1,648 | | |
| Flare Installation | | \$6,980 | | |
| Auto Igniter | \$1,648 | | | |
| Pilot Fuel** | | | \$768 | |
| Maintenance | | | \$2,197 | |
| Subtotal Costs | \$19,817 | \$8,628 | \$2,965 | |
| Annualized Costs*** | \$2,747 | \$575 | \$2,965 | |

*Control cost evaluation based on 2008 Ozone Rulemaking cost survey and producer data. Control device costs were developed based on an oil and gas cost study and information submitted by industry in 2008. However, those costs were escalated by 9.85% to reflect CPI-U increases that have occurred since 2008.⁷

⁴ See “Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination,” Lesair Environmental, Inc., June 2008. Information from this study was previously submitted to the AQCC as part of the 2008 Ozone Action Plan process. For reference or background purposes the Division has cited herein certain information that has been submitted to the AQCC as part of the rulemaking; however, it is not necessarily included with this Cost-Benefit Analysis as an exhibit.

⁵ Currently only flares in the non-attainment area are required to have auto-igniters. Under the current proposal, the auto-igniter requirement would be extended statewide. For the purposes of this cost analysis, it is assumed that auto-igniters will be required statewide. The cost and benefits associated with equipping existing flares outside the non-attainment with auto-igniters are discussed below in Section D.

⁶ Certain parties to the rulemaking have asserted that the actual cost per combustion device is higher based on EPA’s cost analysis conducted in accordance with NSPS OOOO. Based on a review of EPA’s analysis it appears that additional costs were included for surveillance systems that are not applicable to the proposed rule. Additionally, unlike the analysis in NSPS OOOO, the costs that the Division has identified are based on a Colorado specific cost analysis.

** Pilot fuel costs \$3.41/MMBtu (Henry Hub Spot Price - Aug. 2013)

*** Annualized over 15 years at 5% ROR

2. Lowering Statewide Condensate Tank Control Threshold (from 20 tpy to 6 tpy)

The Division is proposing to lower the uncontrolled VOC emission control threshold from 20 tpy down to 6 tpy on condensate storage tanks statewide. Based on an analysis of the Air Pollution Emissions Notice (APEN) database, the Division estimates that statewide there are 588 uncontrolled condensate tank batteries with VOC emissions over six tons per year. Of these 588 tanks, 396 are outside the non-attainment area (NAA) and the remaining 192 are within the current non-attainment area.

| Tank Battery Type | Ozone NAA [count] | Outside NAA [count] | Cancelled Tanks [count] | Total Statewide Tanks [count] |
|------------------------------------|-------------------|---------------------|-------------------------|-------------------------------|
| Controlled Tanks | 4,971 | 490 | | 5,461 |
| Uncontrolled Tanks | 1,451 | 1,132 | 36 | 2,619 |
| All Tanks | 6,422 | 1,622 | 36 | 8,080 |
| | | | | |
| Uncontrolled Tanks (≥ 6 tpy) | 192 | 396 | | 588 |

Based on the reported uncontrolled actual VOC emissions for these 588 tanks, and assuming both that 75% of the VOC emissions are captured and sent to the flare,⁸ and that the flare has a 95% destruction efficiency, the total VOC emission reduction associated with lowering the condensate tank threshold statewide is 5,162 tons per year.

| Tank Battery Type | Uncontrolled VOC Emissions [tons/year] | Controlled VOC Emissions [tons/year] | VOC Emission Reduction [tons/year] |
|--|--|--------------------------------------|------------------------------------|
| NAA Uncontrolled Tanks (≥ 6 tpy) | 2,355 | 677* | 1,678 |
| Outside NAA Uncontrolled Tanks (≥ 6 tpy) | 4,890 | 1,406* | 3,484 |
| Totals: | 7,245 | 2,083 | 5,162 |

*Emission reduction estimated by accounting for 75% capture and 95% destruction efficiency.

⁷ It has been suggested that the Division should have used the Producer Price Index to calculate an escalation from 2008 to 2013 costs. From 2008 to 2013, however, the Producer Price Index for the oil and gas field equipment sector grew at a slower rate than the CPI. Accordingly, the Division's analysis may actually overstate the increase in cost from 2008 to 2013.

⁸ The costs and benefits associated with improving the capture percentage for controlled storage tanks are discussed below in Section B.

The annualized cost of installing 588 flare control devices is about \$3.7 million dollars with an average cost effectiveness of about \$716 per ton of VOC reduced. For the smallest individual tank battery subject to controls (6 tons/year), the flare cost effectiveness is estimated at \$1,471 per ton of VOC reduced.

| Affected Tanks [count] | Each Flare Annualized Cost | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
|---------------------------|-------------------------------|---------------------------|------------------------------|---------------------------|
| 588 | \$6,286.8 | \$3,696,638 | 5,162 | \$716 |

In addition to VOC reductions, this strategy will significantly reduce methane and ethane emissions from currently uncontrolled tanks. To calculate methane and ethane emission reductions, the Division determined the relative proportion of VOCs to methane and ethane based on reported average values from 30 natural gas liquid analyses submitted to the Division. Based on these analyses, methane/ethane emissions from condensate storage tanks are about 38% of the VOC emissions by weight. Accordingly, projected methane/ethane emission reductions from this proposed strategy are 1,963 tons per year or \$1,884 per ton of methane/ethane reduced.

3. Requiring Controls for Produced Water and Crude Oil Tanks

As discussed above, the Division is proposing to eliminate the distinction between condensate tanks and other storage tanks. If the AQCC adopts this proposal, crude oil tanks and produced water tanks with uncontrolled actual VOC emissions of six tons per year or greater will require controls. Because produced water and crude oil tanks are identified separately in the Division’s APEN data base, the costs and benefits for these two types of storage tanks are broken out separately.

The Division is proposing that all statewide produced water tanks with uncontrolled VOC emissions over 6 tons/year be required to install emission controls. Some uncontrolled produced water tanks could be co-located at sites with condensate or crude oil tanks that have flare controls, but pressure and flow differences may require the installation of a separate flare control device for the water tank. Consequently, the control costs are based on the assumption that each water tank battery will install a new flare control device. Based on an analysis of the APEN database, the Division estimates that statewide there are 52 uncontrolled produced water tank batteries with VOC emissions over 6 tons/year.

| Tank Battery Type | Total Statewide Water Tanks |
|---------------------------|-----------------------------|
| Controlled Water Tanks: | 338 |
| Uncontrolled Water Tanks: | 530 |
| Total: | 868 |

| Tank Battery Type | Total Statewide Water Tanks |
|------------------------------------|-----------------------------|
| Uncontrolled Tanks (≥ 6 tpy) | 52 |

Based on the reported uncontrolled actual emissions, the Division estimates that the total VOC emission reduction associated with controlling these produced water tanks statewide is 457 tons per year.

| Tank Battery Type | Uncontrolled VOC Emissions [tons/year] | Controlled VOC Emissions [tons/year] | VOC Emission Reduction [tons/year] |
|------------------------------------|--|--------------------------------------|------------------------------------|
| Uncontrolled Tanks (≥ 6 tpy) | 641.4 | 184.4* | 457 |

*Emission reduction estimated by accounting for 75% capture and 95% destruction efficiency.

The annualized cost of installing 52 flare control devices is about \$327,000, with an average cost effectiveness of about \$715 per ton of VOC reduced. For the smallest individual tank battery (6 tons/year), the flare cost effectiveness is estimated at \$1,471 per ton of VOC reduced.

| Tank Size | Affected Tanks [count] | Each Flare Annualized Cost | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
|--------------|------------------------|----------------------------|------------------------|---------------------------|------------------------|
| ≥ 6 tpy | 52 | \$6,286.8 | \$326,914 | 457 | \$715 |

The Division is proposing that all statewide hydrocarbon liquid storage tanks with VOC emissions over six tons/year must install emission controls. Based on a recent analysis of 2013 APEN data, there are 67 reported crude oil tanks batteries statewide. Thirty seven of the tank batteries are already equipped with controls. Of the remaining thirty, eight are over the proposed six tons/year threshold. Given that approximately 5% of the total wells in the state report crude oil production to the Colorado Oil and Gas Conservation Commission (COGCC),⁹ it appears likely that the Division’s APEN database may be undercounting crude oil tanks, either because these tanks have not been reported or because they are being reported as condensate tanks.¹⁰

⁹ Based on an analysis of 2010 COGCC data.

¹⁰ Prior to 2008 crude oil storage tanks were exempt from APEN reporting requirements, which may explain in part the small numbers of tanks identified in the system.

| Tank Battery Type | Total Statewide Crude Oil Tanks |
|------------------------------------|---------------------------------|
| Controlled Crude Oil Tanks | 36 |
| Uncontrolled Crude Oil Tanks | 29 |
| Total: | 65 |
| Uncontrolled Tanks (≥ 6 tpy) | 8 |

The total VOC emission reduction associated with controlling these 8 crude oil tanks statewide is 118 tons per year.

| Tank Battery Type | Uncontrolled VOC Emissions [tons/year] | Controlled VOC Emissions [tons/year] | VOC Emission Reduction [tons/year] |
|------------------------------------|--|--------------------------------------|------------------------------------|
| Uncontrolled Tanks (≥ 6 tpy) | 165.2 | 47.5* | 117.7 |

*Emission reduction estimated by accounting for 75% capture and 95% destruction efficiency.

The annualized cost of installing eight flare control devices is about \$50,294 dollars with an average cost effectiveness of about \$427 per ton of VOC reduced. For the smallest individual tank battery (6 tons/year), the flare cost effectiveness is estimated at \$1,471 per ton of VOC reduced.

| Tank Size | Affected Tanks [count] | Each Flare Annualized Cost | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$ /ton] |
|--------------|------------------------|----------------------------|------------------------|---------------------------|-------------------------|
| ≥ 6 tpy | 8 | \$6,286.8 | \$50,294.4 | 117.7 | \$427 |

4. Requiring Controls During the First 90 Days of Production Statewide

Under current requirements owners and operators of new and modified storage tanks outside the non-attainment area have 90 days after the date of first production to determine if emissions from the tank trigger the requirement to install a control. Because production is typically at its highest during this initial period, significant emissions can occur before controls are installed. To address this issue in the non-attainment area, the AQCC mandated in the 2008 Ozone Action Plan that all condensate tanks be controlled during the first 90 days. The Division is now proposing to expand this requirement to storage tanks throughout the state.

To calculate the cost effectiveness of this strategy, the Division first determined the number of new and modified storage tanks outside the non-attainment area based on reported APEN data for the period of 2010-2012. Based on this APEN data, there are on average 141 new and modified tanks each year, with yearly reported uncontrolled actual emissions of 7,370 tons VOC. Assuming that emissions during the first 90 days equal 1/4th of the annual reported emissions,¹¹ total uncontrolled actual VOC emissions from these tanks during the first 90 days is 1,842.5 tons. Assuming enhanced capture efficiency for these new tanks (see Section B below) the flare control efficiency is 95%, and thus the calculated benefit from expanding the first 90 day control requirement to tanks outside the non-attainment area will be 1,750.4 tons per year.

While the Division estimates that there are 141 new and modified storage tanks outside the non-attainment area each year, the majority of these, 84, will require control devices regardless of this strategy since their uncontrolled actual emissions are over six tpy. For these 84 tanks, the cost of operating a flare during the first 90 days will be approximately 25% of the total annualized cost, or \$1,571.70 per tank. For the remaining 57 tanks with emissions less than six tons/year, because controls for these tanks will only need to be in place for 90 days, the Division assumes that each flare can control 3 tanks per year, which means that 19 new flares are required to comply with this proposed strategy. For other applications, the annualized cost of a flare is estimated to be \$6,287. Since flares required for this application will be relocated three times a year, the Division assumes an additional \$3,000 in annual relocation costs, for a total annualized cost of about \$9,287 per flare. Based on the emission reductions calculated above, the total cost effectiveness of this requirement is \$176/ton of VOC reduction.

Table 11: Control Cost Estimates for Flare Control Devices Required During the First 90 Days of Production

| Storage Tank Threshold [tpy] | Number of New Storage Tanks | Number of New Flares | Annualized Cost Each Flare | Total Flare Cost | Total VOC Reduction [tons/year] | VOC Control Cost [\$ /ton] |
|------------------------------|-----------------------------|----------------------|----------------------------|------------------|---------------------------------|----------------------------|
| <6 | 57 | 19 | \$9,286.8 | \$176,449.2 | 44.7 | \$3,947 |
| ≥6 | 84 | 84 | \$1,571.7 | \$132,022.8 | 1,705.7 | \$77 |
| | 141 | | | \$308,472 | 1,750.4 | \$176 |

Using the methodology discussed in subsection A.2 above the projected methane/ethane emission reductions from this strategy is 665.5 tons per year or \$464 per ton of methane/ethane reduced.

B. Emission Capture Requirements for Controlled Petroleum Storage Tanks

In order for storage tank control requirements to be effective, emissions from the tank must be routed to the control device. Historically the Division has assumed that 100% of a tank's

¹¹ Because reported emissions typically are based on a calculation assuming a standard rate of production decline after the first 90 days, actual emissions during the first 90 days could be much higher.

emissions will be captured and routed to the control device, typically a flare, resulting in a 95% reduction of emissions. Field observations using infra-red (IR) cameras and other methodologies indicate that in actuality emissions from controlled storage tanks often escape through the thief hatches and pressure relief valves (PRV) and therefore are not being combusted in the flare. This occurs when the tank cannot adequately contain the flashing emissions that occur when pressurized liquids from the separator are dumped into the atmospheric tank. To address this issue, the Division is proposing new regulatory language clarifying that all emissions from controlled storage tanks must be routed to the control device and that these tanks must be operated without venting emissions from thief hatches, PRVs and other openings, except when venting is reasonably necessary for maintenance, gauging, or safety of personnel and equipment.

To assure compliance with these capture standards, the Division’s proposal requires that owners and operators of controlled storage tanks implement a Storage Tank Emission Management (STEM) plan. Pursuant to the STEM plan, owners and operators must evaluate and employ appropriate control technologies and/or operational practices designed to meet the proposed capture requirements, and certify that these technologies and/or operational practices are designed to minimize emissions from the tank. The Division’s STEM proposal also requires implementation of a two-pronged monitoring strategy involving a weekly¹² auditory, visual, and olfactory (AVO) inspection for all controlled tanks, and a periodic instrument based monitoring for tanks using EPA Reference Method 21, an IR camera or other Division approved monitoring device or method. As proposed, the frequency of this instrument based monitoring will depend on the level of uncontrolled actual emissions from the tank.

Table 12: Proposed Tiering for Instrument Based Tank Inspections

| Tank Uncontrolled Actual VOC Emissions | Inspection Frequency |
|--|----------------------|
| ≥ 6 tpy to ≤ 12 tpy | Annually |
| > 12 tpy to ≤ 50 tpy | Quarterly |
| > 50 tpy | Monthly |

In assessing the cost effectiveness of the proposed requirements, the Division first calculated the costs associated with implementing technological and/or operational changes at controlled tanks. For the purposes of this analysis the Division assumed that all tanks with uncontrolled actual emissions greater than or equal to 6 tons per year would need to be controlled consistent with the Division’s proposal discussed in Section A above. Based on reported data, there are currently 5,310 storage tanks statewide with emissions greater than or equal to 6 tons per year. While the Division’s proposal does not specify the type of technology or operational practices that operators will use, for the purposes of this analysis the Division assumed that buffer bottle

¹² There is an exception for the weekly inspection requirement where the operator loads out liquids from the storage tank on less than a weekly basis. In these circumstances the operator must conduct the inspection whenever liquids are loaded out, but no less often than every 30 days. Typically liquids are loaded out multiple times in a given week, meaning that for the majority of the tanks AVO inspections will be required weekly.

technology would be installed on each of the subject tanks.¹³ The buffer bottle technology utilizes a small tank that is installed after the separator which allows for a secondary flash of pressurized liquids prior to dumping into the storage tank. The second-stage flash reduces the pressure of the liquids going to the tank and thereby helps to ensure that the tank can adequately handle the flashing emissions that occur when the liquids are brought to atmospheric pressure. Based on industry provided information, the estimated annual cost of a buffer bottle is set forth in Table 13.¹⁴

Table 13: Annualized Cost Analysis for Buffer Bottle

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |
|-------------------|--------------------------|--------------------------------|-----------------------|------------------------|
| Buffer Bottle | \$11,500 | | | |
| Freight/Engr | | \$600 | | |
| Installation | | \$2,280 | | |
| Maintenance | | | \$2,500 | |
| Subtotal Costs | \$11,500 | \$2,880 | \$2,500 | |
| Annualized Costs* | \$1,593.8 | \$192 | \$2,500 | \$4,285.8 |

* Annualized over 15 years at 5% ROR

The Division also calculated the costs associated with conducting enhanced inspections. Based on the proposed tiering, operators will need to conduct 24,840 tank inspections per year.¹⁵

Assuming that each inspection takes two hours and utilizing a \$103/hour¹⁶ in-house inspection cost and a \$134/hour contractor inspection cost (30% profit added to in-house rate), the total annual cost associated with conducting enhanced inspections under the proposed rule is \$5,392,010, which equates to \$1,015.4 per year for each tank that will be subject to STEM.

¹³ Based on discussions with industry representatives during the stakeholder process there may be other less costly technologies and operational practices that could be used to ensure good emission capture from tanks such as replacing seals, more frequent maintenance, changing the size of piping going to the storage tank, and timing well dumps to avoid overloading the separator. There may also be other options for new facilities that allow for the capture and sale of additional gas such as the installation of high-low pressure separators or utilizing a liquids gathering system that eliminates atmospheric storage tanks at well sites.

¹⁴ For this Cost-Benefit Analysis the Division increased the capital and maintenance costs for buffer bottles based on input from industry stakeholders.

¹⁵ In practice, many operators are already conducting IR camera inspections at storage tanks, however, the Division does not have information regarding how many inspections are currently occurring.

¹⁶ The hourly inspection cost is discussed below in Table 20.

Table 14: Instrument Based Tank Inspections Based on Proposed Tiering

| Tank Uncontrolled Actual VOC Emissions | Inspection Type/Hourly Rate | Number of Tanks | Inspection Frequency | Number of Inspections | STEM Inspection Costs |
|--|-----------------------------|-----------------|----------------------|-----------------------|-----------------------|
| >6 tpy to ≤ 12 tpy | In-House/\$103 | 1,085 | Annually | 1,085 | \$223,510 |
| >12 tpy to ≤ 50 tpy | In-House/\$103 | 2,595 | Quarterly | 10,380 | \$2,138,280 |
| > 50 tpy | In-House/\$103 | 745 | Monthly | 8,940 | \$1,841,640 |
| Subtotal: | | 4,425 | | 20,405 | \$4,203,430 |
| >6 tpy to ≤ 12 tpy | Contractor/\$134 | 323 | Annually | 323 | \$86,564 |
| >12 tpy to ≤ 50 tpy | Contractor/\$134 | 329 | Quarterly | 1,316 | \$352,688 |
| > 50 tpy | Contractor/\$134 | 233 | Monthly | 2,796 | \$749,328 |
| Subtotal: | | 885 | | 4,435 | \$1,188,580 |
| Total: | | 5,310 | | 24,840 | \$5,392,010 |

The Division also considered whether additional costs should be included for conducting periodic AVO inspections. Because these activities are already required for controlled storage tanks under existing regulation, the Division did not include these costs in determining the total cost of the proposed capture requirements. The Division also did not include costs associated with certifying that selected technologies and/or operational practices are designed to minimize emissions, since costs for certifying capture efficiency are already included in the annualized cost of required flares.¹⁷ Accordingly, the total projected annual cost of the proposed capture requirements based on the use of a buffer bottle and enhanced monitoring requirements is \$5,301.2 per tank.

To calculate the projected emissions reduction from the proposed capture requirements, the Division assumed a current capture rate of 75% for controlled tanks based on analytical work that the Division, EPA and others have performed. Based on this capture rate, the Division calculated the emissions reduction that would occur if the capture rate were increased to 100% using the following equation:

$$\text{Emission reduction} = [\text{uncontrolled VOC} * (1 - (0.75 * 0.95))] - [\text{uncontrolled VOC} * (1 - 0.95)],$$

Using this equation as applied to the reported uncontrolled actual emissions from the 5,310 storage tanks statewide with emissions greater than or equal to six tons per day, the projected emission reduction from the proposed capture requirements is 53,386 tons per year. Included in the total are 33 existing crude oil tanks with flare controls (>6 tpy) and 8 crude oil tanks that would need flare controls (>6 tpy).

¹⁷ See “Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination,” Lesair Environmental, Inc., June 2008, at pg. 8.

Table 15: STEM Emission Control Analysis (Statewide)

| Number of Tanks ≥ 6 tpy | Uncontrolled VOC [tons/year] | Controlled VOC (@ 71.25% Control) [tons/year] | Controlled VOC (@ 95% Control) [tons/year] | VOC Reduction [tons/year] |
|------------------------------|------------------------------|---|--|---------------------------|
| 5,269 | 221,569 | 63,701 | 11,078 | 52,623 |
| 41 | 3,213 | 924 | 161 | 763 |
| 5,310 | 224,782 | 64,625 | 11,239 | 53,386 |

Applying this reduction to the costs calculated above, the cost effectiveness of these proposed requirements is \$527/ton of VOC.

Table 16: STEM Control Cost Estimates (Statewide)

| Type of Technology | Number of Tanks | Each Device Annualized Costs [\$ /year] | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$ /ton] |
|--------------------|-----------------|---|------------------------|---------------------------|-------------------------|
| Buffer Bottle | 5,310 | \$5,301.2 | \$28,149,372 | 53,386 | \$527.3 |

Using the average ratio of VOC to methane/ethane emissions from storage tanks, the projected methane/ethane reduction from this strategy is 20,287 tons per year, which equates to \$1,388 per ton of methane/ethane reduced.

During the Division stakeholder process leading up the AQCC rulemaking hearing, certain parties raised questions about the Division’s assumption that currently controlled tanks have a 75% capture efficiency. In light of this the Division has also calculated cost effectiveness based on the assumption that current capture efficiency is 50% and 95%. For the 50% case, current controlled emissions would be 118,011 tpy VOC. Accordingly, the emission reduction benefit from increasing capture to 100% would be 106,772 tons per year (118,011-11,239) and the cost effectiveness would be \$264/ton VOC¹⁸. For the 95% capture scenario, current controlled emissions would be 21,916 tons per year VOC and the emission reduction would be 10,677 tons per year (21,916-11,239). Under this scenario, the cost effectiveness would be \$2,636/ton VOC¹⁹.

While the buffer bottle technology offers a good alternative in a retrofit situation for reducing pressures to the tank and increasing emission capture, for new facilities, installation of a high-low pressure (HLP) separator to satisfy STEM may prove to be a better performing option. This equipment allows for two stages of separation of the gas and the liquids instead of the single stage separation accomplished in traditional separators. By adding a second stage of separation, the pressure of the liquids sent to the tank is significantly reduced, thereby helping to ensure

¹⁸ This may overestimate the cost effectiveness given that if the current capture rate were only 50% additional costs could be required to increase the capture rate to 100%.

¹⁹ This is a conservative calculation given that if the current capture rate were 95% it is likely that the control costs to increase the capture rate to 100% would be significantly less.

complete capture of flashing emissions instead of venting a portion of the emission stream through the thief hatch or PRV. Additionally, rather than being routed to the flare, as in the case of the buffer bottle technology, gas from the second stage of separation can be sent to a vapor recovery unit (VRU), recompressed and sent to the sales line, resulting in increased product recovery. Based on information provided from industry, the Division has calculated that the annual cost of a HLP separator w/VRU is about \$19,341.

Table 17: Annualized Cost Analysis for HLP Separator

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |
|----------------------|-----------------------------|-----------------------------------|--------------------------|---------------------------|
| HLP/VRU | \$90,000 | | | |
| Freight/Engr | | \$1,648 | | |
| HLP/VRU Installation | | \$11,154 | | |
| Maintenance | | | \$9,396 | |
| VRU Recovered NG * | | | \$(3,382) | |
| Subtotal Costs | \$90,000 | \$12,802 | \$6,014 | |
| Annualized Costs** | \$12,474 | \$853 | \$6,014 | \$19,341 |

* Recovered NG fuel costs \$3.5/MCF (Henry Hub Spot Price - Aug. 2013) and average tank battery size of 63.2 tpy – based on 3-yr average of APEN data on storage tanks ≥6 tpy (uncontrolled VOC).

** Annualized over 15 years at 5% ROR

Unlike the retrofit situation analyzed above where the emission controls are already in place, it is appropriate in new installations to aggregate the cost of the HLP separator w/VRU with the costs of the control unit (flare) to determine the overall cost of controlling emissions from the tank. Based on the \$6,286.8 annual cost of a flare and annual instrument based monitoring costs of \$1,015.4 per tank, the total annual control costs for a new tank will be \$26,643 per year.

Based on an analysis of reported data for new tanks during the past three years, the average uncontrolled actual emissions of a new tank is 63.2 tpy. Assuming a 95% overall control efficiency, equipping a tank with an HLP separator and a flare will reduce the emissions from an average new tank by 60 tpy. This yields a cost effectiveness of \$444 per ton VOC reduced. If instead, the highest cost scenario (using a six tpy tank) is assumed, the cost effectiveness is \$4,674 per ton VOC. For methane ethane the cost per ton is \$1,168 per ton reduced on average.

C. Leak Detection and Repair Requirements for Compressor Stations and Well Production Facilities

AQCC Regulation Number 7 requires owners and operators of gas processing plants in Colorado to implement leak detection and repair programs to identify and repair fugitive emission leaks from components at these facilities. Under this requirement, owners and operators must conduct

periodic inspections using EPA Reference Method 21²⁰ and repair leaks within a prescribed time frame.

Although component leaks at compressor stations and well production facilities in Colorado are also a significant source of VOC and methane emissions, Regulation No. 7 does not currently include leak detection and repair requirements for these facilities.²¹ To address these emissions, the Division is proposing regulatory changes that would establish leak detection and repair requirements for compressor stations and well production facilities. Pursuant to this proposal, owners and operators of compressor stations and well production facilities will be required to conduct periodic leak inspections, and repair identified leaks. As specified, required inspections may be done either in accordance with Method 21 or utilizing an infrared (IR) camera. The proposed language also allows the Division to approve other inspection methods as new leak detection technologies are demonstrated to be effective.

The proposed regulation establishes a tiered system to determine inspection frequency. For compressor stations the tiering is based on the uncontrolled actual leak emissions at the facility as follows:

Table 18: Proposed Tiering for Leak Inspections at Compressor Stations

| Component Leak Uncontrolled Actual VOC Emissions | Inspection Frequency |
|--|----------------------|
| ≤ 12 tpy | Annually |
| >12 tpy to ≤ 50 tpy | Quarterly |
| > 50 tpy | Monthly |

For well production facilities the proposed tiering is based on uncontrolled actual emissions from the largest emitting storage tank at the facility as set forth in Table 19. The tiering is based on tank emissions rather than uncontrolled actual leak emissions in order to create a Method 21/IR camera monitoring schedule that is consistent with the monitoring schedule proposed as part of the STEM emission capture requirements discussed in Section B above.²²

²⁰ While Method 21 sets performance standards for inspection equipment rather than specifying technology, typically Method 21 inspections utilize photo ionization detectors (PIDs) to assess leak levels.

²¹ Although leak detection is not currently required at most of these facilities, some operators currently conduct voluntary leak detection and repair programs. Additionally, the Division has issued a limited number of permits that include some leak detection requirements. For the purposes of this analysis, however, the Division assumes that there is no leak detection occurring at well production facilities and compressor stations. Accordingly the actual additional costs that operators may incur may be less than the costs calculated in this analysis.

²² Because there may be a limited number of instances where well production facilities don't have storage tanks, the proposal also provides that for tank-less facilities, the inspection schedule will be based on the facility's total VOC emissions. This provision is intended to apply to large facilities that utilize a liquids gathering system for transporting petroleum liquids to a centralized facility. These facilities are not included in the facility count used in this Cost-Benefit Analysis, but because the number of these facilities in Colorado is extremely small this exclusion should have a negligible impact on the overall costs and emission reduction benefits of the proposed LDAR requirement. Additionally, because the costs and benefits from the proposed LDAR program increase at roughly the

| Tank Uncontrolled Actual VOC Emissions | Inspection Frequency |
|--|----------------------------|
| < 6 tpy | One Time (and Monthly AVO) |
| ≥ 6 tpy to ≤ 12 tpy | Annually |
| >12 tpy to ≤ 50 tpy | Quarterly |
| > 50 tpy | Monthly |

The Division utilized a multi-step process to calculate the estimated costs and benefits associated with the proposed leak detection and repair requirements. First, the Division calculated an hourly inspection rate based on the total annual cost for each inspector divided by an assumed 1,880 annual work hours.²³ To calculate the total annual cost for each inspector, the Division included salary and fringe benefits for each inspector, annualized equipment and vehicle costs, and add-ons to account for supervision, overhead, travel, record keeping, and reporting. Based on the assumptions set forth in Table 20 below, the total annual cost for each inspector will be \$193,629, which equates to an hourly inspection rate of \$103.

| Item | Capital Costs (one time) | Annual Costs | Annualized Total Costs |
|--------------------------------|--------------------------|------------------------|------------------------|
| FLIR Camera | \$122,000 | | |
| FLIR Camera Maintenance/Repair | | \$7,500 | |
| Photo Ionization Detector | \$5,000 | | |
| Vehicle (4x4 Truck) | \$22,000 | | |
| Inspection Staff | | \$75,000 | |
| Supervision (@ 20%) | | \$15,000 | |
| Overhead (@10%) | | \$7,500 | |
| Travel (@15%) | | \$11,250 | |
| Recordkeeping (@10%) | | \$7,500 | |
| Reporting (@10%) | | \$7,500 | |
| Fringe (@30%) | | \$22,500 | |
| Subtotal Costs | \$149,000 | \$153,750 | |
| Annualized Costs* | \$39,879 | \$153,750 | \$193,629 |
| *over 5 years at 6% ROR | | Annualized Hourly Rate | \$103 |

The Division initially assumed that conducting inspections in-house would be the lowest cost option since it would not involve additional profit to be paid to a contractor. For smaller companies that cannot fully utilize an IR camera, however, conducting inspections in-house may

same rate, the cost effectiveness of the program for these facilities should mirror the cost effectiveness of the program as applied to facilities with tanks.

²³ This assumes a 40 hour work week with ten holidays, two weeks of vacation, and one week of sick leave.

not be the most cost effective option. To account for this in the Cost-Benefit Analysis the Division assumed a 30% profit margin for contractors, which it added to the calculated hourly rate in instances where it appeared that contractors would be used to conduct the inspection (\$134 per hour).

Second, the Division calculated the average amount of time that it would take to conduct a Method 21 inspection at compressor stations and well production facilities based on the number of components to be inspected and assuming that a component could be inspected every 30 seconds. The proposed rule also allows owners and operators to use IR cameras either as the sole inspection tool, or as a screening tool to identify potential leaking components followed by a Method 21 inspection. An IR camera inspection or IR Camera/Method 21 hybrid inspection can be conducted more quickly than a Method 21 inspection of each component. While the Division does not currently have actual data regarding how much faster an inspection could be completed using an IR camera, for the purpose of this analysis the Division assumed that an IR camera based inspection would take 50% of the time required for a Method 21 inspection.²⁴

For compressor stations, the Division used reported component counts for compressor stations within each of the tiers identified in Table 18 above. Based on these counts, and the inspection times per component discussed above, the Division calculated that the total inspection time per compressor station facility tier are as follows:

Table 21: Calculated Inspection Time Compressor Station Leak Inspections

| Component Leak Uncontrolled Actual VOC Emissions | Method 21 Inspection | IR Camera/ Hybrid Inspection |
|--|----------------------|------------------------------|
| ≤ 12 tpy | 21.2 hours | 10.6 hours |
| >12 tpy to ≤ 50 tpy | 56.2 hours | 28.1 hours |
| > 50 tpy* | | |

* there are currently no compressor stations in Colorado with calculated leaks at this level

For well production facilities, the Division has limited data on the number of components per facility. Based on this limitation, the Division did not attempt to calculate a separate inspection time for each of the proposed facility tiers, and instead used the overall average component count. Based on the limited available data, however, there does appear to be a distinction between component numbers at well production facilities in the non-attainment area and well production facilities outside the non-attainment area. Accordingly, the Division calculated separate inspection times for well production facilities by area as set forth in Table 22.

Table 22: Calculated Inspection Times for Well Production Facility Leak Inspections

| Area | Method 21 Inspection | IR Camera/ Hybrid |
|------|----------------------|-------------------|
|------|----------------------|-------------------|

²⁴ Based on the Division’s own IR camera inspections, and reports from various parties during the stakeholder and prehearing process it appears that the Division’s assumption may significantly overstate the actual time needed to conduct an IR camera inspection.

| | | Inspection |
|---------------------|------------|------------|
| Non-Attainment Area | 12.2 hours | 6.1 hours |
| Rest of the State | 6.8 hours | 3.4 hours |

In addition to the travel costs that are built into the hourly inspection rate as set forth in Table 20, for the purposes of this Cost-Benefit Analysis the Division also assumed an additional three hours in travel time for each inspection outside the non-attainment area. This assumption reflects the fact that certain well sites in basins outside the non-attainment area may be remote, requiring additional travel.

Next, the Division calculated the projected inspection costs for both compressor stations and well production facilities. To make this calculation the Division used industry reported emission data to determine the number of facilities that will be subject to annual, quarterly and monthly inspections to determine the total number of inspections for each tier, and multiplied these inspections by the calculated inspection time and projected hourly inspection rate. For compressor stations the Division assumed that all inspections would be conducted by 3rd party contractors. For well production facilities, the Division assumed that any company with 500 or more inspections per year would conduct inspections in-house, and that companies with less than 500 inspections per year would use contractors.²⁵ Because the proposed rule also requires owners and operators of well production facilities that are not subject to monthly instrument monitoring to conduct monthly AVO inspections the Division considered whether additional costs should be included for these inspections. Based on information provided during the stakeholder process it appears that operators already routinely conduct such inspections and repair leaks identified during these AVO inspections. Additionally, while the proposed rule may impose recordkeeping and reporting requirements associated with these AVO inspections, given the relatively small number of leaks that are expected to be identified, and the fact that any recordkeeping can be readily included in existing inspection and maintenance records the Division believes that any additional recordkeeping and reporting costs will be nominal relative to the overall cost of the LDAR program.

In its Initial Economic Impact Analysis to the AQCC, the Division did not include the cost to repair leaking components or re-monitor these components post-repair to verify that the repair was effective, assuming that the cost to repair and re-monitor would be offset by the cost savings from capturing additional product as a result of repairs. Based on information that the Conservation Groups submitted as part of their Pre-Hearing Statement to the AQCC, it appears that the Division's assumption in the Initial EIA was reasonable. See Exhibit A to CG-PHS, Testimony of David McCabe at pg. 8. Nevertheless, for this Cost-Benefit Analysis, the Division has included both repair costs and estimated product savings from conducting leak detection activities. To calculate repair costs, the Division used EPA information regarding leaking component rates, component repair times, and hourly repair rates. Specifically, the Division assumed a \$66.24 hourly rate to repair components, and an average repair time of between 0.17

²⁵ Based on this assumption, 3,545 inspections per year will be conducted using 3rd party contractors.

hours and 16 hours, depending on the both type of component and the complexity of the repair.²⁶ To calculate the number of leaking components the Division used industry reported component counts and assumed a 1.18% leaking component rate for facilities subject to annual inspections.²⁷ To account for the projected additional emission reductions from quarterly and monthly inspection schedules the Division used annual leaking component rates of 1.77% for facilities with quarterly inspection schedules and 2.36% for facilities with monthly inspection schedules. To calculate the value of the additional product captured, the Division converted the amount of VOC and methane/ethane reduced to MCF of natural gas, with a price of \$3.50/MCF. With respect to re-monitoring, the Division determined that because of the small number of components that will require repair and the fact that re-monitoring can be undertaken at the same time as repair, any additional costs associated with re-monitoring are negligible.

Based on this methodology, the calculated annual inspection costs for compressor stations are set forth in Table 23.

Table 23: Compressor Station Leak Inspection Costs Using IR Camera/Method 21 Hybrid

| Compressor Station Fugitive VOC Tier [tpy] | Number of Compressor Stations | Annual Inspection Frequency | Time per IR Camera Inspection [hours] | Total Annual Inspection Time [hours] | Total Annual Inspection Cost |
|--|-------------------------------|-----------------------------|---------------------------------------|--------------------------------------|------------------------------|
| ≤ 12 tpy | 147 | 1 | 10.6 | 1,558.2 | \$208,799 |
| >12 to ≤ 50 tpy | 53 | 4 | 28.1 | 5,957.2 | \$798,265 |
| ≥ 50 tpy | 0 | 12 | | | |
| Total: | 200 | | | 7,515.4 | \$1,007,064 |

Repair costs associated with these inspections are set forth in Table 24 and fuel savings associated with these repairs are set forth in Table 25.

Table 24: Compressor Station Leak Repair Costs

| Compressor Station Fugitive VOC Tier [tpy] | Number of Compressor Stations | Leak Repair Rate [\$/hr] | Number of Leaks per Compressor Station | Total Leak Repair Time per CS [hours] | Total Annual Repair Cost |
|--|-------------------------------|--------------------------|--|---------------------------------------|--------------------------|
| ≤ 12 tpy | 147 | \$66.24 | 30.1 | 23.0 | \$223,957.4 |

²⁶ See “Equipment Leak Emission Reduction and Cost Analysis for Well Pads, Gathering and Boosting Stations, and Transmission and Storage Facilities Using Emission and Cost Data From the Uniform Standards,” Bradley Nelson and Heather Brown, April 17, 2012; “Analysis of Emissions Reduction Techniques for Equipment Leaks,” Cindy Hancy, December 21, 2011.

²⁷ This leaking component rate is consistent with the rate that the Louis Berger Group used in their Initial Economic Impact Analysis for Industry’s Proposed Revisions to Colorado’s Air Quality Control Commission Regulation No. 7 (DGS-PHS Ex. C), and is based on the leak rate utilized by Nelson and Brown in their analysis of leak reduction costs and benefits (See footnote 26).

Table 24: Compressor Station Leak Repair Costs

| Compressor Station Fugitive VOC Tier [tpy] | Number of Compressor Stations | Leak Repair Rate [\$/hr] | Number of Leaks per Compressor Station | Total Leak Repair Time per CS [hours] | Total Annual Repair Cost |
|--|-------------------------------|--------------------------|--|---------------------------------------|--------------------------|

| Total: | | \$13,456,302 | \$2,943,202 | \$5,751,016 | \$4,503,532 | \$17,646,988 |

Additionally, based on information in the Division’s APEN reporting system, there are 2,799 well production facilities with uncontrolled actual storage tank emissions less than or equal to 6 tons per year that will be subject to a one-time instrument based inspection. The one-time cost for inspecting these facilities is estimated to be \$1,639,239.²⁸

Table 31: Well Production Facility Leak Inspection Costs Using IR Camera/Method 21 Hybrid

| Uncontrolled VOC at Storage Tank Battery Tier [tpy] | O&G Basin | Number of Facilities and Inspections | Inspection Time Per Inspection [hours] | Inspection Type/Hourly Rate | Total Annual Inspection Cost |
|---|-----------|--------------------------------------|--|-----------------------------|------------------------------|
| ≤ 6 | DJ/NAA | 1,598 | 6.1 | In-House/\$103 | \$1,004,023 |
| ≤ 6 | ROS | 500 | 3.4 | In-House/\$103 | \$175,100 |
| Subtotal: | | 2,098 | | | \$1,179,123 |
| ≤ 6 | DJ/NAA | 389 | 6.1 | Contractor/\$134 | \$317,969 |
| ≤ 6 | ROS | 312 | 3.4 | Contractor/\$134 | \$142,147 |
| Subtotal: | | 701 | | | \$460,116 |

²⁸ To calculate these costs the Division used the same methodology applicable to periodic inspection costs, except that it did not include additional travel time for facilities outside the non-attainment area based on the assumption that companies could coordinate these one-time inspections with visits to the facilities for other purposes.

Total: 2,799**\$1,639,239**

The Division recognizes that there are likely additional facilities not included in the APEN database that will be subject to this one-time inspection requirement, thereby increasing the overall cost of the one-time inspection requirement. Roughly speaking the additional cost for one-time inspections will be proportional to the number of additional facilities, so that if there are twice the number of facilities, the overall cost will be approximately double. However, because the expected emission reduction benefit will increase roughly at the same rate as the cost of inspections, the overall cost-effectiveness of the one-time inspection requirement should remain approximately the same regardless of the number of facilities.

Finally, the Division calculated the cost effectiveness of the proposed leak detection and repair requirements based on the costs identified above and the projected emission reductions. To determine emission reductions the Division first calculated pre-inspection program VOC and methane emissions based on the reported component counts, standard emission factors for these components, and the average fraction of VOC and non-VOC emissions (methane/ethane). Based on EPA reported information, the Division calculated a 40% reduction for annual inspections, a 60% reduction for quarterly inspections, and an 80% reduction for monthly inspections.

Using this information the Division calculated that the total emission reductions from leaks at compressor stations will be 1,107 tpy VOC and 2,321 tons per year methane/ethane.

Table 32: Compressor Station Leak Inspection Emission Reductions

| Comp. Station Fugitive VOC Tier [tpy] | Number of Comp Stations | LDAR Program Reduction % | Fugitive VOC Emissions for each CS tier [tpy] | Total VOC Reduction [tpy] | Fugitive Methane-Ethane Emissions for each CS tier [tpy] | Total Methane-Ethane Reduction [tpy] |
|---------------------------------------|-------------------------|--------------------------|---|---------------------------|--|--------------------------------------|
| ≤ 12 | 147 | 40% | 10.1 | 588.0 | 15.5 | 911.4 |
| > 12 to ≤ 50 | 53 | 60% | 16.4 | 519.4 | 44.3 | 1,409.8 |
| > 50 | | 80% | | | | |
| | 200 | | | 1,107.4 | | 2,321.1 |

Based on these reductions, the cost effectiveness of conducting leak inspections at compressor stations is estimated to be \$994/ton VOC and \$474/ton methane/ethane.

Table 33: Compressor Station Leak Inspection Cost Effectiveness using IR Camera/Method 21

| Comp. Station Fugitive VOC Tier [tpy] | Number of Comp Stations | Total Net Annual Inspection & Repair Cost | LDAR Program Reduction % | Total VOC Reduction [tpy] | VOC Control Cost [\$/ton] | Total Methane-Ethane Reduction [tpy] | Methane-Ethane Control Cost [\$/ton] |
|---------------------------------------|-------------------------|---|--------------------------|---------------------------|---------------------------|--------------------------------------|--------------------------------------|
| ≤ 12 | 147 | \$244,882 | 40% | 588.0 | \$416 | 911.4 | \$269 |
| > 12 to ≤ 50 | 53 | \$855,650 | 60% | 519.4 | \$1,647 | 1,409.8 | \$607 |
| > 50 | | | 80% | | | | |
| | 200 | \$1,100,531 | | 1,107.4 | \$994 | 2,321.2 | \$474 |

For well production facilities the total emission reductions is estimated to be 14,015 tpy VOC and 21,927 tpy methane/ethane.

Table 34: Well Production Facility Leak Inspection Emission Reductions

| Uncontrolled VOC at Tank Battery Tier [tpy] | Number of Facilities | LDAR Program Reduction % | Fugitive VOC Emissions for each Tank Battery [tpy] | Total VOC Reduction [tpy] | Fugitive Methane-Ethane Emissions for each Tank Battery [tpy] | Total Methane-Ethane Reduction [tpy] |
|---|----------------------|--------------------------|--|---------------------------|---|--------------------------------------|
| DJ/NAA | | | | | | |
| > 6 to ≤ 12 | 1,095 | 40% | 4.6 | 1,971.0 | 7.0 | 3,066.0 |
| > 12 to ≤ 50 | 2,600 | 60% | 4.6 | 7,280.0 | 7.0 | 10,920.0 |
| > 50 | 811 | 80% | 4.6 | 3,000.7 | 7.0 | 4,541.6 |
| Subtotal: | 4,506 | | | 12,251.7 | | 18,527.6 |
| Remainder of State | | | | | | |
| > 6 to ≤ 12 | 313 | 40% | 3.9 | 500.8 | 7.5 | 939.0 |
| > 12 to ≤ 50 | 324 | 60% | 3.9 | 745.2 | 7.5 | 1,458.0 |
| > 50 | 167 | 80% | 3.9 | 517.7 | 7.5 | 1,002.0 |
| Subtotal: | 804 | | | 1,763.7 | | 3,399.0 |
| Total: | 5,310 | | | 14,015.4 | | 21,926.6 |

Based on these reductions, the cost effectiveness of conducting ongoing instrument based inspections at well production facilities is estimated to be \$1,259/ton VOC and \$805/ton methane/ethane.

Table 35: Well Production Facility Leak Cost-Effectiveness Using IR Camera/Method 21

| Subtotal: | 804 | \$2,582,791 | | 1,763.7 | \$1,464 | 3,399.0 | \$760 |
| Total: | 5,310 | \$17,646,988 | | 14,015.4 | \$1,259 | 21,926.6 | \$805 |

Additionally, for the 2,799 well production facilities with uncontrolled actual storage tank emissions equal to or less than 6 tons per year that will be subject to a one-time instrument based inspection, the calculated one-time benefit is 4,876 tons VOC and 8,000 tons methane/ethane, assuming a 40% reduction. Based on these reductions, for the one-time inspections of well production facilities with tanks that are less than six tons per year the cost effectiveness of the proposed rule is calculated to be \$409/ton VOC and \$249/ton methane/ethane.

In addition to the component leak detection and repair requirements for compressor stations and well production facilities, the Division's proposal includes additional requirements designed to reduce leaks from open ended lines and valves, reciprocating compressors, and wet seal centrifugal compressors. These requirements mirror existing cost-effective requirements set forth in NSPS OOOO and other federal rules.

For open ended valves and lines at well production facilities and compressor stations, the proposal requires that each such valve or line be equipped with a cap, blind flange, plug or second valve commencing January 1, 2015. Alternatively, the Division's proposal allows operators to treat open-ended lines and valves as components and monitor them in accordance with the proposed LDAR requirements. As part of its LDAR cost effectiveness analysis detailed above, the Division included the costs of inspecting and repairing open ended lines and valves in its overall calculation. While the Division has not identified specific information regarding the costs and emission reduction benefits from equipping open ended lines with a cap, blind flange, plug or second valve, it notes that the requirement has been included in a multitude of federal air quality rules, including NSPS VV, NSPS VVa, MACT H, MACT CC, MACT TT, MACT YY, MACT GGG, MACT III, and MACT MMM, dating back as far as 1983. Based on this widespread prevalence in federal rules the Division believes that the proposal represents a simple

and cost-effective strategy to reduce emissions from open-ended lines and valves. However, to the extent that it is not cost effective in a specific case operators can employ the monitoring option allowed for under the proposed rule.

For centrifugal compressors, the Division’s proposal requires that hydrocarbon emissions from wet seal fluid degassing systems be reduced by 95% beginning January 1, 2015. In its updated technical support document for NSPS OOOO, EPA analyzed the cost-effectiveness of this strategy and found that accounting revenues from the capture of additional product, implementation of this strategy would on a per unit basis reduce VOC emissions by 19.5 tpy, methane emissions by 216.2 tpy, and result in a net cost savings of \$46,974.²⁹

With respect to reciprocating compressors, the Division’s proposal requires that commencing January 1, 2015, the rod packing for reciprocating compressors located at compressor stations be replaced every 26,000 hours of operation or every 36 months. As with the requirement for centrifugal compressors, EPA analyzed this proposed strategy as part of the adoption of NSPS OOOO and found that it was a cost-effective way to reduce VOC and methane emissions. Specifically, EPA found that per compressor the strategy reduces VOC emissions by 1.9 tons per year and methane emissions by 6.8 tons per year, at a net cost of \$43 per ton of VOC reduced and \$12 per ton of methane reduced.³⁰

D. Auto Igniter Requirements on Existing Flare Control Devices Outside the Non-Attainment Area

Unlike the non-attainment area, flares used to control emissions at condensate tank batteries and glycol dehydration units outside the NAA are not required to have auto-igniters. The Division is proposing that all flares used to control emissions at condensate tank batteries and glycol dehydration units statewide should have auto igniters. Based on an analysis of the APEN database, the Division estimates the statewide number of existing flare control devices without auto-igniters on condensate tank batteries, glycol dehydration, produced water tanks, and crude oil tanks is 796. The reported uncontrolled actual emissions from these units are 53,101.1 tons per year VOC.

The estimated annualized cost for an auto-igniter is \$475 based on information that the industry provided to the Division in 2008, adjusted for inflation.³¹

Table 36: Auto Igniter Control Device – Retrofit Cost Analysis

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |
|------|--------------------------|--------------------------------|-----------------------|------------------------|

| | | | | |
|---------------------|---------|--|--------|-------|
| Auto Igniter | \$1,648 | | | |
| Freight/Engineering | | | \$200 | |
| Flare Installation | | | \$500 | |
| Maintenance | | | | \$200 |
| Subtotal Costs | \$1,648 | | \$700 | \$200 |
| Annualized Costs* | \$228.4 | | \$46.7 | \$200 |
| | | | | \$475 |

* Annualized over 15 years at 5% ROR

The Division estimates that a flare without an auto-igniter could experience about 3% pilot light downtime (262.8 hours) over a one year period. During the downtime period, any VOC emissions routed to the flare control device are uncontrolled. Based on the total uncontrolled actual emissions of 53,101.1 tons per year VOC from units equipped with flares without auto-igniters, the emissions during this downtime period will be 1,593.1 tons of VOC. The Division assumes that as a result of the installation of an auto-igniter, the amount of downtime can be eliminated, for a total emission reduction of 1,251.7 tons/year. Given that the annualized cost of installing 796 auto-igniters is about \$378,100 the estimated cost effectiveness of this strategy is about \$302 per ton of VOC reduced.

Table 37: Auto Igniter Emission Reduction Estimates

| Source Type for Existing Flare Controls | Number of Auto Igniters | Uncontrolled VOC [tpy] | Uncontrolled VOC Using 3% Downtime [tpy] | Total VOC Reduction [tpy] |
|---|-------------------------|------------------------|--|---------------------------|
| Condensate Tanks | 490 | 31,170.6 | 935.1 | 666.3 |
| Dehydrators | 131 | 16,372.0 | 491.2 | 466.6 |
| Produced Water Tanks | 172 | 4,842.2 | 145.3 | 103.5 |
| Crude Oil Tanks | 3 | 716.3 | 21.5 | 15.3 |
| | 796 | 53,101.1 | 1,593.1 | 1251.7 |

* Dehydrator flares assumed to have 100% capture and 95% destruction – thus 95% control. Tank flares are assumed to have 75% capture and 95% destruction – thus 71.25% control.

| Number | Each Auto-Igniter Annualized Costs | Total Annualized Costs | VOC Reduction* [tons/year] | Control Costs [\$/ton] |
|--------|------------------------------------|------------------------|----------------------------|------------------------|
| 796 | \$475 | \$378,100 | 1,251.7 | \$302 |

E. Expanding Low Bleed Pneumatics Requirements Statewide

As part of the 2008 Ozone Action Plan the AQCC adopted regulatory requirements mandating the use of low bleed pneumatic controllers in the non-attainment area. The current proposal would expand this requirement statewide.

To estimate the costs and benefits of this proposed strategy, the Division estimated the number of high-bleed pneumatic devices based on Independent Petroleum Association of the Mountain States (IPAMS) survey data from 2006, which identified the average number of such devices per well. The Division then scaled this number up based on 2012 Colorado Oil and Gas Conservation Commission (COGCC) well count data. Based on this methodology, there are 9,877 high-bleed pneumatic devices outside the nonattainment area. Assuming a 95% replacement rate, the proposed rule will result in the replacement of 9,384 high bleed devices with low bleed devices. Based on this count, and the average emission reductions per device replaced identified in the IPAMS survey, the projected benefit from the proposed expansion of the current non-attainment area low bleed pneumatic rule will be approximately 14,921 tons per year VOC (40.9 tons per day). Based on this information and assuming an 80/20 ratio of methane/ethane to VOC by volume, the estimated methane/ethane reduction from this strategy is 17,100 tons per year.

The average retrofit cost of a high-bleed pneumatic device is based on costs from the 2008 cost study³² adjusted for inflation. Utilizing this methodology, the annualized cost for each replaced device is \$169. However, because the reduced bleed rate results in more natural gas being sold, operators will receive additional revenue as a result of the installation of a low bleed device. Based on the emission reduction data from the IPAMS survey and August 2013 spot prices for natural gas, the estimated average value of the recovered gas will be \$1,268 for each device replaced. As a result, the net annual gain is \$1,084 per replaced device. Based on this projected net gain, this strategy will pay for itself in approximately one year and two months.

Table 39: Replace High-Bleed Pneumatics with Low-Bleed Pneumatics – Annualized Cost Analysis*

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |

| Annualized Costs*** | \$143 | \$26 | \$(1,253) | \$(1,084) |
|---------------------|-------|------|-----------|-----------|

* Control device costs were developed based on an Oil and Gas Cost Study and information submitted by industry in 2008. However, those costs were escalated by 9.85% to reflect CPI-U increases that have occurred since 2008.

** Recovered NG fuel costs \$3.5/MCF (Henry Hub Spot Price - Aug. 2013)

*** Annualized over 15 years at 5% ROR

Assuming 9,384 total devices replaced, adoption of this strategy will result in \$10,169,441 in annual cost savings.

| Table 40: Low Bleed Pneumatic Control Cost Estimates (Outside NAA) | | | | |
|---|------------------------------|------------------------|---------------------------|------------------------|
| Number | Each Device Annualized Costs | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
| 9,384 | \$(1,084) | \$(10,169,441) | 14,921 | NA |

The proposed rule also requires the use of no-bleed pneumatic devices if it is technically and economically feasible and where on-site electrical grid power is being used. Use of no-bleed pneumatic devices will further reduce emissions relative to the use of low bleed devices. Since the Division does not have information indicating the number of no-bleed pneumatic devices that could be required, it is not possible to calculate the cost effectiveness of this particular provision. However, because the proposed requirement expressly provides that use of no-bleed pneumatics is only required where economically feasible the Division assumes that any use of no-bleed pneumatic devices pursuant to the proposed rule will be cost effective.

F. Require Newly Constructed Gas Wells be Connected to a Pipeline or Route Emissions to A Control Device

Currently in Colorado, natural gas produced at oil and gas sites is typically routed to a transmission pipeline. With the advent of new drilling technologies, additional areas of the state without established pipeline infrastructure may experience oil and gas exploration and production. This can lead to instances where produced gas is vented or flared instead of being put into a transmission line. To date the Division has identified 61 instances in Colorado where this is occurring. To address this, the proposed regulation provides that for newly constructed, hydraulically fractured, or recompleted wells, the gas stream must either be connected to a pipeline or routed to a control device achieving 95% control efficiency. Currently all of the sites that are not routed to a pipeline are flaring their gas. Additionally, because venting the gas at such sites would create a safety issue, the Division assumes that in the limited future instances where the gas stream is not routed to a pipeline, operators will route the emissions to a flare or other control device. Accordingly, adoption of this portion of the proposed regulation will likely not result in any additional costs.

G. Control Requirements for Glycol Dehydrators

The Division is proposing to revise the control requirements applicable to glycol natural gas dehydrators statewide. Currently any glycol natural gas dehydrator with uncontrolled actual VOC emissions of 2 tons per year or greater that is located at a facility where the sum of uncontrolled actual emissions from all of the dehydrators at the facility is greater than 15 tons per year, must be equipped with a control device that reduces emissions by at least 90%. Under the Division’s proposal, all existing dehydrators with uncontrolled actual emissions of 6 tons per year or greater VOC must be controlled with air pollution control equipment achieving at least 95% reduction. The proposal also provides that existing dehydrators with uncontrolled actual emissions of two tons per year or greater VOC must be controlled if they are located within 1,320 feet of a building unit or designated outside activity area. Finally, the proposal requires that all new dehydrators with uncontrolled actual emissions of two tons per year or greater VOC be controlled. The Division assumes that newly subject glycol dehydrators will be controlled using flares that achieve a 95% destruction efficiency. The annual cost for these units is \$6,286.80 per unit. See Section IV.A.1. above.

Based on industry reported APEN data, there are currently 433 uncontrolled dehydrators at sites with total dehydrator uncontrolled actual VOC emissions below 15 tpy. Of these, 217 have uncontrolled actual emissions greater than or equal to two tons per year. The total uncontrolled actual emissions for these 217 dehydrators are 1,827.5 tpy VOC. There are 148 dehydrators with uncontrolled actual VOC emissions greater than or equal to 6 tons per year. The total uncontrolled actual emissions for these 148 dehydrators are 1,549.7 tpy VOC. Currently, the Division does not have information regarding the location of these uncontrolled dehydrators relative to a building unit or designated outside activity area. Assuming, however, that all of the 2 to 6 ton dehydrators are located within 1,320 feet of a building unit or designated outside activity area and thus will require a control, the proposed requirement will reduce 1,736 tpy of VOC at a cost effectiveness of \$786/ton VOC. For the smallest dehydrator subject to the proposed rule (2 ton/year) the cost effectiveness is estimated to be \$3309 per ton of VOC reduced.

Table 41: Dehydrator Control Cost Estimates (2 TPY Control Threshold)

| Number | Each Device Annualized Costs | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
|--------|------------------------------|------------------------|---------------------------|------------------------|
| 217 | \$6,286.8 | \$1,364,236 | 1,736 | \$786 |

Conversely, if it is assumed that none of the 2 to 6 ton existing dehydrators will require controls the proposed requirement will reduce 1,472 tpy of VOC at a cost effectiveness of \$632/ton VOC.

Table 42: Dehydrator Control Cost Estimates (6 TPY Control Threshold)

| Number | Each Device Annualized Costs | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
|--------|------------------------------|------------------------|---------------------------|------------------------|
| 148 | \$6,286.8 | \$930,446 | 1,472 | \$632 |

H. Control Requirements for Downhole Well Maintenance and Liquids Unloading Events

Historically, Colorado has not regulated air emissions from temporary activities such as well completions and well maintenance at well production sites. Recently, however, EPA, Colorado and other jurisdictions have identified these activities as potentially large sources of emissions from the oil and gas sector. In recognition of this, the Colorado Oil and Gas Conservation Commission and more recently EPA have adopted requirements for green completions to reduce hydrocarbon emissions during well completion activities. The Division is now proposing additional regulatory requirements designed to reduce emissions during well maintenance.

Well maintenance is required when, over time, liquids build up inside the well and reduce gas and oil flow out of the well. To remove these liquids and improve flow, the liquids are blown out of the well under pressure. This process is typically referred to as liquids load-out or well blow-down. Historically emissions from well blow-downs are vented to the atmosphere. EPA has established emission factors for liquid unloading based on fluid equilibrium calculations to calculate the amount of gas needed to blow down a column of fluids blocking a well and Natural Gas STAR partner data on the amount of additional venting after a blow-down. Based on its calculations, EPA estimated that in the United States the combined methane emissions for liquid unloading and well completions in 2009, was 217 billion cubic feet, and that liquid unloading may account for 33% of the uncontrolled methane emissions from the natural gas industry.³³ For Colorado, the Division has calculated that emissions from well blow-downs in 2008 were approximately 9,306 tons of VOC per year.

To address these emissions, the Division is proposing a two pronged requirement aimed at reducing the number of required liquids unloading events and reducing the amount of emissions vented to the atmosphere during these events. Under the Division’s proposal operators shall use best management practices to minimize the need for venting associated with downhole maintenance and liquids unloading. For example, EPA’s Gas Star program advocates the use of a plunger lift system to reduce the need for liquids unloading. According to EPA, use of a plunger lift will on average pay for itself in less than one year through the capture of additional product. The Division’s proposal also provides that emissions during well maintenance and liquids unloading shall be captured or controlled using best management practices to limit venting during well blow-downs to the maximum extent practicable. Based on information provided by Environmental Defense Fund, application of these requirements could result in annual VOC reductions of 2,881 tons and methane reductions of 19,207 tons per year. Given the

³³ See EPA, *Inventory of U.S. Greenhouse Gas Emissions and Sinks, 1990-2009*, April, 2011.

wide variety of practices that this could entail, the Division currently does not have information about the precise cost-effectiveness of this provision. Given the fact that the proposal only requires use of best management practices, which takes into account the cost of the practices in a given situation, the Division assumes that the proposed strategy will be cost effective.

I. Division Regulation Number 7 Implementation Costs

The Division will largely implement the provisions of its proposal through its oil and gas inspection team. This team currently consists of 9 full time inspectors and 4 term limited inspectors. In 2012, in response to the growth in the oil and gas industry in Colorado, the legislature approved increasing the size of the inspection team from 6 inspectors to 9. In 2013, the legislature appropriated additional funds to hire 4 term limited inspectors to conduct infra-red camera inspections at well production facilities in Colorado. The term for these positions runs through June of 2015, but could be extended by the legislature if warranted. The additional inspectors provided during the 2012 and 2013 legislative sessions has significantly expanded the capabilities of the oil and gas inspection team, which will further enable the Division to implement and enforce the proposed requirements if the AQCC chooses to adopt the Division's proposal. The total projected annual cost to the Division for the oil and gas inspection team in fiscal year 2013-14 is \$1,305,304, which includes salary costs, fringe benefits, operating costs (including vehicles, field equipment, and office equipment), travel training and indirect costs.

J. Regulation Number 3 Costs

The proposed revisions to Regulation remove the requirement for sources subject to either a NSPS or NESHAP/MACT adopted into Regulation Number 6, Part A or Number 8, Parts A, C, D, and E to file an APEN and obtain a minor source permit regardless of whether their emissions exceed the reporting or permitting thresholds ("catch-all provisions"). They also simplify the non-criteria reportable pollutant de minimis determination to 250 pounds per year of any individual non-criteria reportable pollutant; and remove the crude oil storage tank permitting exemptions. There is little to no economic impact to the regulated community due to these revisions.

Catch-all Provisions

Removal of the catchall provisions will reduce permitting, reporting and associated cost burdens for the regulated community. By reducing permitting and reporting, the proposed revision will also reduce costs to the Division associated with these activities. There are no anticipated costs to either the regulated community or the government associated with this proposed revision.

Non-Criteria Reportable Pollutants

Revision of the threshold for non-criteria reportable pollutants could result in either cost savings or additional costs to the regulated community depending on the source. Sources that are required to report non-criteria reportable pollutants must pay an emission fee of \$152.90 per ton. Currently Regulation Number 3 contains a complex reporting formula involving multiple and different thresholds, some of which are above and some of which are below the proposed 250 pound threshold. Accordingly, changing the threshold will reduce costs for some sources, while increasing costs for other sources. Based on an analysis of reported emissions, the proposed threshold change will reduce industry fees paid to the Division by \$47,702 per year. Because the emissions from sources that are not currently reporting is unknown it is not possible to calculate the additional costs to sources that will be required to report for the first time under the new proposed threshold.

Additionally, beyond the actual emission fees, the current reporting system is very complex resulting in numerous hours being spent by both the regulated community and Division staff in determining whether reporting is required. Simplifying the reporting system will eliminate the costs associated with this analysis.

Crude Oil Storage Tanks

There are minimal direct costs projected for the affected businesses and industrial sector associated with the removal of the crude oil storage tank permitting exemption. Stationary sources with crude oil storage tanks whose uncontrolled actual emissions exceed the minor source or operating permit thresholds would be required to obtain a permit. In 2008, the Commission removed the reporting exemption for crude oil storage tanks to improve the inventory of uncontrolled actual emissions. Based on the reported data, removal of the crude oil storage tank minor source permitting exemption would require these tanks to obtain minor source permits at a cost of approximately \$19,500. Additionally, permitting these sources will result in some costs to the Division. Given the small number of these sources and the fact that permitting fees offset most of the costs associated with drafting permits, the anticipated cost to the Division is minimal.

V. ADVERSE EFFECTS ON THE ECONOMY

The oil and gas industry plays an important role in Colorado's economy. The industry is a significant employer of highly skilled and well-paid employees. The industry generates large revenues and pays significant taxes in the state. It produces valuable domestic resources that help keep prices low while adding to national stability and security. At the same time, emissions from the oil and gas industry represent a significant portion of the total VOC emissions both in the non-attainment area and throughout the rest of the state. The Division's proposal is intended to achieve significant reductions in air emissions without imposing unreasonable costs that could stifle economic activity.

As discussed above, the Division's proposal is projected to result in a net annual cost to the industry of approximately \$42.4 million. As with any increase in costs, the costs associated with the Division's proposal could have some adverse impact on economic activity associated with the oil and gas industry in Colorado. However, over the past decade Colorado's oil and gas industry has experienced unprecedented growth, even as Colorado has enacted regulatory measures to ensure that development continues in a protective and responsible manner. Moreover, given the relative size of the costs of the current proposal to the overall size of the industry, the total impact of these costs will likely be minimal. In 2012, for example, oil and gas producers in Colorado sold 48,450,717 barrels of oil and 1,661,073,176 MCF of natural gas. Based on the current price of oil, \$96 per barrel, and assuming a price for natural gas of \$3.5/MCF³⁴, annual revenue from the sale of oil and gas in Colorado based on 2012 production levels is approximately \$10.5 billion. Accordingly, the net cost of the Division's proposal is approximately 0.4% of the annual revenues. Given this small percentage, the Division's proposal is unlikely to have any appreciable impact on the economic competitiveness of the industry as a whole. This conclusion is bolstered by the fact that several of the largest oil and gas companies in the state (Anadarko Petroleum Corp., Noble Energy, Inc., Encana Oil and Gas USA, and DCP Midstream) fully support the Division's proposed revisions. Collectively, the Division estimates that these companies will bear approximately 75% of the total annual cost of the proposed rules.

While it is unlikely that the costs associated with the proposed revisions will have any meaningfully adverse impacts on the competitiveness of the industry as a whole in Colorado, the costs could incrementally add to the current costs associated with operating marginally producing wells. This could potentially lead to some wells being shut in and the resultant economic consequences of these shut-ins including lost production revenue, lost royalties, lost severance taxes and potentially lost jobs. To mitigate against this possibility, the Division's has crafted a tiered proposal that triggers requirements based on emission thresholds that are directly tied to production. Based on this, the truly small facilities are subject to less requirements and less costs; for example, only a one-time instrument-based leak inspection, which the Division estimates will cost approximately \$712 .

Finally, it does not appear that the costs associated with the Division's proposal will have any meaningful negative impact on the general public or small businesses that purchase natural gas and other petroleum products. Oil and natural gas are sold on international and national markets, making it extremely unlikely that any increase in production costs in Colorado will be reflected in prices for Colorado consumers.

VI. ALTERNATIVE PROPOSALS

In addition to the Division's proposal, various parties to the rulemaking have submitted 6 different alternative proposals for the AQCC to consider. Some of these proposals request that the AQCC adopt additional requirements that go beyond the Division's proposal, while other

³⁴ The Division assumed a price per MCF of \$3.50 throughout its analysis; however, natural gas prices are currently around \$5 per MCF, suggesting that the Division has underestimated the value of gas saved by the proposal.

alternatives request that the AQCC limit aspects of the Division's proposed revisions. In some cases, the parties submitting the proposals included analyses estimating the costs and benefits associated with their proposals. The section below identifies each of the submitted proposals, discusses how the proposals differ from the Division's proposal, and addresses the projected costs and benefits of each proposal.³⁵

Joint Industry Work Group

A collection of oil and gas companies and industry trade groups have submitted an alternative proposal seeking to limit the requirements set forth in the Division's proposal.³⁶ Specifically, the Joint Industry Work Group request that the AQCC limit the Division's proposal in the following respects: 1) restrict all proposed requirements to the front range ozone non-attainment area; 2) reduce the required frequency proposed for leak inspection and repair; 3) eliminate the proposed requirements for dehydrators; 4) limit proposed requirements for compressor seals and open-ended lines to compressor stations; and 5) eliminate proposed requirements related to well maintenance and liquids unloading. In addition to these proposed limitations, the Joint Industry Work Group have proposed a number of additional changes, which could have some minimal additional impacts on the costs and benefits of the proposal.

Since the Joint Industry Group did not submit an economic analysis detailing the projected costs and benefits of their alternative proposal,³⁷ the Division has conducted an analysis of the Joint Industry Work Group alternative proposal utilizing the same methodologies and assumptions detailed in Section IV above. Based on this analysis, the Division estimates that the Joint Industry Work Group alternative proposal would have a net cost³⁸ to the regulated community of approximately \$32.2 million, and would reduce emissions of VOCs by 56,525 tons per year and methane/ethane by 33,058 tons per year. The decrease in net costs should have some positive impact on the indirect costs associated with potential well shut-ins, but the Division is unable to reasonably calculate this impact. The decrease in costs relative to the Division's proposal includes a decrease in the number of facility inspections, which would result in fewer new

³⁵ In instances where a party submitted an analysis of the costs and benefits associated with their proposal, such analysis is attached. Where parties submitted proposal without an analysis of their own proposal, the Division has endeavored to analyze the costs and benefits of these proposals using the same methodologies used to analyze the costs and benefits of the Division's proposal.

³⁶ A copy of this alternative proposal is attached to this Cost Benefit Analysis as Exhibit A.

³⁷ The group did submit an analysis of the Division's proposal showing substantially higher costs than reflected in the Division's analysis. A copy of this analysis is attached hereto as Exhibit B. It should be noted that while the Joint Industry Work Group predicts much higher costs from the Division's proposals, Anadarko Petroleum Corporation, Noble Energy, Inc. and Encana Oil and Gas USA have submitted information during the rulemaking supporting the reasonableness of the Division's cost and benefit calculations. Submissions from these companies can be found at the following link.

<ftp://ft.dphe.state.co.us/apc/aqcc/REBUTTAL%20STATEMENTS,%20EXHIBITS%20%26%20ALT%20PROPOSAL%20REVISIONS/>

³⁸ Net cost reflects the cost of implementing the proposed strategy less the value of the additional product captured as a result of the proposed strategies.

inspector jobs attributable to the proposal. Finally, because the Joint Industry Work Group proposal would result in less VOC and methane emission reductions, the economic benefits associated with these reductions discussed in Section III above would be reduced.

WPX Energy

WPX is the largest natural gas producer in the state. In the current rulemaking WPX has offered an alternative proposal that would decrease the total number of leak inspections by allowing well production facilities with low leak rates during two consecutive inspections to reduce inspection frequency from monthly to quarterly, or from quarterly to annually depending on the size of the facility.³⁹ While it is difficult to predict in advance how many facilities would be able to take advantage of this reduced inspection rate, for the purposes of this Cost Benefit Analysis the Division assumes that one half of the facilities would be able to utilize the reduced frequency. Based on this assumption, adoption of WPX's alternative proposal would reduce the total net annual cost of the proposed revisions from approximately \$42.4 million to approximately \$36.8 million. This change would also decrease the amount of emission reductions from the Division's proposal by 1,845 tons per year of VOC and 2,757 tons per year of methane/ethane.

The decrease in net costs should have some positive impact on the indirect costs associated with potential well shut-ins, but the Division is unable to reasonably calculate this impact. Given the relatively small difference in net costs between the two proposals, any positive impact should be fairly small. The decrease in costs relative to the Division's proposal includes a decrease in the number of facility inspections, which would result in fewer new inspector jobs attributable to the proposal. Based on the number of inspection hours for each proposal, the number of new inspector jobs would decrease. Finally, because the WPX proposal would result in less VOC and methane emission reductions, the economic benefits associated with these reductions discussed in Section III above would be reduced.

Conservation Groups

As part of the rulemaking a number of conservation groups have submitted an alternative proposal requiring additional leak detection inspections for well production facilities and compressor stations relative to the Division's proposal. In addition, the Conservation Groups' alternative proposal increases the number of pneumatic devices that would need to be retrofitted. A copy of the Conservation Groups' alternative proposal is attached as Exhibit D. Additionally, their analysis of the costs and benefits associated with their alternative proposal is attached as Exhibit E.

³⁹ In addition to this change, WPX has proposed a limited number of additional changes and clarifications that do not impact the cost and benefit calculations conducted for the Division's proposal. A copy of WPX's alternative proposal is attached as Exhibit C.

Local Community Organizations

A group of local community organizations have submitted an alternative proposal aimed at increasing the stringency of the Division's proposal for facilities that are located within 1,320 feet of a building unit or designated outdoor activity area. Specifically, for such facilities the Local Community Organizations' alternative proposal would decrease the threshold for controls from petroleum storage tanks from 6 tons per year (as proposed by the Division) to two tons per year. Additionally, facilities located within 1,320 feet of these designated areas would be subject to a more stringent leak inspection schedule. Copies of the Local Community Organizations' alternative proposal and their assessment of costs and emission reduction benefits are attached as Exhibits F and G.

Local Government Coalition

The Local Government Coalition consists of a number of county and city governments including Adams County, Boulder County, La Plata County, Pitkin County and San Miguel County, Fort Collins, the City of Boulder, and the City and County of Denver. In their alternative proposal, the Local Government Coalition seeks to increase the number of leak detection inspections for compressor stations and well production facilities relative to the Division's proposal. The Local Government Coalition also seeks to require that well production facilities be tied in to a gas gathering line within 90 days after the date of first production, unless the Division approves an extension of this deadline. Copies of the Local Government Coalition's alternative proposal and documents assessing the costs and benefits of that proposal are attached hereto as Exhibits H through L.

Worldwide Liquid Solutions, LLC

Worldwide Liquid Solutions (WLS) is a manufacturer of emission reduction technology designed to control VOC emissions from petroleum storage tanks. According to WLS, their emission reduction technology cannot control methane and ethane and therefore cannot meet the control standards for tanks reflected in the Division proposal. To address this, WLS has submitted an alternative proposal that would only require reductions of VOCs from tanks and not methane/ethane. As an alternative to their alternative, WLS has proposed rejecting all of the proposed changes to Regulation No. 7 set forth in the Division's proposal. Copies of WLS' alternative proposal and their assessment of costs and emission reduction benefits are attached as Exhibits M and N.

Conclusion

The Division has in good faith developed this comprehensive Cost-Benefit Analysis that complies with all requirements of 24-4-103(2.5.), C.R.S. The Division believes that the proposal before the AQCC reflects a balanced approach that includes proven and cost effective strategies to reduce emissions from the oil and gas sector, while enabling the sector to continue to grow in

a responsible and protective manner. The Division looks forward to the AQCC's consideration of its proposal and alternate proposals of other parties at the February 2014 hearing.

FINAL
ECONOMIC IMPACT ANALYSIS
PER § 25-7-110.5(4), C.R.S.

For proposed revisions to
Colorado Air Quality Control Commission
Regulation Number 7 (5 CCR 1001-9)

I. INTRODUCTION

The Colorado Air Pollution Control Division (Division) submits the following Final Economic Impact Analysis in conjunction with its proposed revisions to Colorado Air Quality Control Commission (AQCC) Regulation Number 7 (5 CCR 1001-9). The Regulation Number 7 rulemaking package proposes revisions that expand existing oil and gas control requirements and establish additional monitoring, recordkeeping and reporting requirements. Among other things, the Division proposes to: increase control requirements and improve capture efficiency requirements for oil and gas storage tanks; minimize fugitive emissions of hydrocarbons (including volatile organic compounds, methane and ethane) from leaking components at compressor stations and well production facilities; expand control requirements for pneumatic devices, increase control requirements for glycol dehydrators; and minimize venting at oil and gas production facilities.

In this Final Economic Impact Analysis, the Division has assessed the costs and benefits associated with each of the proposed strategies based on the reasonably available data. In collecting this data, the Division has sought input from various stakeholders in an effort to generate the most complete and accurate assessment of the costs and benefits of the proposed strategies. Where data was not reasonably available, the Division utilized assumptions that are set forth in this analysis.

II. REQUIREMENTS FOR A FINAL ECONOMIC IMPACT ANALYSIS

Section 25-7-110.5(4), C.R.S. requires the proponent to submit a final economic impact analysis for any proposed rule. Section 25-7-110.5(4)(a), C.R.S. The statute further provides that:

The proponent and the division shall select one or more of the following economic impact analyses. The commission may ask affected industry to submit information with regard to the cost of compliance with the proposed rule, and, if it is not provided, it shall not be considered reasonably available. The economic impact analysis required by this subsection (4) shall be based upon reasonably available data

Section 25-7-110.5(4)(c), C.R.S.. For the purposes of this Final Economic Impact Analysis, the Division has chosen to utilize the methodology set forth in § 25-7-110.5(4)(c)(I), C.R.S., which requires the following:

(I) Cost-effectiveness analyses for air pollution control that identify:

(A) The cumulative cost including but not limited to the total capital, operation, and maintenance costs of any proposed controls for affected business entity or industry to comply with the provisions of the proposal;

(B) Any direct costs to be incurred by the general public to comply with the provisions of the proposal;

(C) Air pollution reductions caused by the proposal;

(D) The cost per unit of air pollution reductions caused by the proposal;

(E) The cost for the division to implement the provisions of the proposal;

III. OVERVIEW OF PROPOSED REGULATORY CHANGES

The Division is proposing revisions to AQCC Regulation Number 7 in an effort to enhance the effectiveness of Colorado's air quality requirements for the oil and gas exploration and production sector. These proposed revisions consist of the following:

- 1) Enhancing the existing control program for petroleum storage tanks by:
 - a. Lowering the existing control requirement threshold for condensate storage tanks from 20 to 6 tons per year of uncontrolled actual volatile organic compound (VOC) emissions;
 - b. Requiring controls for crude oil and produced water storage tanks with uncontrolled actual VOC emissions that are equal or greater than 6 tons per year; and
 - c. Expanding non-attainment area requirements for tank controls during the first 90 days of production to the rest of the state;
- 2) Establishing requirements to ensure that emissions from controlled storage tanks are captured and routed to the control device;
- 3) Establishing leak detection and repair requirements for compressor stations and well production facilities, including requirements to reduce emissions from compressor seals and open ended lines consistent with current federal requirements;
- 4) Expanding the existing non-attainment area requirements for auto-igniters on flare devices to the rest of the state;
- 5) Expanding the existing non-attainment area requirements for low bleed pneumatic devices to the rest of the state and where feasible requiring no-bleed pneumatic devices;
- 6) Requiring that the gas stream at newly constructed well production facilities either be connected to a pipeline or routed to a control device from the date of first production;

- 7) Lowering the existing control requirement threshold for existing glycol dehydrators to 6 tons per year of uncontrolled actual VOC emissions and 2 tons per year of uncontrolled actual VOC emissions for dehydrators located within 1,320 feet of a building, and establishing a 2 ton per year control threshold for all new glycol dehydrators; and
- 8) Establishing requirements for the use of best management practices both to minimize the need for downhole well maintenance and liquids unloading and to minimize emissions during well maintenance and liquids unloading events.

IV. COST/BENEFIT ANALYSIS:

The Division's assessment of the costs and benefits for the proposed strategies is set forth below. For each strategy, these assessments identify the cumulative costs for the affected industry, the estimated air pollution reduction, and the projected cost per unit of air pollution reduced. The Division also assessed whether any of the proposed strategies would impose a direct cost on the general public to comply, and determined that based on the available data there will be no direct costs on the general public for any of the proposed requirements. Finally, the Division considered whether there would be any additional costs for the Division to implement the proposed requirements beyond current expenditures. Currently the Division has 12 inspectors dedicated to inspecting oil and gas facilities. If the proposed rules are adopted, the Division intends to utilize these existing resources to ensure compliance with these rules. The costs associated with these inspectors are detailed below.

A. Control Requirements for Petroleum Storage Tanks

Commencing in 2004 the Air Quality Control Commission has adopted a series of requirements aimed at reducing emissions from petroleum storage tanks at well production facilities, compressor stations and gas processing plants. Currently, condensate tanks with uncontrolled actual emissions of 20 tons per year or greater of VOC must be equipped with a control device that has a control efficiency of at least 95%. Additionally, with certain exceptions, operators in non-attainment areas must achieve a 90% system-wide reduction of VOC emissions from condensate tanks during the period from May 1 through September 30, and 70% during the period from October 1 through April 30. These current requirements only apply to tanks that store condensate, which is defined in the AQCC's Common Provisions regulation as "hydrocarbon liquids . . . with an API gravity of 40 degrees or greater." While most of the petroleum liquid produced in Colorado qualifies as condensate, there are heavier hydrocarbon liquids, typically referred to as crude oil, with an API gravity below 40 degrees that are not subject to the current control requirements. Additionally, there are a number of high volume produced water tanks that have VOC emissions above 6 tons per year that are not currently regulated under the existing requirements.

While Colorado has achieved considerable success in controlling emissions from condensate tanks since 2004, petroleum storage tanks at oil and gas production and midstream facilities continue to be the most significant source of VOC emissions from this sector. To address this

emission source the Division is proposing the following strategies: 1) reducing the control threshold from 20 tons per year VOC to 6 tons per year; 2) eliminating the distinction between condensate and other liquids and requiring controls strictly based on emission levels; and 3) extending the current requirement that all condensate tanks in the non-attainment area be controlled during the first 90 days of production to storage tanks throughout the state. In order to meet each of these three strategies, the Division assumes that owners and operators will equip tanks with enclosed flares, as is the typical practice under the existing tank control requirements. The estimated costs associated with installing and maintaining an enclosed flare are set forth in subsection 1 below. Utilizing the calculated flare costs, the estimated costs and benefits for each of the three tank control strategies are discussed in subsections 2-4 below.

1. General Cost Estimates for Flares

The estimated cost for a flare control device is based on identified costs from a 2008 oil and gas cost study¹ adjusted for inflation. Based on this data, the estimated annualized cost of a flare control device with auto-igniter² is about \$6,287.³

Table 1: Flare Control Device with Auto Igniter – Annualized Cost Analysis*

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |
|---------------------|-----------------------------|-----------------------------------|--------------------------|---------------------------|
| Flare | \$18,169 | | | |
| Freight/Engineering | | \$1,648 | | |
| Flare Installation | | \$6,980 | | |
| Auto Igniter | \$1,648 | | | |
| Pilot Fuel** | | | \$768 | |
| Maintenance | | | \$2,197 | |
| Subtotal Costs | \$19,817 | \$8,628 | \$2,965 | |
| Annualized Costs*** | \$2,747 | \$575 | \$2,965 | |

*Control cost evaluation based on 2008 Ozone Rulemaking cost survey and producer data. Control device costs were developed based on an oil and gas cost study and information submitted by industry in 2008. However, those costs were escalated by 9.85% to reflect CPI-U increases that have occurred since 2008.⁴

¹ See “Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination,” Lesair Environmental, Inc., June 2008. Information from this study was previously submitted to the AQCC as part of the 2008 Ozone Action Plan process.

² Currently only flares in the non-attainment area are required to have auto-igniters. Under the current proposal, the auto-igniter requirement would be extended statewide. For the purposes of this cost analysis, it is assumed that auto-igniters will be required statewide. The cost and benefits associated with equipping existing flares outside the non-attainment with auto-igniters are discussed below in Section D.

³ Certain parties to the rulemaking have asserted that the actual cost per combustion device is higher based on EPA’s cost analysis conducted in accordance with NSPS OOOO. Based on a review of EPA’s analysis it appears that additional costs were included for surveillance systems that are not applicable to the proposed rule. Additionally, unlike the analysis in NSPS OOOO, the costs that the Division has identified are based on a Colorado specific cost analysis.

⁴ It has been suggested that the Division should have used the Producer Price Index to calculate an escalation from 2008 to 2013 costs. From 2008 to 2013, however, the Producer Price Index for the oil and gas field equipment

** Pilot fuel costs \$3.41/MMBtu (Henry Hub Spot Price - Aug. 2013)

*** Annualized over 15 years at 5% ROR

2. Lowering Statewide Condensate Tank Control Threshold (from 20 tpy to 6 tpy)

The Division is proposing to lower the uncontrolled VOC emission control threshold from 20 tpy down to 6 tpy on condensate storage tanks statewide. Based on an analysis of the Air Pollution Emissions Notice (APEN) database, the Division estimates that statewide there are 588 uncontrolled condensate tank batteries with VOC emissions over six tons per year. Of these 588 tanks, 396 are outside the non-attainment area and the remaining 192 are within the current non-attainment area.

Table 2: Condensate Tank Battery Analysis

| Tank Battery Type | Ozone NAA [count] | Outside NAA [count] | Cancelled Tanks [count] | Total Statewide Tanks [count] |
|------------------------------------|-------------------|---------------------|-------------------------|-------------------------------|
| Controlled Tanks | 4,971 | 490 | | 5,461 |
| Uncontrolled Tanks | 1,451 | 1,132 | 36 | 2,619 |
| All Tanks | 6,422 | 1,622 | 36 | 8,080 |
| | | | | |
| Uncontrolled Tanks (≥ 6 tpy) | 192 | 396 | | 588 |

Based on the reported uncontrolled actual VOC emissions for these 588 tanks, and assuming both that 75% of the VOC emissions are captured and sent to the flare,⁵ and that the flare has a 95% destruction efficiency, the total VOC emission reduction associated with lowering the condensate tank threshold statewide is 5,162 tons per year.

Table 3: Condensate Tank Battery Emissions Analysis for Lowering Statewide Threshold

| Tank Battery Type | Uncontrolled VOC Emissions [tons/year] | Controlled VOC Emissions [tons/year] | VOC Emission Reduction [tons/year] |
|--|--|--------------------------------------|------------------------------------|
| NAA Uncontrolled Tanks (≥ 6 tpy) | 2,355 | 677* | 1,678 |
| Outside NAA Uncontrolled Tanks (≥ 6 tpy) | 4,890 | 1,406* | 3,484 |
| Totals: | 7,245 | 2,083 | 5,162 |

*Emission reduction estimated by accounting for 75% capture and 95% destruction efficiency.

The annualized cost of installing 588 flare control devices is about \$3.7 million dollars with an average cost effectiveness of about \$716 per ton of VOC reduced. For the smallest individual

sector grew at a slower rate than the CPI. Accordingly, the Division's analysis may actually overstate the increase in cost from 2008 to 2013.

⁵ The costs and benefits associated with improving the capture percentage for controlled storage tanks are discussed below in Section B.

tank battery subject to controls (6 tons/year), the flare cost effectiveness is estimated at \$1,471 per ton of VOC reduced.

Table 4: Tanks over 6 tpy – Control Cost Estimates for Flare Control Devices

| Affected Tanks [count] | Each Flare Annualized Cost | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
|---------------------------|-------------------------------|---------------------------|------------------------------|---------------------------|
| 588 | \$6,286.8 | \$3,696,638 | 5,162 | \$716 |

In addition to VOC reductions, this strategy will significantly reduce methane and ethane emissions from currently uncontrolled tanks. To calculate methane and ethane emission reductions, the Division determined the relative proportion of VOCs to methane and ethane based on reported average values from 30 natural gas liquid analyses submitted to the Division. Based on these analyses, methane/ethane emissions from condensate storage tanks are about 38% of the VOC emissions by weight. Accordingly, projected methane/ethane emission reductions from this proposed strategy are 1,963 tons per year or \$1,884 per ton of methane/ethane reduced.

3. Requiring Controls for Produced Water and Crude Oil Tanks

As discussed above, the Division is proposing to eliminate the distinction between condensate tanks and other storage tanks. If the AQCC adopts this proposal, crude oil tanks and produced water tanks with uncontrolled actual VOC emissions of six tons per year or greater will require controls. Because produced water and crude oil tanks are identified separately in the Division’s APEN data base, the costs and benefits for these two types of storage tanks are broken out separately.

The Division is proposing that all statewide produced water tanks with uncontrolled VOC emissions over 6 tons/year be required to install emission controls. Some uncontrolled produced water tanks could be co-located at sites with condensate or crude oil tanks that have flare controls, but pressure and flow differences may require the installation of a separate flare control device for the water tank. Consequently, the control costs are based on the assumption that each water tank battery will install a new flare control device. Based on an analysis of the APEN database, the Division estimates that statewide there are 52 uncontrolled produced water tank batteries with VOC emissions over 6 tons/year.

Table 5: Produced Water Tank Battery Analysis

| Tank Battery Type | Total Statewide Water Tanks |
|---------------------------|-----------------------------|
| Controlled Water Tanks: | 338 |
| Uncontrolled Water Tanks: | 530 |
| Total: | 868 |

| Tank Battery Type | Total Statewide Water Tanks |
|------------------------------------|-----------------------------|
| Uncontrolled Tanks (≥ 6 tpy) | 52 |

Based on the reported uncontrolled actual emissions, the Division estimates that the total VOC emission reduction associated with controlling these produced water tanks statewide is 457 tons per year.

| Tank Battery Type | Uncontrolled VOC Emissions [tons/year] | Controlled VOC Emissions [tons/year] | VOC Emission Reduction [tons/year] |
|------------------------------------|--|--------------------------------------|------------------------------------|
| Uncontrolled Tanks (≥ 6 tpy) | 641.4 | 184.4* | 457 |

*Emission reduction estimated by accounting for 75% capture and 95% destruction efficiency.

The annualized cost of installing 52 flare control devices is about \$327,000, with an average cost effectiveness of about \$715 per ton of VOC reduced. For the smallest individual tank battery (6 tons/year), the flare cost effectiveness is estimated at \$1,471 per ton of VOC reduced.

| Tank Size | Affected Tanks [count] | Each Flare Annualized Cost | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
|--------------|------------------------|----------------------------|------------------------|---------------------------|------------------------|
| ≥ 6 tpy | 52 | \$6,286.8 | \$326,914 | 457 | \$715 |

The Division is proposing that all statewide hydrocarbon liquid storage tanks with VOC emissions over six tons/year must install emission controls. Based on a recent analysis of 2013 APEN data, there are 67 reported crude oil tanks batteries statewide. Thirty seven of the tank batteries are already equipped with controls. Of the remaining thirty, eight are over the proposed six tons/year threshold. Given that approximately 5% of the total wells in the state report crude oil production to the Colorado Oil and Gas Conservation Commission (COGCC),⁶ it appears likely that the Division’s APEN database may be undercounting crude oil tanks, either because these tanks have not been reported or because they are being reported as condensate tanks.⁷

⁶ Based on an analysis of 2010 COGCC data.

⁷ Prior to 2008 crude oil storage tanks were exempt from APEN reporting requirements, which may explain in part the small numbers of tanks identified in the system.

| Tank Battery Type | Total Statewide Crude Oil Tanks |
|------------------------------------|---------------------------------|
| Controlled Crude Oil Tanks | 36 |
| Uncontrolled Crude Oil Tanks | 29 |
| Total: | 65 |
| Uncontrolled Tanks (≥ 6 tpy) | 8 |

The total VOC emission reduction associated with controlling these 8 crude oil tanks statewide is 118 tons per year.

| Tank Battery Type | Uncontrolled VOC Emissions [tons/year] | Controlled VOC Emissions [tons/year] | VOC Emission Reduction [tons/year] |
|------------------------------------|--|--------------------------------------|------------------------------------|
| Uncontrolled Tanks (≥ 6 tpy) | 165.2 | 47.5* | 117.7 |

*Emission reduction estimated by accounting for 75% capture and 95% destruction efficiency.

The annualized cost of installing eight flare control devices is about \$50,294 dollars with an average cost effectiveness of about \$427 per ton of VOC reduced. For the smallest individual tank battery (6 tons/year), the flare cost effectiveness is estimated at \$1,471 per ton of VOC reduced.

| Tank Size | Affected Tanks [count] | Each Flare Annualized Cost | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$ /ton] |
|--------------|------------------------|----------------------------|------------------------|---------------------------|-------------------------|
| ≥ 6 tpy | 8 | \$6,286.8 | \$50,294.4 | 117.7 | \$427 |

4. Requiring Controls During the First 90 Days of Production Statewide

Under current requirements owners and operators of new and modified storage tanks outside the non-attainment area have 90 days after the date of first production to determine if emissions from the tank trigger the requirement to install a control. Because production is typically at its highest during this initial period, significant emissions can occur before controls are installed. To address this issue in the non-attainment area, the AQCC mandated in the 2008 Ozone Action Plan that all condensate tanks be controlled during the first 90 days. The Division is now proposing to expand this requirement to storage tanks throughout the state.

To calculate the cost effectiveness of this strategy, the Division first determined the number of new and modified storage tanks outside the non-attainment area based on reported APEN data for the period of 2010-2012. Based on this APEN data, there are on average 141 new and modified tanks each year, with yearly reported uncontrolled actual emissions of 7,370 tons VOC. Assuming that emissions during the first 90 days equal 1/4th of the annual reported emissions,⁸ total uncontrolled actual VOC emissions from these tanks during the first 90 days is 1,842.5 tons. Assuming enhanced capture efficiency for these new tanks (See Section B) the flare control efficiency is 95%, thus the calculated benefit from expanding the first 90 day control requirement to tanks outside the non-attainment area will be 1,750.4 tons per year.

While the Division estimates that there are 141 new and modified storage tanks outside the non-attainment area each year, the majority of these, 84, will require control devices regardless of this strategy since their uncontrolled actual emissions are over six tpy. For these 84 tanks, the cost of operating a flare during the first 90 days will be approximately 25% of the total annualized cost, or \$1,571.70 per tank. For the remaining 57 tanks with emissions less than six tons/year, because controls for these tanks will only need to be in place for 90 days, the Division assumes that each flare can control 3 tanks per year, which means that 19 new flares are required to comply with this proposed strategy. For other applications, the annualized cost of a flare is estimated to be \$6,287. Since flares required for this application will be relocated three times a year, the Division assumes an additional \$3,000 in annual relocation costs, for a total annualized cost of about \$9,287 per flare. Based on the emission reductions calculated above, the total cost effectiveness of this requirement is \$176/ton of VOC reduction.

Table 11: Control Cost Estimates for Flare Control Devices Required During the First 90 Days of Production

| Storage Tank Threshold [tpy] | Number of New Storage Tanks | Number of New Flares | Annualized Cost Each Flare | Total Flare Cost | Total VOC Reduction [tons/year] | VOC Control Cost [\$ /ton] |
|------------------------------|-----------------------------|----------------------|----------------------------|------------------|---------------------------------|----------------------------|
| <6 | 57 | 19 | \$9,286.8 | \$176,449.2 | 44.7 | \$3,947 |
| ≥6 | 84 | 84 | \$1,571.7 | \$132,022.8 | 1,705.7 | \$77 |
| | 141 | | | \$308,472 | 1,750.4 | \$176 |

Using the methodology discussed in subsection A.2 above the projected methane/ethane emission reductions from this strategy is 665.5 tons per year or \$464 per ton of methane/ethane reduced.

B. Emission Capture Requirements for Controlled Petroleum Storage Tanks

⁸ Because reported emissions typically are based on a calculation assuming a standard rate of production decline after the first 90 days, actual emissions during the first 90 days could be much higher.

In order for storage tank control requirements to be effective, emissions from the tank must be routed to the control device. Historically the Division has assumed that 100% of a tank's emissions will be captured and routed to the control device, typically a flare, resulting in a 95% reduction of emissions. Field observations using infra-red (IR) cameras and other methodologies indicate that in actuality emissions from controlled storage tanks often escape through the thief hatches and pressure relief valves (PRV) and therefore are not being combusted in the flare. This occurs when the tank cannot adequately contain the flashing emissions that occur when pressurized liquids from the separator are dumped into the atmospheric tank. To address this issue, the Division is proposing new regulatory language clarifying that all emissions from controlled storage tanks must be routed to the control device and that these tanks must be operated without venting emissions from thief hatches, PRVs and other openings, except when venting is reasonably necessary for maintenance, gauging, or safety of personnel and equipment.

To assure compliance with these capture standards, the Division's proposal requires that owners and operators of controlled storage tanks implement a Storage Tank Emission Management (STEM) plan. Pursuant to the STEM plan, owners and operators must evaluate and employ appropriate control technologies and/or operational practices designed to meet the proposed capture requirements, and certify that these technologies and/or operational practices are designed to minimize emissions from the tank. The Division's STEM proposal also requires implementation of a two-pronged monitoring strategy involving a weekly⁹ auditory, visual, and olfactory (AVO) inspection for all controlled tanks, and a periodic instrument based monitoring for tanks using Method 21, an IR camera or other Division approved monitoring device or method. As proposed, the frequency of this instrument based monitoring will depend on the level of uncontrolled actual emissions from the tank.

| <i>Table 12: Proposed Tiering for Instrument Based Tank Inspections</i> | |
|--|-----------------------------|
| Tank Uncontrolled Actual VOC Emissions | Inspection Frequency |
| ≥ 6 tpy to ≤ 12 tpy | Annually |
| > 12 tpy to ≤ 50 tpy | Quarterly |
| > 50 tpy | Monthly |

In assessing the cost effectiveness of the proposed requirements, the Division first calculated the costs associated with implementing technological and/or operational changes at controlled tanks. For the purposes of this analysis the Division assumed that all tanks with uncontrolled actual emissions greater than or equal to 6 tons per year would need to be controlled consistent with the Division's proposal discussed in Section A above. Based on reported data, there are currently 5,310 storage tanks statewide with emissions greater than or equal to 6 tons per year. While the Division's proposal does not specify the type of technology or operational practices that

⁹ There is an exception for the weekly inspection requirement where the operator loads out liquids from the storage tank on less than a weekly basis. In these circumstances the operator must conduct the inspection whenever liquids are loaded out, but no less often than every 30 days. Typically liquids are loaded out multiple times in a given week, meaning that for the majority of the tanks AVO inspections will be required weekly.

operators will use, for the purposes of this analysis the Division assumed that buffer bottle technology would be installed on each of the subject tanks.¹⁰ The buffer bottle technology utilizes a small tank that is installed after the separator which allows for a secondary flash of pressurized liquids prior to dumping into the storage tank. The second-stage flash reduces the pressure of the liquids going to the tank and thereby helps to ensure that the tank can adequately handle the flashing emissions that occur when the liquids are brought to atmospheric pressure. Based on industry provided information, the estimated annual cost of a buffer bottle is set forth in Table 13.¹¹

Table 13: Annualized Cost Analysis for Buffer Bottle

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |
|-------------------|--------------------------|--------------------------------|-----------------------|------------------------|
| Buffer Bottle | \$11,500 | | | |
| Freight/Engr | | \$600 | | |
| Installation | | \$2,280 | | |
| Maintenance | | | \$2,500 | |
| Subtotal Costs | \$11,500 | \$2,880 | \$2,500 | |
| Annualized Costs* | \$1,593.8 | \$192 | \$2,500 | \$4,285.8 |

* Annualized over 15 years at 5% ROR

The Division also calculated the costs associated with conducting enhanced inspections. Based on the proposed tiering, operators will need to conduct 24,840 tank inspections per year.¹²

Assuming that each inspection takes two hours and utilizing a \$103/hour¹³ in-house inspection cost and a \$134/hour contractor inspection cost (30% profit added to in-house rate), the total annual cost associated with conducting enhanced inspections under the proposed rule is \$5,392,010, which equates to \$1,015.4 per year for each tank that will be subject to STEM.

¹⁰ Based on discussions with industry representatives during the stakeholder process there may be other less costly technologies and operational practices that could be used to ensure good emission capture from tanks such as replacing seals, more frequent maintenance, changing the size of piping going to the storage tank, and timing well dumps to avoid overloading the separator. There may also be other options for new facilities that allow for the capture and sale of additional gas such as the installation of high-low pressure separators or utilizing a liquids gathering system that eliminates atmospheric storage tanks at well sites.

¹¹ For this Final EIA the Division increased the capital and maintenance costs for buffer bottles based on input from industry stakeholders.

¹² In practice, many operators are already conducting IR camera inspections at storage tanks, however, the Division does not have information regarding how many inspections are currently occurring.

¹³ The hourly inspection cost is discussed below in Table 20.

Table 14: Instrument Based Tank Inspections Based on Proposed Tiering

| Tank Uncontrolled Actual VOC Emissions | Inspection Type/Hourly Rate | Number of Tanks | Inspection Frequency | Number of Inspections | STEM Inspection Costs |
|--|-----------------------------|-----------------|----------------------|-----------------------|-----------------------|
| >6 tpy to ≤ 12 tpy | In-House/\$103 | 1,085 | Annually | 1,085 | \$223,510 |
| >12 tpy to ≤ 50 tpy | In-House/\$103 | 2,595 | Quarterly | 10,380 | \$2,138,280 |
| > 50 tpy | In-House/\$103 | 745 | Monthly | 8,940 | \$1,841,640 |
| Subtotal: | | 4,425 | | 20,405 | \$4,203,430 |
| >6 tpy to ≤ 12 tpy | Contractor/\$134 | 323 | Annually | 323 | \$86,564 |
| >12 tpy to ≤ 50 tpy | Contractor/\$134 | 329 | Quarterly | 1,316 | \$352,688 |
| > 50 tpy | Contractor/\$134 | 233 | Monthly | 2,796 | \$749,328 |
| Subtotal: | | 885 | | 4,435 | \$1,188,580 |
| Total: | | 5,310 | | 24,840 | \$5,392,010 |

The Division also considered whether additional costs should be included for conducting periodic AVO inspections. Because these activities are already required for controlled storage tanks under existing regulation, the Division did not include these costs in determining the total cost of the proposed capture requirements. The Division also did not include costs associated with certifying that selected technologies and/or operational practices are designed to minimize emissions, since costs for certifying capture efficiency are already included in the annualized cost of required flares.¹⁴ Accordingly, the total projected annual cost of the proposed capture requirements based on the use of a buffer bottle and enhanced monitoring requirements is \$5,301.2 per tank.

To calculate the projected emissions reduction from the proposed capture requirements, the Division assumed a current capture rate of 75% for controlled tanks based on analytical work that the Division, EPA and others have performed. Based on this capture rate, the Division calculated the emissions reduction that would occur if the capture rate were increased to 100% using the following equation:

$$\text{Emission reduction} = [\text{uncontrolled VOC} * (1 - (0.75 * 0.95))] - [\text{uncontrolled VOC} * (1 - 0.95)],$$

Using this equation as applied to the reported uncontrolled actual emissions from the 5,310 storage tanks statewide with emissions greater than or equal to six tons per day, the projected emission reduction from the proposed capture requirements is 53,386 tons per year. Included in the total are 33 existing crude oil tanks with flare controls (>6 tpy) and 8 crude oil tanks that would need flare controls (>6 tpy).

¹⁴ See “Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination,” Lesair Environmental, Inc., June 2008, at pg. 8.

Table 15: STEM Emission Control Analysis (Statewide)

| Number of Tanks ≥ 6 tpy | Uncontrolled VOC [tons/year] | Controlled VOC (@ 71.25% Control) [tons/year] | Controlled VOC (@ 95% Control) [tons/year] | VOC Reduction [tons/year] |
|------------------------------|------------------------------|---|--|---------------------------|
| 5,269 | 221,569 | 63,701 | 11,078 | 52,623 |
| 41 | 3,213 | 924 | 161 | 763 |
| 5,310 | 224,782 | 64,625 | 11,239 | 53,386 |

Applying this reduction to the costs calculated above, the cost effectiveness of these proposed requirements is \$527/ton of VOC.

Table 16: STEM Control Cost Estimates (Statewide)

| Type of Technology | Number of Tanks | Each Device Annualized Costs [\$/year] | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
|--------------------|-----------------|--|------------------------|---------------------------|------------------------|
| Buffer Bottle | 5,310 | \$5,301.2 | \$28,149,372 | 53,386 | \$527.3 |

Using the average ratio of VOC to methane/ethane emissions from storage tanks, the projected methane/ethane reduction from this strategy is 20,287 tons per year, which equates to \$1,388 per ton of methane/ethane reduced.

During the stakeholder process certain parties have raised questions about the Division’s assumption that currently controlled tanks have a 75% capture efficiency. In light of this the Division has also calculated cost effectiveness based on the assumption that current capture efficiency is 50% and 95%. For the 50% case, current controlled emissions would be 118,011 tpy VOC. Accordingly, the emission reduction benefit from increasing capture to 100% would be 106,772 tons per year (118,011-11,239) and the cost effectiveness would be \$264/ton VOC¹⁵. For the 95% capture scenario, current controlled emissions would be 21,916 tons per year VOC and the emission reduction would be 10,677 tons per year (21,916-11,239). Under this scenario, the cost effectiveness would be \$2,636/ton VOC¹⁶.

While the buffer bottle technology offers a good alternative in a retrofit situation for reducing pressures to the tank and increasing emission capture, for new facilities, installation of a high-low pressure (HLP) separator to satisfy STEM may prove to be a better performing option. This equipment allows for two stages of separation of the gas and the liquids instead of the single stage separation accomplished in traditional separators. By adding a second stage of separation,

¹⁵ This may overestimate the cost effectiveness given that if the current capture rate were only 50% additional costs could be required to increase the capture rate to 100%.

¹⁶ This is a conservative calculation given that if the current capture rate were 95% it is likely that the control costs to increase the capture rate to 100% would be significantly less.

the pressure of the liquids sent to the tank is significantly reduced, thereby helping to ensure complete capture of flashing emissions instead of venting a portion of the emission stream through the thief hatch or PRV. Additionally, rather than being routed to the flare, as in the case of the buffer bottle technology, gas from the second stage of separation can be sent to a vapor recovery unit (VRU), recompressed and sent to the sales line, resulting in increased product recovery. Based on information provided from industry, the Division has calculated that the annual cost of a HLP separator w/VRU is about \$19,341.

Table 17: Annualized Cost Analysis for HLP Separator

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |
|----------------------|-----------------------------|-----------------------------------|--------------------------|---------------------------|
| HLP/VRU | \$90,000 | | | |
| Freight/Engr | | \$1,648 | | |
| HLP/VRU Installation | | \$11,154 | | |
| Maintenance | | | \$9,396 | |
| VRU Recovered NG * | | | \$(3,382) | |
| Subtotal Costs | \$90,000 | \$12,802 | \$6,014 | |
| Annualized Costs** | \$12,474 | \$853 | \$6,014 | \$19,341 |

* Recovered NG fuel costs \$3.5/MCF (Henry Hub Spot Price - Aug. 2013) and average tank battery size of 63.2 tpy – based on 3-yr average of APEN data on storage tanks ≥ 6 tpy (uncontrolled VOC).

** Annualized over 15 years at 5% ROR

Unlike the retrofit situation analyzed above where the emission controls are already in place, it is appropriate in new installations to aggregate the cost of the HLP separator w/VRU with the costs of the control unit (flare) to determine the overall cost of controlling emissions from the tank. Based on the \$6,286.8 annual cost of a flare and annual instrument based monitoring costs of \$1,015.4 per tank, the total annual control costs for a new tank will be \$26,643 per year.

Based on an analysis of reported data for new tanks during the past three years, the average uncontrolled actual emissions of a new tank is 63.2 tpy. Assuming a 95% overall control efficiency, equipping a tank with an HLP separator and a flare will reduce the emissions from an average new tank by 60 tpy. This yields a cost effectiveness of \$444 per ton VOC reduced. If instead, the highest cost scenario (using a six tpy tank) is assumed, the cost effectiveness is \$4,674 per ton VOC. For methane ethane the cost per ton is \$1,168 per ton reduced on average.

C. Leak Detection and Repair Requirements for Compressor Stations and Well Production Facilities

AQCC Regulation Number 7 requires owners and operators of gas processing plants in Colorado to implement leak detection and repair programs to identify and repair fugitive emission leaks from components at these facilities. Under this requirement, owners and operators must conduct

periodic inspections using EPA Reference Method 21¹⁷ and repair leaks within a prescribed time frame.

Although component leaks at compressor stations and well production facilities in Colorado are also a significant source of VOC and methane emissions, Regulation No. 7 does not currently include leak detection and repair requirements for these facilities.¹⁸ To address these emissions, the Division is proposing regulatory changes that would establish leak detection and repair requirements for compressor stations and well production facilities. Pursuant to this proposal, owners and operators of compressor stations and well production facilities will be required to conduct periodic leak inspections, and repair identified leaks. As specified, required inspections may be done either in accordance with Method 21 or utilizing an IR camera. The proposed language also allows the Division to approve other inspection methods as new leak detection technologies are demonstrated to be effective.

The proposed regulation establishes a tiered system to determine inspection frequency. For compressor stations the tiering is based on the uncontrolled actual leak emissions at the facility as follows:

Table 18: Proposed Tiering for Leak Inspections at Compressor Stations

| Component Leak Uncontrolled Actual VOC Emissions | Inspection Frequency |
|--|----------------------|
| ≤ 12 tpy | Annually |
| >12 tpy to ≤ 50 tpy | Quarterly |
| > 50 tpy | Monthly |

For well production facilities the proposed tiering is based on uncontrolled actual emissions from the largest emitting storage tank at the facility as set forth in Table 19. The tiering is based on tank emissions rather than uncontrolled actual leak emissions in order to create a Method 21/IR camera monitoring schedule that is consistent with the monitoring schedule proposed as part of the STEM emission capture requirements discussed in Section B above.¹⁹

¹⁷ While Method 21 sets performance standards for inspection equipment rather than specifying technology, typically Method 21 inspections utilize photo ionization detectors (PIDs) to assess leak levels.

¹⁸ Although leak detection is not currently required at most of these facilities, some operators currently conduct voluntary leak detection and repair programs. Additionally, the Division has issued a limited number of permits that include some leak detection requirements. For the purposes of this analysis, however, the Division assumes that there is no leak detection occurring at well production facilities and compressor stations. Accordingly the actual additional costs that operators may incur may be less than the costs calculated in this analysis.

¹⁹ Because there may be a limited number of instances where well production facilities don't have storage tanks, the proposal also provides that for tank-less facilities, the inspection schedule will be based on the facility's total VOC emissions. This provision is intended to apply to large facilities that utilize a liquids gathering system for transporting petroleum liquids to a centralized facility. These facilities are not included in the facility count used in this EIA, but because the number of these facilities in Colorado is extremely small this exclusion should have a negligible impact on the overall costs and emission reduction benefits of the proposed LDAR requirement. Additionally, because the costs and benefits from the proposed LDAR program increase at roughly the same rate,

| Tank Uncontrolled Actual VOC Emissions | Inspection Frequency |
|--|----------------------------|
| < 6 tpy | One Time (and Monthly AVO) |
| ≥ 6 tpy to ≤ 12 tpy | Annually |
| >12 tpy to ≤ 50 tpy | Quarterly |
| > 50 tpy | Monthly |

The Division utilized a multi-step process to calculate the estimated costs and benefits associated with the proposed leak detection and repair requirements. First, the Division calculated an hourly inspection rate based on the total annual cost for each inspector divided by an assumed 1,880 annual work hours.²⁰ To calculate the total annual cost for each inspector, the Division included salary and fringe benefits for each inspector, annualized equipment and vehicle costs, and add-ons to account for supervision, overhead, travel, record keeping, and reporting. Based on the assumptions set forth in Table 20 below, the total annual cost for each inspector will be \$193,629, which equates to an hourly inspection rate of \$103.

| Item | Capital Costs (one time) | Annual Costs | Annualized Total Costs |
|-----------------------------------|-----------------------------|------------------------|---------------------------|
| FLIR Camera | \$122,000 | | |
| FLIR Camera Maintenance/Repair | | \$7,500 | |
| Photo Ionization Detector | \$5,000 | | |
| Vehicle (4x4 Truck) | \$22,000 | | |
| Inspection Staff | | \$75,000 | |
| Supervision (@ 20%) | | \$15,000 | |
| Overhead (@10%) | | \$7,500 | |
| Travel (@15%) | | \$11,250 | |
| Recordkeeping (@10%) | | \$7,500 | |
| Reporting (@10%) | | \$7,500 | |
| Fringe (@30%) | | \$22,500 | |
| Subtotal Costs | \$149,000 | \$153,750 | |
| Annualized Costs* | \$39,879 | \$153,750 | \$193,629 |
| *over 5 years at 6% ROR | | Annualized Hourly Rate | \$103 |

In the Initial EIA the Division assumed that conducting inspections in-house would be the lowest cost option since it would not involve additional profit to be paid to a contractor. For smaller

the cost effectiveness of the program for these facilities should mirror the cost effectiveness of the program as applied to facilities with tanks.

²⁰ This assumes a 40 hour work week with ten holidays, two weeks of vacation, and one week of sick leave.

companies that cannot fully utilize an IR camera, however, conducting inspections in-house may not be the most cost effective option. To account for this in the Final EIA the Division assumed a 30% profit margin for contractors, which it added to the calculated hourly rate in instances where it appeared that contractors would be used to conduct the inspection (\$134 per hour).

Second, the Division calculated the average amount of time that it would take to conduct a Method 21 inspection at compressor stations and well production facilities based on the number of components to be inspected and assuming that a component could be inspected every 30 seconds. The proposed rule also allows owners and operators to use IR cameras either as the sole inspection tool, or as a screening tool to identify potential leaking components followed by a Method 21 inspection. An IR camera inspection or IR Camera/Method 21 hybrid inspection can be conducted more quickly than a Method 21 inspection of each component. While the Division does not currently have actual data regarding how much faster an inspection could be completed using an IR camera, for the purpose of this analysis the Division assumed that an IR camera based inspection would take 50% of the time required for a Method 21 inspection.²¹

For compressor stations, the Division used reported component counts for compressor stations within each of the tiers identified in Table 18 above. Based on these counts, and the inspection times per component discussed above, the Division calculated that the total inspection time per compressor station facility tier are as follows:

| Table 21: Calculated Inspection Time Compressor Station Leak Inspections | | |
|---|----------------------|------------------------------|
| Component Leak Uncontrolled Actual VOC Emissions | Method 21 Inspection | IR Camera/ Hybrid Inspection |
| ≤ 12 tpy | 21.2 hours | 10.6 hours |
| >12 tpy to ≤ 50 tpy | 56.2 hours | 28.1 hours |
| > 50 tpy* | | |

* there are currently no compressor stations in Colorado with calculated leaks at this level

For well production facilities, the Division has limited data on the number of components per facility. Based on this limitation, the Division did not attempt to calculate a separate inspection time for each of the proposed facility tiers, and instead used the overall average component count. Based on the limited available data, however, there does appear to be a distinction between component numbers at well production facilities in the non-attainment area and well production facilities outside the non-attainment area. Accordingly, the Division calculated separate inspection times for well production facilities by area as set forth in Table 22.

Table 22: Calculated Inspection Times for Well Production Facility Leak Inspections

²¹ Based on the Division’s own IR camera inspections, and reports from various parties during the stakeholder and prehearing process it appears that the Division’s assumption may significantly overstate the actual time needed to conduct an IR camera inspection.

| Area | Method 21 Inspection | IR Camera/ Hybrid Inspection |
|---------------------|----------------------|------------------------------|
| Non-Attainment Area | 12.2 hours | 6.1 hours |
| Rest of the State | 6.8 hours | 3.4 hours |

In addition to the travel costs that are built into the hourly inspection rate as set forth in Table 20, for the purposes of this Final EIA the Division also assumed an additional three hours in travel time for each inspection outside the non-attainment area. This assumption reflects the fact that certain well sites in basins outside the non-attainment area may be remote, requiring additional travel.

Next, the Division calculated the projected inspection costs for both compressor stations and well production facilities. To make this calculation the Division used industry reported emission data to determine the number of facilities that will be subject to annual, quarterly and monthly inspections to determine the total number of inspections for each tier, and multiplied these inspections by the calculated inspection time and projected hourly inspection rate. For compressor stations the Division assumed that all inspections would be conducted by 3rd party contractors. For well production facilities, the Division assumed that any company with 500 or more inspections per year would conduct inspections in-house, and that companies with less than 500 inspections per year would use contractors.²² Because the proposed rule also requires owners and operators of well production facilities that are not subject to monthly instrument monitoring to conduct monthly AVO inspections the Division considered whether additional costs should be included for these inspections. Based on information provided during the stakeholder process it appears that operators already routinely conduct such inspections and repair leaks identified during these AVO inspections. Additionally, while the proposed rule may impose recordkeeping and reporting requirements associated with these AVO inspections, given the relatively small number of leaks that are expected to be identified, and the fact that any recordkeeping can be readily included in existing inspection and maintenance records the Division believes that any additional recordkeeping and reporting costs will be nominal relative to the overall cost of the LDAR program.

In its Initial EIA the Division did not include the cost to repair leaking components or re-monitor these components post-repair to verify that the repair was effective, assuming that the cost to repair and re-monitor would be offset by the cost savings from capturing additional product as a result of repairs. Based on information that the Conservation Groups submitted as part of their Pre-Hearing Statement, it appears that the Division's assumption in the Initial EIA was reasonable. See Exhibit A, Testimony of David McCabe at pg. 8. Nevertheless, for this Final EIA, the Division has included both repair costs and estimated product savings from conducting leak detection activities. To calculate repair costs, the Division used EPA information regarding leaking component rates, component repair times, and hourly repair rates. Specifically, the Division assumed a \$66.24 hourly rate to repair components, and an average repair time of between 0.17 hours and 16 hours, depending on the both type of component and the complexity

²² Based on this assumption, 3,545 inspections per year will be conducted using 3rd party contractors.

of the repair.²³ To calculate the number of leaking components the Division used industry reported component counts and assumed a 1.18% leaking component rate for facilities subject to annual inspections.²⁴ To account for the projected additional emission reductions from quarterly and monthly inspection schedules the Division used annual leaking component rates of 1.77% for facilities with quarterly inspection schedules and 2.36% for facilities with monthly inspection schedules. To calculate the value of the additional product captured, the Division converted the amount of VOC and methane/ethane reduced to MCF of natural gas, with a price of \$3.50/MCF. With respect to re-monitoring, the Division determined that because of the small number of components that will require repair and the fact that re-monitoring can be undertaken at the same time as repair, any additional costs associated with re-monitoring are negligible.

Based on this methodology, the calculated annual inspection costs for compressor stations are set forth in Table 23.

Table 23: Compressor Station Leak Inspection Costs Using IR Camera/Method 21 Hybrid

| Compressor Station Fugitive VOC Tier [tpy] | Number of Compressor Stations | Annual Inspection Frequency | Time per IR Camera Inspection [hours] | Total Annual Inspection Time [hours] | Total Annual Inspection Cost |
|--|-------------------------------|-----------------------------|---------------------------------------|--------------------------------------|------------------------------|
| ≤ 12 tpy | 147 | 1 | 10.6 | 1,558.2 | \$208,799 |
| >12 to ≤ 50 tpy | 53 | 4 | 28.1 | 5,957.2 | \$798,265 |
| ≥ 50 tpy | 0 | 12 | | | |
| Total: | 200 | | | 7,515.4 | \$1,007,064 |

Repair costs associated with these inspections are set forth in Table 24 and fuel savings associated with these repairs are set forth in Table 25.

Table 24: Compressor Station Leak Repair Costs

| Compressor Station Fugitive VOC Tier [tpy] | Number of Compressor Stations | Leak Repair Rate [\$/hr] | Number of Leaks per Compressor Station | Total Leak Repair Time per CS [hours] | Total Annual Repair Cost |
|--|-------------------------------|--------------------------|--|---------------------------------------|--------------------------|
| ≤ 12 tpy | 147 | \$66.24 | 30.1 | 23.0 | \$223,957.4 |

²³ See “Equipment Leak Emission Reduction and Cost Analysis for Well Pads, Gathering and Boosting Stations, and Transmission and Storage Facilities Using Emission and Cost Data From the Uniform Standards,” Bradley Nelson and Heather Brown, April 17, 2012; “Analysis of Emissions Reduction Techniques for Equipment Leaks,” Cindy Hancy, December 21, 2011.

²⁴ This leaking component rate is consistent with the rate that the Louis Berger Group used in their Initial Economic Impact Analysis for Industry’s Proposed Revisions to Colorado’s Air Quality Control Commission Regulation No. 7 (DGS-PHS Ex. C), and is based on the leak rate utilized by Nelson and Brown in their analysis of leak reduction costs and benefits (See footnote 22).

Table 24: Compressor Station Leak Repair Costs

| Compressor Station Fugitive VOC Tier [tpy] | Number of Compressor Stations | Leak Repair Rate [\$/hr] | Number of Leaks per Compressor Station | Total Leak Repair Time per CS [hours] | Total Annual Repair Cost |
|--|-------------------------------|--------------------------|--|---------------------------------------|--------------------------|
| >12 to ≤ 50 tpy | 53 | \$66.24 | 119.4 | 85.2 | \$299,113.3 |
| ≥ 50 tpy | 0 | \$66.24 | - | - | - |

| > 6 to ≤12 | DJ/NAA | \$593,744 | \$122,610 | \$855,887 | \$631,136 | \$941,105 |
| > 12 to ≤ 50 | DJ/NAA | \$6,149,800 | \$500,249 | \$3,048,365 | \$2,280,460 | \$7,417,954 |
| > 50 | DJ/NAA | \$5,224,943 | \$1,157,438 | \$1,267,807 | \$945,050 | \$6,705,138 |
| Subtotal: | | \$11,968,487 | \$1,780,297 | \$5,172,059 | \$3,856,646 | \$15,064,197 |
| > 6 to ≤12 | ROS | \$114,042 | \$120,064 | \$159,645 | \$180,407 | \$213,344 |
| > 12 to ≤ 50 | ROS | \$464,077 | \$507,699 | \$248,956 | \$276,061 | \$944,671 |
| > 50 | ROS | \$909,696 | \$535,142 | \$170,356 | \$190,418 | \$1,424,776 |
| Subtotal: | | \$1,487,815 | \$1,162,905 | \$578,957 | \$646,886 | \$2,582,791 |
| Total: | | \$13,456,302 | \$2,943,202 | \$5,751,016 | \$4,503,532 | \$17,646,988 |

Additionally, based on information in the Division’s APEN reporting system, there are 2,799 well production facilities with uncontrolled actual storage tank emissions less than or equal to 6 tons per year that will be subject to a one-time instrument based inspection. The one-time cost for inspecting these facilities is estimated to be \$1,639,239.²⁵

| Uncontrolled VOC at Storage Tank Battery Tier [tpy] | O&G Basin | Number of Facilities and Inspections | Inspection Time Per Inspection [hours] | Inspection Type/Hourly Rate | Total Annual Inspection Cost |
|---|-----------|--------------------------------------|--|-----------------------------|------------------------------|
| ≤ 6 | DJ/NAA | 1,598 | 6.1 | In-House/\$103 | \$1,004,023 |
| ≤ 6 | ROS | 500 | 3.4 | In-House/\$103 | \$175,100 |
| Subtotal: | | 2,098 | | | \$1,179,123 |

²⁵ To calculate these costs the Division used the same methodology applicable to periodic inspection costs, except that it did not include additional travel time for facilities outside the non-attainment area based on the assumption that companies could coordinate these one-time inspections with visits to the facilities for other purposes.

| | | | | | |
|---------------|--------|--------------|-----|------------------|--------------------|
| ≤ 6 | DJ/NAA | 389 | 6.1 | Contractor/\$134 | \$317,969 |
| ≤ 6 | ROS | 312 | 3.4 | Contractor/\$134 | \$142,147 |
| Subtotal: | | 701 | | | \$460,116 |
| Total: | | 2,799 | | | \$1,639,239 |

The Division recognizes that there are likely additional facilities not included in the APEN database that will be subject to this one-time inspection requirement, thereby increasing the overall cost of the one-time inspection requirement. Roughly speaking the additional cost for one-time inspections will be proportional to the number of additional facilities, so that if there are twice the number of facilities, the overall cost will be approximately double. However, because the expected emission reduction benefit will increase roughly at the same rate as the cost of inspections the overall cost-effectiveness of the one-time inspection requirement should remain approximately the same regardless of the number of facilities.

Finally, the Division calculated the cost effectiveness of the proposed leak detection and repair requirements based on the costs identified above and the projected emission reductions. To determine emission reductions the Division first calculated pre-inspection program VOC and methane emissions based on the reported component counts, standard emission factors for these components, and the average fraction of VOC and non-VOC emissions (methane/ethane). Based on EPA reported information, the Division calculated a 40% reduction for annual inspections, a 60% reduction for quarterly inspections, and an 80% reduction for monthly inspections.

Using this information the Division calculated that the total emission reductions from leaks at compressor stations will be 1,107 tpy VOC and 2,321 tons per year methane/ethane.

| Comp. Station Fugitive VOC Tier [tpy] | Number of Comp Stations | LDAR Program Reduction % | Fugitive VOC Emissions for each CS tier [tpy] | Total VOC Reduction [tpy] | Fugitive Methane-Ethane Emissions for each CS tier [tpy] | Total Methane-Ethane Reduction [tpy] |
|---------------------------------------|-------------------------|--------------------------|---|---------------------------|--|--------------------------------------|
| ≤ 12 | 147 | 40% | 10.1 | 588.0 | 15.5 | 911.4 |
| > 12 to ≤ 50 | 53 | 60% | 16.4 | 519.4 | 44.3 | 1,409.8 |
| > 50 | | 80% | | | | |
| | 200 | | | 1,107.4 | | 2,321.1 |

Based on these reductions, the cost effectiveness of conducting leak inspections at compressor stations is estimated to be \$994/ton VOC and \$474/ton methane/ethane.

Table 33: Compressor Station Leak Inspection Cost Effectiveness using IR Camera/Method 21

| Comp. Station Fugitive VOC Tier [tpy] | Number of Comp Stations | Total Net Annual Inspection & Repair Cost | LDAR Program Reduction % | Total VOC Reduction [tpy] | VOC Control Cost [\$ /ton] | Total Methane-Ethane Reduction [tpy] | Methane-Ethane Control Cost [\$ /ton] |
|---------------------------------------|-------------------------|---|--------------------------|---------------------------|----------------------------|--------------------------------------|---------------------------------------|
| ≤ 12 | 147 | \$244,882 | 40% | 588.0 | \$416 | 911.4 | \$269 |
| > 12 to ≤ 50 | 53 | \$855,650 | 60% | 519.4 | \$1,647 | 1,409.8 | \$607 |
| > 50 | | | 80% | | | | |
| | 200 | \$1,100,531 | | 1,107.4 | \$994 | 2,321.2 | \$474 |

For well production facilities the total emission reductions is estimated to be 14,015 tpy VOC and 21,927 tpy methane/ethane.

Table 34: Well Production Facility Leak Inspection Emission Reductions

| Uncontrolled VOC at Tank Battery Tier [tpy] | Number of Facilities | LDAR Program Reduction % | Fugitive VOC Emissions for each Tank Battery [tpy] | Total VOC Reduction [tpy] | Fugitive Methane-Ethane Emissions for each Tank Battery [tpy] | Total Methane-Ethane Reduction [tpy] |
|---|----------------------|--------------------------|--|---------------------------|---|--------------------------------------|
| DJ/NAA | | | | | | |
| > 6 to ≤ 12 | 1,095 | 40% | 4.6 | 1,971.0 | 7.0 | 3,066.0 |

| > 50 | 811 | 80% | 4.6 | 3,000.7 | 7.0 | 4,541.6 |
| Subtotal: | 4,506 | | | 12,251.7 | | 18,527.6 |
| Remainder of State | | | | | | |
| > 6 to ≤ 12 | 313 | 40% | 3.9 | 500.8 | 7.5 | 939.0 |
| > 12 to ≤ 50 | 324 | 60% | 3.9 | 745.2 | 7.5 | 1,458.0 |
| > 50 | 167 | 80% | 3.9 | 517.7 | 7.5 | 1,002.0 |
| Subtotal: | 804 | | | 1,763.7 | | 3,399.0 |
| Total: | 5,310 | | | 14,015.4 | | 21,926.6 |

Based on these reductions, the cost effectiveness of conducting ongoing instrument based inspections at well production facilities is estimated to be \$1,259/ton VOC and \$805/ton methane/ethane.

Table 35: Well Production Facility Leak Cost-Effectiveness Using IR Camera/Method 21

| Uncont. VOC at Tank Battery Tier [tpy] | Number of Tanks | Total Net Annual Leak Inspection & Repair Cost | LDAR Program Reduction % | Total VOC Reduction [tpy] | VOC Control Cost [\$/ton] | Total Methane-Ethane Reduction [tpy] | Methane-Ethane Control Cost [\$/ton] |
|--|-----------------|--|--------------------------|---------------------------|---------------------------|--------------------------------------|--------------------------------------|
| DJ/NAA | | | | | | | |
| > 6 to ≤ 12 | 1,095 | \$941,105 | 40% | 1,971.0 | \$477 | 3,066.0 | \$307 |
| > 12 to ≤ 50 | 2,600 | \$7,417,954 | 60% | 7,280.0 | \$1,019 | 10,920.0 | \$679 |
| > 50 | 811 | \$6,705,138 | 80% | 3,000.7 | \$2,235 | 4,541.6 | \$1,476 |
| Subtotal: | 4,506 | \$15,064,197 | | 12,251.7 | \$1,230 | 18,527.6 | \$813 |
| ROS | | | | | | | |
| > 6 to ≤ 12 | 313 | \$213,344 | 40% | 500.8 | \$426 | 939.0 | \$227 |
| > 12 to ≤ 50 | 324 | \$944,671 | 60% | 745.2 | \$1,268 | 1,458.0 | \$648 |
| > 50 | 167 | \$1,424,776 | 80% | 517.7 | \$2,752 | 1,002.0 | \$1,422 |
| Subtotal: | 804 | \$2,582,791 | | 1,763.7 | \$1,464 | 3,399.0 | \$760 |
| Total: | 5,310 | \$17,646,988 | | 14,015.4 | \$1,259 | 21,926.6 | \$805 |

Additionally, for the 2,799 well production facilities with uncontrolled actual storage tank emissions equal to or less than 6 tons per year that will be subject to a one-time instrument based inspection, the calculated one-time benefit is 4,876 tons VOC and 8,000 tons methane/ethane, assuming a 40% reduction. Based on these reductions, for the one-time inspections of well production facilities with tanks that are less than six tons per year the cost effectiveness of the proposed rule is calculated to be \$409/ton VOC and \$249/ton methane/ethane.

In addition to the component leak detection and repair requirements for compressor stations and well production facilities, the Division’s proposal includes additional requirements designed to reduce leaks from open ended lines and valves, reciprocating compressors, and wet seal centrifugal compressors. These requirements mirror existing cost-effective requirements set forth in NSPS OOOO and other federal rules.

For open ended valves and lines at well production facilities and compressor stations, the proposal requires that each such valve or line be equipped with a cap, blind flange, plug or second valve commencing January 1, 2015. Alternatively, the Division’s proposal allows operators to treat open-ended lines and valves as components and monitor them in accordance with the proposed LDAR requirements. As part of its LDAR cost effectiveness analysis detailed above, the Division included the costs of inspecting and repairing open ended lines and valves in its overall calculation. While the Division has not identified specific information regarding the costs and emission reduction benefits from equipping open ended lines with a cap, blind flange,

plug or second valve it notes that the requirement has been included in a multitude of federal air quality rules, including NSPS VV, NSPS VVa, MACT H, MACT CC, MACT TT, MACT YY, MACT GGG, MACT III, and MACT MMM, dating back as far as 1983. Based on this widespread prevalence in federal rules the Division believes that the proposal represents a simple and cost-effective strategy to reduce emissions from open-ended lines and valves. However, to the extent that it is not cost effective in a specific case operators can employ the monitoring option allowed for under the proposed rule.

For centrifugal compressors, the Division's proposal requires that hydrocarbon emissions from wet seal fluid degassing systems be reduced by 95% beginning January 1, 2015. In its updated technical support document for NSPS OOOO, EPA analyzed the cost-effectiveness of this strategy and found that accounting revenues from the capture of additional product, implementation of this strategy would on a per unit basis reduce VOC emissions by 19.5 tpy, methane emissions by 216.2 tpy, and result in a net cost savings of \$46,974.²⁶

With respect to reciprocating compressors, the Division's proposal requires that commencing January 1, 2015, the rod packing for reciprocating compressors located at compressor stations be replaced every 26,000 hours of operation or every 36 months. As with the requirement for centrifugal compressors, EPA analyzed this proposed strategy as part of the adoption of NSPS OOOO and found that it was a cost-effective way to reduce VOC and methane emissions. Specifically, EPA found that per compressor the strategy reduces VOC emissions by 1.9 tons per year and methane emissions by 6.8 tons per year, at a net cost of \$43 per ton of VOC reduced and \$12 per ton of methane reduced.²⁷

D. Auto Igniter Requirements on Existing Flare Control Devices Outside the Non-Attainment Area

Unlike the non-attainment area, flares used to control emissions at condensate tank batteries and glycol dehydration units outside the NAA are not required to have auto-igniters. The Division is proposing that all flares used to control emissions at condensate tank batteries and glycol dehydration units statewide should have auto igniters. Based on an analysis of the APEN database, the Division estimates the statewide number of existing flare control devices without auto-igniters on condensate tank batteries, glycol dehydration, produced water tanks, and crude oil tanks is 796. The reported uncontrolled actual emissions from these units are 53,101.1 tons per year VOC.

The estimated annualized cost for an auto-igniter is \$475 based on information that the industry provided to the Division in 2008, adjusted for inflation.²⁸

²⁶ See APCD-PHS Ex. HHHH pp. 6-1—6-3

²⁷ See initial technical support document for NSPS OOOO (submitted as DGS-PHS Ex. NN) at pp. 6-12—6-17.

²⁸ See "Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination," Lesair Environmental, Inc., June 2008.

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |
|---------------------|-----------------------------|-----------------------------------|--------------------------|---------------------------|
| Auto Igniter | \$1,648 | | | |
| Freight/Engineering | | \$200 | | |
| Flare Installation | | \$500 | | |
| Maintenance | | | \$200 | |
| Subtotal Costs | \$1,648 | \$700 | \$200 | |
| Annualized Costs* | \$228.4 | \$46.7 | \$200 | \$475 |

* Annualized over 15 years at 5% ROR

The Division estimates that a flare without an auto-igniter could experience about 3% pilot light downtime (262.8 hours) over a one year period. During the downtime period, any VOC emissions routed to the flare control device are uncontrolled. Based on the total uncontrolled actual emissions of 53,101.1 tons per year VOC from units equipped with flares without auto-igniters, the emissions during this downtime period will be 1,593.1 tons of VOC. The Division assumes that as a result of the installation of an auto-igniter, the amount of downtime can be eliminated, for a total emission reduction of 1,251.7 tons/year. Given that the annualized cost of installing 796 auto-igniters is about \$378,100 the estimated cost effectiveness of this strategy is about \$302 per ton of VOC reduced.

| Source Type for Existing Flare Controls | Number of Auto Igniters | Uncontrolled VOC [tpy] | Uncontrolled VOC Using 3% Downtime [tpy] | Total VOC Reduction [tpy] |
|--|-------------------------------|---------------------------|--|---------------------------------|
| Condensate Tanks | 490 | 31,170.6 | 935.1 | 666.3 |
| Dehydrators | 131 | 16,372.0 | 491.2 | 466.6 |
| Produced Water Tanks | 172 | 4,842.2 | 145.3 | 103.5 |
| Crude Oil Tanks | 3 | 716.3 | 21.5 | 15.3 |
| | 796 | 53,101.1 | 1,593.1 | 1251.7 |

* Dehydrator flares assumed to have 100% capture and 95% destruction – thus 95% control. Tank flares are assumed to have 75% capture and 95% destruction – thus 71.25% control.

| Number | Each Auto-Igniter Annualized Costs | Total Annualized Costs | VOC Reduction* [tons/year] | Control Costs [\$/ton] |
|--------|---------------------------------------|---------------------------|-------------------------------|---------------------------|
| 796 | \$475 | \$378,100 | 1,251.7 | \$302 |

E. Expanding Low Bleed Pneumatics Requirements Statewide

As part of the 2008 Ozone Action Plan the AQCC adopted regulatory requirements mandating the use of low bleed pneumatic controllers in the non-attainment area. The current proposal would expand this requirement statewide.

To estimate the costs and benefits of this proposed strategy, the Division estimated the number of high-bleed pneumatic devices based on Independent Petroleum Association of the Mountain States (IPAMS) survey data from 2006, which identified the average number of such devices per well. The Division then scaled this number up based on 2012 Colorado Oil and Gas Conservation Commission (COGCC) well count data. Based on this methodology, there are 9,877 high-bleed pneumatic devices outside the nonattainment area. Assuming a 95% replacement rate, the proposed rule will result in the replacement of 9,384 high bleed devices with low bleed devices. Based on this count, and the average emission reductions per device replaced identified in the IPAMS survey, the projected benefit from the proposed expansion of the current non-attainment area low bleed pneumatic rule will be approximately 14,921 tons per year VOC (40.9 tons per day). Based on this information and assuming an 80/20 ratio of methane/ethane to VOC by volume, the estimated methane/ethane reduction from this strategy is 17,100 tons per year.

The average retrofit cost of a high-bleed pneumatic device is based on costs from the 2008 cost study²⁹ adjusted for inflation. Utilizing this methodology, the annualized cost for each replaced device is \$169. However, because the reduced bleed rate results in more natural gas being sold, operators will receive additional revenue as a result of the installation of a low bleed device. Based on the emission reduction data from the IPAMS survey and August 2013 spot prices for natural gas, the estimated average value of the recovered gas will be \$1,268 for each device replaced. As a result, the net annual gain is \$1,084 per replaced device. Based on this projected net gain, this strategy will pay for itself in approximately one year and two months.

Table 39: Replace High-Bleed Pneumatics with Low-Bleed Pneumatics – Annualized Cost Analysis*

| Item | Capital Costs (one time) | Non-Recurring Costs (one time) | O&M Costs (recurring) | Annualized Total Costs |
|----------------------|--------------------------|--------------------------------|-----------------------|------------------------|
| Low/No Bleed Device* | \$1,033 | | | |
| Labor | | \$387 | | |
| Value of NG Saved** | | | \$(1,268) | |
| Maintenance | | | \$16 | |

²⁹ See “Oil & Gas Emissions Reduction Strategies Cost Analysis and Control Efficiency Determination,” Lesair Environmental, Inc., June 2008.

| | | | | |
|---------------------|---------|-------|-----------|-----------|
| Subtotal Costs | \$1,033 | \$387 | \$(1,253) | |
| Annualized Costs*** | \$143 | \$26 | \$(1,253) | \$(1,084) |

* Control device costs were developed based on an Oil and Gas Cost Study and information submitted by industry in 2008. However, those costs were escalated by 9.85% to reflect CPI-U increases that have occurred since 2008.

** Recovered NG fuel costs \$3.5/MCF (Henry Hub Spot Price - Aug. 2013)

*** Annualized over 15 years at 5% ROR

Assuming 9,384 total devices replaced, adoption of this strategy will result in \$10,169,441 in annual cost savings.

| Table 40: Low Bleed Pneumatic Control Cost Estimates (Outside NAA) | | | | |
|---|------------------------------|------------------------|---------------------------|------------------------|
| Number | Each Device Annualized Costs | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
| 9,384 | \$(1,084) | \$(10,169,441) | 14,921 | NA |

The proposed rule also requires the use of no-bleed pneumatic devices if it is technically and economically feasible and where on-site electrical grid power is being used. Use of no-bleed pneumatic devices will further reduce emissions relative to the use of low bleed devices. Since the Division does not have information indicating the number of no-bleed pneumatic devices that could be required, it is not possible to calculate the cost effectiveness of this particular provision. However, because the proposed requirement expressly provides that use of no-bleed pneumatics is only required where economically feasible the Division assumes that any use of no-bleed pneumatic devices pursuant to the proposed rule will be cost effective.

F. Require Newly Constructed Gas Wells be Connected to a Pipeline or Route Emissions to A Control Device

Currently in Colorado, natural gas produced at oil and gas sites is typically routed to a transmission pipeline. With the advent of new drilling technologies, additional areas of the state without established pipeline infrastructure may experience oil and gas exploration and production. This can lead to instances where produced gas is vented or flared instead of being put into a transmission line. To date the Division has identified 61 instances in Colorado where this is occurring. To address this, the proposed regulation provides that for newly constructed, hydraulically fractured, or recompleted wells, the gas stream must either be connected to a pipeline or routed to a control device achieving 95% control efficiency. Currently all of the sites that are not routed to a pipeline are flaring their gas. Additionally, because venting the gas at such sites would create a safety issue, the Division assumes that in the limited future instances where the gas stream is not routed to a pipeline, operators will route the emissions to a flare or other control device. Accordingly, adoption of this portion of the proposed regulation will likely not result in any additional costs.

G. Control Requirements for Glycol Dehydrators

The Division is proposing to revise the control requirements applicable to glycol natural gas dehydrators statewide. Currently any glycol natural gas dehydrator with uncontrolled actual VOC emissions of 2 tons per year or greater that is located at a facility where the sum of uncontrolled actual emissions from all of the dehydrators at the facility is greater than 15 tons per year, must be equipped with a control device that reduces emissions by at least 90%. Under the Division’s proposal, all existing dehydrators with uncontrolled actual emissions of 6 tons per year or greater VOC must be controlled with air pollution control equipment achieving at least 95% reduction. The proposal also provides that existing dehydrators with uncontrolled actual emissions of two tons per year or greater VOC must be controlled if they are located within 1,320 feet of a building unit or designated outside activity area. Finally, the proposal requires that all new dehydrators with uncontrolled actual emissions of two tons per year or greater VOC be controlled. The Division assumes that newly subject glycol dehydrators will be controlled using flares that achieve a 95% destruction efficiency. The annual cost for these units is \$6,286.80 per unit. See Section IV.A.1. above.

Based on industry reported APEN data, there are currently 433 uncontrolled dehydrators at sites with total dehydrator uncontrolled actual VOC emissions below 15 tpy. Of these, 217 have uncontrolled actual emissions greater than or equal to two tons per year. The total uncontrolled actual emissions for these 217 dehydrators are 1,827.5 tpy VOC. There are 148 dehydrators with uncontrolled actual VOC emissions greater than or equal to 6 tons per year. The total uncontrolled actual emissions for these 148 dehydrators are 1,549.7 tpy VOC. Currently, the Division does not have information regarding the location of these uncontrolled dehydrators relative to a building unit or designated outside activity area. Assuming, however, that all of the 2 to 6 ton dehydrators are located within 1,320 feet of a building unit or designated outside activity area and thus will require a control, the proposed requirement will reduce 1,736 tpy of VOC at a cost effectiveness of \$786/ton VOC. For the smallest dehydrator subject to the proposed rule (2 ton/year) the cost effectiveness is estimated to be \$3309 per ton of VOC reduced.

Table 41: Dehydrator Control Cost Estimates (2 TPY Control Threshold)

| Number | Each Device Annualized Costs | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
|--------|------------------------------|------------------------|---------------------------|------------------------|
| 217 | \$6,286.8 | \$1,364,236 | 1,736 | \$786 |

Conversely, if it is assumed that none of the 2 to 6 ton existing dehydrators will require controls the proposed requirement will reduce 1,472 tpy of VOC at a cost effectiveness of \$632/ton VOC.

| Number | Each Device Annualized Costs | Total Annualized Costs | VOC Reduction [tons/year] | Control Costs [\$/ton] |
|--------|------------------------------|------------------------|---------------------------|------------------------|
| 148 | \$6,286.8 | \$930,446 | 1,472 | \$632 |

H. Control Requirements for Downhole Well Maintenance and Liquids Unloading Events

Historically, Colorado has not regulated air emissions from temporary activities such as well completions and well maintenance at well production sites. Recently, however, EPA, Colorado and other jurisdictions have identified these activities as potentially large sources of emissions from the oil and gas sector. In recognition of this, the Colorado Oil and Gas Conservation Commission and more recently EPA have adopted requirements for green completions to reduce hydrocarbon emissions during well completion activities. The Division is now proposing additional regulatory requirements designed to reduce emissions during well maintenance.

Well maintenance is required when, over time, liquids build up inside the well and reduce gas and oil flow out of the well. To remove these liquids and improve flow, the liquids are blown out of the well under pressure. This process is typically referred to as liquids load-out or well blow-down. Historically emissions from well blow-downs are vented to the atmosphere. EPA has established emission factors for liquid unloading based on fluid equilibrium calculations to calculate the amount of gas needed to blow down a column of fluids blocking a well and Natural Gas STAR partner data on the amount of additional venting after a blow-down. Based on its calculations, EPA estimated that in the United States the combined methane emissions for liquid unloading and well completions in 2009, was 217 billion cubic feet, and that liquid unloading may account for 33% of the uncontrolled methane emissions from the natural gas industry.³⁰ For Colorado, the Division has calculated that emissions from well blow-downs in 2008 were approximately 9,306 tons of VOC per year.

To address these emissions, the Division is proposing a two pronged requirement aimed at reducing the number of required liquids unloading events and reducing the amount of emissions vented to the atmosphere during these events. Under the Division’s proposal operators shall use best management practices to minimize the need for venting associated with downhole maintenance and liquids unloading. For example, EPA’s Gas Star program advocates the use of a plunger lift system to reduce the need for liquids unloading. According to EPA, use of a plunger lift will on average pay for itself in less than one year through the capture of additional product. The Division’s proposal also provides that emissions during well maintenance and liquids unloading shall be captured or controlled using best management practices to limit venting during well blow-downs to the maximum extent practicable. Based on information provided by Environmental Defense Fund, application of these requirements could result in

³⁰ See EPA, *Inventory of U.S. Greenhouse Gas Emissions and Sinks, 1990-2009*, April, 2011.

annual VOC reductions of 2,881 tons and methane reductions of 19,207 tons per year. Given the wide variety of practices that this could entail, the Division currently does not have information about the precise cost-effectiveness of this provision. Given the fact that the proposal only requires use of best management practices, which takes into account the cost of the practices in a given situation, the Division assumes that the proposed strategy will be cost effective.

I. Division Implementation Costs

The Division will implement the provisions of its proposal through its oil and gas inspection team. This team currently consists of 9 full time inspectors and 4 term limited inspectors. In 2012, in response to the growth in the oil and gas industry in Colorado, the legislature increased the size of the inspection team from 6 inspectors to 9. In 2013, the legislature appropriated additional funds to hire 4 additional term limited inspectors to conduct infra-red camera inspections at well production facilities in Colorado. The term for these positions runs through June of 2015, but could be extended by the legislature if warranted. The additional inspectors provided during the 2012 and 2013 legislative sessions has significantly expanded the capabilities of the oil and gas inspection team, which will allow the Division to implement and enforce the proposed requirements if the Commission chooses to adopt the Division's proposal. The total projected annual cost to the Division for the oil and gas inspection team in fiscal year 2013-14 is \$1,305,304, which includes salary costs, fringe benefits, operating costs (including vehicles, field equipment, and office equipment), travel training and indirect costs.

V. CONCLUSION

The Division projects that the proposal will reduce VOC emissions in Colorado by approximately 93,500 tons per year and methane/ethane emissions by approximately 65,000 per year at a cost of approximately \$42.5 million per year. Another portion of the proposal requires one-time leak detection and repair on well production facilities <6 tons/year, which will reduce VOC emissions by about 4,900 tons, methane emissions by about 8,000 tons and cost approximately \$2 million dollars. The calculated cost per ton of VOC reduced ranges from between \$176 and \$1,259 per ton. The overall cost effectiveness for the entire package is approximately \$453 per ton of VOC reduced.

The Division prepared this Final Economic Impact Analysis in accordance with the requirements of Section 25-7-110.5(4), C.R.S. Specifically, the Division utilized the methodology identified in § 25-7-110.5(4)(c)(I), C.R.S. In completing this analysis, the Division assessed the costs and benefits associated with each of the proposed strategies based on the reasonably available data. In collecting this data, the Division sought input from various stakeholders in an effort to generate the most complete and accurate assessment of the costs and benefits of the proposed strategies. Where data was not reasonably available, the Division utilized assumptions that are set forth in the analysis. To the extent that other parties to the rulemaking provide additional data regarding the costs and benefits of the proposed strategies, the Commission should consider such data in assessing the cost-effectiveness of the proposed strategies.

REBELLION PHOTONICS

As a solutions provider with proven technology to help reduce methane emissions from the oil and gas sector, Rebellion Photonics would like to provide comments on EPA's draft rule in order to ensure it reflects the current state of methane science and technology to address this issue.

Oil and gas companies emit 7 million tons of methane from their operations every year. Methane escaping from the oil and gas industry has the same 20-year climate impact as 160 coal-fired power plants, and represents enough wasted natural gas to heat over 5 million homes. These emissions are currently projected to increase 25 percent over the next decade. Methane emissions are a significant climate and energy-waste problem that's only going to grow.

We believe there are ways the draft rule could be improved and our technology could help solve this problem. Gas Cloud Imaging technology such as Rebellion Photonics camera is an available, cost effective, and proven solution for detection and reduction of methane and other VOC's from the installation of new equipment, upgrades, and modified sources in the oil and gas industry.

While we credit the EPA with their initial proposal for bi-annual leak detection inspections, the step up and down provisions based on the number of leaking components is based on faulty logic. Studies have shown that leaks by nature are random and thus make comprehensive and frequent LDAR critical. Emerging data show that a disproportionate share of fugitive emissions can come from a relatively small percentage of leaks that can appear almost anywhere, anytime – at new and old facilities, and big and small ones. A well site that looks good today might be a big problem tomorrow. . More frequent intervals such as monthly or quarterly inspections are what is needed and still just as cost effective. Stepping up the frequency of inspections allows for better identification and fixing of leaks which will greatly impact the overall reduction of methane.

Rebellion's Gas Cloud Imaging Camera employs advanced hyperspectral infrared imaging technology, engages advanced detection algorithms, and employs powerful data storage and transmittal technology. The GCI is different from other leak imagers because ***leak detection is automated, identification and quantification are possible, and wide areas can be monitored.*** With the ability to "see" the leak, operators can pinpoint the leak source to initiate repair on the spot. The GCI has the potential to catch leaks early and help operators avoid walking into a hazardous cloud. It will also aid operators when making process safety decisions to avoid leak escalation that can lead to "low-frequency, high-consequence" incidents.

We have seen in Colorado, where state regulations are the strictest in the country that significant reductions can be made cost-effectively. Our technology, which is an approved instrument monitoring method for Colorado Air Quality Control Commission Regulation No 7 STEM and LDAR, is cost effective at just \$250 per site for inspections.....This is affordable even for the low producing well sites. We believe these Colorado regulations could be a model for the nation. Customers there are complying with the law, reducing emissions

REBELLION

PHOTONICS

in a cost-effective manner. With some customers, we can cover in upwards of 25 sites per day and have monitored over 1,100 pieces of overall equipment in one week. Our camera allows for speedy, efficient leak detection and with the ability to quickly scan sites, it enables companies to perform inspections more often. It also supports our customers' ability to prioritize maintenance and repair of sites which thus reduces spent labor, time, and gas losses. When putting all of these factors together in dollars and cents, it more than pays for the service operation of the camera.

Well site inspections in Colorado have also offered to us numerous examples of the importance of more frequent LDAR inspections. A simple thief hatch proves to be quite the culprit in a large percentage of the leaks we find.....This leak at times can be traced back to something as simple as a dirty seal.....A dirty seal that may have shown not to be leaking one month ago or even one day ago. Again, leaks are random in nature. So, inspecting a piece of equipment such as a thief hatch proves to be something that is more effective on an increased basis versus a decreased basis if we're working to cut methane emissions.

The importance of follow up surveys after repair is just as critical to ensure correct maintenance/repair of the emitting equipment and also that correcting one leaking component does not create a new one. Again, this is where Colorado leads the nation in how they approach their regulations....They have companies keep logs of inspections, leaks, 1st or 2nd or 3rd attempt of leak repair, and then finally inspection of the fixed equipment. Rebellion creates a turnkey approach to this for our customers by providing a web portal included in our \$250 per site that can store well site inspection videos, both of leaks and then post leak repair, and the required maintenance logs.

EPA's proposed rule covers new and modified sources. We would encourage EPA to take an expansive approach to how it treats modified sources, particularly when it comes to the application of LDAR for modified sources. As we've discussed, much of what drives fugitive emissions is human error. When equipment is modified, we've very often seen it done incorrectly, leading to large leaks. The only way to know confidently whether equipment that has been modified is working correctly is by conducting LDAR on it.

In the end, we are finding the forward charge of the EPA and the thought of potentially stricter methane regulations have made companies take note and begin to implement actions with their sites by utilizing our proven technology in an attempt to capture fugitive emissions and reduce lost product. In the end, lower methane emissions are good for companies, good for the industry as a whole, and good for the environment.

Leak Detection and Repair Cost-Effectiveness Analysis

Prepared for Environmental Defense Fund

December 4, 2015

Project Outline

- Motivation for the Analysis
- Objective of the Stochastic LDAR Analysis
- Modeling Concept
- Limitations of Analysis
- Segment Specific Data Sources
- Segment Specific Scenarios and Assumptions
- Segment Specific Results

Motivation for the Analysis

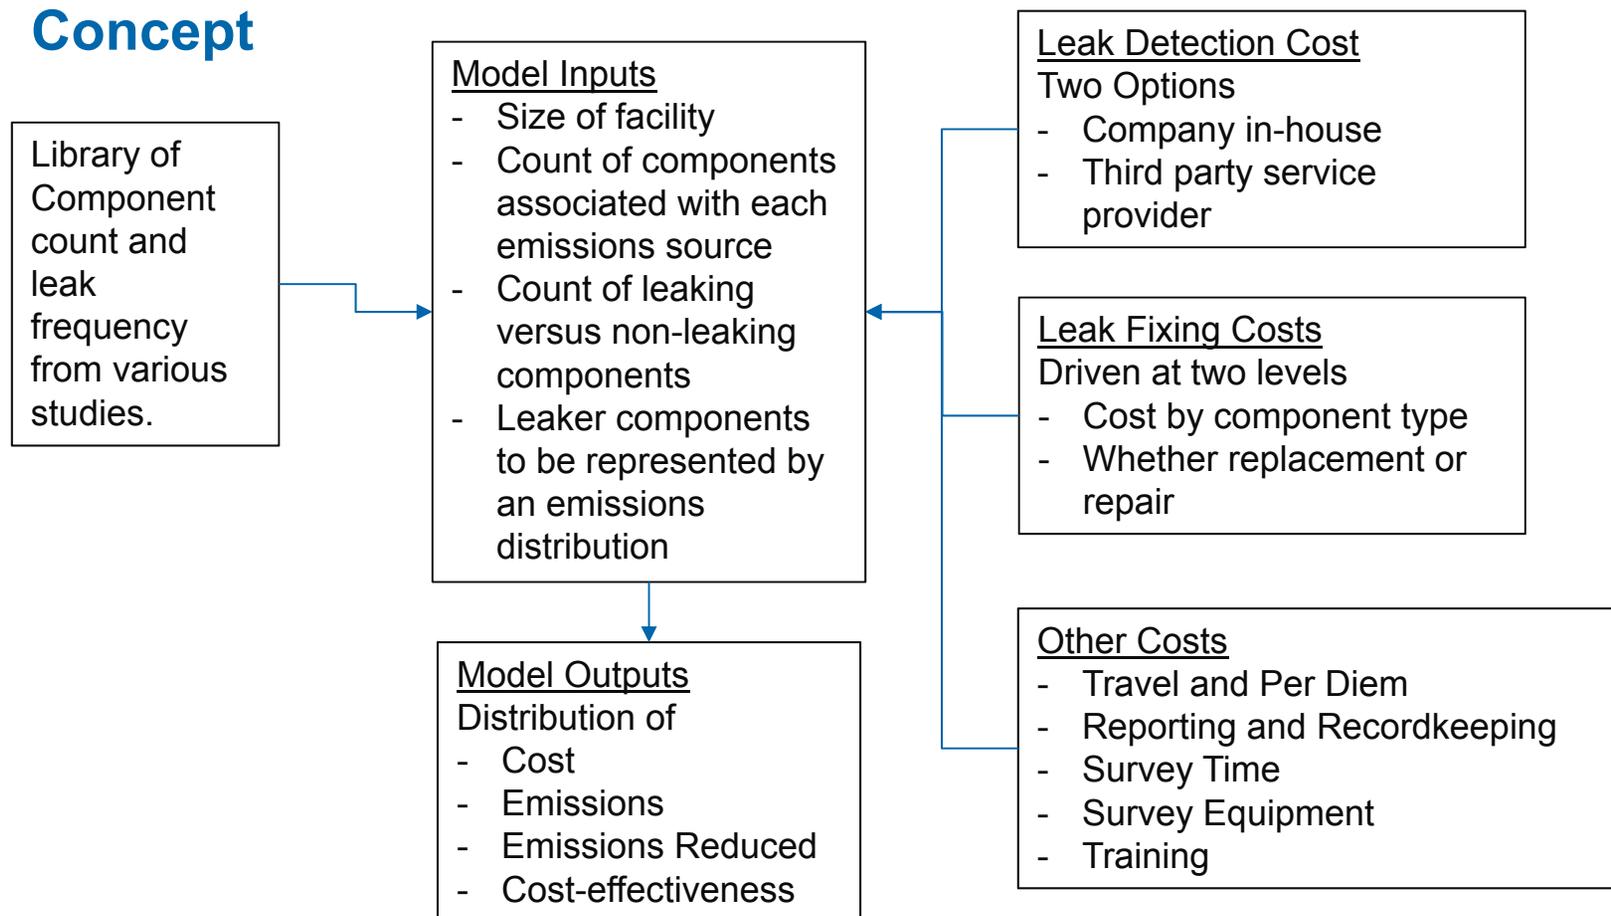

- Much of current LDAR costs and emissions reduction analysis based on average values
 - However, there is a wide variation in the size of the facilities and types of equipment at each facility
 - Average values do not take into account the variation in emissions rate (and therefore reductions), specifically from super-emitters
 - Difficult to analyze multiple scenarios when using average values
- Propose a LDAR stochastic modeling approach

Objective of Stochastic LDAR Analysis

- Develop facility models that replicate the real world and capture variations in facility size and characteristics
- Use Monte Carlo simulation to analyze facility emissions, reductions, and costs
 - Model includes inter-relationships between different factors, such as leak frequency and time required to conduct LDAR
 - Includes correlations between activity data, count of reciprocating and centrifugal compressors at compressor stations are correlated with each other and the total count of compressor at the station
 - Emissions rate and activity represented by statistical distributions
 - Use data from multiple publications and studies as appropriate
 - Ability to develop multiple scenarios, including impact of changing frequency of LDAR
- Evaluate LDAR cost-effectiveness from the following segments – production well-pads, gathering and boosting stations, processing plants, transmission compressor stations, and storage stations

LDAR Modelling Concept

Model Concept - Inputs

- Emission sources include –
 - Fugitive sources - valves, connectors, pressure relief valves (PRV), compressor PRVs, open-ended lines (OEL), compressor starter OELs, compressor blowdown valves, pressure regulators, orifice meters
- Statistical distributions assigned to each emission source activity factor and emissions rate
- Leak frequency identifying percentage of components leaking
 - Range of leak frequencies based on data on number of leaking components from field studies that provide raw data that allows for distribution fitting
- Economic Factors
 - Gas Price, Labor Cost, Time to Survey Equipment, Repair/Maintenance Cost, Survey Equipment Costs, Other Costs
- GWP=25

Model Concept - Simulation

- The simulation is run for 10,000 iterations with each iteration representing a unique and random combination of;
 - Facility characteristics, such as size, type of equipment, count of emissions source
 - Number of leakers for each emissions source
 - Leak rate of each leaking unit of leakers for each emissions source
- General simulation model steps
 - Step 1 – Select random facility characteristic, example – well-pad with specific number of wells and equipment
 - Step 2 – Determine the count of associated components (emissions sources)
 - Step 3 – Determine the survey time and associated costs based on component count
 - Step 4 – Randomly select the percentage of each components that are leaking
 - Step 5 – Randomly assign leak rates to each leaking component
 - Step 6 – Determine if each leak has to be repaired or replaced; assign costs accordingly
 - Step 7 – Determine reductions achieved from repair or replacement
 - Step 8 – Calculate output statistics

Model Concept - Output

- Distribution of emissions per facility
- Distribution of costs associated with conducting LDAR at various frequencies – annual, semi-annual, and quarterly
- Trends in LDAR cost-effectiveness, i.e. \$/Mcf-reduced, over time
- The \$/Mcf-reduced metric is the ratio of the total cost to conduct an LDAR survey to the difference in Mcf of emissions from the baseline each year where the baseline is assumed to be the uncontrolled emissions in the first year

Limitations of Analysis

- Model results are driven by data inputs
 - The representativeness of results to national, state, company, or facility level is limited by representativeness of the data
- Limited time series data is available on the impact of different LDAR frequencies on reduction in leak frequencies in each subsequent survey
 - Assumption in this study is based on best available data from Colorado
- Costs to repair or replace can vary depending on location and complexity of leak
 - This study uses best available data from Gas STAR published documents and expert judgement where no data was available

Production Segment Assumptions and Results

Production Model Data Sources

- Data Sources used to model facility
 - Subpart W
 - EPA/ GRI
 - City of Fort Worth Natural Gas Air Quality Study
 - UT Study - Methane Emissions in the Natural Gas Supply Chain: Production
 - UT Study - Methane Emissions from Process Equipment at Natural Gas Production Sites in the United States Pneumatic Controllers
 - Jonah Energy LLC WCCA Spring Meeting Presentation

Component Replacement and Maintenance Costs

| Emission Source | Default Replacement Cost | Default Maintenance Cost |
|----------------------------------|--------------------------|--------------------------|
| Valve | \$112.00 | \$41.67 |
| Connection | \$226.67 | \$20.00 |
| Pressure Relief Valve | \$500.00 | \$100.00 |
| Compressor Pressure Relief Valve | \$1,000.00 | \$200.00 |
| Open-Ended Line | \$150.00 | \$45.00 |
| Starter Open Ended Line | \$500.00 | \$250.00 |
| Pressure Regulators | \$300.00 | \$200.00 |
| Orifice Meters | \$775.00 | \$200.00 |

Time to Measure Individual Components

| Emission Source | Estimated Time to Survey in Minutes |
|----------------------------------|-------------------------------------|
| Valve | 0.1 |
| Connection | 0.1 |
| Pressure Relief Valve | 0.5 |
| Compressor Pressure Relief Valve | 0.5 |
| Open-Ended Line | 0.5 |
| Starter Open Ended Line | 0.5 |
| Pressure Regulators | 0.1 |
| Orifice Meters | 0.1 |

Survey Equipment Costs Default

| Component | Default Costs |
|---------------------|---------------|
| IR Camera | \$115,000 |
| Hi Flow Sampler | \$20,000 |
| Calibrated Bag | \$500 |
| Vehicle (4x4 Truck) | \$22,000 |

Other Costs

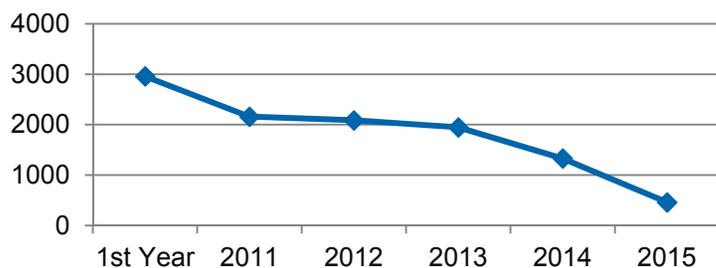

| Emission Source | Estimated Time to Survey in Minutes |
|---|-------------------------------------|
| Prep Time per 4 hours or Working (Hours) | 0.25 |
| Percentage of Year Contractor Utilizes Equipment | 75% |
| Contractor Scalar | 30% |
| Years Contractors Recoup Survey Equipment Costs | 3 |
| Profit Percentage for Contractors on Survey Equipment | 25% |
| Hours of Training for In-House Operations | 80 |
| Lodging and Per Diem | 250 |
| Supervision (Inhouse) | \$31,200 |
| Fringe (Inhouse) | \$46,800 |
| Training for Contractor | \$15,600 |
| Reporting and Record Keeping | \$100 |

Leak Frequency and Emission Truncation Over Future Surveys

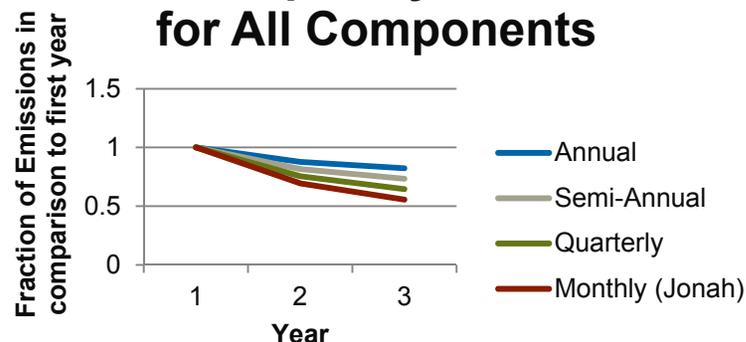

- Leaks occur less frequently over subsequent LDAR surveys
- Reduction in leak frequency was designed based on data from Colorado monthly survey results
- Annual, semi-annual and quarterly surveys assumed to experience slower reductions in leak frequencies

Leaks Identified Per Year Raw Data

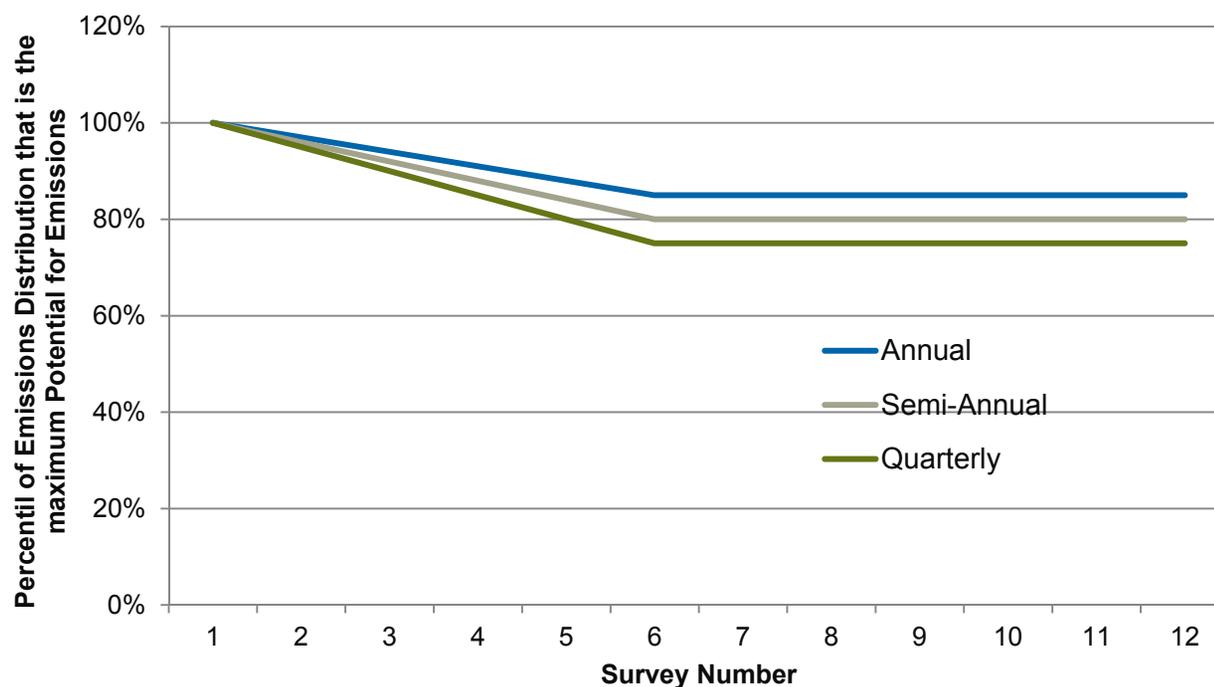

Leak Frequency Over Time for All Components

Emission Truncation Over Future Surveys

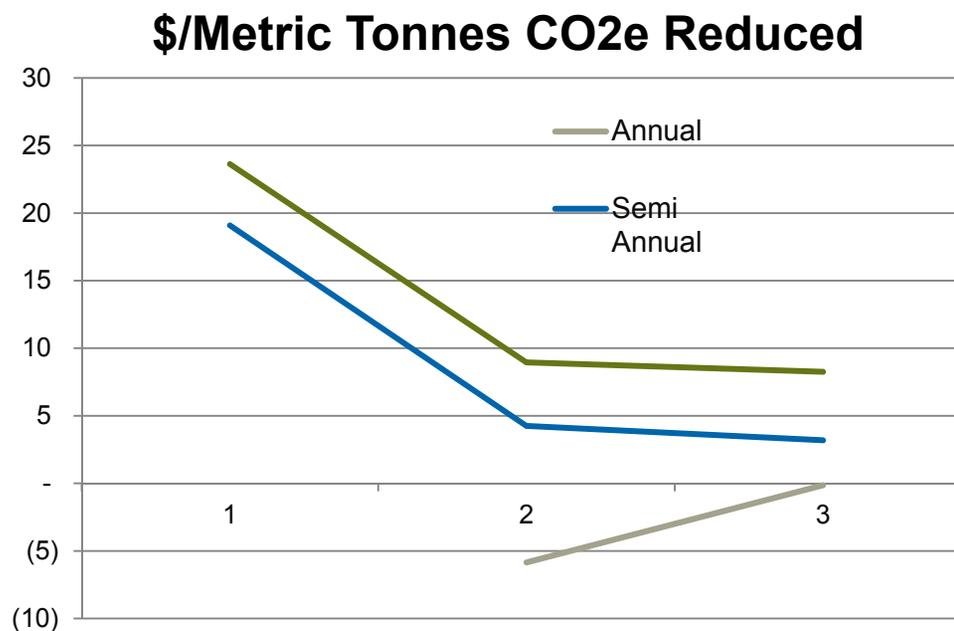

- Fewer high emitting leaks are identified from subsequent LDAR surveys
- Trend has been captured by truncating the right tail of emissions rate distributions

Emission Truncation Percentiles

Fugitive Sources Case 1

- Case 1 Parameters:
 - Gas price: \$3 dollars/Mcf
 - Evaluates fugitive sources
 - Assumes two contractors are hired

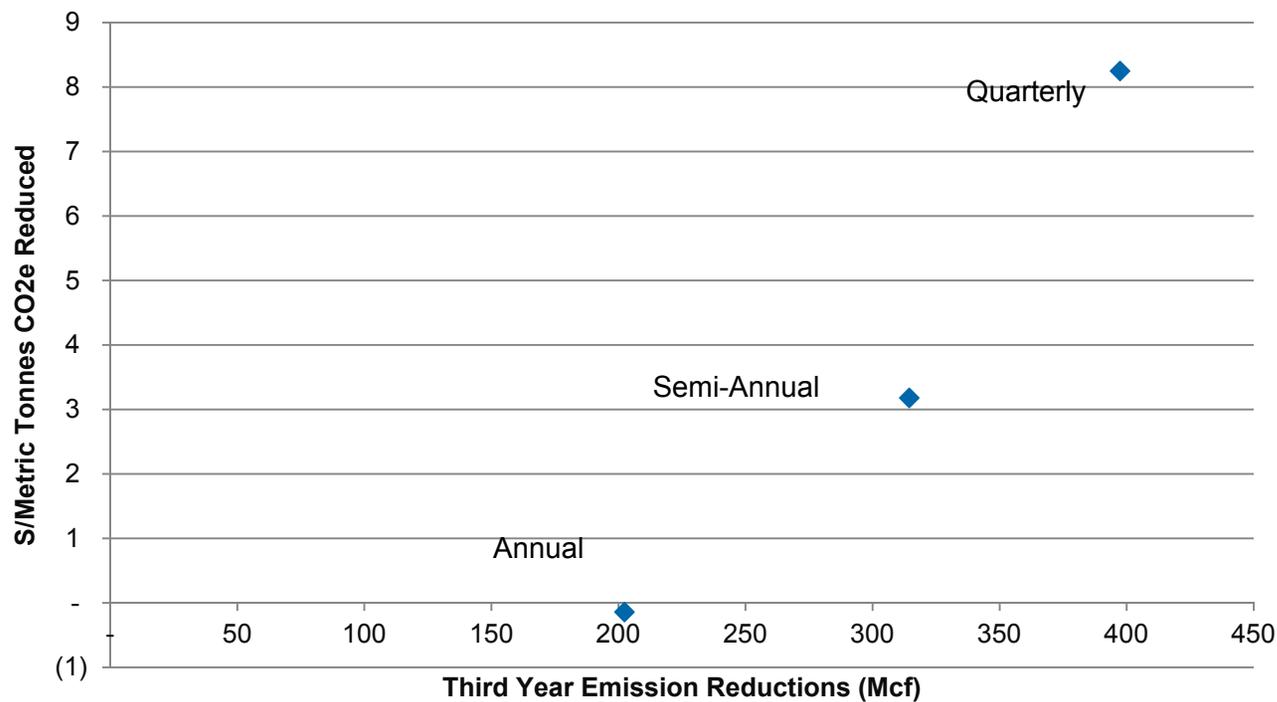

Fugitive Sources Case 1

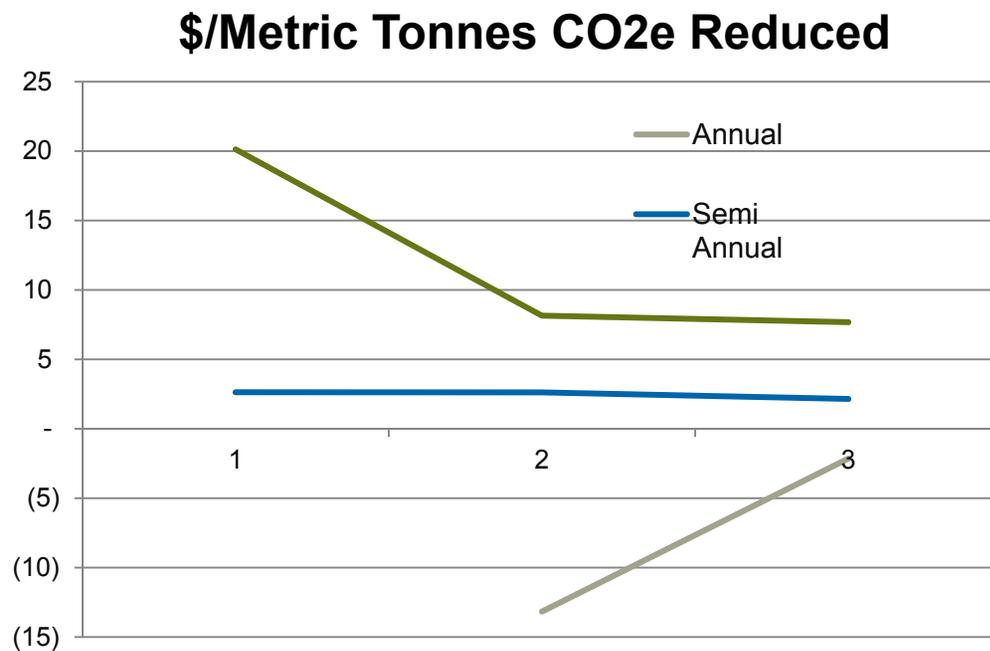

- Total emissions reduced in year three plotted against average cost effectiveness of reductions in year 3.

Third Year Emission Reductions vs. Cost Effectiveness

Fugitive Sources Case 2

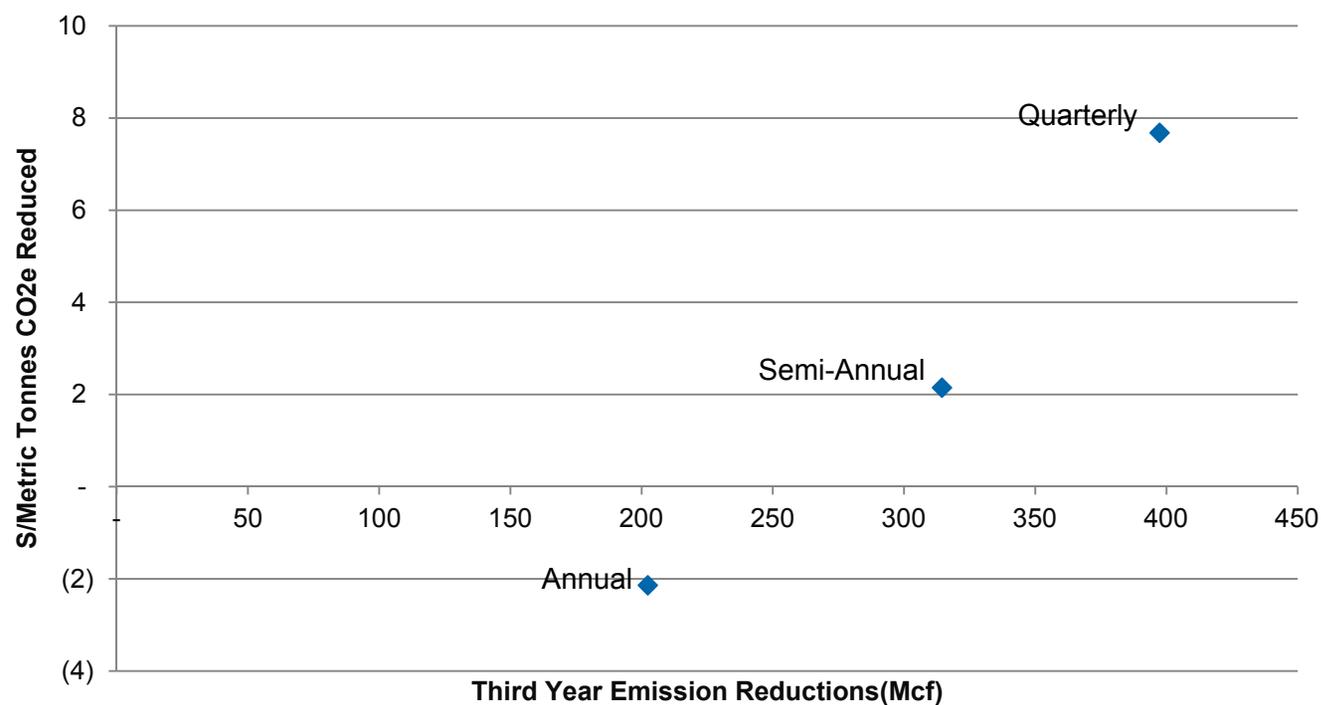

- Case 2 Parameters
 - Gas price: \$4 dollars/Mcf
 - Evaluates fugitive sources
 - Assumes two contractors are hired

Fugitive Sources Case 2

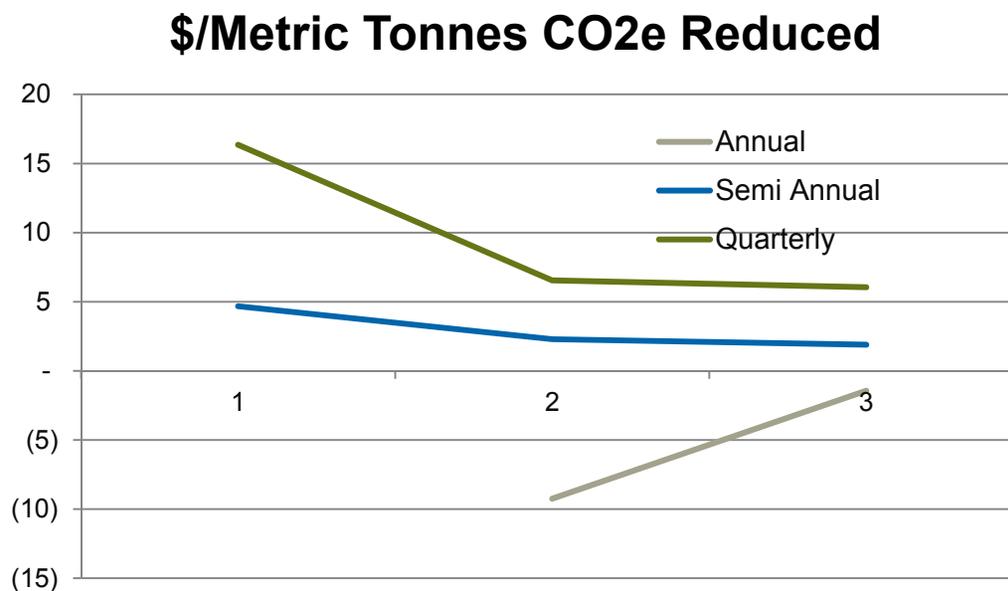

- Total emissions reduced in year three plotted against average cost effectiveness of reductions in year 3.

Third Year Emission Reductions vs. Cost Effectiveness

Fugitive Sources Case 3

- Case 3 Parameters:
 - Gas price: \$3 dollars/Mcf
 - Evaluates fugitive sources
 - Assumes one contractor is hired

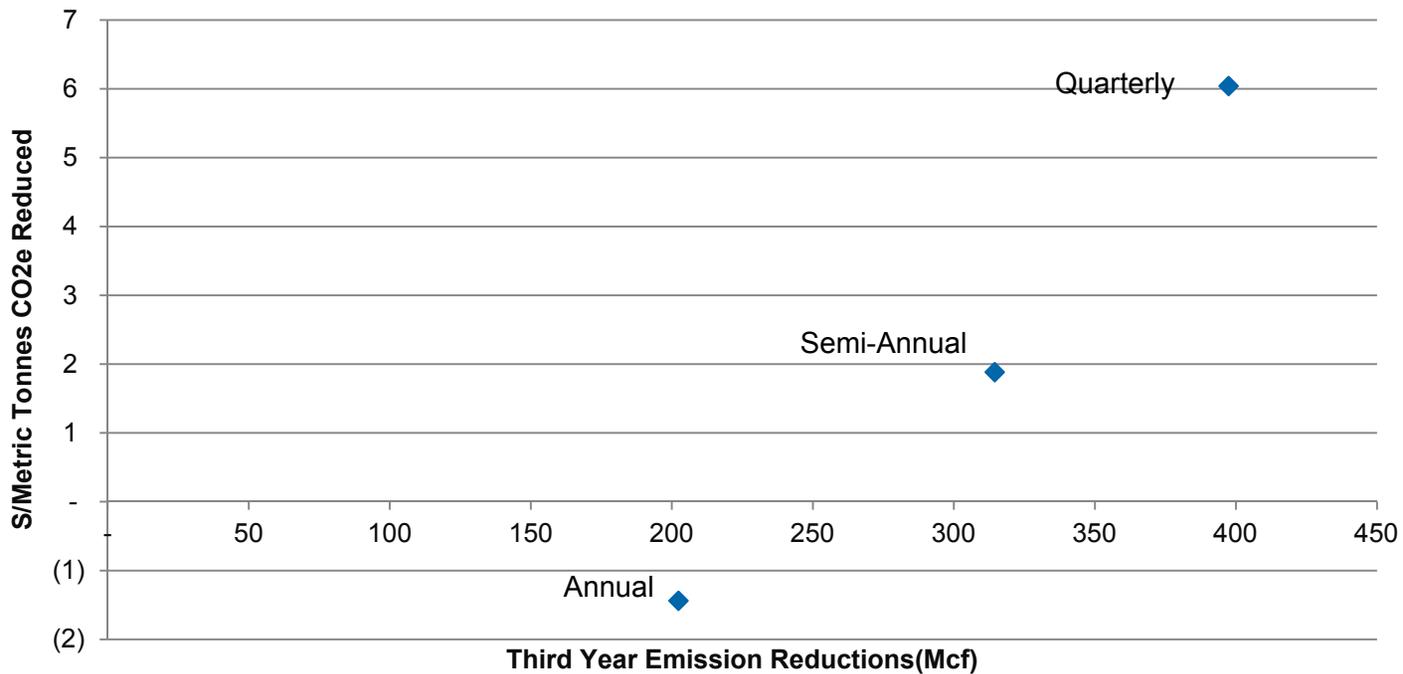

Fugitive Sources Case 3

- Total emissions reduced in year three plotted against average cost effectiveness of reductions in year 3.

Third Year Emission Reductions vs. Cost Effectiveness

Total Three Year Production Mean Fugitive Results

| | \$/Metric Tonnes CO2e Reduced | | |
|-------------|-------------------------------|---------|------------------------|
| | \$3/Mcf | \$4/Mcf | \$3/Mcf One Contractor |
| Annual | -4.76 | -11.19 | -7.86 |
| Semi-annual | 4.94 | 2.39 | 2.29 |
| Quarterly | 11.56 | 10.32 | 8.27 |

GWP=25

**WYOMING DEPARTMENT OF ENVIRONMENTAL QUALITY
AIR QUALITY DIVISION
STANDARDS AND REGULATIONS**

Nonattainment Area Regulations

CHAPTER 8

Section 1. Introduction to nonattainment area regulations.

(a) Chapter 8 establishes regulations specific to areas not attaining the National Ambient Air Quality Standards. Section 2 applies exclusively to Sweetwater County, Wyoming particulate matter regulations. Section 3 applies to general federal actions, excluding those covered under Section 4, within any federally designated nonattainment area of the state. Section 4 applies to specific transportation projects within any federally designated nonattainment area of the state. Section 5 establishes requirements for the submittal of emission inventories from facilities or sources located in an ozone nonattainment area(s) pursuant to the requirements of the Clean Air Act, Section 182. Section 6 establishes requirements for all PAD and single-well oil and gas production facilities or sources, and all compressor stations, located in the Upper Green River Basin (UGRB) ozone nonattainment area that were existing as of January 1, 2014. Sections 7 through 9 are reserved. Section 10 incorporates by reference all Code of Federal Regulations (CFRs) cited in this chapter, including their Appendices.

Section 2. Sweetwater County particulate matter regulations.

(a) Notwithstanding other provisions in these regulations concerning the emission of particulate matter or required fugitive dust control measures, the requirements and emission limitations set forth in Chapter 8, Section 2(b) and (c) for the specific sources and activities enumerated are applicable. Sources and/or activities which cause particulate matter to be emitted into the air and which are not addressed in this section are subject to the requirements of other sections.

(b) Point Source Particulate Matter Emission Rate Allowables:

The following tables specify the maximum allowable particulate matter emission rate for each of the listed sources. The emission of particulate matter is measured as specified in Chapter 3, Section 2(h)(iv) of these regulations.

(i) Stauffer Chemical Company of Wyoming, Green River Soda Ash Plant.

| <u>Source Description</u> | <u>Allowable Emission Rate lb/hr</u> |

(c) Fugitive Dust Controls. The following subparagraphs specify fugitive dust control measures required for the delineated activities and sources and the schedules for completion of such measures. If, at any time, the Administrator is satisfied that the applicable suspended particulate matter standards have been attained and will be maintained, uncompleted programs may be completed at the option of the owner of the facility if failure to complete same will not in the opinion of the Administrator adversely affect such attainment status.

(i) Allied Chemical, Green River

Unpaved Roads – Pave all roads in facility area that encounter frequent traffic and maintain such roads in a clean condition through the use of a vacuum sweeper as required. Complete: November 30, 1980.

Distressed Area – Reclaim the distressed area outside the east fence or apply suitable soil binders. Complete: December 1, 1981.

Coal Stockpile – The active coal stockpile is to be enclosed or a dust suppression system installed and used during periods of activity. Complete: December 31, 1982.

Equipment Movement – Equipment movement around the periphery of the trona stockpile should be further reduced. Complete: June 1, 1979.

(ii) FMC Corporation

Stockpile – Installation and effective operation of the following abatement program elements is required to control excessive fugitive emissions from the coal

handling facilities.

(A) Dust collectors with pick-ups at the transfer points.

(B) A dust suppression spray system to apply wetting agents to coal being unloaded, transferred, reclaimed, crushed and handled.

(C) Rapid unloading railroad cars.

(D) Use of counter weighted hood-type doors on the coal stacker.

Ore Stockpile – Install variable height booms so that the free fall distance of the ore is held to a minimum and install shroud (wind shield) to contain the ore as much as possible after it drops from the end of the boom. Complete: Sesqui Areas – January 1, 1981; Mono Areas – April 1, 1981.

Loadout Facilities – The mono loadout facilities are to be equipped with hoods around product chutes of adequate size to cap hatches of slot top or hatch top rail cars. The resultant dust generated due to displacement shall be aspirated to adequate dust collectors. The above requirements also apply to any truck bulk product loadout facilities. Complete: July 1, 1982.

Unpaved Roads – All unpaved roads that encounter frequent traffic in the facility area shall be paved and maintained in a clean condition through the use of a vacuum sweeper as required. Infrequently traveled roads are to be treated with oil or other suitable dust suppressants. Complete: October 1, 1980.

Overflow Chutes – Overflow or spillover chutes which discharge in the open, are to be eliminated or emptied into closed containers. Chutes for housekeeping purposes are to be eliminated and replaced with a vacuum dust system that utilizes a dust collector. Complete: October 1, 1980.

(iii) Stauffer Chemical, Green River

Ore Stockpile – Install and utilize a variable height boom so that the free fall distance of the ore is held to a minimum. A shroud (wind shield) to contain the ore as much as possible after it drops from the end of the boom is to be installed and utilized. Complete: July 1981.

Product Loadout – Rail loadout facilities are to be equipped with hoods around product chutes of adequate size to cap hatches of slot and portal top rail cars. The resultant dust generated due to displacement should be aspirated to adequate dust collectors. The above requirements will also apply to any truck bulk product loadout facilities. Maintenance or redesigning of existing baghouse collectors will also be necessary at these facilities. Complete: September 1982.

Product Handling and Storage – Product silo vents are to be equipped with dust collectors. Proper maintenance and/or redesign of existing dust collectors is also required in this area. Complete: September 1982.

Crusher Area – The removing of accumulated dust from crusher building by sweeping or dumping the material outside the building is to be eliminated. Housekeeping chores in this area as well as other areas are to be accomplished by the use of a vacuum system and dust collector. Existing baghouse collectors are to be properly maintained and if necessary other control measures installed and utilized at all transfer points in and around the crusher area. Complete: September 1982.

Overflow Chutes – Overflow or spillover chutes which discharge in the open are to be eliminated or emptied into closed containers. Complete: March 1979.

Unpaved Roads – All roads within the facility area that encounter frequent traffic are to be paved and maintained in a clean condition through the use of a vacuum sweeper as required. All other less frequently used roads are to be treated with oil or other suitable dust suppressants. Complete: September 1982.

Distressed Areas – Distressed areas to the south of the facility which contain distressed product piles and tailing pond dredgings are to be reclaimed and treated with dust suppressants. Complete: September 1979.

Section 3. Conformity of general federal actions to state implementation plans.

(a) Prohibition.

(i) No department, agency or instrumentality of the Federal Government shall engage in, support in any way or provide financial assistance for, license or permit, or approve any activity which does not conform to an applicable implementation plan.

(ii) A Federal agency must make a determination that a Federal action conforms to the applicable implementation plan in accordance with the requirements of this section before the action is taken.

(iii) [Reserved]

(iv) Notwithstanding any provision of this section, a determination that an action is in conformance with the applicable implementation plan does not exempt the action from any other requirements of the applicable implementation plan, the National Environmental Policy Act (NEPA), or the CAA.

(v) If an action would result in emissions originating in more than one nonattainment or maintenance area, the conformity must be evaluated for each area separately.

(b) Definitions. Terms used but not defined in this section shall have the meaning given them by the CAA and EPA's regulations (40 CFR Chapter I), in that order of priority.

“Affected Federal land manager” means the Federal agency or the Federal official charged with direct responsibility for management of an area designated Class I under the CAA (42 U.S.C. 7472) that is located within 100 km of the proposed Federal action.

“Applicability analysis” is the process of determining if your Federal action must be supported by a conformity determination.

“Applicable implementation plan or applicable SIP” means the portion (or portions) of the SIP or most recent revision thereof, which has been approved under section 110(k) of the CAA, or promulgated under section 110(c) of the CAA (Federal implementation plan), or a plan promulgated or approved pursuant to section 301(d) of the CAA (Tribal implementation plan or TIP) and which implements the relevant requirements of the CAA.

“Areawide air quality modeling analysis” means an assessment on a scale that includes the entire nonattainment or maintenance area which uses an air quality dispersion model or photochemical grid model to determine the effects of emissions on air quality, for example, an assessment using EPA's community multi-scale air quality (CMAQ) modeling system.

“CAA” means the Clean Air Act, as amended.

“Cause or contribute to a new violation” means a Federal action that:

(i) Causes a new violation of a national ambient air quality standard (NAAQS) at a location in a nonattainment or maintenance area which would otherwise not be in violation of the standard during the future period in question if the Federal action were not taken; or

(ii) Contributes, in conjunction with other reasonably foreseeable actions, to a new violation of a NAAQS at a location in a nonattainment or maintenance area in a manner that would increase the frequency or severity of the new violation.

“Caused by”, as used in the terms “direct emissions” and “indirect emissions,” means emissions that would not otherwise occur in the absence of the Federal action.

“Confidential business information (CBI)” means information that has been determined by a Federal agency, in accordance with its applicable regulations, to be a trade secret, or commercial or financial information obtained from a person and privileged or confidential and is exempt from required disclosure under the Freedom of

Information Act (5 U.S.C. 552(b)(4)).

“Conformity determination” is the evaluation (made after an applicability analysis is completed) that a Federal action conforms to the applicable implementation plan and meets the requirements of this section.

“Conformity evaluation” is the entire process from the applicability analysis through the conformity determination that is used to demonstrate that the Federal action conforms to the requirements of this section.

“Continuing program responsibility” means a Federal agency has responsibility for emissions caused by:

(i) Actions it takes itself; or

(ii) Actions of non-Federal entities that the Federal agency, in exercising its normal programs and authorities, approves, funds, licenses or permits, provided the agency can impose conditions on any portion of the action that could affect the emissions.

“Continuous program to implement” means that the Federal agency has started the action identified in the plan and does not stop the actions for more than an 18-month period, unless it can demonstrate that such a stoppage was included in the original plan.

“Criteria pollutant or standard” means any pollutant for which there is established a NAAQS at 40 CFR part 50.

“Direct emissions” means those emissions of a criteria pollutant or its precursors that are caused or initiated by the Federal action and originate in a nonattainment or maintenance area and occur at the same time and place as the action and are reasonably foreseeable.

“Emergency” means a situation where extremely quick action on the part of the Federal agencies involved is needed and where the timing of such Federal activities makes it impractical to meet the requirements of this section, such as natural disasters like hurricanes or earthquakes, civil disturbances such as terrorist acts and military mobilizations.

“Emissions budgets” are those portions of the applicable SIP’s projected emission inventories that describe the levels of emissions (mobile, stationary, area, etc.) that provide for meeting reasonable further progress milestones, attainment, and/or maintenance for any criteria pollutant or its precursors.

“Emission inventory” means a listing of information on the location, type of source, type and quantity of pollutant emitted as well as other parameters of the emissions.

“Emissions offsets”, for purposes of Subsection (h), are emissions reductions which are quantifiable, consistent with the applicable SIP attainment and reasonable further progress demonstrations, surplus to reductions required by, and credited to, other applicable SIP provisions, enforceable at both the State and Federal levels, and permanent within the timeframe specified by the program.

“EPA” means the U.S. Environmental Protection Agency.

“Federal action” means any activity engaged in by a department, agency, or instrumentality of the Federal government, or any activity that a department, agency or instrumentality of the Federal government supports in any way, provides financial assistance for, licenses, permits, or approves, other than activities related to transportation plans, programs, and projects developed, funded, or approved under Title 23 U.S.C. or the Federal Transit Act (49 U.S.C. 1601 *et seq.*). Where the Federal action is a permit, license, or other approval for some aspect of a non-Federal undertaking, the relevant activity is the part, portion, or phase of the non-Federal undertaking that requires the Federal permit, license, or approval.

“Federal agency” means, for purposes of this section, a Federal department, agency, or instrumentality of the Federal government.

“Increase the frequency or severity of any existing violation of any standard in any area” means to cause a nonattainment area to exceed a standard more often or to cause a violation at a greater concentration than previously existed and/or would otherwise exist during the future period in question, if the project were not implemented.

“Indirect emissions” means those emissions of a criteria pollutant or its precursors:

- (i) That are caused or initiated by the Federal action and originate in the same nonattainment or maintenance area but occur at a different time or place as the action;
- (ii) That are reasonably foreseeable;
- (iii) That the Federal agency can practically control; and
- (iv) For which the Federal agency has continuing program responsibility.

For the purposes of this definition, even if a Federal licensing, rulemaking or other approving action is a required initial step for a subsequent activity that causes emissions, such initial steps do not mean that a Federal agency can practically control any resulting emissions.

“Local air quality modeling analysis” means an assessment of localized impacts

on a scale smaller than the entire nonattainment or maintenance area, including, for example, congested roadways on a Federal facility, which uses an air quality dispersion model (e.g., Industrial Source Complex Model or Emission and Dispersion Model System) to determine the effects of emissions on air quality.

“Maintenance area” means an area that was designated as nonattainment and has been re-designated in 40 CFR part 81 to attainment, meeting the provisions of section 107(d)(3)(E) of the CAA and has a maintenance plan approved under section 175A of the CAA.

“Maintenance plan” means a revision to the applicable SIP, meeting the requirements of section 175A of the CAA.

“Metropolitan Planning Organization (MPO)” means the policy board of an organization created as a result of the designation process in 23 U.S.C. 134(d).

“Milestone” has the meaning given in sections 182(g)(1) and 189(c)(1) of the CAA.

“Mitigation measure” means any method of reducing emissions of the pollutant or its precursor taken at the location of the Federal action and used to reduce the impact of the emissions of that pollutant caused by the action.

“National ambient air quality standards (NAAQS)” are those standards established pursuant to section 109 of the CAA and include standards for carbon monoxide (CO), lead (Pb), nitrogen dioxide (NO₂), ozone, particulate matter (PM₁₀ and PM_{2.5}), and sulfur dioxide (SO₂).

“NEPA” is the National Environmental Policy Act of 1969, as amended (42 U.S.C. 4321 et seq.).

“Nonattainment area (NAA)” means an area designated as nonattainment under section 107 of the CAA and described in 40 CFR part 81.

“Precursors of a criteria pollutant” are:

(i) For ozone, nitrogen oxides (NO_x), unless an area is exempted from NO_x requirements under section 182(f) of the CAA, and volatile organic compounds (VOC).

(ii) For PM₁₀, those pollutants described in the PM₁₀ nonattainment area applicable SIP as significant contributors to the PM₁₀ levels.

(iii) For PM_{2.5}:

(A) Sulfur dioxide (SO₂) in all PM_{2.5} nonattainment and

maintenance areas,

(B) Nitrogen oxides in all PM_{2.5} nonattainment and maintenance areas unless both the State and EPA determine that it is not a significant precursor, and

(C) Volatile organic compounds (VOC) and ammonia (NH₃) only in PM_{2.5} nonattainment or maintenance areas where either the State or EPA determines that they are significant precursors.

“Reasonably foreseeable emissions” are projected future direct and indirect emissions that are identified at the time the conformity determination is made; the location of such emissions is known and the emissions are quantifiable as described and documented by the Federal agency based on its own information and after reviewing any information presented to the Federal agency.

“Regional water and/or wastewater projects” include construction, operation, and maintenance of water or wastewater conveyances, water or wastewater treatment facilities, and water storage reservoirs which affect a large portion of a nonattainment or maintenance area.

“Restricted information” is information that is privileged or that is otherwise protected from disclosure pursuant to applicable statutes, Executive Orders, or regulations. Such information includes, but is not limited to: Classified national security information, protected critical infrastructure information, sensitive security information, and proprietary business information.

“Take or start the Federal action” means the date that the Federal agency signs or approves the permit, license, grant or contract or otherwise physically begins the Federal action that requires a conformity evaluation under this section.

“Total of direct and indirect emissions” means the sum of direct and indirect emissions increases and decreases caused by the Federal action; i.e., the “net” emissions considering all direct and indirect emissions. The portion of emissions which are exempt or presumed to conform under Subsections (c)(iii), (iv), (v), or (vi) are not included in the “total of direct and indirect emissions.” The “total of direct and indirect emissions” includes emissions of criteria pollutants and emissions of precursors of criteria pollutants.

(c) Applicability.

(i) Conformity determinations for Federal actions related to transportation plans, programs, and projects developed, funded, or approved under Title 23 U.S.C. or the Federal Transit Act (49 U.S.C. 1601 et seq.) must meet the procedures and criteria of Chapter 8, Section 4, in lieu of the procedures set forth in this section.

(ii) For Federal actions not covered by paragraph (i) of this subsection, a conformity determination is required for each criteria pollutant or precursor where the

total of direct and indirect emissions of the criteria pollutant or precursor in a nonattainment or maintenance area caused by a Federal action would equal or exceed any of the rates in paragraphs (ii)(A) or (B) of this subsection.

(A) For purposes of paragraph (ii) of this subsection, the following rates apply in nonattainment areas (NAAs):

| | <u>Tons/Year</u> |
|--|------------------|
| Ozone (VOCs or NO _x): | |
| Serious NAAs | 50 |
| Severe NAAs | 25 |
| Extreme NAAs | 10 |
| Other ozone NAAs outside an ozone transport region | 100 |
| Other ozone NAAs inside an ozone transport region: | |
| VOC | 50 |
| NO _x | 100 |
| Carbon monoxide: | |
| All NAAs | 100 |
| SO ₂ or NO ₂ : | |
| All NAAs | 100 |
| PM ₁₀ : | |
| Moderate NAAs | 100 |
| Serious NAAs | 70 |
| PM _{2.5} : | |
| Direct emissions | 100 |
| SO ₂ | 100 |
| NO _x (unless determined not to be significant precursors) | 100 |
| VOC or ammonia (if determined to be significant precursors) | 100 |
| Pb: | |
| All NAAs | 25 |

(B) For purposes of paragraph (ii) of this subsection, the following rates apply in maintenance areas:

| | <u>Tons/Year</u> |
|--|------------------|
| Ozone (NO _x , SO ₂ or NO ₂): | |
| All Maintenance Areas | 100 |
| Ozone (VOCs): | |
| Maintenance areas inside an ozone transport region | 50 |
| Maintenance areas outside an ozone transport region | 100 |

| | | |
|---------------------|--|-----|
| Carbon monoxide: | | |
| | All maintenance areas | 100 |
| PM ₁₀ : | | |
| | All maintenance areas | 100 |
| PM _{2.5} : | | |
| | Direct emissions | 100 |
| | SO ₂ | 100 |
| | NO _x (unless determined not to be significant precursors) | 100 |
| | VOC or ammonia (if determined to be significant precursors) | 100 |
| Pb: | | |
| | All maintenance areas | 25 |

(iii) The requirements of this section shall not apply to the following Federal actions:

(A) Actions where the total of direct and indirect emissions are below the emissions levels specified in paragraph (ii) of this subsection.

(B) Actions which would result in no emissions increase or an increase in emissions that is clearly de minimus:

(I) Judicial and legislative proceedings.

(II) Continuing and recurring activities such as permit renewals where activities conducted will be similar in scope and operation to activities currently being conducted.

(III) Rulemaking and policy development and issuance.

(IV) Routine maintenance and repair activities, including repair and maintenance of administrative sites, roads, trails, and facilities.

(V) Civil and criminal enforcement activities, such as investigations, audits, inspections, examinations, prosecutions, and the training of law enforcement personnel.

(VI) Administrative actions such as personnel actions, organization changes, debt management or collection, cash management, internal agency audits, program budget proposals, and matters relating to the administration and collection of taxes, duties and fees.

(VII) The routine, recurring transportation of material and personnel.

(VIII) Routine movement of mobile assets, such as ships and aircraft, in home port reassignments and stations (when no new support facilities or personnel are required) to perform as operational groups and/or for repair or overhaul.

(IX) Maintenance dredging and debris disposal where no new depths are required, applicable permits are secured, and disposal will be at an approved disposal site.

(X) Actions, such as the following, with respect to existing structures, properties, facilities and lands where future activities conducted will be similar in scope and operation to activities currently being conducted at the existing structures, properties, facilities, and lands; for example, relocation of personnel, disposition of federally-owned existing structures, properties, facilities, and lands, rent subsidies, operation and maintenance cost subsidies, the exercise of receivership or conservatorship authority, assistance in purchasing structures, and the production of coins and currency.

(XI) The granting of leases, licenses such as for exports and trade, permits, and easements where activities conducted will be similar in scope and operation to activities currently being conducted.

(XII) Planning, studies, and provision of technical assistance.

(XIII) Routine operation of facilities, mobile assets and equipment.

(XIV) Transfers of ownership, interests, and titles in land, facilities, and real and personal properties, regardless of the form or method of the transfer.

(XV) The designation of empowerment zones, enterprise communities, or viticultural areas.

(XVI) Actions by any of the Federal banking agencies or the Federal Reserve Banks, including actions regarding charters, applications, notices, licenses, the supervision or examination of depository institutions or depository institution holding companies, access to the discount window, or the provision of financial services to banking organizations or to any department, agency or instrumentality of the United States.

(XVII) Actions by the Board of Governors of the Federal Reserve System or any Federal Reserve Bank necessary to effect monetary or exchange rate policy.

(XVIII) Actions that implement a foreign affairs function of the United States.

(XIX) Actions (or portions thereof) associated with transfers of land, facilities, title, and real properties through an enforceable contract or lease agreement where the delivery of the deed is required to occur promptly after a specific, reasonable condition is met, such as promptly after the land is certified as meeting the requirements of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), and where the Federal agency does not retain continuing authority to control emissions associated with the lands, facilities, title, or real properties.

(XX) Transfers of real property, including land, facilities, and related personal property from a Federal entity to another Federal entity and assignments of real property, including land, facilities, and related personal property from a Federal entity to another Federal entity for subsequent deeding to eligible applicants.

(XXI) Actions by the Department of the Treasury to effect fiscal policy and to exercise the borrowing authority of the United States.

(XXII) Air traffic control activities and adopting approach, departure, and enroute procedures for aircraft operations above the mixing height specified in the applicable SIP. Where the applicable SIP does not specify a mixing height, the Federal agency can use the 3,000 feet above ground level as a default mixing height, unless the agency demonstrates that use of a different mixing height is appropriate because the change in emissions at and above that height caused by the Federal action is *de minimis*.

(C) Actions where the emissions are not reasonably foreseeable, such as the following:

(I) Initial Outer Continental Shelf lease sales which are made on a broad scale and are followed by exploration and development plans on a project level.

(II) Electric power marketing activities that involve the acquisition, sale and transmission of electric energy.

(D) Actions which implement a decision to conduct or carry out a conforming program such as prescribed burning actions which are consistent with a conforming land management plan.

(iv) Notwithstanding the other requirements of this section, a conformity determination is not required for the following Federal actions (or portion thereof):

(A) The portion of an action that includes major or minor new or modified stationary sources that require a permit under the new source review (NSR)

program (Section 110(a)(2)(C) and section 173 of the CAA) or the prevention of significant deterioration (PSD) program (Title I, part C of the CAA);

(B) Actions in response to emergencies which are typically commenced on the order of hours or days after the emergency and, if applicable, which meet the requirements of paragraph (v) of this subsection;

(C) Research, investigations, studies, demonstrations, or training (other than those exempted under paragraph (iii)(B) of this subsection), where no environmental detriment is incurred and/or, the particular action furthers air quality research, as determined by the State agency primarily responsible for the applicable SIP;

(D) Alteration and additions of existing structures as specifically required by new or existing applicable environmental legislation or environmental regulations (e.g., hush houses for aircraft engines and scrubbers for air emissions);

(E) Direct emissions from remedial and removal actions carried out under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) and associated regulations to the extent such emissions either comply with the substantive requirements of the PSD/NSR permitting program or are exempted from other environmental regulation under the provisions of CERCLA and applicable regulations issued under CERCLA.

(v) Federal actions which are part of a continuing response to an emergency or disaster under paragraph (iv)(B) of this subsection and which are to be taken more than 6 months after the commencement of the response to the emergency or disaster under paragraph (iv)(B) of this subsection are exempt from the requirements of this section only if:

(A) The Federal agency taking the actions makes a written determination that, for a specified period not to exceed an additional 6 months, it is impractical to prepare the conformity analyses which would otherwise be required and the actions cannot be delayed due to overriding concerns for public health and welfare, national security interests and foreign policy commitments; or

(B) For actions which are to be taken after those actions covered by paragraph (v)(A) of this subsection, the Federal agency makes a new determination as provided in paragraph (v)(A) of this subsection and:

(I) Provides a draft copy of the written determinations required to affected EPA Regional office(s), the affected State(s) and/or air pollution control agencies, and any Federal recognized Indian tribal government in the nonattainment or maintenance area. Those organizations must be allowed 15 days from the beginning of the extension period to comment on the draft determination; and

(II) Within 30 days after making the determination, publish a notice of the determination by placing a prominent advertisement in a daily newspaper of general circulation in the area affected by the action.

(C) If additional actions are necessary in response to an emergency or disaster under paragraph (iv)(B) of this subsection beyond the specified time period in paragraph (v)(B) of this subsection, a Federal agency can make a new written determination as described in (v)(B) of this subsection for as many 6-month periods as needed, but in no case shall this exemption extend beyond three 6-month periods except where an agency:

(I) Provides information to EPA and the State stating that the conditions that gave rise to the emergency exemption continue to exist and how such conditions effectively prevent the agency from conducting a conformity evaluation.

(vi) Notwithstanding other requirements of this section, actions specified by individual Federal agencies that have met the criteria set forth in either paragraphs (vii)(A), (vii)(B), or (vii)(C) of this subsection and the procedures set forth in paragraph (viii) of this subsection are “presumed to conform”, except as provided in paragraph (x) of this subsection. Actions specified by individual Federal agencies as “presumed to conform” may not be used in combination with one another when the total direct and indirect emissions from the combination of actions would equal or exceed any of the rates specified in paragraphs (ii)(A) or (ii)(B) of this subsection.

(vii) The Federal agency must meet the criteria for establishing activities that are presumed to conform by fulfilling the requirements set forth in either paragraphs (vii)(A), (vii)(B), or (vii)(C) of this subsection:

(A) The Federal agency must clearly demonstrate using methods consistent with this section that the total of direct and indirect emissions from the type of activities which would be presumed to conform would not:

(I) Cause or contribute to any new violation of any standard in any area;

(II) Interfere with provisions in the applicable SIP for maintenance of any standard;

(III) Increase the frequency or severity of any existing violation of any standard in any area; or

(IV) Delay timely attainment of any standard or any required interim emission reductions or other milestones in any area including, where applicable, emission levels specified in the applicable SIP for purposes of:

progress;

(1.) A demonstration of reasonable further

(2.) A demonstration of attainment;

(3.) A maintenance plan; or

(B) The Federal agency must provide documentation that the total of direct and indirect emissions from such future actions would be below the emission rates for a conformity determination that are established in paragraph (ii) of this subsection, based, for example, on similar actions taken over recent years.

(C) The Federal agency must clearly demonstrate that the emissions from the type or category of actions and the amount of emissions from the action are included in the applicable SIP and the State, local, or tribal air quality agencies responsible for the SIP(s) provide written concurrence that the emissions from the actions along with all other expected emissions in the area will not exceed the emission budget in the SIP.

(viii) In addition to meeting the criteria for establishing exemptions set forth in paragraphs (vii)(A), (vii)(B), or (vii)(C) of this subsection, the following procedures must also be complied with to presume that activities will conform:

(A) The Federal agency must identify through publication in the Federal Register its list of proposed activities that are “presumed to conform” and the basis for the presumptions. The notice must clearly identify the type and size of the action that would be “presumed to conform” and provide criteria for determining if the type and size of action qualifies it for the presumption;

(B) The Federal agency must notify the appropriate EPA Regional Office(s), State and local air quality agencies and, where applicable, the agency designated under §174 of the CAA and the MPO and provide at least 30 days for the public to comment on the list of proposed activities “presumed to conform”. If the “presumed to conform” action has regional or national application (e.g., the action will cause emission increases in excess of the *de minimis* levels identified in paragraph (ii) of this subsection in more than one of EPA’s Regions), the Federal agency, as an alternative to sending it to EPA Regional Offices, can send the draft conformity determination to U.S. EPA, Office of Air Quality Planning and Standards;

(C) The Federal Agency must document its response to all the comments received and make the comments, response, and final list of activities available to the public upon request; and

(D) The Federal agency must publish the final list of such activities in the Federal Register.

(ix) Emissions from the following actions are “presumed to conform”:

(A) Actions at installations with facility-wide emission budgets meeting the requirements in Subsection (k) provided that the State has included the emission budget in the EPA-approved SIP and the emissions from the action along with all other emissions from the installation will not exceed the facility-wide emission budget.

(B) Prescribed fires conducted in accordance with a smoke management program (SMP) which meets the requirements of EPA’s Interim Air Quality Policy on Wildland and Prescribed Fires or an equivalent replacement EPA policy.

(C) Emissions for actions that the State identifies in the EPA-approved SIP as “presumed to conform”.

(x) Even though an action would otherwise be “presumed to conform” under paragraphs (vi) or (ix) of this subsection, an action shall not be “presumed to conform” and the requirements of Subsection (a), 40 CFR 93.151, Subsections (d) through (j) and Subsections (l) through (n) shall apply to the action if EPA or a third party shows that the action would:

(A) Cause or contribute to any new violation of any standard in any area;

(B) Interfere with provisions in the applicable SIP for maintenance of any standard;

(C) Increase the frequency or severity of any existing violation of any standard in any area; or

(D) Delay timely attainment of any standard or any required interim emissions reductions or other milestones in any area including, where applicable, emission levels specified in the applicable SIP for purposes of:

(I) A demonstration of reasonable further progress;

(II) A demonstration of attainment; or

(III) A maintenance plan.

(xi) The provisions of this section shall apply in all nonattainment and maintenance areas except conformity requirements for newly designated nonattainment areas are not applicable until 1 year after the effective date of the final nonattainment designation for each NAAQS and pollutant in accordance with section 176(c)(6) of the CAA.

(d) Federal Agency Conformity Responsibility. Any department, agency, or instrumentality of the Federal government taking an action subject to this section must make its own conformity determination consistent with the requirements of this section. In making its conformity determination, a Federal agency must follow the requirements in Subsections (e) through (j) and Subsections (l) through (o) and must consider comments from any interested parties. Where multiple Federal agencies have jurisdiction for various aspects of a project, a Federal agency may choose to adopt the analysis of another Federal agency or develop its own analysis in order to make its conformity determination.

(e) Reporting Requirements.

(i) A Federal agency making a conformity determination under Subsections (d) through (j) and Subsections (l) through (n) must provide to the appropriate EPA Regional Office(s), State and local air quality agencies, any federally-recognized Indian tribal government in the nonattainment or maintenance area, and, where applicable, affected Federal Land Managers, the agency designated under section 174 of the CAA and the MPO, a 30-day notice which describes the proposed action and the Federal agency's draft conformity determination on the action. If the action has multi-regional or national impacts (e.g., the action will cause emission increases in excess of the *de minimis* levels identified in Subsection (c)(ii) in three or more of EPA's Regions), the Federal agency, as an alternative to sending it to EPA Regional Offices, can provide the notice to EPA's Office of Air Quality Planning and Standards.

(ii) A Federal agency must notify the appropriate EPA Regional Office(s), State and local air quality agencies, any federally-recognized Indian tribal government in the nonattainment or maintenance area, and, where applicable, affected Federal Land Managers, the agency designated under section 174 of the Clean Air Act and the MPO, within 30 days after making a final conformity determination under this section.

(iii) The draft and final conformity determination shall exclude any restricted information or confidential business information. The disclosure of restricted information and confidential business information shall be controlled by the applicable laws, regulations, security manuals, or executive orders concerning the use, access, and release of such materials. Subject to applicable procedures to protect restricted information from public disclosure, any information or materials excluded from the draft or final conformity determination or supporting materials may be made available in a restricted information annex to the determination for review by Federal and State representatives who have received appropriate clearances to review the information.

(f) Public Participation.

(i) Upon request by any person regarding a specific Federal action, a Federal agency must make available, subject to the limitation in paragraph (v) of this section, for review its draft conformity determination under Subsection (d) with

supporting materials which describe the analytical methods and conclusions relied upon in making the applicability analysis and draft conformity determination.

(ii) A Federal agency must make public its draft conformity determination under Subsection (d) by placing a notice by prominent advertisement in a daily newspaper of general circulation in the area affected by the action and by providing 30 days for written public comment prior to taking any formal action on the draft determination. This comment period may be concurrent with any other public involvement, such as occurs in the NEPA process. If the action has multi-regional or national impacts (e.g., the action will cause emission increases in excess of the *de minimis* levels identified in Subsection (c)(ii) in three or more of EPA's Regions), the Federal agency, as an alternative to publishing separate notices, can publish a notice in the Federal Register.

(iii) A Federal agency must document its response to all the comments received on its draft conformity determination under Subsection (d) and make the comments and responses available, subject to the limitation in paragraph (v) of this subsection, upon request by any person regarding a specific Federal action, within 30 days of the final conformity determination.

(iv) A Federal agency must make public its final conformity determination under Subsection (d) for a federal action by placing a notice by prominent advertisement in a daily newspaper of general circulation in the area affected by the action within 30 days of the final conformity determination. If the action would have multi-regional or national impacts, the Federal agency, as an alternative, can publish the notice in the Federal Register.

(v) The draft and final conformity determination shall exclude any restricted information or confidential business information. The disclosure of restricted information and confidential business information shall be controlled by the applicable laws, regulations or executive orders concerning the release of such materials.

(g) Reevaluation of Conformity.

(i) Once a conformity determination is completed by a Federal agency, that determination is not required to be reevaluated if the agency has maintained a continuous program to implement the action; the determination has not lapsed as specified in paragraph (ii) of this subsection; or any modification to the action does not result in an increase in emissions above the levels specified in Subsection (c)(ii). If a conformity determination is not required for the action at the time the NEPA analysis is completed, the date of the finding of no significant impact (FONSI) for an Environmental Assessment, a record of decision (ROD) for an Environmental Impact Statement, or a categorical exclusion determination can be used as a substitute date for the conformity determination date.

(ii) The conformity status of a Federal action automatically lapses 5 years from the date a final conformity determination is reported under Subsection (e), unless the Federal action has been completed or a continuous program to implement the Federal action has commenced.

(iii) Ongoing Federal activities at a given site showing continuous progress are not new actions and do not require periodic redeterminations so long as such activities are within the scope of the final conformity determination reported under Section (e).

(iv) If the Federal agency originally determined through the applicability analysis that a conformity determination was not necessary because the emissions for the action were below the limits in Subsection (c)(ii) and changes to the action would result in the total emissions from the action being above the limits in Subsection (c)(ii), then the Federal agency must make a conformity determination.

(h) Criteria for Determining Conformity of General Federal Actions.

(i) An action required under Subsection (c) to have a conformity determination for a specific pollutant, will be determined to conform to the applicable SIP if, for each pollutant that exceeds the rates in Subsection (c)(ii), or otherwise requires a conformity determination due to the total of direct and indirect emissions from the action, the action meets the requirements of paragraph (iii) of this subsection, and meets any of the following requirements:

(A) For any criteria pollutant or precursor, the total of direct and indirect emissions from the action are specifically identified and accounted for in the applicable SIP's attainment or maintenance demonstration or reasonable further progress milestone or in a facility-wide emission budget included in a SIP in accordance with Subsection (k);

(B) For precursors of ozone, nitrogen dioxide, or PM, the total of direct and indirect emissions from the action are fully offset within the same nonattainment or maintenance area (or nearby area of equal or higher classification provided the emissions from that area contribute to the violations, or have contributed to violations in the past, in the area with the Federal action) through a revision to the applicable SIP or a similarly enforceable measure that effects emissions reductions so that there is no net increase in emissions of that pollutant;

(C) For any directly-emitted criteria pollutant, the total of direct and indirect emissions from the action meets the requirements:

(I) Specified in paragraph (ii) of this subsection, based on areawide air quality modeling analysis and local air quality modeling analysis; or

(II) Meet the requirements of paragraph (i)(E) of this subsection and, for local air quality modeling analysis, the requirement of paragraph (ii) of this subsection;

(D) For CO or directly emitted PM₁₀:

(I) Where the State agency primarily responsible for the applicable SIP determines that an areawide air quality modeling analysis is not needed, the total of direct and indirect emissions from the action meet the requirements specified in paragraph (ii) of this subsection, based on local air quality modeling analysis; or

(II) Where the State agency primarily responsible for the applicable SIP determines that an areawide air quality modeling analysis is appropriate and that a local air quality modeling analysis is not needed, the total of direct and indirect emissions from the action meet the requirements specified in paragraph (ii) of this subsection, based on areawide modeling, or meet the requirements of paragraph (i)(E) of this subsection; or

(E) For ozone or nitrogen dioxide, and for purposes of paragraphs (i)(C)(II) and (i)(D)(II) of this subsection, each portion of the action or the action as a whole meets any of the following requirements:

(I) Where EPA has approved a revision to the applicable implementation plan after the area was designated as nonattainment and the State makes a determination as provided in paragraph (i)(E)(I)(1.) of this subsection or where the State makes a commitment as provided in paragraph (i)(E)(I)(2.) of this subsection:

(1.) The total of direct and indirect emissions from the action (or portion thereof) is determined and documented by the State agency primarily responsible for the applicable SIP to result in a level of emissions which, together with all other emissions in the nonattainment (or maintenance) area, would not exceed the emissions budgets specified in the applicable SIP.

(2.) The total of direct and indirect emissions from the action (or portion thereof) is determined by the State agency responsible for the applicable SIP to result in a level of emissions which, together with all other emissions in the nonattainment (or maintenance) area, would exceed an emissions budget specified in the applicable SIP and the State Governor or the Governor's designee for SIP actions makes a written commitment to EPA which includes the following:

a. A specific schedule for adoption and submittal of a revision to the SIP which would achieve the needed emission reductions prior to the time emissions from the Federal action would occur;

b. Identification of specific measures for incorporation into the SIP which would result in a level of emissions which, together with

all other emissions in the nonattainment or maintenance area, would not exceed any emissions budget specified in the applicable SIP;

c. A demonstration that all existing applicable SIP requirements are being implemented in the area for the pollutants affected by the Federal action, and that local authority to implement additional requirements has been fully pursued;

d. A determination that the responsible Federal agencies have required all reasonable mitigation measures associated with their action; and

e. Written documentation including all air quality analyses supporting the conformity determination.

(3.) Where a Federal agency made a conformity determination based on a State's commitment under paragraph (i)(E)(I)(2.) of this subsection and the State has submitted a SIP to EPA covering the time period during which the emissions will occur or is scheduled to submit such a SIP within 18 months of the conformity determination, the State commitment is automatically deemed a call for a SIP revision by EPA under section 110(k)(5) of the CAA, effective on the date of the Federal conformity determination and requiring response within 18 months or any shorter time within which the State commits to revise the applicable SIP;

(4.) Where a Federal agency made a conformity determination based on a State commitment under paragraph (i)(E)(I)(2.) of this subsection and the State has not submitted a SIP covering the time period when the emissions will occur or is not scheduled to submit such a SIP within 18 months of the conformity determination, the State must, within 18 months, submit to EPA a revision to the existing SIP committing to include the emissions in the future SIP revision.

(II) The action (or portion thereof), as determined by the MPO, is specifically included in a current transportation plan and transportation improvement program which have been found to conform to the applicable SIP under Chapter 8, Section 4, or 40 CFR part 93, Subpart A;

(III) The action (or portion thereof) fully offsets its emissions within the same nonattainment or maintenance area (or nearby area of equal or higher classification provided the emissions from that area contribute to the violations, or have contributed to violations in the past, in the area with the Federal action) through a revision to the applicable SIP or an equally enforceable measure that effects emissions reductions equal to or greater than the total of direct and indirect emissions from the action so that there is no net increase in emissions of that pollutant;

(IV) Where EPA has not approved a revision to the relevant SIP since the area was redesignated or reclassified, the total of direct and indirect

emissions from the action for the future years (described in Subsection (i)(iv)) do not increase emissions with respect to the baseline emissions:

(1.) The baseline emissions reflect the historical activity levels that occurred in the geographic area affected by the proposed Federal action during:

a. The most current calendar year with a complete emission inventory available before an area is designated unless EPA sets another year; or

b. The emission budget in the applicable SIP;

c. The year of the baseline inventory in the PM₁₀ applicable SIP;

(2.) The baseline emissions are the total of direct and indirect emissions calculated for the future years (described in Subsection (i)(iv)) using the historic activity levels (described in paragraph (i)(E)(IV)(1.) of this subsection) and appropriate emission factors for the future years; or

(V) Where the action involves regional water and/or wastewater projects, such projects are sized to meet only the needs of population projections that are in the applicable SIP.

(ii) The areawide and/or local air quality modeling analyses must:

(A) Meet the requirements in Subsection (i); and

(B) Show that the action does not:

(I) Cause or contribute to any new violation of any standard in any area; or

(II) Increase the frequency or severity of any existing violation of any standard in any area.

(iii) Notwithstanding any other requirements of this subsection, an action subject to this section may not be determined to conform to the applicable SIP unless the total of direct and indirect emissions from the action is in compliance or consistent with all relevant requirements and milestones contained in the applicable SIP, such as elements identified as part of the reasonable further progress schedules, assumptions specified in the attainment or maintenance demonstration, prohibitions, numerical emission limits, and work practice requirements.

(iv) Any analyses required under this subsection must be completed, and any mitigation requirements necessary for a finding of conformity must be identified before the determination of conformity is made.

(i) Procedures for Conformity Determinations of General Federal Actions.

(i) The analyses required under this section must be based on the latest planning assumptions.

(A) All planning assumptions must be derived from the estimates of population, employment, travel, and congestion most recently approved by the MPO, or other agency authorized to make such estimates, where available.

(B) Any revisions to these estimates used as part of the conformity determination, including projected shifts in geographic location or level of population, employment, travel, and congestion, must be approved by the MPO or other agency authorized to make such estimates for the urban area.

(ii) The analyses required under this section must be based on the latest and most accurate emission estimation techniques available as described below, unless such techniques are inappropriate. If such techniques are inappropriate, the Federal agency may obtain written approval from the appropriate EPA Regional Administrator for modification or substitution, of another technique on a case-by-case basis or, where appropriate, on a generic basis for a specific Federal agency program.

(A) For motor vehicle emissions, the most current version of the motor vehicle emissions model specified by EPA and available for use in the preparation or revision of SIPs in that State must be used for the conformity analysis as specified in paragraphs (ii)(A)(I) and (II) of this subsection:

(I) The EPA must publish in the Federal Register a notice of availability of any new motor vehicle emissions model; and

(II) A grace period of three months shall apply during which the motor vehicle emissions model previously specified by EPA as the most current version may be used unless EPA announces a longer grace period in the Federal Register. Conformity analyses for which the analysis was begun during the grace period or no more than 3 months before the Federal Register notice of availability of the latest emission model may continue to use the previous version of the model specified by EPA.

(B) For non-motor vehicle sources, including stationary and area source emissions, the latest emission factors specified by EPA in the “Compilation of Air Pollutant Emission Factors” (AP-42) must be used for the conformity analysis unless more accurate emission data are available, such as actual stack test data from stationary sources which are part of the conformity analysis.

(iii) The air quality modeling analyses required under this section must be based on the applicable air quality models, databases, and other requirements specified in the most recent version of the “Guideline on Air Quality Models” (Appendix W to 40 CFR part 51), unless:

(A) The guideline techniques are inappropriate, in which case the model may be modified or another model substituted on a case-by-case basis or, where appropriate, on a generic basis for a specific Federal agency program; and

(B) Written approval of the EPA Regional Administrator is obtained for any modification or substitution.

(iv) The analyses required under this section must be based on the total of direct and indirect emissions from the action and must reflect emission scenarios that are expected to occur under each of the following cases:

(A) The attainment year specified in the SIP, or if the SIP does not specify an attainment year, the latest attainment year possible under the CAA; or

(B) The last year for which emissions are projected in the maintenance plan;

(C) The year during which the total of direct and indirect emissions from the action is expected to be the greatest on an annual basis; and

(D) Any year for which the applicable SIP specifies an emissions budget.

(j) Mitigation of Air Quality Impacts.

(i) Any measures that are intended to mitigate air quality impacts must be identified and the process for implementation and enforcement of such measures must be described, including an implementation schedule containing explicit timelines for implementation.

(ii) Prior to determining that a Federal action is in conformity, the Federal agency making the conformity determination must obtain written commitments from the appropriate persons or agencies to implement any mitigation measures which are identified as conditions for making conformity determinations.

(iii) Persons or agencies voluntarily committing to mitigation measures to facilitate positive conformity determinations must comply with the obligations of such commitments.

(iv) In instances where the Federal agency is licensing, permitting or otherwise approving the action of another governmental or private entity, approval by the

Federal agency must be conditioned on the other entity meeting the mitigation measures set forth in the conformity determination.

(v) When necessary because of changed circumstances, mitigation measures may be modified so long as the new mitigation measures continue to support the conformity determination. Any proposed change in the mitigation measures is subject to the reporting requirements of Subsection (e) and the public participation requirements of Subsection (f).

(vi) Written commitments to mitigation measures must be obtained prior to a positive conformity determination and that such commitments must be fulfilled.

(vii) After a State revises its SIP and EPA approves that SIP revision, any agreements, including mitigation measures, necessary for a conformity determination will be both State and federally enforceable. Enforceability through the applicable SIP will apply to all persons who agree to mitigate direct and indirect emissions associated with a Federal action for a conformity determination.

(k) Conformity Evaluation for Federal Installations With Facility-Wide Emission Budgets.

(i) The State or local agency responsible for implementing and enforcing the SIP can in cooperation with Federal agencies or third parties authorized by the agency that operate installations subject to Federal oversight develop and adopt a facility-wide emission budget to be used for demonstrating conformity under Subsection (h)(i)(A). The facility-wide budget must meet the following criteria:

(A) Be for a set time period;

(B) Cover the pollutants or precursors of the pollutants for which the area is designated nonattainment or maintenance;

(C) Include specific quantities allowed to be emitted on an annual or seasonal basis;

(D) The emissions from the facility along with all other emissions in the area will not exceed the emission budget for the area;

(E) Include specific measures to ensure compliance with the budget, such as periodic reporting requirements or compliance demonstration, when the Federal agency is taking an action that would otherwise require a conformity determination;

(F) Be submitted to EPA as a SIP revision;

(G) The SIP revision must be approved by EPA.

(ii) The facility-wide budget developed and adopted in accordance with paragraph (i) of this subsection can be revised by following the requirements in paragraph (i) of this subsection.

(iii) Total direct and indirect emissions from Federal actions in conjunction with all other emissions subject to General Conformity from the facility that do not exceed the facility budget adopted pursuant to paragraph (i) of this subsection are “presumed to conform” to the SIP and do not require a conformity analysis.

(iv) If the total direct and indirect emissions from the Federal actions in conjunction with the other emissions subject to General Conformity from the facility exceed the budget adopted pursuant to paragraph (i) of this subsection, the action must be evaluated for conformity. A Federal agency can use the compliance with the facility-wide emissions budget as part of the demonstration of conformity, i.e., the agency would have to mitigate or offset the emissions that exceed the emission budget.

(v) If the SIP for the area includes a category for construction emissions, the negotiated budget can exempt construction emissions from further conformity analysis.

(l) Emissions Beyond the Time Period Covered by the SIP. If a Federal action would result in total direct and indirect emissions above the applicable thresholds which would be emitted beyond the time period covered by the SIP, the Federal agency can:

(i) Demonstrate conformity with the last emission budget in the SIP; or

(ii) Request the State to adopt an emissions budget for the action for inclusion in the SIP. The State must submit a SIP revision to EPA within 18 months either including the emissions in the existing SIP or establishing an enforceable commitment to include the emissions in future SIP revisions based on the latest planning assumptions at the time of the SIP revision. No such commitment by a State shall restrict a State’s ability to require RACT, RACM or any other control measures within the State’s authority to ensure timely attainment of the NAAQS.

(m) Timing of Offsets and Mitigation Measures.

(i) The emissions reductions from an offset or mitigation measure used to demonstrate conformity must occur during the same calendar year as the emission increases from the action except, as provided in paragraph (ii) of this subsection.

(ii) The State may approve emissions reductions in other years provided:

(A) The reductions are greater than the emission increases by the following ratios:

- (I) Extreme nonattainment areas 1.5:1
- (II) Severe nonattainment areas 1.3:1
- (III) Serious nonattainment areas 1.2:1
- (IV) Moderate nonattainment areas 1.15:1
- (V) All other areas 1.1:1

(B) The time period for completing the emissions reductions must not exceed twice the period of the emissions.

(C) The offset or mitigation measure with emissions reductions in another year will not:

(I) Cause or contribute to a new violation of any air quality standard;

(II) Increase the frequency or severity of any existing violation of any air quality standard; or

(III) Delay the timely attainment of any standard or any interim emissions reductions or other milestones in any area.

(iii) The approval by the State of an offset or mitigation measure with emissions reductions in another year does not relieve the State of any obligation to meet any SIP or CAA milestone or deadline. The approval of an alternate schedule for mitigation measures is at the discretion of the State, and they are not required to approve an alternate schedule.

(n) Inter-precursor Mitigation Measures and Offsets. Federal agencies must reduce the same type of pollutant as being increased by the Federal action except the State may approve offsets or mitigation measures of different precursors of the same criteria pollutant, if such trades are allowed by a State in a SIP approved NSR regulation, is technically justified, and has a demonstrated environmental benefit.

(o) Early Emission Reduction Credit Programs at Federal Facilities and Installation Subject to Federal Oversight.

(i) Federal facilities and installations subject to Federal oversight can, with the approval of the State agency responsible for the SIP in that area, create an early emissions reductions credit program. The Federal agency can create the emission reduction credits in accordance with the requirements in paragraph (ii) of this subsection and can use them in accordance with paragraph (iii) of this subsection.

(ii) Creation of Emission Reduction Credits.

(A) Emissions reductions must be quantifiable through the use of standard emission factors or measurement techniques. If non-standard factors or techniques to quantify the emissions reductions are used, the Federal agency must receive approval from the State agency responsible for the implementation of the SIP and from EPA's Regional Office. The emission reduction credits do not have to be quantified before the reduction strategy is implemented, but must be quantified before the credits are used in the General Conformity evaluation.

(B) The emission reduction methods must be consistent with the applicable SIP attainment and reasonable further progress demonstrations.

(C) The emissions reductions cannot be required by or credited to other applicable SIP provisions.

(D) Both the State and Federal air quality agencies must be able to take legal action to ensure continued implementation of the emission reduction strategy. In addition, private citizens must also be able to initiate action to ensure compliance with the control requirement.

(E) The emissions reductions must be permanent or the timeframe for the reductions must be specified.

(F) The Federal agency must document the emissions reductions and provide a copy of the document to the State air quality agency and the EPA Regional Office for review. The documentation must include a detailed description of the emission reduction strategy and a discussion of how it meets the requirements of paragraphs (ii)(A) through (E) of this subsection.

(iii) Use of Emission Reduction Credits. The emission reduction credits created in accordance with paragraph (ii) of this subsection can be used, subject to the following limitations, to reduce the emissions increase from a Federal action at the facility for the conformity evaluation.

(A) If the technique used to create the emission reduction is implemented at the same facility as the Federal action and could have occurred in conjunction with the Federal action, then the credits can be used to reduce the total direct and indirect emissions used to determine the applicability of the regulation as required in Subsection (c) and as offsets or mitigation measures required by Subsection (h).

(B) If the technique used to create the emission reduction is not implemented at the same facility as the Federal action or could not have occurred in conjunction with the Federal action, then the credits cannot be used to reduce the total direct and indirect emissions used to determine the applicability of the regulation as

required in Subsection (c), but can be used to offset or mitigate the emissions as required by Subsection (h).

(C) Emissions reductions credits must be used in the same year in which they are generated.

(D) Once the emission reduction credits are used, they cannot be used as credits for another conformity evaluation. However, unused credits from a strategy used for one conformity evaluation can be used for another conformity evaluation as long as the reduction credits are not double counted.

(E) Federal agencies must notify the State air quality agency responsible for the implementation of the SIP and EPA Regional Office when the emission reduction credits are being used.

Section 4. **Transportation conformity.**

(a) Definitions. Terms used but not defined in this subpart shall have the meaning given them by the CAA, titles 23 and 49 U.S.C., other Environmental Protection Agency (EPA) regulations, or other DOT regulations, in that order of priority.

“Applicable implementation plan” is defined in §302(q) of the CAA and means the portion (or portions) of the implementation plan, or most recent revision thereof, which has been approved under §110, or promulgated under §110(c), or promulgated or approved pursuant to regulations promulgated under §301(d) and which implements the relevant requirements of the CAA.

“CAA” means the Clean Air Act, as amended.

“Cause or contribute to a new violation” for a project means:

(A) To cause or contribute to a new violation of a standard in the area substantially affected by the project or over a region which would otherwise not be in violation of the standard during the future period in question, if the project were not implemented, or

(B) To contribute to a new violation in a manner that would increase the frequency or severity of a new violation of a standard in such area.

“Control strategy implementation plan revision” is the applicable implementation plan which contains specific strategies for controlling the emissions of and reducing ambient levels of pollutants in order to satisfy CAA requirements for demonstrations of reasonable further progress and attainment (CAA §§182(b)(1), 182(c)(2)(A), 182(c)(2)(B), 187(a)(7), 189(a)(1)(B), and 189(b)(1)(A); and §§192(a) and 192(b), for nitrogen dioxide).

“Control strategy period” with respect to particulate matter less than 10 microns in diameter (PM₁₀), carbon monoxide (CO), nitrogen dioxide (NO₂), and/or ozone precursors (volatile organic compounds and oxides of nitrogen), means that period of time after EPA approves control strategy implementation plan revisions containing strategies for controlling PM₁₀, NO₂, CO, and/or ozone, as appropriate. This period ends when a State submits and EPA approves a request under §107(d) of the CAA for redesignation to an attainment area.

“Design concept” means the type of facility identified by the project, e.g., freeway, expressway, arterial highway, grade-separated highway, reserved right-of-way rail transit, mixed-traffic rail transit, exclusive busway, etc.

“Design scope” means the design aspects which will affect the proposed facility’s impact on regional emissions, usually as they relate to vehicle or person carrying capacity and control, e.g., number of lanes or tracks to be constructed or added, length of project, signalization, access control including approximate number and location of interchanges, preferential treatment for high-occupancy vehicles, etc.

“Division” means the Air Quality Division of the Department of Environmental Quality.

“DOT” means the United States Department of Transportation.

“EPA” means the Environmental Protection Agency.

“FHWA” means the Federal Highway Administration of DOT.

“FHWA/FTA project” for the purpose of this subpart, is any highway or transit project which is proposed to receive funding assistance and approval through the Federal-Aid Highway program or the Federal mass transit program, or requires Federal Highway Administration (FHWA) or Federal Transit Administration (FTA) approval for some aspect of the project, such as connection to an interstate highway or deviation from applicable design standards on the interstate system.

“FTA” means the Federal Transit Administration of DOT.

“Forecast period” with respect to a transportation plan is the period covered by the transportation plan pursuant to 23 CFR part 450.

“Highway project” is an undertaking to implement or modify a highway facility or highway-related program. Such an undertaking consists of all required phases necessary for implementation. For analytical purposes, it must be defined sufficiently to:

(A) Connect logical termini and be of sufficient length to address environmental matters on a broad scope;

(B) Have independent utility or significance, i.e., be usable and be a reasonable expenditure even if no additional transportation improvements in the area are made; and

(C) Not restrict consideration of alternatives for other reasonably foreseeable transportation improvements.

“Horizon year” is a year for which the transportation plan describes the envisioned transportation system according to Chapter 8, Section 4(f).

“Hot-spot analysis” is an estimation of likely future localized CO and PM₁₀ pollutant concentrations and a comparison of those concentrations to the national ambient air quality standards. Pollutant concentrations to be estimated should be based on the total emissions burden which may result from the implementation of a single, specific project, summed together with future background concentrations (which can be estimated using the ratio of future to current traffic multiplied by the ratio of future to current emission factors) expected in the area. The total concentration must be estimated and analyzed at appropriate receptor locations in the area substantially affected by the project. Hot-spot analysis assesses impacts on a scale smaller than the entire nonattainment or maintenance area, including, for example, congested roadway intersections and highways or transit terminals, and uses an air quality dispersion model to determine the effects of emissions on air quality.

“Incomplete data area” means any ozone nonattainment area which EPA has classified, in 40 CFR part 81, as an incomplete data area.

“Increase the frequency or severity” means to cause a location or region to exceed a standard more often or to cause a violation at a greater concentration than previously existed and/or would otherwise exist during the future period in question, if the project were not implemented.

“ISTEA” means the Intermodal Surface Transportation Efficiency Act of 1991.

“Maintenance area” means any geographic region of the United States previously designated nonattainment pursuant to the CAA Amendments of 1990 and subsequently redesignated to attainment subject to the requirement to develop a maintenance plan under §175A of the CAA, as amended.

“Maintenance period” with respect to a pollutant or pollutant precursor means that period of time beginning when a State submits and EPA approves a request under §107(d) of the CAA for redesignation to an attainment area, and lasting for 20 years, unless the applicable implementation plan specifies that the maintenance period shall last for more than 20 years.

“Metropolitan planning organization (MPO)” is that organization designated as being responsible, together with the State, for conducting the continuing, cooperative,

and comprehensive planning process under 23 U.S.C. 134 and 49 U.S.C. 1607. It is the forum for cooperative transportation decision-making.

“Milestone” has the meaning given in §182(g)(1) and §189(c) of the CAA. A milestone consists of an emissions level and the date on which it is required to be achieved.

“Motor vehicle emissions budget” is that portion of the total allowable emissions defined in a revision to the applicable implementation plan (or in an implementation plan revision which was endorsed by the Governor or his or her designee, subject to a public hearing, and submitted to EPA, but not yet approved by EPA) for a certain date for the purpose of meeting reasonable further progress milestones or attainment or maintenance demonstrations, for any criteria pollutant or its precursors, allocated by the applicable implementation plan to highway and transit vehicles. The applicable implementation plan for an ozone nonattainment area may also designate a motor vehicle emissions budget for oxides of nitrogen (NO_x) for a reasonable further progress milestone year if the applicable implementation plan demonstrates that this NO_x budget will be achieved with measures in the implementation plan (as an implementation plan must do for VOC milestone requirements). The applicable implementation plan for an ozone nonattainment area includes a NO_x budget if NO_x reductions are being substituted for reductions in volatile organic compounds in milestone years required for reasonable further progress.

“National ambient air quality standards (NAAQS)” are those standards established pursuant to §109 of the CAA.

“NEPA” means the National Environmental Policy Act of 1969, as amended (42 U.S.C. 4321 et seq.).

“NEPA process completion”, for the purposes of this subpart, with respect to FHWA or FTA, means the point at which there is a specific action to make a determination that a project is categorically excluded, to make a Finding of No Significant Impact, or to issue a record of decision on a Final Environmental Impact Statement under NEPA.

“Nonattainment area” means any geographic region of the United States which has been designated as nonattainment under §107 of the CAA for any pollutant for which a national ambient air quality standard exists.

“Not classified area” means any carbon monoxide nonattainment area which EPA has not classified as either moderate or serious.

“Phase II of the interim period” with respect to a pollutant or pollutant precursor, means that period of time after the effective date of this rule, lasting until the earlier of the following:

(A) Submission to EPA of the relevant control strategy implementation plan revisions which have been endorsed by the Governor (or his or her designee) and have been subject to a public hearing, or

(B) The date that the Clean Air Act requires relevant control strategy implementation plans to be submitted to EPA, provided EPA has made a finding of the State's failure to submit any such plans and the State, MPO, and DOT have received notice of such finding of the State's failure to submit any such plans. The precise end of Phase II of the interim period is defined in Chapter 8, Section 4(bb).

“Project” means a highway project or transit project.

“Recipient of funds designated under Title 23 U.S.C. or the Federal Transit Act” means any agency at any level of State, county, city, or regional government that routinely receives Title 23 U.S.C. or Federal Transit Act funds to construct FHWA/FTA projects, operate FHWA/FTA projects or equipment, purchase equipment, or undertake other services or operations via contracts or agreements. This definition does not include private landowners or developers, or contractors or entities that are only paid for services or products created by their own employees.

“Regionally significant project” means a transportation project (other than an exempt project) that is on a facility which serves regional transportation needs (such as access to and from the area outside of the region, major activity centers in the region, major planned developments such as new retail malls, sports complexes, etc., or transportation terminals as well as most terminals themselves) and would normally be included in the modeling of a metropolitan area's transportation network, including at a minimum all principal arterial highways, all fixed guideway transit facilities that offer an alternative to regional highway travel and any project that the Division identifies as having the potential to affect air quality on a regional basis, after consultation in accordance with Chapter 8, Section 4(e).

“Rural transport ozone nonattainment area” means an ozone nonattainment area that does not include, and is not adjacent to, any part of a Metropolitan Statistical Area, or, where one exists, a Consolidated Metropolitan Statistical Area (as defined by the United States Bureau of the Census) and is classified under Clean Air Act §182(h) as a rural transport area.

“Standard” means a national ambient air quality standard.

“Submarginal area” means any ozone nonattainment area which EPA has classified as submarginal in 40 CFR part 81.

“Title 23 U.S.C.” means Title 23 of the United States Code.

“Transit” is mass transportation by bus, rail, or other conveyance which provides general or special service to the public on a regular and continuing basis. It does not include school buses or charter or sightseeing services.

“Transit project” is an undertaking to implement or modify a transit facility or transit-related program, purchase transit vehicles or equipment, or provide financial assistance for transit operations. It does not include actions that are solely within the jurisdiction of local transit agencies, such as changes in routes, schedules, or fares. It may consist of several phases. For analytical purposes, it must be defined inclusively enough to:

(A) Connect logical termini and be of sufficient length to address environmental matters on a broad scope;

(B) Have independent utility or independent significance, i.e., be a reasonable expenditure even if no additional transportation improvements in the area are made; and

(C) Not restrict consideration of alternatives for other reasonably foreseeable transportation improvements.

“Transitional area” means any ozone nonattainment area which EPA has classified as transitional in 40 CFR part 81.

“Transitional period” with respect to a pollutant or pollutant precursor means that period of time which begins after submission to EPA of the relevant control strategy implementation plan which has been endorsed by the Governor (or his or her designee) and has been subject to a public hearing. The transitional period lasts until EPA takes final approval or disapproval action on the control strategy implementation plan submission or finds it to be incomplete. The precise beginning and end of the transitional period is defined in Chapter 8, Section 4(bb).

“Transportation control measure (TCM)” is any measure that is specifically identified and committed to in the applicable implementation plan that is either one of the types listed in §108 of the CAA, or any other measure for the purpose of reducing emissions or concentrations of air pollutants from transportation sources by reducing vehicle use or changing traffic flow or congestion conditions. Notwithstanding the above, vehicle technology-based, fuel-based, and maintenance-based measures which control the emissions from vehicles under fixed traffic conditions are not TCMs for the purposes of this subpart.

“Transportation improvement program (TIP)” means a staged, multiyear, intermodal program of transportation projects covering a metropolitan planning area which is consistent with the metropolitan transportation plan, and developed pursuant to 23 CFR part 450.

“Transportation plan” means the official intermodal metropolitan transportation plan that is developed through the metropolitan planning process for the metropolitan planning area, developed pursuant to 23 CFR part 450.

“Transportation project” is a highway project or a transit project.

“WYDOT” means the Wyoming Department of Transportation.

(b) Applicability.

(i) Action Applicability.

(A) Except as provided for in paragraph (iii) of this section or Chapter 8, Section 4(hh), conformity determinations are required for:

(I) The adoption, acceptance, approval or support of transportation plans developed pursuant to 23 CFR part 450 or 49 CFR part 613 by an MPO or DOT;

(II) The adoption, acceptance, approval or support of TIPs developed pursuant to 23 CFR part 450 or 49 CFR part 613 by an MPO or DOT; and

(III) The approval, funding, or implementation of FHWA/FTA projects.

(B) Conformity determinations are not required under this rule for individual projects which are not FHWA/FTA projects. However, Chapter 8, Section 4(cc) applies to such projects if they are regionally significant.

(ii) Geographic Applicability.

(A) The provisions of this subpart shall apply in all nonattainment and maintenance areas for transportation-related criteria pollutants for which the area is designated nonattainment or has a maintenance plan.

(B) The provisions of this subpart apply with respect to emissions of the following criteria pollutants: ozone, carbon monoxide, nitrogen dioxide, and particles with an aerodynamic diameter less than or equal to a nominal 10 micrometers (PM₁₀).

(C) The provisions of this subpart apply with respect to emissions of the following precursor pollutants:

(I) Volatile organic compounds and nitrogen oxides in ozone areas (unless the Administrator determines under §182(f) of the CAA that additional reductions of NO_x would not contribute to attainment);

(II) Nitrogen oxides in nitrogen dioxide areas; and

(III) Volatile organic compounds, nitrogen oxides, and PM₁₀ in PM₁₀ areas if:

(1.) During the interim period, the EPA Regional Administrator or the Director of the State air agency has made a finding (including a finding as part of an applicable implementation plan or a submitted implementation revision) that transportation-related precursor emissions within the nonattainment area are a significant contributor to the PM₁₀ nonattainment problem and has so notified the MPO and DOT; or

(2.) During the transitional, control strategy, and maintenance periods, the applicable implementation plan (or implementation plan submission) establishes a budget for such emissions as part of the reasonable further progress, attainment or maintenance strategy.

(iii) Limitations.

(A) Projects subject to this regulation for which the NEPA process and a conformity determination have been completed by FHWA or FTA may proceed toward implementation without further conformity determinations if one of the following major steps has occurred within the most recent three-year period: NEPA process completion; start of final design; acquisition of a significant portion of the right-of-way; or approval of the plans, specifications and estimates. All phases of such projects which were considered in the conformity determination are also included, if those phases were for the purpose of funding, final design, right-of-way acquisition, construction, or any combination of these phases.

(B) A new conformity determination for the project will be required if there is a significant change in project design concept and scope, if a supplemental environmental document for air quality purposes is initiated, or if no major steps to advance the project have occurred within the most recent three-year period.

(c) Priority. When assisting or approving any action with air quality-related consequences, FHWA and FTA shall give priority to the implementation of those transportation portions of an applicable implementation plan prepared to attain and maintain the NAAQS. This priority shall be consistent with statutory requirements for allocation of funds among States or other jurisdictions.

(d) Frequency of Conformity Determinations.

(i) Conformity determinations and conformity redeterminations for transportation plans, TIPS, and FHWA/FTA projects must be made according to the requirements of this section and the applicable implementation plan.

(ii) Transportation Plans.

(A) Each new transportation plan must be found to conform before the transportation plan is approved by the MPO or accepted by DOT.

(B) All transportation plan revisions must be found to conform before the transportation plan revisions are approved by MPO or accepted by DOT, unless the revision merely adds or deletes exempt projects listed in Chapter 8, Section 4(hh) and has been made in accordance with the notification process provisions of Chapter 8, Section 4(e)(iii)(A)(VII). The conformity determination must be based on the transportation plan and the revision taken as a whole.

(C) The existing conformity determination will lapse unless conformity of the existing transportation plans is redetermined:

(I) By May 1, 1995 (unless previously redetermined in accordance with 40 CFR part 51 Subpart T); or

(II) Within 18 months of EPA approval of an implementation plan revision which:

(1.) Establishes or revises a transportation-related emissions budget (as required by CAA §§175A(a), 182(b)(1), 182(c)(2)(A), 182(c)(2)(B), 187(a)(7), 189(a)(1)(B), and 189(b)(1)(A); and §§192(a) and 192(b), for nitrogen dioxide; or

(2.) Adds, deletes, or changes TCMs; and

(III) Within 18 months of EPA promulgation of an implementation plan which establishes or revises a transportation-related emissions budget or adds, deletes, or changes TCMs.

(D) In any case, conformity determinations must be made no less frequently than every three years, or the existing conformity determination will lapse.

(iii) Transportation Improvement Programs.

(A) A new TIP must be found to conform before the TIP is approved by the MPO or accepted by DOT.

(B) A TIP amendment requires a new conformity determination for the entire TIP before the amendment is approved by the MPO or accepted by DOT, unless the amendment merely adds or deletes exempt projects listed in Chapter 8, Section 4(hh) and has been made in accordance with the notification process provisions of Chapter 8, Section 4(e)(iii)(A)(VII).

(C) After an MPO adopts a new or revised transportation plan, conformity must be redetermined by the MPO and DOT within six months from the date of adoption of the plan, unless the new or revised plan merely adds or deletes exempt projects listed in Chapter 8, Section 4(hh) and has been made in accordance with the notification process provisions of Chapter 8, Section 4(e)(iii)(A)(VII). Otherwise, the existing conformity determination for the TIP will lapse.

(D) In any case, conformity determinations must be made no less frequently than every three years or the existing conformity determination will lapse.

(iv) Projects. FHWA/FTA projects must be found to conform before they are adopted, accepted, approved, or funded. Conformity must be redetermined for any FHWA/FTA project if none of the following major steps has occurred within the most recent three-year period: NEPA process completion; start of final design; acquisition of a significant portion of the right-of-way; or approval of the plans, specifications and estimates.

(e) Consultation.

(i) General. This rule provides procedures for interagency consultation (Federal, State, and local) and resolution of conflicts. Such consultation procedures shall be undertaken by the WYDOT, MPOs and the DOT with the Division and EPA before making conformity determinations, and by the Division and EPA with MPOs, the WYDOT and DOT in developing and revising applicable implementation plans.

(ii) Interagency Consultation Procedures: General Factors.

(A) Representatives of the MPOs, the Division and the WYDOT shall undertake an interagency consultation process in accordance with this section with each other, with representatives of appropriate cities, towns, and counties and with local or regional offices of EPA, FHWA, and FTA on the development of the implementation plan, the list of TCMs in the applicable implementation plan, the unified planning work program under 23 CFR §450.314, the transportation plan, the TIP, any revisions to the preceding documents, and all conformity determinations required by this rule.

(B) The agency with the responsibility for a transportation plan, program, project, or applicable implementation plan shall also be responsible for preparing the final document of decision subject to the interagency consultation process and shall be the lead agency. It shall be the affirmative responsibility of the lead agency to initiate the process by notifying other participants, to convene consultation meetings early in the process of decision on the final document, to appoint the conveners of technical meetings, and to assure that all relevant documents and information are supplied to all participants in the consultation process in a timely manner.

(C) Regular consultation on routine activities such as the selection of models or any determination of conformity on transportation projects shall include meetings at regular, scheduled quarterly intervals, if determined necessary by the lead agency and shall be on the agenda of at least one meeting attended by representatives at the policy level of each agency. In addition, technical meetings shall be convened as necessary.

(D) Each lead agency in the consultation process required under this section shall confer with all other agencies identified under paragraph (A) with an interest in the document to be developed, provide all information to those agencies needed for meaningful input, and, prior to taking any action, consider the views of each such agency and respond to those views in a timely, substantive written manner prior to any final decision on such document. Such views and written response shall be made part of the record of any decision or action, if any.

(iii) Interagency Consultation Procedures: Specific Processes.

(A) An interagency consultation process in accordance with Chapter 8, Section 4(e)(ii) involving the MPO, the Division, the WYDOT, EPA, and DOT shall be undertaken for the following:

(I) Evaluating and choosing each model (or models) and associated methods and assumptions to be used in hot-spot analyses and regional emissions analyses, including vehicle miles traveled (“VMT”) forecasting, to be initiated by the WYDOT and conducted in accordance with Chapter 8, Section 4(e)(ii).

(II) Determining which minor arterials and other transportation projects should be considered “regionally significant” for the purposes of regional emissions analysis (in addition to those functionally classified as principal arterial or higher or fixed guideway systems or extension that offer an alternative to regional highway travel), and which projects should be considered to have a significant change in design concept and scope from the transportation plan of TIP, to be initiated by the WYDOT and conducted in accordance with Chapter 8, Section 4(e)(ii).

(III) Evaluate whether projects otherwise exempted from meeting the requirements of this section should be treated as non-exempt in cases where potential adverse emissions impacts may exist for any reason, to be initiated by the Division and conducted in accordance with Chapter 8, Section 4(e)(ii).

(IV) Make a determination, as required by Chapter 8, Section 4(m)(iii)(A), whether past obstacles to implementation of TCMs which are behind the schedule established in the applicable implementation plan have been identified and are being overcome, and whether State and local agencies with influence over approvals or funding for TCMs are giving maximum priority to approval or funding for TCMs, to be initiated by the Division and conducted in accordance with Chapter 8, Section 4(e)(ii). This consultation process shall also consider whether delays in TCM

implementation necessitate revisions to the applicable implementation plan to remove TCMs or substitute TCMs or other emission reduction measures.

(V) Making a determination, as required by Chapter 8, Section 4(cc)(ii), whether the project is included in the regional emission analysis supporting the currently conforming TIP's conformity determination, even if the project is not strictly "included" in the TIP for the purposes of MPO project selection or endorsement, and whether the project's design concept and scope have not changed significantly from those which were included in the regional emissions analysis, or in a manner which would significantly impact use of the facility, to be initiated by the WYDOT and conducted in accordance with Chapter 8, Section 4(e)(ii).

(VI) Identify, as required by Chapter 8, Section 4(ee)(iv), projects located at sites in PM₁₀ nonattainment areas which have vehicle and roadway emission and dispersion characteristics which are essentially identical to those at sites which have violations verified by monitoring, and therefore require quantitative PM₁₀ hot-spot analysis, to be initiated by the Division and conducted in accordance with Chapter 8, Section 4(e)(ii).

(VII) Notification of transportation plan or TIP revisions or amendments which merely add or delete exempt projects listed in Chapter 8, Section 4(hh), to be initiated by the WYDOT and conducted in accordance with Chapter 8, Section 4(e)(ii).

(VIII) Determining what forecast of vehicle miles traveled (VMT) to use in establishing or tracking emissions budgets, developing transportation plans, TIPS, or applicable implementation plans, or making conformity determinations, to be initiated by the WYDOT and conducted in accordance with Chapter 8, Section 4(e)(ii).

(B) An interagency consultation process in accordance with Chapter 8, Section 4(e)(ii) involving the MPO, the Division and the WYDOT, shall be undertaken for the following:

(I) Evaluating events which will trigger new conformity determinations in addition to those triggering events established in Chapter 8, Section 4(d), to be initiated by the Division and conducted in accordance with Chapter 8, Section 4(e)(ii); and

(II) Consulting on emissions analysis for transportation activities which cross the borders of MPOs or nonattainment areas or air basins, to be initiated by the Division and conducted in accordance with Chapter 8, Section 4(e)(ii).

(C) Where any metropolitan planning area does not include an entire nonattainment or maintenance area, an interagency consultation process in accordance with Chapter 8, Section 4(e)(ii) involving the MPO and the WYDOT shall be

undertaken for cooperative planning and analysis purposes of determining conformity of all projects outside the metropolitan area and within the nonattainment or maintenance area, to be initiated by the WYDOT and conducted in accordance with Chapter 8, Section 4(e)(ii).

(D) (I) An interagency consultation process in accordance with Chapter 8, Section 4(e)(ii) involving the MPO, the Division, the WYDOT, and recipients of funds designated under Title 23 U.S.C. or the Federal Transit Act shall be undertaken to assure that plans for construction of regionally significant projects which are not FHWA/FTA projects (including projects for which alternative locations, design concept and scope, or the no-build option are still being considered), including those by recipients of funds designated under Title 23 U.S.C. or the Federal Transit Act, are disclosed to the MPO on a regular basis, and to assure that any changes to those plans are immediately disclosed.

(II) The sponsor of any such regionally significant project, and any agency that becomes aware of any such project through applications for approval, permitting or funding or otherwise, shall disclose such project to the MPO in a timely manner. Such disclosure shall be made not later than the first occasion on which any of the following actions are sought: any policy board action necessary for the project to proceed, the issuance of administrative permits for the facility or for construction of the facility, the execution of a contract to design or construct the facility, the execution of any indebtedness for the facility, any final action of a board, commission or administrator authorizing or directing employees to proceed with design, permitting or construction of the project, or the execution of any contract to design or construct or any approval needed for any facility that is dependent on the completion of a regionally significant project.

(III) In the case of any such regionally significant project that has not been disclosed to the MPO and other interested agencies participating in the consultation process in a timely manner, such regionally significant project shall be deemed not to be included in the regional emissions analysis supporting the currently conforming TIP's conformity determination and not to be consistent with the motor vehicle emissions budget in the applicable implementation plan, for the purposes of Chapter 8, Section 4(cc).

(IV) For the purposes of this section and Chapter 8, Section 4(cc), the phrase "adopt or approve of a regionally significant project" means the first time any action necessary to authorizing a project occurs, such as any policy board action necessary for the project to proceed, the issuance of administrative permits for the facility or for construction of the facility, the execution of a contract to construct the facility, any final action of a board, commission or administrator authorizing or directing employees to proceed with construction of the project, or any written decision or authorization from the MPO that the project may be adopted or approved.

(E) An interagency cooperation process in accordance with Chapter 8, Section 4(e)(ii) involving the MPO and any other recipients of funds

designated under Title 23 U.S.C. or the Federal Transit Act shall be undertaken for assuming the location and design concept and scope of projects which are disclosed to the MPO under Chapter 8, Section 4(e)(iii)(E) of this section but whose sponsors have not yet decided these features, in sufficient detail to perform the regional emissions analysis according to the requirements of Chapter 8, Section 4(dd), to be initiated by the MPO and conducted in accordance with Chapter 8, Section 4(e)(ii).

(F) An interagency consultation process in accordance with Chapter 8, Section 4(e)(ii) involving any MPO, the Division and the WYDOT shall be undertaken for the design, schedule, and funding of research and data collection efforts and regional transportation model development by the MPO (e.g., household/travel transportation surveys), to be initiated by the MPO and conducted in accordance with Chapter 8, Section 4(e)(ii).

(iv) Resolving Conflicts.

(A) Any conflict among State agencies or between State agencies and an MPO shall be escalated to the Governor if the conflict cannot be resolved by the heads of the involved agencies. In the first instance, such agencies shall make every effort to resolve any differences, including personal meetings between the heads of such agencies or their policy-level representatives, to the extent possible.

(B) The Division has 14 calendar days to appeal a proposed determination of conformity to the Governor after the WYDOT or MPO has notified the Division of the resolution of all comments on such proposed determination of conformity or policy decision. Such 14-day period shall commence when the MPO or the WYDOT has confirmed receipt by the Administrator of the Division of the resolution of the comments of the Division.

(C) The final conformity decision must have the concurrence of the Governor if the Division appeals a conformity decision. If there is no appeal by the Division, the MPO or the WYDOT may proceed with the final conformity determination.

(D) The Division must provide notice of any appeal under Chapter 8, Section 4(e)(iv)(B) to the WYDOT and MPO.

(E) The Governor may delegate his/her role in the appeal process to anyone except the head or staff of the Division, the WYDOT, the Wyoming Environmental Quality Council, the Wyoming Transportation Commission or an MPO.

(v) Public Participation.

(A) Affected agencies making conformity determinations on transportation plans, programs, and projects shall establish a proactive public involvement process which provides opportunity for public review and comment prior to taking formal action on a conformity determination for all transportation plans and TIPs,

consistent with the requirements of 23 CFR 450, including §§450.316(b)(1), 450.322(c), and 450.324(c) as in effect on the date of adoption of this rule. In addition, any such agency must specifically address in writing in all public comments that known plans for a regionally significant project which is not receiving FHWA or FTA funding or approval have not been properly reflected in the emissions analysis supporting a proposed conformity finding for a transportation plan or TIP. Any such agency shall also provide opportunity for public involvement in conformity determination for projects to the extent otherwise required by law.

(B) The opportunity for public involvement provided under this subsection shall include access to information, emissions data, analyses, models and modeling assumptions used to perform a conformity determination, and the obligation of any such agency to consider and respond to significant comments.

(C) No transportation plan, TIP, or project may be found to conform unless the determination of conformity has been subject to a public involvement process in accordance with this subsection, without regard to whether the DOT has certified any process under 23 CFR part 450.

(f) Content of Transportation Plans.

(i) Transportation Plans Adopted After January 1, 1995 in Serious, Severe, or Extreme Ozone Nonattainment Areas and in Serious Carbon Monoxide Nonattainment Areas. The transportation plan must specifically describe the transportation system envisioned for certain future years which shall be called horizon years.

(A) The agency or organization developing the transportation plan, after consultation in accordance with Chapter 8, Section 4(e), may choose any years to be horizon years, subject to the following restrictions:

(I) Horizon years may be no more than 10 years apart.

(II) The first horizon year may be no more than 10 years from the base year used to validate the transportation demand planning model.

(III) If the attainment year is in the time span of the transportation plan, the attainment year must be a horizon year.

(IV) The last horizon year must be the last year of the transportation plan's forecast period.

(B) For these horizon years:

(I) The transportation plan shall quantify and document the demographic and employment factors influencing expected transportation demand,

including land use forecasts, in accordance with implementation plan provisions and Chapter 8, Section 4(e).

(II) The highway and transit system shall be described in terms of the regionally significant additions or modifications to the existing transportation network which the transportation plan envisions to be operational in the horizon years. Additions and modifications to the highway network shall be sufficiently identified to indicate intersections with existing regionally significant facilities, and to determine their effect on route options between transportation analysis zones. Each added or modified highway segment shall also be sufficiently identified in terms of its design concept and design scope to allow modeling of travel times under various traffic volumes, consistent with the modeling methods for area-wide transportation analysis in use by the MPO. Transit facilities, equipment, and services envisioned for the future shall be identified in terms of design concept, design scope, and operating policies sufficiently to allow modeling of their transit ridership. The description of additions and modifications to the transportation network shall also be sufficiently specific to show that there is a reasonable relationship between expected land use and the envisioned transportation system; and

(III) Other future transportation policies, requirements, services, and activities, including intermodal activities, shall be described.

(ii) Moderate Areas Reclassified to Serious. Ozone or CO nonattainment areas which are reclassified from moderate to serious must meet the requirements of paragraph (i) of this section within two years from the date of reclassification.

(iii) Transportation Plans for Other Areas. Transportation plans for other areas must meet the requirements of paragraph (a) of this section at least to the extent it has been the previous practice of the MPO to prepare plans which meet those requirements. Otherwise, transportation plans must describe the transportation system envisioned for the future specifically enough to allow determination of conformity according to the criteria and procedures of Chapter 8, Section 4(i)-(aa).

(iv) Savings. The requirements of this section supplement other requirements of applicable law or regulation governing the format or content of transportation plans.

(g) Relationship of Transportation Plan and TIP Conformity With the NEPA Process. The degree of specificity required in the transportation plan and the specific travel network assumed for air quality modeling do not preclude the consideration of alternatives in the NEPA process or other project development studies. Should the NEPA process result in a project with design concept and scope significantly different from that in the transportation plan or TIP, the project must meet the criteria in Chapter 8, Section 4(i)-(aa) for projects not from a TIP before NEPA process completion.

(h) Fiscal Constraints for Transportation Plans and TIPS. Transportation plans and TIPS shall be fiscally constrained and meet the requirements of 23 CFR 450.332(b)(11) and 450.324(e) as in effect on the date of adoption of this section in order to be found in conformity. The determination that a transportation plan or TIP is fiscally constrained shall be subject to consultation in accordance with Chapter 8, Section 4(e).

(i) Criteria and Procedures for Determining Conformity of Transportation Plans, Programs, and Projects: General.

(i) In order to be found to conform, each transportation plan, program, and FHWA/FTA project must satisfy the applicable criteria and procedures in Chapter 8, Section 4(j)-(aa) as listed in Table 1 in paragraph (ii) of this section, and must comply with all applicable conformity requirements of implementation plans and of court orders for the area which pertain specifically to conformity determination requirements. The criteria for making conformity determinations differ based on the action under review (transportation plans, TIPS, and FHWA/FTA projects), the time period in which the conformity determination is made, and the relevant pollutant.

(ii) The following table indicates the criteria and procedures in Chapter 8, Section 4(j)-(aa) which apply for each action in each time period.

Table 1. Conformity Criteria

| DURING ALL PERIODS | |
|--|-------------------|
| Action | Criteria |
| Transportation Plan | j,k,l,m(ii). |
| TIP | j,k,l,m(iii). |
| Project (From a conforming plan and TIP) | j,k,l,n,o,p,q |
| Project (Not from a conforming plan and TIP) | j,k,l,m(iv),n,p,q |

Table 1. Conformity Criteria (continued)

PHASE II OF THE INTERIM PERIOD

| Action | Criteria |
|--|----------|
| Transportation Plan | v,y |
| TIP | w,z |
| Project (From a conforming plan and TIP) | u |
| Project (Not from a conforming plan and TIP) | u,x,aa |

TRANSITIONAL PERIOD

| Action | Criteria |
|--|----------|
| Transportation Plan | r,v,y |
| TIP | s,w,z |
| Project (From a conforming plan and TIP) | u |
| Project (Not from a conforming plan and TIP) | t,u,x,aa |

CONTROL STRATEGY AND MAINTENANCE PERIODS

| Action | Criteria |
|--|------------------------|
| Transportation Plan | r |
| TIP | s |
| Project (From a conforming plan and TIP) | No additional criteria |
| Project (Not from a conforming plan and TIP) | t |

- (j) The conformity determination must be based on the latest planning assumptions.
- (k) The conformity determination must be based on the latest emission estimation model available.
- (l) The MPO must make the conformity determination according to the consultation procedures of this rule and the implementation plan revision required by 40 CFR part 51, Subpart T.
- (m) The transportation plan, TIP, or FHWA/FTA project which is not from a conforming plan and TIP must provide for the timely implementation of TCMs from the applicable implementation plan.
- (n) There must be a currently conforming transportation plan and currently conforming TIP at the time of project approval.

- (o) The project must come from a conforming transportation plan and program.
- (p) The FHWA/FTA project must not cause or contribute to any new localized CO or PM₁₀ violations or increase the frequency or severity of any existing CO or PM₁₀ violations in CO and PM₁₀ nonattainment and maintenance areas.
- (q) The FHWA/FTA project must comply with PM₁₀ control measures in the applicable implementation plan.
- (r) The transportation plan must be consistent with the motor vehicle emissions budget(s) in the applicable implementation plan or implementation plan submission.
- (s) The TIP must be consistent with the motor vehicle emissions budget(s) in the applicable implementation plan or implementation plan submission.
- (t) The project which is not from a conforming transportation plan and conforming TIP must be consistent with the motor vehicle emissions budget(s) in the applicable implementation plan or implementation plan submission.
- (u) The FHWA/FTA project must eliminate or reduce the severity and number of localized CO violations in the area substantially affected by the project (in CO nonattainment areas).
- (v) The transportation plan must contribute to emissions reductions in ozone and CO nonattainment areas.
- (w) The TIP must contribute to emissions reductions in ozone and CO nonattainment areas.
- (x) The project which is not from a conforming transportation plan and TIP must contribute to emissions reductions in ozone and CO nonattainment areas.
- (y) The transportation plan must contribute to emission reductions or must not increase emissions in PM₁₀ and NO₂ nonattainment areas.
- (z) The TIP must contribute to emission reductions or must not increase emissions in PM₁₀ and NO₂ nonattainment areas.
- (aa) The project which is not from a conforming transportation plan and TIP must contribute to emission reductions or must not increase emissions in PM₁₀ and NO₂ nonattainment areas.

(j) Criteria and Procedures: Latest Planning Assumptions.

(i) During all periods the conformity determination, with respect to all other applicable criteria in Chapter 8, Sections 4(k)-(aa), must be based upon the most recent planning assumptions in force at the time of the conformity determination. This criterion applies during all periods. The conformity determination must satisfy the requirements of paragraphs (ii) through (vi) of this section.

(ii) Assumptions (including, but not limited to, vehicle miles traveled per capita or per household, trip generation per household, vehicle occupancy, household size, vehicle fleet mix, vehicle ownership, and the geographic distribution of population growth) must be derived from the estimates of current and future population, employment, travel, and congestion most recently developed by the MPO or other agency authorized to make such estimates and approved by the MPO. The conformity

determination must also be based on the latest assumptions about current and future background concentrations. Any revisions to these estimates used as part of the conformity determination, including projected shifts in geographic location or level of population, employment, travel, and congestion, must be approved by the MPO or other agency authorized to make such estimates for the area, after consultation with the Division.

(iii) The conformity determination for each transportation plan and TIP must discuss how transit operating policies (including fares and service levels) and assumed transit ridership have changed since the previous conformity determination.

(iv) The conformity determination must include reasonable assumptions about transit service and increases in transit fares and road and bridge tolls over time.

(v) The conformity determination must use the latest existing information regarding the effectiveness of the TCMs which have already been implemented.

(vi) Key assumptions shall be specified and included in the draft documents and supporting materials used for the interagency and public consultation required by Chapter 8, Section 4(e).

(k) Criteria and Procedures: Latest Emissions Model.

(i) During all periods the conformity determination shall be based on the latest emission estimation model available. This criterion is satisfied if the most current version of the motor vehicle emissions model specified by EPA for use in the preparation or revision of implementation plans in that State or area is used for the conformity analysis. Where EMFAC is the motor vehicle emissions model used in preparing or revising the applicable implementation plan, new versions must be approved by EPA before they are used in the conformity analysis.

(ii) EPA will consult with DOT to establish a grace period following the specification of any new model.

(A) The grace period will be no less than three months and no more than 24 months after notice of availability is published in the Federal Register.

(B) The length of the grace period will depend on the degree of change in the model and the scope of re-planning likely to be necessary by MPOs in order to assure conformity. If the grace period will be longer than three months, EPA will announce the appropriate grace period in the Federal Register.

(iii) Conformity analyses for which the emissions analysis was begun during the grace period or before the Federal Register notice of availability of the latest emission model may continue to use the previous version of the model for transportation plans and TIPs. The previous model may also be used for projects if the analysis was

begun during the grace period or before the Federal Register notice of availability, provided no more than three years have passed since the draft environmental document was issued.

(l) **Criteria and Procedures: Consultation.** All conformity determinations shall be made according to the consultation procedures in Chapter 8, Section 4(e), and according to the public involvement procedures established by the MPO in compliance with 23 CFR part 450. This criterion applies during all periods. Until the implementation plan revision required by 40 CFR part 51, Subpart T is approved by EPA, the conformity determination must be made according to the procedures in 40 CFR 51.402(a)(2) and 40 CFR 51.402(e). Once the implementation plan revision has been approved by EPA, this criterion is satisfied if the conformity determination is made consistent with the implementation plan's consultation requirements.

(m) **Criteria and Procedures: Timely Implementation of TCMs.**

(i) The transportation plan, TIP, or FHWA/FTA project which is not from a conforming plan and TIP must provide for the timely implementation of TCMs from the applicable implementation plan. This criterion applies during all periods.

(ii) For transportation plans, this criterion is satisfied if the following two conditions are met:

(A) The transportation plan, in describing the envisioned future transportation system, provides for the timely completion or implementation of all TCMs in the applicable implementation plan, including, but not limited to, those which are eligible for funding under Title 23 U.S.C. or the Federal Transit Act, consistent with schedules included in the applicable implementation plan.

(B) Nothing in the transportation plan interferes with the implementation of any TCM in the applicable implementation plan.

(iii) For TIPs, this criterion is satisfied if the following conditions are met:

(A) An examination of the specific steps and funding source(s) needed to fully implement each TCM indicates that TCMs, including, but not limited to, those which are eligible for funding under Title 23 U.S.C. or the Federal Transit Act are on or ahead of the schedule established in the applicable implementation plan, or, if such TCMs are behind the schedule established in the applicable implementation plan, the MPO and DOT have determined that past obstacles to implementation of the TCMs have been identified and have been or are being overcome, and that all State and local agencies with influence over approvals or funding for TCMs are giving maximum priority to approval or funding of TCMs over other projects within their control, including projects in locations outside the nonattainment or maintenance area. Maximum priority to approval or funding of TCMs includes demonstrations with respect to funding

acceleration, commitment of staff or other agency resources, diligent efforts to seek approvals, and similar actions.

(B) If TCMs in the applicable implementation plan have previously been programmed for Federal funding but the funds have not been obligated and the TCMs are behind the schedule in the implementation plan, then the TIP cannot be found to conform if the funds intended for those TCMs are reallocated to projects in the TIP other than TCMs, or if there are no other TCMs in the TIP, if the funds are reallocated to projects in the TIP other than projects which are eligible for Federal funding under ISTEA's Congestion Mitigation and Air Quality Improvement Program.

(C) Nothing in the TIP may interfere with the implementation of any TCM in the applicable implementation plan.

(iv) For FHWA/FTA projects which are not from a conforming transportation plan and TIP, this criterion is satisfied if the project does not interfere with the implementation of any TCM in the applicable implementation plan.

(n) Criteria and Procedures: Currently Conforming Transportation Plan and TIP. There must be a currently conforming transportation plan and currently conforming TIP at the time of project approval. This criterion applies during all periods. It is satisfied if the current transportation plan and TIP have been found to conform to the applicable implementation plan by the MPO and DOT according to the criteria and procedures of this subpart. Only one conforming transportation plan or TIP may exist in an area at any time; conformity determinations of a previous transportation plan or TIP expire once the current plan or TIP is found to conform by DOT. The conformity determination on a transportation plan or TIP will also lapse if conformity is not determined according to the frequency requirements of Chapter 8, Section 4(d).

(o) Criteria and Procedures: Projects From a Plan and TIP.

(i) The project must come from a conforming plan and program. This criterion applies during all periods. If this criterion is not satisfied, the project must satisfy all criteria in Table 1 for a project not from a conforming transportation plan and TIP. A project is considered to be from a conforming transportation plan if it meets the requirements of paragraph (ii) of this section and from a conforming program if it meets the requirements of paragraph (iii) of this section.

(ii) A project is considered to be from a conforming transportation plan if one of the following conditions applies:

(A) For projects which are required to be identified in the transportation plan in order to satisfy §51.404, the project is specifically included in the conforming transportation plan and the project's design concept and scope have not changed significantly from those which were described in the transportation plan, or in a manner which would significantly impact use of the facility; or

(B) For projects which are not required to be specifically identified in the transportation plan, the project is identified in the conforming transportation plan, or is consistent with the policies and purpose of the transportation plan and will not interfere with other projects specifically included in the transportation plan.

(iii) A project is considered to be from a conforming program if the following conditions are met:

(A) The project is included in the conforming TIP and the design concept and scope of the project were adequate at the time of the TIP conformity determination to determine its contribution to the TIP's regional emissions and have not changed significantly from those which were described in the TIP, or in a manner which would significantly impact use of the facility; and

(B) If the TIP describes a project design concept and scope which includes project-level emissions mitigation or control measures, enforceable written commitments to implement such measures must be obtained from the project sponsor and/or operator as required by Chapter 8, Section 4(gg)(i) in order for the project to be considered from a conforming program. Any change in these mitigation or control measures that would significantly reduce their effectiveness constitutes a change in the design concept and scope of the project.

(p) Criteria and Procedures: Localized CO and PM₁₀ Violations (Hotspots).

(i) The FHWA/FTA project must not cause or contribute to any new localized CO or PM₁₀ violations or increase the frequency or severity of any existing CO or PM₁₀ violations in CO and PM₁₀ nonattainment and maintenance areas. This criterion applies during all periods. This criterion is satisfied if it is demonstrated that no new local violations will be created and the severity or number of existing violations will not be increased as a result of the project.

(ii) The demonstration must be performed according to the requirements of Chapter 8, Sections 4(e) and (ee).

(iii) For projects which are not of the type identified by Chapter 8, Section 4(ee)(i) or Chapter 8, Section 4(ee)(iv), this criterion may be satisfied if consideration of local factors clearly demonstrates that no local violations presently exist and no new local violations will be created as a result of the project. Otherwise, in CO nonattainment and maintenance areas, a quantitative demonstration must be performed according to the requirements of Chapter 8, Section 4(ee)(ii).

(q) Criteria and Procedures: Compliance With PM₁₀ Control Measures. The FHWA/FTA project must comply with PM₁₀ control measures in the applicable implementation plan. This criterion applies during all periods. It is satisfied if control

measures (for the purpose of limiting PM₁₀ emissions from the construction activities and/or normal use and operation associated with the project) contained in the applicable implementation plan are included in the final plans, specifications, and estimates for the project.

(r) Criteria and Procedures: Motor Vehicle Emissions Budget (Transportation Plan).

(i) The transportation plan must be consistent with the motor vehicle emissions budget(s) in the applicable implementation plan (or implementation plan submission). This criterion applies during the transitional period and the control strategy and maintenance periods, except as provided in Chapter 8, Section 4(jj). This criterion may be satisfied if the requirements in paragraphs (ii) and (iii) of this section are met:

(ii) A regional emissions analysis shall be performed as follows:

(A) The regional analysis shall estimate emissions of any of the following pollutants and pollutant precursors for which the area is in nonattainment or maintenance and for which the applicable implementation plan (or implementation plan submission) establishes an emissions budget:

(I) VOC as an ozone precursor;

(II) NO_x as an ozone precursor, unless the Administrator determines that additional reductions of NO_x would not contribute to attainment;

(III) CO;

(IV) PM₁₀ (and its precursors VOC and/or NO_x if the applicable implementation plan or implementation plan submission identifies transportation-related precursor emissions within the nonattainment area as a significant contributor to the PM₁₀ nonattainment problem or establishes a budget for such emissions); or

(V) NO_x (in NO₂ nonattainment or maintenance areas);

(B) The regional emissions analysis shall estimate emissions from the entire transportation system, including all regionally significant projects contained in the transportation plan and all other regionally significant highway and transit projects expected in the nonattainment or maintenance area in the time frame of the transportation plan;

(C) The emissions analysis methodology shall meet the requirements of Chapter 8, Section 4(dd);

(D) For areas with a transportation plan that meets the content requirements of Chapter 8, Section 4(f)(i), the emissions analysis shall be performed for each horizon year. Emissions in milestone years which are between the horizon years may be determined by interpolation; and

(E) For areas with a transportation plan that does not meet the content requirements of Chapter 8, Section 4(f)(i), the emissions analysis shall be performed for any years in the time span of the transportation plan provided they are not more than ten years apart and provided the analysis is performed for the last year of the plan's forecast period. If the attainment year is in the time span of the transportation plan, the emissions analysis must also be performed for the attainment year. Emissions in milestone years which are between these analysis years may be determined by interpolation.

(iii) The regional emissions analysis shall demonstrate that for each of the applicable pollutants or pollutant precursors in paragraph (ii)(A) of this section the emissions are less than or equal to the motor vehicle emissions budget as established in the applicable implementation plan or implementation plan submission as follows:

(A) If the applicable implementation plan or implementation plans submission establishes emissions budgets for milestone years, emissions in each milestone year are less than or equal to the motor vehicle emissions budget established for that year;

(B) For nonattainment areas, emissions in the attainment year are less than or equal to the motor vehicle emissions budget established in the applicable implementation plan or implementation plan submission for that year;

(C) For nonattainment areas, emissions in each analysis or horizon year after the attainment year are less than or equal to the motor vehicle emissions budget established by the applicable implementation plan or implementation plan submission for the attainment year. If emissions budgets are established for years after the attainment year, emission in each analysis year or horizon year must be less than or equal to the motor vehicle emissions budget for that year, if any, or the motor vehicle emissions budget for the most recent budget year prior to the analysis year or horizon year; and

(D) For maintenance areas, emissions in each analysis or horizon year are less than or equal to the motor vehicle emissions budget established by the maintenance plan for that year, if any, or the emissions budget for the most recent budget year prior to the analysis or horizon year.

(s) Criteria and Procedures: Motor Vehicle Emissions Budget (TIP)

(i) The TIP must be consistent with the motor vehicle emissions budget(s) in the applicable implementation plan (or implementation plan submission). This criterion applies during the transitional period and the control strategy and maintenance

periods, except as provided in Chapter 8, Section 4(jj). This criterion may be satisfied if the requirements in paragraphs (ii) and (iii) of this section are met:

(ii) For areas with a conforming transportation plan that fully meets the content requirements of Chapter 8, Section 4(f)(i), this criterion may be satisfied without additional regional analysis if:

(A) Each program year of the TIP is consistent with the Federal funding which may be reasonably expected for that year, and required State/local matching funds and funds for State/local funding-only projects are consistent with the revenue sources expected over the same period; and

(B) The TIP is consistent with the conforming transportation plan such that the regional emissions analysis already performed for the plan applies to the TIP also. This requires a demonstration that:

(I) The TIP contains all projects which must be started in the TIP's time frame in order to achieve the highway and transit system envisioned by the transportation plan in each of its horizon years;

(II) All TIP projects which are regionally significant are part of the specific highway or transit system envisioned in the transportation plan's horizon years; and

(III) The design concept and scope of each regionally significant project in the TIP is not significantly different from that described in the transportation plan.

(C) If the requirements in paragraphs (ii)(A) and (ii)(B) of this section are not met, then:

(I) The TIP may be modified to meet those requirements;

or

(II) The transportation plan must be revised so that the requirements in paragraphs (ii)(A) and (ii)(B) of this section are met. Once the revised plan has been found to conform, this criterion is met for the TIP with no additional analysis except a demonstration that the TIP meets the requirements of paragraphs (ii)(A) and (ii)(B) of this section.

(iii) For areas with a transportation plan that does not meet the content requirements of Chapter 8, Section 4(f)(i), a regional emissions analysis must meet all of the following requirements:

(A) The regional emissions analysis shall estimate emissions from the entire transportation system, including all projects contained in the proposed TIP, the

transportation plan, and all other regionally significant highway and transit projects expected in the nonattainment or maintenance area in the time frame of the transportation plan;

(B) The analysis methodology shall meet the requirements of Chapter 8, Section 4(dd)(iii); and

(C) The regional analysis shall satisfy the requirements of Chapter 8, Sections 4(r)(ii)(A), (r)(ii)(E), and (r)(iii).

(t) Criteria and Procedures: Motor Vehicle Emissions Budget (Project Not From a Plan and TIP).

(i) The project which is not from a conforming transportation plan and a conforming TIP must be consistent with the motor vehicle emissions budget(s) in the applicable implementation plan (or implementation plan submission). This criterion applies during the transitional period and the control strategy and maintenance periods, except as provided in Chapter 8, Section 4(jj). It is satisfied if emissions from the implementation of the project, when considered with the emissions from the projects in the conforming transportation plan and TIP and all other regionally significant projects expected in the area, do not exceed the motor vehicle emissions budget(s) in the applicable implementation plan (or implementation plan submission).

(ii) For areas with a conforming transportation plan that meets the content requirements of Chapter 8, Section 4(f)(i):

(A) This criterion may be satisfied without additional regional analysis if the project is included in the conforming transportation plan, even if it is not specifically included in the latest conforming TIP. This requires a demonstration that:

(I) Allocating funds to the project will not delay the implementation of projects in the transportation plan or TIP which are necessary to achieve the highway and transit system envisioned by the transportation plan in each of its horizon years;

(II) The project is not regionally significant or is part of the specific highway or transit system envisioned in the transportation plan's horizon years; and

(III) The design concept and scope of the project is not significantly different from that described in the transportation plan.

(B) If the requirements in paragraph (ii)(A) of this section are not met, a regional emissions analysis must be performed as follows:

(I) The analysis methodology shall meet the requirements of Chapter 8, Section 4(ee);

(II) The analysis shall estimate emissions from the transportation system, including the proposed project and all other regionally significant projects expected in the nonattainment or maintenance area in the time frame of the transportation plan. The analysis must include emissions from all previously approved projects which were not from a transportation plan and TIP; and

(III) The emissions analysis shall meet the requirements of Chapter 8, Sections 4(r)(ii)(A), (r)(ii)(D), and (r)(iii).

(iii) For areas with a transportation plan that does not meet the content requirements of Chapter 8, Section 4(f)(i), a regional emissions analysis must be performed for the project together with the conforming TIP and all other regionally significant projects expected in the nonattainment or maintenance area. This criterion may be satisfied if:

(A) The analysis methodology meets the requirements of Chapter 8, Section 4(dd)(iii);

(B) The analysis estimates emissions from the transportation system, including the proposed project, and all other regionally significant projects expected in the nonattainment or maintenance area in the time frame of the transportation plan; and

(C) The regional analysis satisfies the requirements of Chapter 8, Sections 4(r)(ii)(A), (r)(ii)(E), and (r)(iii).

(u) Criteria and Procedures: Localized CO Violations (Hot Spots) in the Interim Period.

(i) Each FHWA/FTA project must eliminate or reduce the severity and number of localized CO violations in the area substantially affected by the project (in CO nonattainment areas). This criterion applies during the interim and transitional periods only. This criterion is satisfied with respect to existing localized CO violations if it is demonstrated that existing localized CO violations will be eliminated or reduced in severity and number as a result of the project.

(ii) The demonstration must be performed according to the requirements of Chapter 8, Sections 4(e) and (ee).

(iii) For projects which are not of the type identified by Chapter 8, Section 4(ee)(i), this criterion may be satisfied if consideration of local factors clearly demonstrates that existing CO violations will be eliminated or reduced in severity and

number. Otherwise, a quantitative demonstration must be performed according to the requirements of Chapter 8, Section 4(ee)(ii).

(v) Criteria and Procedures: Interim Period Reductions in Ozone and CO Areas (Transportation Plan).

(i) A transportation plan must contribute to emissions reductions in ozone and CO Nonattainment areas. This criterion applies during the interim and transitional periods only, except as otherwise provided in Chapter 8, Section 4(jj). It applies to the net effect on emissions of all projects contained in a new or revised transportation plan. This criterion may be satisfied if a regional emissions analysis is performed as described in paragraphs (ii) through (vi) of this section.

(ii) Determine the analysis years for which emissions are to be estimated. Analysis years shall be no more than ten years apart. The first analysis year shall be no later than the first milestone year (1995 in CO nonattainment areas and 1996 in ozone nonattainment areas). The second analysis year shall be either the attainment year for the area, or if the attainment year is the same as the first analysis year or earlier, the second analysis year shall be at least five years beyond the first analysis year. The last year of the transportation plan's forecast period shall also be an analysis year.

(iii) Define the 'Baseline' scenario for each of the analysis years to be the future transportation system that would result from current programs, composed of the following (except that projects listed in Chapter 8, Sections 4(hh) and (ii) need not be explicitly considered):

(A) All in-place regionally significant highway and transit facilities, services and activities;

(B) All ongoing travel demand management or transportation system management activities; and

(C) Completion of all regionally significant projects, regardless of funding source, which are currently under construction or are undergoing right-of-way acquisition (except for hardship acquisition and protective buying); come from the first three years of the previously conforming transportation plan and/or TIP; or have completed the NEPA process. (For the first conformity determination on the transportation plan after November 24, 1993, a project may not be included in the 'Baseline' scenario if one of the following major steps has not occurred within the past three years: NEPA process completion; start of final design; acquisition of a significant portion of the right-of-way; or approval of the plans, specifications and estimates. Such a project must be included in the 'Action' scenario, as described in paragraph (iv) of this section.)

(iv) Define the 'Action' scenario for each of the analysis years as the transportation system that will result in that year from the implementation of the

proposed transportation plan, TIPs adopted under it, and other expected regionally significant projects in the nonattainment area. It will include the following (except that projects listed in Chapter 8, Sections 4(hh) and (ii) need not be explicitly considered):

(A) All facilities, services, and activities in the ‘Baseline’ scenario;

(B) Completion of all TCMs and regionally significant projects (including facilities, services, and activities) specifically identified in the proposed transportation plan which will be operational or in effect in the analysis year, except that regulatory TCMs may not be assumed to begin at a future time unless the regulation is already adopted by the enforcing jurisdiction or the TCM is identified in the applicable implementation plan;

(C) All travel demand management programs and transportation system management activities known to the MPO, but not included in the applicable implementation plan or utilizing any Federal funding or approval, which have been fully adopted and/or funded by the enforcing jurisdiction or sponsoring agency since the last conformity determination on the transportation plan;

(D) The incremental effects of any travel demand management programs and transportation system management activities known to the MPO, but not included in the applicable implementation plan or utilizing any Federal funding or approval, which were adopted and/or funded prior to the date of the last conformity determination on the transportation plan, but which have been modified since then to be more stringent or effective;

(E) Completion of all expected regionally significant highway and transit projects which are not from a conforming transportation plan and TIP; and

(F) Completion of all expected regionally significant non-FHWA/FTA highway and transit projects that have clear funding sources and commitments leading toward their implementation and completion by the analysis year.

(v) Estimate the emissions predicted to result in each analysis year from travel on the transportation systems defined by the ‘Baseline’ and ‘Action’ scenarios and determine the difference in regional VOC and NO_x emissions (unless the Administrator determines that additional reductions of NO_x would not contribute to attainment) between the two scenarios for CO nonattainment areas. The analysis must be performed for each of the analysis years according to the requirements of Chapter 8, Section 4(dd). Emissions in milestone years which are between the analysis years may be determined by interpolation.

(vi) This criterion is met if the regional VOC and NO_x emissions (for ozone nonattainment areas) and CO emissions (for CO nonattainment areas) predicted in the ‘Action’ scenario are less than the emissions predicted from the ‘Baseline’ scenario in

each analysis year, and if this can reasonably be expected to be true in the periods between the first milestone year and the analysis years. The regional analysis must show that the 'Action' scenario contributes to a reduction in emissions from the 1990 emissions by any non-zero amount.

(w) Criteria and Procedures: Interim Period Reductions in Ozone and CO Areas (TIP).

(i) A TIP must contribute to emissions reductions in ozone and CO nonattainment areas. This criterion applies during the interim and transitional periods only, except as otherwise provided in Chapter 8, Section 4(jj). It applies to the net effect on emissions of all projects contained in a new or revised TIP. This criterion may be satisfied if a regional emissions analysis is performed as described in paragraphs (ii) through (vi) of this section.

(ii) Determine the analysis years for which emissions are to be estimated. The first analysis year shall be no later than the first milestone year (1995 in CO nonattainment areas and 1996 in ozone nonattainment areas). The analysis years shall be no more than ten years apart. The second analysis year shall be either the attainment year for the area, or if the attainment year is the same as the first analysis year or earlier, the second analysis year shall be at least five years beyond the first analysis year. The last year of the transportation plan's forecast period shall also be an analysis year.

(iii) Define the 'Baseline' scenario as the future transportation system that would result from current programs, composed of the following (except that projects listed in Chapter 8, Sections 4(hh) and (ii) need not be explicitly considered):

(A) All in-place regionally significant highway and transit facilities, services and activities;

(B) All ongoing travel demand management or transportation system management activities; and

(C) Completion of all regionally significant projects, regardless of funding source, which are currently under construction or are undergoing right-of-way acquisition (except for hardship acquisition and protective buying); come from the first three years of the previously conforming TIP; or have completed the NEPA process. (For the first conformity determination on the TIP after (November 24, 1993), a project may not be included in the 'Baseline' scenario if one of the following major steps has not occurred within the past three years: NEPA process completion; start of final design; acquisition of a significant portion of the right-of-way; or approval of the plans, specifications and estimates. Such a project must be included in the 'Action' scenario, as described in paragraph (d) of this section.)

(iv) Define the 'Action' scenario as the future transportation system that will result from the implementation of the proposed TIP and other expected regionally

significant projects in the nonattainment area in the time frame of the transportation plan. It will include the following (except that projects listed in Chapter 8, Sections 4(hh) and (ii) need not be explicitly considered):

(A) All facilities, services, and activities in the ‘Baseline’ scenario;

(B) Completion of all TCMs and regionally significant projects (including facilities, services, and activities) included in the proposed TIP, except that regulatory TCMs may not be assumed to begin at a future time unless the regulation is already adopted by the enforcing jurisdiction or the TCM is contained in the applicable implementation plan;

(C) All travel demand management programs and transportation system management activities known to the MPO, but not included in the applicable implementation plan or utilizing any Federal funding or approval, which have been fully adopted and/or funded by the enforcing jurisdiction or sponsoring agency since the last conformity determination on the TIP;

(D) The incremental effects of any travel demand management programs and transportation system management activities known to the MPO, but not included in the applicable implementation plan or utilizing any Federal funding or approval, which were adopted and/or funded prior to the date of the last conformity determination on the TIP, but which have been modified since then to be more stringent or effective;

(E) Completion of all expected regionally significant highway and transit projects which are not from a conforming transportation plan and TIP; and

(F) Completion of all expected regionally significant non-FHWA/FTA highway and transit projects that have clear funding sources and commitments leading toward their implementation and completion by the analysis year.

(v) Estimate the emissions predicted to result in each analysis year from travel on the transportation systems defined by the ‘Baseline’ and ‘Action’ scenarios, and determine the difference in regional VOC and NO_x emissions (unless the Administrator determines that additional reductions of NO_x would not contribute to attainment) between the two scenarios for ozone nonattainment areas and the difference in CO emissions between the two scenarios for CO nonattainment areas. The analysis must be performed for each of the analysis years according to the requirements of Chapter 8, Section 4(dd). Emissions in milestone years which are between analysis years may be determined by interpolation.

(vi) This criterion is met if the regional VOC and NO_x emissions in ozone nonattainment areas and CO emissions in CO nonattainment areas predicted in the ‘Action’ scenario are less than the emissions predicted from the ‘Baseline’ scenario in

each analysis year, and if this can reasonably be expected to be true in the period between the analysis years. The regional analysis must show that the 'Action' scenario contributes to a reduction in emissions from the 1990 emissions by any non-zero amount.

(x) Criteria and Procedures: Interim Period Reductions for Ozone and CO Areas (Project Not From a Plan and TIP). A transportation project which is not from a conforming transportation plan and TIP must contribute to emissions reductions in ozone and CO nonattainment areas. This criterion applies during the interim and transitional periods only, except as otherwise provided in Chapter 8, Section 4(jj). This criterion is satisfied if a regional emissions analysis is performed which meets the requirements of Chapter 8, Section 4(v) and which includes the transportation plan and project in the 'Action' scenario. If the project which is not from a conforming transportation plan and TIP is a modification of a project currently in the plan or TIP, the 'Baseline' scenario must include the project with its original design concept and scope, and the 'Action' scenario must include the project with its new design concept and scope.

(y) Criteria and Procedures: Interim Period Reductions for PM₁₀ and NO₂ Areas (Transportation Plan).

(i) A transportation plan must contribute to emission reductions or must not increase emissions in PM₁₀ and NO₂ nonattainment areas. This criterion applies only during the interim and transitional periods. It applies to the net effect on emissions of all projects contained in a new or revised transportation plan. This criterion may be satisfied if the requirements of either paragraph (ii) or (iii) of this section are met.

(ii) Demonstrate that implementation of the plan and all other regionally significant projects expected in the nonattainment area will contribute to reductions in emissions of PM₁₀ in a PM₁₀ nonattainment area (and of each transportation-related precursor of PM₁₀ in PM₁₀ nonattainment areas if the EPA Regional Administrator or the Director of the State air agency has made a finding that such precursor emissions from within the nonattainment area are a significant contributor to the PM₁₀ nonattainment problem and has so notified the MPO and DOT) and of NO_x in an NO₂ nonattainment area, by performing a regional emissions analysis as follows:

(A) Determine the analysis years for which emissions are to be estimated. Analysis years shall be no more than ten years apart. The first analysis year shall be no later than 1996 (for NO₂ areas) or four years and six months following the date of designation (for PM₁₀ areas). The second analysis year shall be either the attainment year for the area, or if the attainment year is the same as the first analysis year or earlier, the second analysis year shall be at least five years beyond the first analysis year. The last year of the transportation plan's forecast period shall also be an analysis year.

(B) Define for each of the analysis years the 'Baseline' scenario, as defined in Chapter 8, Section 4(v)(iii), and the 'Action' scenario, as defined in Chapter 8, Section 4(v)(iv).

(C) Estimate the emissions predicted to result in each analysis year from travel on the transportation systems defined by the 'Baseline' and 'Action' scenarios and determine the difference between the two scenarios in regional PM₁₀ emissions in a PM₁₀ nonattainment area (and transportation-related precursors of PM₁₀ in PM₁₀ nonattainment areas if the EPA Regional Administrator or the Director of the State air agency has made a finding that such precursor emissions from within the nonattainment area are a significant contributor to the PM₁₀ nonattainment problem and has so notified the MPO and DOT) and in NO_x emissions in an NO₂ nonattainment area. The analysis must be performed for each of the analysis years according to the requirements of Chapter 8, Section 4(dd). The analysis must address the periods between the analysis years and the periods between 1990, the first milestone year (if any), and the first of the analysis years. Emissions in milestone years which are between the analysis years may be determined by interpolation.

(D) Demonstrate that the regional PM₁₀ emissions and PM₁₀ precursor emissions, where applicable, (for PM₁₀ nonattainment areas) and NO_x emissions (for NO₂ nonattainment areas) predicted in the 'Action' scenario are less than the emissions predicted from the 'Baseline' scenario in each analysis year, and that this can reasonably be expected to be true in the periods between the first milestone year (if any) and the analysis years.

(iii) Demonstrate that when the projects in the transportation plan and all other regionally significant projects expected in the nonattainment area are implemented, the transportation system's total highway and transit emissions of PM₁₀ in a PM₁₀ nonattainment area (and transportation-related precursors of PM₁₀ in PM₁₀ nonattainment areas if the EPA regional Administrator or the Director of the State air agency has made a finding that such precursor emissions from within the nonattainment area are a significant contributor to the PM₁₀ nonattainment problem and has so notified the MPO and DOT) and of NO_x in an NO₂ nonattainment area will not be greater than baseline levels, by performing a regional emissions analysis as follows:

(A) Determine the baseline regional emissions of PM₁₀ and PM₁₀ precursors, where applicable (for PM₁₀ nonattainment areas) and NO_x (for NO₂ nonattainment areas) from highway and transit sources. Baseline emissions are those estimated to have occurred during calendar year 1990, unless the implementation plan revision required by 40 CFR part 51, Subpart T defines the baseline emissions for a PM₁₀ area to be those occurring in a different calendar year for which a baseline emissions inventory was developed for the purpose of developing a control strategy implementation plan.

(B) Estimate the emissions of the applicable pollutant(s) from the entire transportation system, including projects in the transportation plan and TIP and all other regionally significant projects in the nonattainment area, according to the requirements of Chapter 8, Section 4(dd). Emissions shall be estimated for analysis years which are no more than ten years apart. The first analysis year shall be no later than 1996

(for NO₂ areas) or four years and six months following the date of designation (for PM₁₀ areas). The second analysis year shall be either the attainment year for the area, or if the attainment year is the same as the first analysis year or earlier, the second analysis year shall be at least five years beyond the first analysis year. The last year of the transportation plan's forecast period shall also be an analysis year.

(C) Demonstrate that for each analysis year the emissions estimated in paragraph (iii)(B) of this section are no greater than baseline emissions of PM₁₀ and PM₁₀ precursors, where applicable (for PM₁₀ nonattainment areas) or NO_x (for NO₂ nonattainment areas) from highway and transit sources.

(z) Criteria and Procedures: Interim Period Reductions for PM₁₀ and NO₂ Areas (TIP).

(i) A TIP must contribute to emission reductions or must not increase emissions in PM₁₀ and NO₂ nonattainment areas. This criterion applies only during the interim and transitional periods. It applies to the net effect on emission of all projects contained in a new or revised TIP. This criterion may be satisfied if the requirements of either paragraph (ii) or paragraph (iii) of this section are met.

(ii) Demonstrate that implementation of the plan and TIP and all other regionally significant projects expected in the nonattainment area will contribute to reductions in emissions of PM₁₀ in a PM₁₀ nonattainment area (and transportation-related precursors of PM₁₀ in PM₁₀ nonattainment areas if the EPA Regional Administrator or the Director of the State air agency has made a finding that such precursor emissions from within the nonattainment area are a significant contributor to the PM₁₀ nonattainment problem and has so notified the MPO and DOT) and of NO_x in an NO₂ nonattainment area, by performing a regional emissions analysis as follows:

(A) Determine the analysis years for which emissions are to be estimated, according to the requirements of Chapter 8, Section 4(y)(ii)(A).

(B) Define for each of the analysis years the 'Baseline' scenario, as defined in Chapter 8, Section 4(w)(iii), and the 'Action' scenario, as defined in Chapter 8, Section 4(w)(iv).

(C) Estimate the emissions predicted to result in each analysis year from travel on the transportation systems defined by the 'Baseline' and 'Action' scenarios as required by Chapter 8, Section 4(y)(ii)(C), and make the demonstration required by Chapter 8, Section 4(y)(ii)(D).

(iii) Demonstrate that when the projects in the transportation plan and TIP and all other regionally significant projects expected in the area are implemented, the transportation system's total highway and transit emissions of PM₁₀ in a PM₁₀ nonattainment area (and transportation-related precursors of PM₁₀ in PM₁₀ nonattainment areas if the EPA Regional Administrator or the Director of the State air agency has made

a finding that such precursor emissions from within the nonattainment area are a significant contributor to the PM₁₀ nonattainment problem and has so notified the MPO and DOT) and of NO_x in an NO₂ nonattainment area will not be greater than baseline levels, by performing a regional emissions analysis as required by Chapter 8, Sections 4(y)(iii)(A)-(C).

(aa) Criteria and Procedures: Interim Period Reductions for PM₁₀ and NO₂ Areas (Project Not From a Plan and TIP). A transportation project which is not from a conforming transportation plan and TIP must contribute to emission reductions or must not increase emissions in PM₁₀ and NO₂ nonattainment areas. This criterion applies during the interim and transitional periods only. This criterion is met if a regional emissions analysis is performed which meets the requirements of Chapter 8, Section 4(y) and which includes the transportation plan and project in the 'Action' scenario. If the project which is not from a conforming transportation plan and TIP is a modification of a project currently in the transportation plan or TIP, and Chapter 8, Section 4(y)(ii) is used to demonstrate satisfaction of this criterion, the 'Baseline' scenario must include the project with its original design concept and scope, and the 'Action' scenario must include the project with its new design concept and scope.

(bb) Transition From the Interim Period to the Control Strategy Period.

(i) Areas Which Submit a Control Strategy Implementation Plan Revision After November 24, 1993.

(A) The transportation plan and TIP must be demonstrated to conform according to transitional period criteria and procedures by one year from the date the Clean Air Act requires submission of such control strategy implementation plan revision. Otherwise, the conformity status of the transportation plan and TIP will lapse, and no new project-level conformity determinations may be made.

(I) The conformity of new transportation plans and TIPs may be demonstrated according to Phase II interim period criteria and procedures for 90 days following submission of the control strategy implementation plan revision, provided the conformity of such transportation plans and TIPs is redetermined according to transitional period criteria and procedures as required in paragraph (i)(A) of this section.

(II) Beginning 90 days after submission of the control strategy implementation plan revision, new transportation plans and TIPs shall demonstrate conformity according to transitional period criteria and procedures.

(B) If EPA disapproves the submitted control strategy implementation plan revision and so notifies the State, MPO, and DOT, which initiates the sanction process under Clean Air Act sections 179 or 110(m), the conformity status of the transportation plan and TIP shall lapse 120 days after EPA's disapproval, and no new project-level conformity determinations may be made. No new transportation plan, TIP, or project may be found to conform until another control strategy implementation plan

revision is submitted and conformity is demonstrated according to transitional period criteria and procedures.

(C) Notwithstanding paragraph (i)(B) of this section, if EPA disapproves the submitted control strategy implementation plan revision but determines that the control strategy contained in the revision would have been considered approvable with respect to requirements for emission reductions if all committed measures had been submitted in enforceable form as required by Clean Air Act §110(a)(2)(A), the provisions of paragraph (i)(A) of this section shall apply for 12 months following the date of disapproval. The conformity status of the transportation plan and TIP shall lapse 12 months following the date of disapproval unless another control strategy implementation plan revision is submitted to EPA and found to be complete.

(ii) Areas Which Have Not Submitted a Control Strategy Implementation Plan Revision.

(A) For areas whose Clean Air Act deadline for submission of the control strategy implementation plan revision is after November 24, 1993 and EPA has notified the State, MPO, and DOT of the State's failure to submit a control strategy implementation plan revision, which initiates the sanction process under Clean Air Act sections 179 or 110(m):

(I) No new transportation plans or TIPs may be found to conform beginning 120 days after the Clean Air Act deadline; and

(II) The conformity status of the transportation plan and TIP shall lapse one year after the Clean Air Act deadline, and no new project-level conformity determinations may be made.

(B) For areas whose Clean Air Act deadline for submission of the control strategy implementation plan was before November 24, 1993 and EPA has made a finding of failure to submit a control strategy implementation plan revision, which initiates the sanction process under Clean Air Act sections 179 or 110(m), the following apply unless the failure has been remedied and acknowledged by a letter from the EPA Regional Administrator:

(I) No new transportation plans or TIPs may be found to conform beginning March 24, 1994; and

(II) The conformity status of the transportation plan and TIP shall lapse November 25, 1994, and no new project-level conformity determinations may be made.

(III) Notwithstanding paragraphs (iii)(B)(I) and (II) of this section, if EPA notes in its incompleteness finding that the submittal would have been considered complete with respect to requirements for emission reductions if all

committed measures had been submitted in enforceable form as required by Clean Air Act §110(a)(2)(A), the provisions of paragraph (iv)(A) of this section shall apply for a period of 12 months following the date of the incompleteness determination. The conformity status of the transportation plan and TIP shall lapse 12 months following the date of the incompleteness determination unless another control strategy implementation plan revision is submitted to EPA and found to be complete.

(iv) Areas Which Submitted a Control Strategy Implementation Plan Before November 24, 1993.

(A) The transportation plan and TIP must be demonstrated to conform according to transitional period criteria and procedures by November 25, 1994. Otherwise, their conformity status will lapse, and no new project-level conformity determinations may be made.

(I) The conformity of new transportation plans and TIPs may be demonstrated according to Phase II interim period criteria and procedures until February 22, 1994, provided the conformity of such transportation plans and TIPs is redetermined according to transitional period criteria and procedures as required in paragraph (iv)(A) of this section.

(II) Beginning February 22, 1994, new transportation plans and TIPs shall demonstrate conformity according to transitional period criteria and procedures.

(B) If EPA has disapproved the most recent control strategy implementation plan submission, the conformity status of the transportation plan and TIP shall lapse March 24, 1994, and no new project-level conformity determinations may be made. No new transportation plans, TIPs, or projects may be found to conform until another control strategy implementation plan revision is submitted and conformity is demonstrated according to transitional period criteria and procedures.

(C) Notwithstanding paragraph (iv)(B) of this section, if EPA has disapproved the submitted control strategy implementation plan revision but determines that the control strategy contained in the revision would have been considered approvable with respect to requirements for emission reductions if all committed measures had been submitted in enforceable form as required by Clean Air Act §110(a)(2)(A), the provisions of paragraph (iv)(A) of this section shall apply for 12 months following November 24, 1993. The conformity status of the transportation plan and TIP shall lapse 12 months following November 24, 1993 unless another control strategy implementation plan revision is submitted to EPA and found to be complete.

(v) Projects. If the currently conforming transportation plan and TIP have not been demonstrated to conform according to transitional period criteria and procedures, the requirements of paragraphs (v)(A) and (B) of this section must be met.

(A) Before a FHWA/FTA project which is regionally significant and increases single-occupant vehicle capacity (a new general purpose highway on a new location or adding general purpose lanes) may be found to conform, the State air agency must be consulted on how the emissions which the existing transportation plan and TIPs conformity determination estimates for the 'Action' scenario (as required by Chapter 8, Sections 4(v)-(aa)) compare to the motor vehicle emissions budget in the implementation plan submission or the projected motor vehicle emissions budget in the implementation plan under development.

(B) In the event of unresolved disputes on such project-level conformity determinations, the State air agency may escalate the issue to the Governor consistent with the procedure in Chapter 8, Section 4(e), which applies for any State air agency comments on a conformity determination.

(vi) Redetermination of Conformity of the Existing Transportation Plan and TIP According to the Transitional Period Criteria and Procedures.

(A) The redetermination of the conformity of the existing transportation plan and TIP according to transitional period criteria and procedures (as required by paragraphs (i)(A) and (iv)(A) of this section) does not require new emissions analysis and does not have to satisfy the requirements of Chapter 8, Sections 4(j) and (k) if:

(I) The control strategy implementation plan revision submitted to EPA uses the MPO's modeling of the existing transportation plan and TIP for its projections of motor vehicle emissions; and

(II) The control strategy implementation plan does not include any transportation projects which are not included in the transportation plan and TIP.

(B) A redetermination of conformity as described in paragraph (vi)(A) of this section is not considered a conformity determination for the purposes of Chapter 8, Sections 4(d)(ii)(D) or (d)(iii)(D) regarding the maximum intervals between conformity determinations. Conformity must be determined according to all the applicable criteria and procedures of Chapter 8, Section 4(i) within three years of the last determination which did not rely on paragraph (vi)(A) of this section.

(vii) Ozone Nonattainment Areas.

(A) The requirements of paragraph (ii)(A) of this section apply if a serious or above ozone nonattainment area has not submitted the implementation plan revisions which Clean Air Act §§182(c)(2)(A) and 182(c)(2)(B) require to be submitted to EPA November 15, 1994, even if the area has submitted the implementation plan revision which Clean Air Act §182(b)(1) requires to be submitted to EPA November 15, 1993.

(B) The requirements of paragraph (ii)(A) of this section apply if a moderate ozone nonattainment area which is using photochemical dispersion modeling to demonstrate the “specific annual reductions as necessary to attain” required by Clean Air Act §182(b)(1), and which has permission from EPA to delay submission of such demonstration until November 15, 1994, does not submit such demonstration by that date. The requirements of paragraph (ii)(A) of this section apply in this case even if the area has submitted the 15% emission reduction demonstration required by Clean Air Act §182(b)(1).

(C) The requirements of paragraph (i) of this section apply when the implementation plan revisions required by Clean Air Act §§182(c)(2)(A) and 182(c)(2)(B) are submitted.

(viii) Nonattainment Areas Which Are Not Required to Demonstrate Reasonable Further Progress and Attainment. If an area listed in Chapter 8, Section 4(jj) submits a control strategy implementation plan revision, the requirements of paragraphs (i) and (v) of this section apply. Because the areas listed in Chapter 8, Section 4(jj) are not required to demonstrate reasonable further progress and attainment and therefore have no Clean Air Act deadline, the provisions of paragraph (ii) of this section do not apply to these areas at any time.

(ix) Maintenance Plans. If a control strategy implementation plan revision is not submitted to EPA but a maintenance plan required by Clean Air Act §175 is submitted to EPA, the requirements of paragraphs (i) or (iv) of this section apply, with the maintenance plan submission treated as a “control strategy implementation plan revision” for the purposes of those requirements.

(cc) Requirements for Adoption or Approval of Projects By Recipients of Funds Designated Under Title 23 U.S.C. or the Federal Transit Act. No recipient of Federal funds designated under Title 23 U.S.C. or the Federal Transit Act shall adopt or approve a regionally significant highway or transit project, regardless of funding source, unless there is a currently conforming transportation plan and TIP consistent with the requirements of Chapter 8, Section 4(n) and the requirements of one of the following paragraphs (i) through (v) are met:

(i) The project comes from a conforming plan and program consistent with the requirements of Chapter 8, Section 4(o);

(ii) The project is included in the regional emissions analysis supporting the currently conforming TIPs conformity determination, even if the project is not strictly “included” in the TIP for the purposes of MPO project selection or endorsement, and the project’s design concept and scope have not changed significantly from those which were included in the regional emissions analysis, or in a manner which would significantly impact use of the facility;

(iii) During the control strategy or maintenance period, the project is consistent with the motor vehicle emissions budget(s) in the applicable implementation plan consistent with the requirements of Chapter 8, Section 4(t);

(iv) During Phase II of the interim period, the project contributes to emissions reductions or does not increase emissions consistent with the requirements of Chapter 8, Section 4(x) (in ozone and CO nonattainment areas) or Chapter 8, Section 4(aa) (in PM₁₀ and NO₂ nonattainment areas); or

(v) During the transitional period, the project satisfies the requirements of both paragraphs (iii) and (iv) of this section.

(dd) Procedures for Determining Regional Transportation-Related Emissions.

(i) General Requirements.

(A) The regional emissions analysis for the transportation plan, TIP, or project not from a conforming plan and TIP shall include all regionally significant projects expected in the nonattainment or maintenance area, including FHWA/FTA projects proposed in the transportation plan and TIP and all other regionally significant projects which are disclosed to the MPO as required by Chapter 8, Section 4(e). Projects which are not regionally significant are not required to be explicitly modeled, but VMT from such projects must be estimated in accordance with reasonable professional practice. The effects of TCMs and similar projects that are not regionally significant may also be estimated in accordance with reasonable professional practice.

(B) The emissions analysis may not include for emissions reduction credit any TCMs which have been delayed beyond the scheduled date(s) until such time as implementation has been assured. If the TCM has been partially implemented and it can be demonstrated that it is providing quantifiable emission reduction benefits, the emissions analysis may include that emissions reduction credit.

(C) Emissions reduction credit from projects, programs, or activities which require a regulation in order to be implemented may not be included in the emissions analysis unless the regulation is already adopted by the enforcing jurisdiction. Adopted regulations are required for demand management strategies for reducing emissions which are not specifically identified in the applicable implementation plan, and for control programs which are external to the transportation system itself, such as tailpipe or evaporative emission standards, limits on gasoline volatility, inspection and maintenance programs, and oxygenated or reformulated gasoline or diesel fuel. A regulatory program may also be considered to be adopted if an opt-in to a Federally enforced program has been approved by EPA, if EPA has promulgated the program (if the control program is a Federal responsibility, such as tailpipe standards), or if the Clean Air Act requires the program without need for individual State action and without any discretionary authority for EPA to set its stringency, delay its effective date, or not implement the program.

(D) Notwithstanding paragraph (i)(C) of this section, during the transitional period, control measures or programs which are committed to in an implementation plan submission as described in Chapter 8, Sections 4(r)-(t), but which has not received final EPA action in the form of a finding of incompleteness, approval, or disapproval may be assumed for emission reduction credit for the purpose of demonstrating that the requirements of Chapter 8, Sections 4(r)-(t) are satisfied.

(E) A regional emissions analysis for the purpose of satisfying the requirements of Chapter 8, Sections 4(v)-(x) may account for the programs in paragraph (i)(D) of this section, but the same assumptions about these programs shall be used for both the 'Baseline' and 'Action' scenarios.

(ii) Serious, Severe, and Extreme Ozone Nonattainment Areas and Serious Carbon Monoxide Areas After January 1, 1995. Estimates of regional transportation-related emissions used to support conformity determinations must be made according to procedures which meet the requirements in paragraphs (ii)(A) through (E) of this section.

(A) A network-based transportation demand model or models relating travel demand and transportation system performance to land-use patterns, population demographics, employment, transportation infrastructure, and transportation policies must be used to estimate travel within the metropolitan planning area of the nonattainment area. Such a model shall possess the following attributes:

(I) The modeling methods and the functional relationships used in the model(s) shall in all respects be in accordance with acceptable professional practice, and reasonable for purposes of emission estimation;

(II) The network-based model(s) must be validated against ground counts for a base year that is not more than 10 years prior to the date of the conformity determination. Land use, population, and other inputs must be based on the best available information and appropriate to the validation base year;

(III) For peak-hour or peak-period traffic assignments, a capacity sensitive assignment methodology must be used;

(IV) Zone-to-zone travel times used to distribute trips between origin and destination pairs must be in reasonable agreement with the travel times which result from the process of assignment of trips to network links. Where use of transit currently is anticipated to be a significant factor in satisfying transportation demand, these times should also be used for modeling mode splits;

(V) Free-flow speeds on network links shall be based on empirical observations;

(VI) Peak and off-peak travel demand and travel times must be provided;

(VII) Trip distribution and mode choice must be sensitive to pricing, where pricing is a significant factor, if the network model is capable of such determinations and the necessary information is available;

(VIII) The model(s) must utilize and document a logical correspondence between the assumed scenario of land development and use and the future transportation system for which emissions are being estimated. Reliance on a formal land-use model is not specifically required but is encouraged;

(IX) A dependence of trip generation on the accessibility of destinations via the transportation system (including pricing) is strongly encouraged but not specifically required, unless the network model is capable of such determinations and the necessary information is available;

(X) A dependence of regional economic and population growth on the accessibility of destinations via the transportation system is strongly encouraged but not specifically required, unless the network model is capable of such determinations and the necessary information is available; and

(XI) Consideration of emissions increases from construction-related congestion is not specifically required.

(B) Highway Performance Monitoring System (HPMS) estimates of vehicle miles traveled shall be considered the primary measure of vehicle miles traveled within the portion of the nonattainment or maintenance area and for the functional classes of roadways included in HPMS, for urban areas which are sampled on a separate urban area basis. A factor (or factors) shall be developed to reconcile and calibrate the network-based model estimates of vehicle miles traveled in the base year of its validation to the HPMS estimates for the same period, and these factors shall be applied to model estimates of future vehicle miles traveled. In this factoring process, consideration will be given to differences in the facility coverage of the HPMS and the modeled network description. Departure from these procedures is permitted with the concurrence of DOT and EPA.

(C) Reasonable methods shall be used to estimate nonattainment area vehicle travel on off-network roadways within the urban transportation planning area, and on roadways outside the urban transportation planning area.

(D) Reasonable methods in accordance with good practice must be used to estimate traffic speeds and delays in a manner that is sensitive to the estimated volume of travel on each roadway segment represented in the network model.

(E) Ambient temperatures shall be consistent with those used to establish the emissions budget in the applicable implementation plan. Factors other than temperatures, for example the fraction of travel in a hot stabilized engine mode, may be modified after interagency consultation according to Chapter 8, Section 4(e) if the newer estimates incorporate additional or more geographically specific information or represent a logically estimated trend in such factors beyond the period considered in the applicable implementation plan.

(iii) Areas Which Are Not Serious, Severe, or Extreme Ozone Nonattainment Areas or Serious Carbon Monoxide Areas, or Before January 1, 1995.

(A) Procedures which satisfy some or all of the requirements of paragraph (i) of this section shall be used in all areas not subject to paragraph (i) of this section in which those procedures have been the previous practice of the MPO.

(B) Regional emissions may be estimated by methods which do not explicitly or comprehensively account for the influence of land use and transportation infrastructure on vehicle miles traveled and traffic speeds and congestion. Such methods must account for VMT growth by extrapolating historical VMT or projecting future VMT by considering growth in population and historical growth trends for vehicle miles traveled per person. These methods must also consider future economic activity, transit alternatives, and transportation system policies.

(iv) Projects Not From a Conforming Plan and TIP in Isolated Rural Nonattainment and Maintenance Areas. This paragraph applies to any nonattainment or maintenance area or any portion thereof which does not have a metropolitan transportation plan or TIP and whose projects are not part of the emissions analysis of any MPO's metropolitan transportation plan or TIP (because the nonattainment or maintenance area or portion thereof does not contain a metropolitan planning area or portion of a metropolitan planning area and is not part of a Metropolitan Statistical Area or Consolidated Metropolitan Statistical Area which is or contains a nonattainment or maintenance area).

(A) Conformity demonstrations for projects in these areas may satisfy the requirements of Chapter 8, Section 4(t)(x)(aa) with one regional emissions analysis which includes all the regionally significant projects in the nonattainment or maintenance area (or portion thereof).

(B) The requirements of Chapter 8, Section 4(t) shall be satisfied according to the procedures in Chapter 8, Section 4(t)(iii), with references to the "transportation plan" taken to mean the statewide transportation plan.

(C) The requirements of Chapter 8, Sections 4(x) and (aa) which reference "transportation plan" or "TIP" shall be taken to mean those projects in the statewide transportation plan or statewide TIP which are in the nonattainment or maintenance area (or portion thereof).

(D) The requirement of Chapter 8, Section 4(cc)(ii) shall be satisfied if:

(I) The project is included in the regional emissions analysis which includes all regionally significant highway and transportation projects in the nonattainment or maintenance area (or portion thereof) and supports the most recent conformity determination made according to the requirements of Chapter 8, Sections 4(t)(x) or (aa) (as modified by paragraphs (iv)(B) and (iv)(C) of this section), as appropriate for the time period and pollutant; and

(II) The project's design concept and scope have not changed significantly from those which were included in the regional emissions analysis, or in a manner which would significantly impact use of the facility.

(v) PM₁₀ From Construction-Related Fugitive Dust.

(A) For areas in which the implementation plan does not identify construction-related fugitive PM₁₀ as a contributor to the nonattainment problem, the fugitive PM₁₀ emissions associated with highway and transit project construction are not required to be considered in the regional emissions analysis.

(B) In PM₁₀ nonattainment and maintenance areas with implementation plans which identify construction-related fugitive PM₁₀ as a contributor to the nonattainment problem, the regional PM₁₀ emissions analysis shall consider construction-related fugitive PM₁₀ control measures in the applicable implementation plan, and the dust-producing capacity of the proposed activities.

(ee) Procedures for Determining Localized CO and PM₁₀ Concentrations (Hot-Spot Analysis).

(i) In the following cases, CO hot-spot analyses must be based on the applicable air quality models, databases, and other requirements specified in 40 CFR part 51, Appendix W ("Guideline on Air Quality Models" (Revised 1988), supplement A (1987) and supplement B (1993), EPA publication no. 450/2-78-027R), unless, after the interagency consultation process described in Chapter 8, Section 4(e) and with the approval of the EPA Regional Administrator, these models, databases, and other requirements are determined to be inappropriate:

(A) For projects in or affecting locations, areas, or categories of sites which are identified in the applicable implementation plan as sites of current violation or possible current violation;

(B) For those intersections at Level-of-Service D, E, or F, or those that will change to Level-of-Service D, E, or F because of increased traffic volumes related to a new project in the vicinity;

(C) For any project involving or affecting any of the intersections which the applicable implementation plan identifies as the top three intersections in the nonattainment or maintenance area based on the highest traffic volumes;

(D) For any project involving or affecting any of the intersections which the applicable implementation plan identifies as the top three intersections in the nonattainment or maintenance area based on the worst Level-of-Service; and

(E) Where use of the “Guideline” models is practicable and reasonable given the potential for violations.

(ii) In cases other than those described in paragraph (i) of this section, other quantitative methods may be used if they represent reasonable and common professional practice.

(iii) CO hot-spot analyses must include the entire project, and may be performed only after the major design features which will significantly impact CO concentrations have been identified. The background concentration can be estimated using the ratio of future to current traffic multiplied by the ratio of future to current emission factors.

(iv) PM₁₀ hot-spot analysis must be performed for projects which are located at sites at which violations have been verified by monitoring, and at sites which have essentially identical vehicle and roadway emission and dispersion characteristics (including sites near one at which a violation has been monitored). The projects which require PM₁₀ hot-spot analysis shall be determined through the interagency consultation process required in Chapter 8, Section 4(e). In PM₁₀ nonattainment and maintenance areas, new or expanded bus and rail terminals and transfer points which increase the number of diesel vehicles congregating at a single location require hot-spot analysis. DOT may choose to make a categorical conformity determination on bus and rail terminals or transfer points based on appropriate modeling of various terminal sizes, configurations, and activity levels. The requirements of this paragraph for quantitative hot-spot analysis will not take effect until EPA releases modeling guidance on this subject and announces in the Federal Register that these requirements are in effect.

(v) Hot-spot analysis assumptions must be consistent with those in the regional emissions analysis for those inputs which are required for both analyses.

(vi) PM₁₀ or CO mitigation or control measures shall be assumed in the hot-spot analysis only where there are written commitments from the project sponsor and/or operator to the implementation of such measures, as required by Chapter 8, Section 4(gg)(i).

(vii) CO and PM₁₀ hot-spot analyses are not required to consider construction-related activities which cause temporary increases in emissions. Each site

which is affected by construction-related activities shall be considered separately, using established “Guideline” methods. Temporary increases are defined as those which occur only during the construction phase and last five years or less at any individual site.

(ff) Using the Motor Vehicle Emissions Budget in the Applicable Implementation Plan (or Implementation Plan Submission).

(i) In interpreting an applicable implementation plan (or implementation plan submission) with respect to its motor vehicle emissions budget(s), the MPO and DOT may not infer additions to the budget(s) that are not explicitly intended by the implementation plan (or submission). Unless the implementation plan explicitly quantifies the amount by which motor vehicle emissions could be higher while still allowing a demonstration of compliance with the milestone, attainment, or maintenance requirement and explicitly states an intent that some or all of this additional amount should be available to the MPO and DOT in the emission budget for conformity purposes, the MPO may not interpret the budget to be higher than the implementation plan’s estimate of future emissions. This applies in particular to applicable implementation plans (or submissions) which demonstrate that after implementation of control measures in the implementation plan:

(A) Emissions from all sources will be less than the total emissions that would be consistent with a required demonstration of an emissions reduction milestone;

(B) Emissions from all sources will result in achieving attainment prior to the attainment deadline and/or ambient concentrations in the attainment deadline year will be lower than needed to demonstrate attainment; or

(C) Emissions will be lower than needed to provide for continued maintenance.

(ii) If an applicable implementation plan submitted before November 24, 1993 demonstrates that emissions from all sources will be less than the total emissions that would be consistent with attainment and quantifies that “safety margin,” the State may submit a SIP revision which assigns some or all of this safety margin to highway and transit mobile sources for the purposes of conformity. Such a SIP revision, once it is endorsed by the Governor and has been subject to a public hearing, may be used for the purposes of transportation conformity before it is approved by EPA.

(iii) A conformity demonstration shall not trade emissions among budgets which the applicable implementation plan (or implementation plan submission) allocates for different pollutants or precursors, or among budgets allocated to motor vehicles and other sources, without a SIP revision or a SIP which establishes mechanisms for such trades.

(iv) If the applicable implementation plan (or implementation plan submission) estimates future emissions by geographic subarea of the nonattainment area, the MPO and DOT are not required to consider this to establish subarea budgets, unless the applicable implementation plan (or implementation plan submission) explicitly indicates an intent to create such subarea budgets for the purposes of conformity.

(v) If a nonattainment area includes more than one MPO, the SIP may establish motor vehicle emissions budgets for each MPO, or else the MPOs must collectively make a conformity determination for the entire nonattainment area.

(gg) Enforceability of Design Concept and Scope and Project-Level Mitigation and Control Measures.

(i) Prior to determining that a transportation project is in conformity, the MPO, other recipient of funds designated under Title 23 U.S.C. or the Federal Transit Act, FHWA, or FTA must obtain from the project sponsor and/or operator written commitments to implement in the construction of the project and operation of the resulting facility or service and project-level mitigation or control measures which are identified as conditions for NEPA process completion with respect to local PM₁₀ or CO impacts. Before making conformity determinations written commitments must also be obtained for project-level mitigation or control measures which are conditions for making conformity determinations for a transportation plan or TIP and included in the project design concept and scope which is used in the regional emissions analysis required by Chapter 8, Sections 4(r)-(t) and Chapter 8, Sections (v)-(x) or used in the project-level hot-spot analysis required by Chapter 8, Sections 4(p) and (u).

(ii) Project sponsors voluntarily committing to mitigation measures to facilitate positive conformity determinations must comply with the obligations of such commitments.

(iii) The implementation plan revision required in 40 CFR part 51, Subpart T shall provide that written commitments to mitigation measures must be obtained prior to a positive conformity determination, and that project sponsors must comply with such commitments.

(iv) During the control strategy and maintenance periods, if the MPO or project sponsor believes the mitigation or control measure is no longer necessary for conformity, the project sponsor or operator may be relieved of its obligation to implement the mitigation or control measure if it can demonstrate that the requirements of Chapter 8, Sections 4(p), (r), and (s) are satisfied without the mitigation or control measure, and so notifies the agencies involved in the interagency consultation process required under Chapter 8, Section 4(e). The MPO and DOT must confirm that the transportation plan and TIP still satisfy the requirements of Chapter 8, Sections 4(r) and (s) and that the project still satisfies the requirements of Chapter 8, Section 4(p), and therefore that the conformity determinations for the transportation plan, TIP, and project are still valid.

(hh) Exempt Projects. Notwithstanding the other requirements of this subpart, highway and transit projects of the types listed in Table 2 are exempt from the requirement that a conformity determination be made. Such projects may proceed toward implementation even in the absence of a conforming transportation plan and TIP. A particular action of the type listed in Table 2 is not exempt if the MPO in consultation with other agencies (see Chapter 8, Section 4(e)), the EPA, and the FHWA (in the case of a highway project) or the FTA (in the case of a transit project) concur that it has potentially adverse emissions impacts for any reason. States and MPOs must ensure that exempt projects do not interfere with TCM implementation.

Table 2. – Exempt Projects

SAFETY

Railroad/highway crossing
Hazard elimination program
Safer non-Federal-aid system roads
Shoulder improvements
Increasing sight distance
Safety improvement program
Traffic control devices and operating assistance other than signalization projects
Railroad/highway crossing warning devices
Guardrails, median barriers, crash cushions
Pavement resurfacing and/or rehabilitation
Pavement marking demonstration
Emergency relief (23 U.S.C. 125)
Fencing
Skid treatments
Safety roadside rest areas
Adding medians
Truck climbing lanes outside the urbanized area
Lighting improvements
Widening narrow pavements or reconstructing bridges (no additional travel lanes)
Emergency truck pullovers

MASS TRANSIT

Operating assistance to transit agencies
Purchase of support vehicles
Rehabilitation of transit vehicles¹
Purchase of office, shop, and operating equipment for existing facilities
Purchase of operating equipment for vehicles (e.g., radios, fareboxes, lifts, etc.)
Construction or renovation of power, signal, and communications systems
Construction of small passenger shelters and information kiosks
Reconstruction or renovation of transit buildings and structures (e.g., rail or bus buildings, storage and maintenance facilities, stations, terminals, and ancillary structures)

Rehabilitation or reconstruction of track structures, track, and trackbed in existing rights-of-way
Purchase of new buses and rail cars to replace existing vehicles or for minor expansions of the fleet¹
Construction of new bus or rail storage/maintenance facilities categorically excluded in 23 CFR 771

AIR QUALITY

Continuation of ride-sharing and van-pooling promotion activities at current levels
Bicycle and pedestrian facilities

OTHER

Specific activities which do not involve or lead directly to construction, such as:

- Planning and technical studies
- Grants for training and research programs
- Planning activities conducted pursuant to Titles 23 and 49 U.S.C.
- Federal-aid systems revisions

Engineering to assess social, economic, and environmental effects of the proposed action or alternatives to that action
Noise attenuation
Advance land acquisitions (23 CFR 712 or 23 CFR 771)
Acquisition of scenic easements
Plantings, landscaping, etc.
Sign removal
Directional and informational signs
Transportation enhancement activities (except rehabilitation and operation of historic transportation buildings, structures, or facilities)
Repair of damage caused by natural disasters, civil unrest, or terrorist acts, except projects involving substantial functional, locational or capacity changes

¹In PM₁₀ nonattainment or maintenance areas, such projects are exempt only if they are in compliance with control measures in the applicable implementation plan.

(ii) Projects Exempt From Regional Emissions Analyses. Notwithstanding the other requirements of this subpart, highway and transit projects of the types listed in Table 3 are exempt from regional emissions analysis requirements. The local effects of these projects with respect to CO or PM₁₀ concentrations must be considered to determine hot-spot analysis is required prior to making a project-level conformity determination. These projects may then proceed to the project development process even in the absence of a conforming transportation plan and TIP. A particular action of the type listed in Table 3 is not exempt from regional emissions analysis if the MPO in consultation with other agencies (see Chapter 8, Section 4(e)), the EPA, and the FHWA

(in the case of a highway project) or the FTA (in the case of a transit project) concur that it has potential regional impacts for any reason.

Table 3. – Projects Exempt From Regional Emissions Analyses

Intersection channelization projects
Intersection signalization projects at individual intersections
Interchange reconfiguration projects
Changes in vertical and horizontal alignment
Truck size and weight inspection stations
Bus terminals and transfer points

(jj) Special Provisions for Nonattainment Areas Which Are Not Required to Demonstrate Reasonable Further Progress and Attainment.

(i) Application. This section applies in the following areas:

- (A) Rural transport ozone nonattainment areas;
- (B) Marginal ozone areas;
- (C) Submarginal ozone areas;
- (D) Transitional ozone areas;
- (E) Incomplete data ozone areas;
- (F) Moderate CO areas with a design value of 12.7 ppm or less;

and

- (G) Not classified CO areas.

(ii) Default Conformity Procedures. The criteria and procedures in Chapter 8, Sections 4(v)-(x) will remain in effect throughout the control strategy period for transportation plans, TIPs, and projects (not from a conforming plan and TIP) in lieu of the procedures in Chapter 8, Sections 4(r)-(t), except as otherwise provided in paragraph (iii) of this section.

(iii) Optional Conformity Procedures. The State or MPO may voluntarily develop an attainment demonstration and corresponding motor vehicle emissions budget like those required in areas with higher nonattainment classifications. In this case, the State must submit an implementation plan revision which contains that budget and attainment demonstration. Once EPA has approved this implementation plan revision, the procedures in Chapter 8, Sections 4(r)-(t) apply in lieu of the procedures in Chapter 8, Sections 4(v)-(x).

Section 5. Ozone nonattainment emission inventory rule.

(a) Applicability.

(i) This rule applies to a facility or source operating in an ozone nonattainment area(s), as identified in 40 CFR part 81, if:

(A) The facility or source has been granted permit approval to construct and/or operate under Chapter 6 of the Wyoming Air Quality Standards and Regulations (WAQSR); or

(B) It is an individual oil or gas facility or source; or

(C) Actual emissions from the stationary facility or source are greater than or equal to twenty-five (25) tons per year of volatile organic compounds (VOCs) as defined in Chapter 3, Section 6(a) of the WAQSR, or oxides of nitrogen (NO_x).

(I) If NO_x or VOCs are emitted from a facility or source at or above the applicability threshold identified in subsection (a)(i)(C), both air contaminants must be included in the emission inventory even if one of the air contaminants is emitted at a level below the applicability threshold.

(ii) Compliance with emission inventory requirements established under WAQSR Chapter 6, Section 3(f)(v)(G), satisfies the requirements of this rule.

(b) Reporting and Recordkeeping Requirements.

(i) As specified in the forms required in subsection (b)(v), each emission inventory shall include:

(A) Actual emissions of NO_x, VOC, and any other air contaminants as determined by the Division Administrator, in tons per year for any calendar year emission inventory, or in tons for any partial year emission inventory;

(B) The physical location at which the actual emissions occurred;

(C) The name and address of the person or entity operating or owning the facility or source; and

(D) The nature of the facility or source.

(ii) The emission inventory submittal dates are as follows:

(A) By April 30th of each year for all emissions that occurred during the previous calendar year; and

(B) No later than ninety (90) days after the end of a partial year inventory for emissions that occurred during the partial year as determined by the Division Administrator.

(iii) After the owner or operator submits an emission inventory for all facility or source emissions that occurred during calendar year 2014, the owner or operator shall submit an emission inventory for such facility or source every year thereafter.

(iv) Each owner or operator of a facility or source shall maintain a copy of the emission inventory submitted to the Division, and records indicating how the information submitted was determined, including any calculations, data, and measurements used.

(A) Records shall be kept for a period of at least five (5) years from the required submittal date listed in subsection (b)(ii) for each emission inventory.

(B) The owner or operator of the facility or source shall make the records required in subsection (b)(iv) available for inspection by any representative of the Division upon request.

(v) The owner or operator shall submit emission inventories using Division-prescribed hard copy or electronic formats.

(vi) All emission inventory submissions shall be certified as being true, accurate, and complete by a responsible official to the best of their knowledge. A responsible official is an individual who is responsible for the data provided in the emission inventory, and who accepts responsibility for the emission accuracy.

(c) Compliance. Compliance with WAQSR Chapter 8, Section 5, does not relieve any owner or operator of a facility or source from the responsibility to comply with any other applicable reporting requirements set forth in any federal or State law, rule or regulation, or in any permit.

Section 6. Upper Green River Basin permit by rule for existing sources

(a) Applicability.

(i) These regulations apply to all PAD and single-well oil and gas production facilities or sources, and all compressor stations, located in the Upper Green River Basin (UGRB) ozone nonattainment area that exist as of January 1, 2014. The UGRB ozone nonattainment area is that area which was adopted by reference from 40 CFR part 81.351, revised and published as of July 1, 2013, not including any later amendments. Copies of the Code of Federal Regulations (CFR) are available for public inspection and can be purchased from the Department of Environmental Quality, Air

Quality Division, Cheyenne Office. Contact information for the Cheyenne Office is available at: <http://deq.wyoming.gov/>. Copies of the CFR can also be purchased from Government Institutes, 15200 NBN Way, Building B, Blue Ridge Summit, PA 17214, or online at: <http://www.gpo.gov/fdsys/browse/collectionCfr.action?collectionCode=CFR>.

(ii) PAD and single-well oil and gas production facilities or sources, shall comply with all applicable requirements of these regulations unless a Wyoming Air Quality Standards and Regulations (WAQSR) Chapter 6, Section 2 permit has been issued that meets or exceeds the control requirements of these regulations; and

(iii) A compressor station, as defined in Subsection (b), shall comply with the requirements of Subsection (g) of these regulations unless a WAQSR Chapter 6, Section 2 permit has been issued that meets or exceeds the Subsection (g) requirements; and

(iv) In spite of the requirements of Chapter 6, Section 2(a)(i) and (iii) of the WAQSR, a preconstruction permit under Chapter 6, Section 2 is not required for any control device (flare/enclosed combustion unit) or equipment identified in these regulations unless a facility or source is required to obtain a permit under Chapter 6, Section 4 or Section 13.

(v) A WAQSR Chapter 6, Section 2 permit will be required for the use of any alternative emission control device and/or equipment to be used in lieu of, or in combination with, a combustion device required by these regulations.

(b) Definitions.

“Composite extended hydrocarbon analysis” are averaged extended hydrocarbon compositions based on samples from at least five wells producing from the same formation and under similar conditions (± 25 psig).

“Compressor station” means any permanent combination of one or more compressors that move natural gas at increased pressure from fields, in transmission pipelines, or into storage.

“Dehydration unit” means a system that uses glycol to absorb water from produced gas before it is introduced into gas sales or collection lines.

“Extended hydrocarbon analysis” means a gas chromatograph analysis performed on pressurized hydrocarbon liquid (oil/condensate) and gas samples, and shall include speciated hydrocarbons from methane (C1) through decane (C10), and the following Hazardous Air Pollutants (HAP): benzene, toluene, ethyl-benzene, xylenes (BTEX), n-hexane, and 2-2-4-trimethylpentane.

“Facility components” consist of flanges, connectors (other than flanges), open-ended lines, pumps, valves and “other” components listed in Table 2-4 from EPA-453/R-95-017 at the site grouped by stream (gas, light oil, heavy oil, water/oil). Table 2-4 from EPA-453/R-95-017 is available online at: <http://deq.wyoming.gov/aqd/> or <http://www.epa.gov/ttnchie1/efdocs/equiplks.pdf>.

“Flashing emissions” means VOC emissions, including HAP components, that occur when gases are released from produced liquids (oil, condensate, produced water, or a mixture thereof) that are exposed to temperature increases or pressure drops as they are transferred from pressurized vessels to lower pressure separation vessels or to atmospheric storage tanks.

“Optical gas imaging instrument” means an instrument that makes visible, emissions that may otherwise be invisible to the naked eye.

“PAD facility” means a location where more than one well and/or associated production equipment are located, where some or all production equipment is shared by more than one well or where well streams from more than one well are routed through individual production trains at the same location.

“Separation vessels” means all gun barrels, production and test separators, production and test treaters, water knockouts, gas boots, flash separators, and drip pots.

“Single-well facility” means a facility where production equipment is associated with only one well.

“Storage tanks” means any tanks that contain oil, condensate, produced water, or some mixture thereof.

(c) Flashing Emissions at Existing PAD and Single-Well Facilities or Sources as of January 1, 2014.

(i) VOC emissions from all existing storage tanks and all existing separation vessels are subject to these regulations.

(A) For total uncontrolled VOC emissions from flashing that are greater than or equal to 4 tons per year (tpy), flashing emissions from all produced oil, condensate, water tanks, and separation vessels shall be controlled to at least 98% manufacturer-designed VOC destruction efficiency by January 1, 2017.

(B) Storage tanks that are on site for use during emergency or upset conditions are not subject to the control requirements in this Subsection.

(C) Emergency, open-top, and/or blowdown tanks shall not be used as active storage tanks but may be used for temporary storage.

(I) Emergency tanks shall only be utilized for unavoidable equipment malfunctions as defined in Chapter 1, Section 5 of the WAQSR.

(II) If emergency, open-top, and/or blowdown tanks are utilized, they must be emptied within seven (7) calendar days after the liquid volume reaches 100 barrels, or in no event less frequently than once every ninety (90) calendar days.

(III) All tanks subject to this Subsection must have a liquid level gauge, or equivalent device, in place by January 1, 2017.

(D) Control Removal. The removal of flashing emissions control devices will be allowed pursuant to the requirements in Subparagraph (h)(iii)(E), after one (1) year from the date of installation if uncontrolled VOC flashing emissions have declined to less than, and will remain below 4 tpy.

(ii) Calculation for Flashing Emissions.

(A) Determine the average daily condensate/oil production for the previous twelve (12) calendar months in barrels per day (bpd).

(B) Use any generally accepted model in accordance with 40 CFR 60, Subpart OOOO or direct measurement of tank emissions to determine uncontrolled VOC emissions.

(C) Model input shall consist of:

(I) A site-specific analysis of liquids, or composite extended hydrocarbon analysis of liquids, taken from the pressurized, upstream separation equipment under normal operating conditions;

(II) Average daily condensate/oil production rate as determined in Subparagraph (c)(ii)(A) of these regulations;

(III) Site-specific or composite extended hydrocarbon analyses will be no older than three (3) years from date of flashing emissions calculation including;

(1.) The average, actual equipment operational parameters, including separator temperature and pressure; and

(2.) American Petroleum Institute (API) gravity and Reid vapor pressure (RVP) of sales oil.

(d) Dehydration Units at Existing PAD and Single-Well Facilities or Sources as of January 1, 2014.

(i) VOC emissions released from all existing dehydration units are subject to these regulations.

(A) For total uncontrolled VOC emissions from all dehydration units that are greater than or equal to 4 tpy, VOC emissions from all dehydration units shall be controlled to at least 98% manufacturer-designed VOC destruction efficiency and equipped with reboiler still vent condensers by January 1, 2017.

(B) Control Removal. The removal of combustion units used to achieve the 98% manufacturer-designed VOC destruction efficiency will be allowed pursuant to the requirements in Subparagraph (h)(iii)(E), after one (1) year from the date of installation if total uncontrolled VOC emissions from all dehydration units are less than, and will remain below 4 tpy, and all dehydration units are equipped with reboiler still vent condensers.

(ii) Calculation for Dehydration Units.

(A) Determine the average daily gas production rate for the previous twelve (12) calendar months in million cubic feet per day (MMCFD).

(B) Use the model GRI-GLYCalc, Version 4.0 or higher, and the annualized average daily production rate to determine annualized uncontrolled VOC emissions from the dehydration unit process vents. Process vents include reboiler still vents and glycol flash separators.

(C) Model input shall consist of:

(I) A site-specific wet gas analysis or composite extended hydrocarbon analysis of wet gas taken upstream of the contact tower under normal operating conditions;

(II) Average daily gas production rate as determined in Subparagraph (d)(ii)(A) of these regulations; and

(III) Site-specific or composite extended hydrocarbon analyses shall be no older than three (3) years from date of the dehydration unit calculation including;

(1.) The average, actual equipment operational parameters, including wet gas temperature and pressure, dry gas water content, glycol flash separator temperature and pressure, stripping gas source and rate; and

(2.) The maximum lean glycol circulation rate in gallons per minute (gpm) for the glycol circulation pump in use.

(e) Existing Pneumatic Pumps at PAD and Single-Well Facilities or Sources as of January 1, 2014. VOC emissions associated with the discharge streams of all natural gas-operated pneumatic pumps shall be controlled to at least 98% manufacturer-designed VOC destruction efficiency, or the pump discharge streams shall be routed into a sales line, collection line, fuel supply line, other closed loop system, or replaced with solar, electric, or air driven pumps by January 1, 2017.

(f) Existing Pneumatic Controllers at PAD and Single-Well Facilities or Sources as of January 1, 2014. Natural gas-operated pneumatic controllers shall be low (less than 6 standard cubic feet per hour (scfh)) or zero bleed controllers or the controller discharge streams shall be routed into a sales line, collection line, fuel supply line, or other closed loop system by January 1, 2017.

(g) Fugitive Emissions.

(i) For PAD and single-well facilities or sources, and compressor stations, in existence prior to January 1, 2014, with fugitive emissions greater than or equal to 4 tpy of VOCs, including HAP components, operators shall develop and implement a Leak Detection and Repair (LDAR) Protocol by January 1, 2017.

(A) The LDAR Protocol inspection monitoring schedule shall be no less frequent than quarterly; and

(B) Shall include a leak repair schedule; and

(C) Each quarterly inspection shall consist of some combination of 40 CFR part 60, Appendix A, Method 21, an optical gas imaging instrument, other instrument-based technologies, or audio-visual-olfactory (AVO) inspections.

(D) An LDAR Protocol consisting of only AVO inspections will not satisfy the requirements of this Subsection.

(ii) Calculation for Fugitive Emissions.

(A) Fugitive emissions shall be estimated using Table 2-4 from EPA-453/R-95-017, Protocol for Equipment Leak Emission Estimates, and the owner(s) or operator(s) facility component count.

(I) PAD and single-well facility or source component counts shall be determined by actual field count, or a representative component count from the same geographical area, taken from no less than one hundred (100) wells located at a PAD or single-well facility.

(II) Compressor station component counts shall be determined by actual field count.

(III) Emission factors in the Protocol for Equipment Leak Emission Estimates are not intended to be used to represent emissions from components that are improperly designed or equipment not maintained properly.

(B) Site-specific speciated hydrocarbon emission rates can be estimated by multiplying the total hydrocarbon emission rate, estimated in Subparagraph (g)(ii)(A) above, by measured VOC and HAP weight fractions.

(h) Monitoring, Recordkeeping, and Reporting.

(i) Monitoring. The owner(s) or operator(s) of each PAD and single-well facility or source, or compressor station, shall comply with all applicable monitoring requirements as specified by this Paragraph.

(A) Operation of a combustion device used to control emissions shall be continually monitored using any device(s) that sense and record a parameter(s) that indicates whether the combustion device is functioning to achieve the 98% manufacturer-designed VOC destruction efficiency requirements as specified by these regulations.

(I) The combustion device shall be designed, constructed, operated, and maintained to be smokeless, to satisfy the requirements of Chapter 3, Section 6(b)(i) of the WAQSR.

(II) Visible emissions shall not exceed a total of five (5) minutes during any two (2) consecutive hours as determined by 40 CFR part 60, Appendix A, Method 22.

(B) All emission control devices and equipment used to reduce VOC emissions at any PAD and single-well facility or source shall be operated and maintained pursuant to manufacturer specifications or equivalent, and consistent with good engineering and maintenance practices.

(C) Owner(s) or operator(s) shall conduct a quarterly site evaluation of control equipment, systems, and devices that include, but are not limited to, combustion units, reboiler overheads condensers, storage tanks, drip tanks, vent lines, connectors, fittings, valves, relief valves, hatches, and any other appurtenance employed to, or involved with, eliminating, reducing, containing or collecting vapors and routing them to an emission control system or device.

(I) At least one (1) of the quarterly evaluations per calendar year shall consist of 40 CFR part 60, Appendix A, Method 21, an optical gas imaging instrument, or other instrument-based technologies.

(II) Owner(s) or operator(s) required to implement an LDAR Protocol have satisfied the requirements of Subparagraph (C) above.

(ii) Recordkeeping. The owner(s) or operator(s) of each PAD and single-well facility or source, or compressor station, shall comply with all applicable recordkeeping requirements as specified by this Paragraph. Records shall be maintained for a period of five (5) years and made available to the Division upon request.

(A) All emission control devices and equipment are adequately designed and sized to achieve the control efficiency required by these regulations and to accommodate fluctuations in emissions.

(B) Owner(s) or operator(s) shall maintain the following records for each combustion device:

(I) Manufacturer-designed VOC destruction efficiency.

(II) Records of the parameter monitoring during active site operation under Subparagraph (h)(i)(A) including;

(1.) A description of the reason(s) for the absence of the monitored parameter;

(2.) The steps taken to return the combustion device back to the 98% manufacturer-designed VOC destruction efficiency; and

(3.) Date and duration of periods when the combustion device and/or the associated containment and collection equipment is not functioning to achieve the 98% manufacturer-designed VOC destruction efficiency.

(III) Date and duration of visible emissions from the combustion device.

(C) Owner(s) or operator(s) shall record and maintain records for fugitive emissions pursuant to Subsection (g) of these regulations. These records shall include the dates and results of all LDAR inspections performed pursuant to the LDAR protocol for a PAD and single-well facility or source, or compressor station, including the date(s) and type of corrective action taken as a result of the required inspections.

(D) Records of the date, duration, and reason for emergency and/or blowdown tank usage, shall be maintained pursuant to Subparagraph (c)(i)(C) of these regulations.

(E) Owners or operators that utilize emergency, open-top, and/or blowdown tanks pursuant to Subsection (c) shall record and maintain monthly records for volume stored in tanks, volume removed from tanks, and the date when the removal of liquid occurred.

(iii) Reporting. The owner(s) or operator(s) of each PAD and single-well facility or source, or compressor station, shall comply with all applicable reporting requirements as specified by this Subsection.

(A) The owner(s) or operator(s) shall provide the name and location of the PAD and single-well facility or source, or compressor station, anticipated to require the installation of a combustion device, replacement of equipment, or implementation of an LDAR Protocol, if applicable, by January 1, 2016.

(B) Installation Notification of Control Device(s) and Associated Equipment (including pneumatic pumps). Owner(s) or operator(s) of each PAD and single-well facility or source subject to the requirements of these regulations shall submit a report to the Division thirty (30) days after the end of each calendar quarter, beginning January 1, 2016, containing the following, if applicable:

(I) The number of pollution control devices or equipment installed;

(II) Pollution control installation date, type of control, and equipment controlled;

(III) Name and location of the PAD and/or single-well facility or source where controls are installed.

(C) Installation Notification of Pneumatic Controller(s). Owner(s) or operator(s) of each PAD and single-well facility or source subject to the requirements of these regulations shall submit a report to the Division thirty (30) days after the end of each calendar quarter, beginning January 1, 2016, containing the following, if applicable:

(I) The number and type of pneumatic controllers installed and date of installation; and

(II) Name and location of the PAD and/or single-well facility or source where pneumatic controllers are installed.

(D) The final, quarterly notification of installation required under Subsections (B) and (C) above, shall be submitted no later than January 31, 2017, if applicable.

(E) Removal Notification of Control Device(s). The owner(s) or operator(s) of each PAD and single-well facility or source subject to the requirements of these regulations shall submit a demonstration to the Division for approval prior to removal of any pollution control device. This demonstration shall contain at a minimum:

(I) The average daily condensate/oil or gas production rate for the previous twelve (12) calendar months;

(II) Emissions as determined by utilizing paragraph (I) above, and the calculation for flashing emissions in Paragraph (c)(ii), and/or the calculation for dehydration units in Paragraph (d)(ii) of these regulations;

(III) Any additional supporting data used to calculate emissions, including but not limited to, a site specific or composite extended hydrocarbon analysis no older than three (3) years from the proposed removal date; and

(IV) Name and location of the PAD and/or single-well facility or source where controls are proposed for removal.

(F) Any PAD and single-well facility or source, or compressor station, subject to requirements of Subsection (g) of these regulations shall submit, for Division review and approval, the LDAR Protocol prior to implementation of the protocol.

(G) All report and notification submissions shall be certified as being true, accurate, and complete by a responsible official to the best of their knowledge. A responsible official is an individual who is responsible for the information provided in the reports and notifications, and who accepts responsibility for the reports and notifications.

(H) The owner(s) or operator(s) shall submit notifications or reports as required in this Subsection to the Division electronically through <https://airimpact.wyo.gov> or by hard copy to the Cheyenne Office and Lander Field Office. Contact information for the Cheyenne and Lander offices is located at: <http://deq.wyoming.gov/>.

(i) Compliance. Compliance with Chapter 8, Section 6 of the WAQSR, does not relieve any owner(s) or operator(s) of a PAD and single-well facility or source, or compressor station, from the responsibility to comply with any other applicable requirements set forth in any federal or State law, rule or regulation, or in any permit.

Section 7. **[Reserved.]**

Section 8. **[Reserved.]**

Section 9. **[Reserved.]**

Section 10. **Incorporation by reference.**

(a) Code of Federal Regulations (CFR). All Code of Federal Regulations (CFRs) cited in this chapter, including their Appendices, revised and published as of July

1, 2013, not including any later amendments, are incorporated by reference. Copies of the Code of Federal Regulations are available for public inspection and can be obtained at cost from the Department of Environmental Quality, Division of Air Quality, Cheyenne Office. Contact information for the Cheyenne Office can be obtained at: <http://deq.wyoming.gov/>. Copies of the CFRs can also be obtained at cost from Government Institutes, 15200 NBN Way, Building B, Blue Ridge Summit, PA 17214, or online at: <http://www.gpo.gov/fdsys/browse/collectionCfr.action?collectionCode=CFR>.

Oil and Gas Production Facilities Chapter 6, Section 2 Permitting Guidance

June 1997
Revised November 1998
Revised January 2000
Revised August 2001
Revised July 28, 2004 (specific guidance for Jonah/Pinedale Anticline Area)
Revised August 2007
Revised March 2010
Revised September 2013 (Added specific guidance for UGRB and revisions to JPAD)
Revised May 2016

Under § 35-11-801(e) of the Wyoming Environmental Quality Act, construction or modification of an oil and gas exploration or production well may occur prior to permitting, as long as the facility (1) is not a major source; (2) is permitted within 90 days of the first date of production (FDOP); and (3) applies Best Available Control Technology (BACT). However, any owner or operator may instead apply for a construction or modification permit under Chapter 6, Section 2 of the Wyoming Air Quality Standards and Regulations prior to construction or modification of a facility.

This interpretive guidance discusses the Division's current understanding of BACT for the purpose of assisting owners and operators who choose to construct or modify oil and gas production facilities prior to initiating the permitting process. This interpretive policy is not binding on the agency, the regulated community, or any person; it is for informational purposes and does not create any rights, responsibilities, or liabilities for the Division, members of the regulated community, or any other person.

Owners and operators should be advised that this Guidance represents the agency's current understanding of BACT as of May 12, 2016.

This Guidance applies to surface oil and gas production facilities where hydrocarbon fluids are produced, processed and/or treated prior to custody transfer from the facility.

This Guidance does not apply to sour (H₂S containing) oil production sites. This Guidance also may not be used for sour gas (H₂S) production facilities unless the only emissions of H₂S will be those associated with fugitive losses from valves, fittings, surface piping and pneumatic devices, etc. If there will be H₂S emissions associated with vented gas or tank vapors or if sour gas will be flared the applicant shall contact the Division for permitting guidance prior to construction to determine BACT requirements.

This Guidance does not apply to greenhouse gas emissions (GHGs) or major sources as defined under Wyoming Air Quality Standards and Regulations Chapter 6, Section 3 or Chapter 6, Section 13.

This Guidance does not apply to reciprocating internal combustion engines located at oil and gas production facilities unless the engine is natural gas-fired, used to power a pumping unit, is less than or equal to 50 horsepower, and meets BACT. Reciprocating internal combustion engines larger than 50 horsepower are required to obtain an air quality permit or permit waiver prior to installation.

The Presumptive BACT permitting requirements under this Guidance apply to facilities with associated wells that have a first date of production (FDOP) on/after July 1, 2016 and to facilities with a modification occurring on/after July 1, 2016.

Start up or modification of a facility may occur prior to obtaining an Air Quality Permit or Waiver only when the Presumptive BACT permitting requirements under this Guidance are met. Otherwise, an Air Quality Permit or Waiver shall be obtained prior to start up or modification of a facility.

For the purposes of this Guidance **SWA (STATEWIDE AREA)** refers to all facilities not located in the **UGRB** or **JPAD/NPL**.

UGRB refers to facilities located in the **Upper Green River Basin**.

JPAD/NPL refers to facilities located in the **Jonah and Pinedale Anticline Development Area and Normally Pressured Lance**.

Introduction

The Oil and Gas Production Facilities Chapter 6 Section 2 Permitting Guidance (C6 S2 Guidance) document is an interpretive policy intended to publicize the Division's current understanding of BACT for certain types of emission sources at certain types of oil and gas production facilities. This interpretive policy is not binding on the agency, the regulated community, or any person; it is for informational purposes and does not create any rights, responsibilities, or liabilities for the Division, members of the regulated community, or any person. Any owners or operators seeking site-specific BACT analyses may choose to follow the standard Chapter 6, Section 2 permitting process prior to the construction or modification of a facility.

Applicability

When is a permit needed?

If **ANY** air pollutant will be released to the atmosphere from a new or modified facility, the facility is subject to the Wyoming Air Quality Standards and Regulations (**WAQSR**) and the Wyoming Environmental Quality Act. This Guidance does not apply to greenhouse gas emissions, sour oil production sites, or reciprocating internal combustion engines greater than 50 horsepower. This Guidance also may not be used for sour gas production facilities unless the only emissions of H₂S will be those associated with fugitive losses from valves, fittings, surface piping and pneumatic devices, etc.

Owners/operators of **ALL** regulated air emission sources constructed or modified after May 29, 1974 shall comply with the WAQSR Chapter 6, Section 2 permitting requirements. To obtain a copy of the WAQSR contact the Wyoming Air Quality Division at (307) 777-7391 or download an electronic version from the Wyoming Secretary of State (<http://soswy.state.wy.us/Rules/default.aspx>). A link to the Secretary of State's website is available on the WDEQ's Air Quality website at <http://deq.wyoming.gov/aqd/>.

Under the Wyoming Environmental Quality Act, certain oil and gas production facilities may be constructed or modified prior to obtaining a permit or waiver, as long as they are minor sources, obtain a permit within 90 days of FDOP, and utilize BACT. Wyo. Stat. Ann. § 35-11-801(e).

Failure to comply with the Wyoming Environmental Quality Act and Wyoming Air Quality Regulations may result in an enforcement action undertaken by the State in the form of a "Notice of Violation", a complaint filed in District Court, or any other enforcement action allowed by law. The Wyoming Environmental Quality Act authorizes the assessment of penalties of up to \$10,000.00 per violation per day and/or injunctive relief.

Which pollutants are associated with oil and gas (O&G) production facilities?

The following air pollutants are commonly associated with O&G production facilities:

Volatile Organic Compounds (VOC): Hydrocarbon compounds excluding methane (C₁) and ethane (C₂). VOCs are also referred to as C₃⁺ compounds – propane, butane, pentane, hexane, etc.

Hazardous Air Pollutants (HAP): HAPs commonly associated with O&G production are BTEX and n-hexane (benzene, toluene, ethyl-benzene, xylenes and n-C₆). Section 112(b) of the Clean Air Act identified the regulated HAPs.

Nitrogen Oxides (NO_x): NO_x emissions are the result of natural gas combustion.

Carbon Monoxide (CO): CO emissions are the result of natural gas combustion.

Hydrogen Sulfide (H₂S): Contained within fields that produce sour gas.

Sulfur Dioxide (SO₂): Created when H₂S is combusted.

Production Facility Emission Sources

O&G production facilities emission sources:

Storage Tanks: Vapors containing regulated air pollutants are released from solution as oil, condensate and water are transferred from separation equipment to atmospheric storage tanks. These vapors are called **flashing losses**. Vapors evaporated or displaced from tanks are called **working and breathing (also called standing) losses (S/W/B)**.

Dehydration Units: Glycol, usually tri-ethylene glycol (TEG), is used in dehydration units to absorb water from wet produced gas. “Lean” TEG contacts the wet gas and absorbs water. The TEG, now considered “rich” is routed through a flash separator and/or reboiler for regeneration. Vapors released from the flash separator and reboiler still vent contain regulated air pollutants.

Pressurized Process Vessels: Vapors vented from gun barrels, separators, treaters, water knockouts, gas boots, flash separators, drip pots, etc. contain regulated air pollutants. The discharge lines and vents from all of these vessels shall be considered when determining emission sources.

Natural Gas-Fired Equipment: Some of the byproducts of natural gas combustion in process heaters, boilers, burners, flares, engines, etc. are regulated air pollutants.

Fugitives: All production facilities contain numerous equipment components such as valves, flanges, threaded connections, tubing connections, open-ended lines, pump seals, etc., which are manufactured and installed in ways intended to contain gases or liquids. Over time some of them begin to leak. Emissions associated with leaks are called fugitive emissions. For purposes of this Guidance, emissions from components that are improperly designed (e.g. enardo valves over pressurizing, failure of thief hatches to reseal after over pressurizing) or equipment not maintained properly (e.g., thief hatch left open) are not considered to be fugitive emissions.

Pneumatic Pumps & Controllers: The discharge vapors from natural gas-operated pneumatic equipment contain regulated air pollutants.

Truck Loading: Vapors displaced from truck tanks during the loading of produced liquids that contain regulated air pollutants.

Venting & Blowdown: Natural gas and liquids contain regulated air pollutants.

Well Completions: Activities that occur after a well is drilled that are undertaken to produce hydrocarbon fluids from the well. These include casing, cementing, perforating, gravel packing and installing a production tree.

INTENTIONALLY LEFT BLANK

BACT and Presumptive BACT

Under WAQSR Chapter 6, Section 2(c), all new or modified sources or facilities, which may generate regulated air emissions shall be permitted prior to construction or modification and **Best Available Control Technology (BACT)** shall be applied to reduce or eliminate emissions, with consideration given for technical feasibility and economical reasonableness. **BACT** is a process, not an emission limit. Regulations do not set a minimum emission threshold below which **BACT** does not need to be considered.

At O&G facilities production rates and associated pollutant emissions are usually unknown prior to start up. The AQD has tailored a permitting program allowing for the start up or modification of O&G facilities prior to permitting provided specific emission control requirements are met.

This is the **Presumptive BACT** permitting process for O&G production facilities.

Presumptive BACT requirements have been established for emissions associated with:

- Flashing & S/W/B losses from atmospheric storage tanks and pressurized vessels
- Dehydration unit process vents
- Natural gas-operated pneumatic equipment
- Natural gas-fired pumping unit engines
- Truck loading
- Produced water tanks
- Well completions
- Well blowdown/venting

If emissions **are known prior to** construction or modification, a permit shall be obtained **PRIOR TO CONSTRUCTION or MODIFICATION** and BACT, including Presumptive BACT requirements, shall be addressed in the application. Examples include:

- Construction of a central tank battery for collecting and processing production from surrounding existing wells with known production rates
- Consolidation of multiple existing facilities for which production rates have been established
- Installation of a dehydration unit for an existing well with an established gas production rate
- Installation of larger capacity equipment to replace undersized equipment
- Replacement of an emission control system or device with a different system or device

Presumptive BACT requirements have been established for three (3) areas:

SWA refers to all facilities not located in the **UGRB** or **JPAD/NPL**.

UGRB refers to facilities located in the **Upper Green River Basin**.

JPAD/NPL refers to facilities located in the **Jonah and Pinedale Anticline Development Area and Normally Pressured Lance**.

The **UGRB** area is defined, in accordance with the public land survey system, as:

Sublette County: (all)

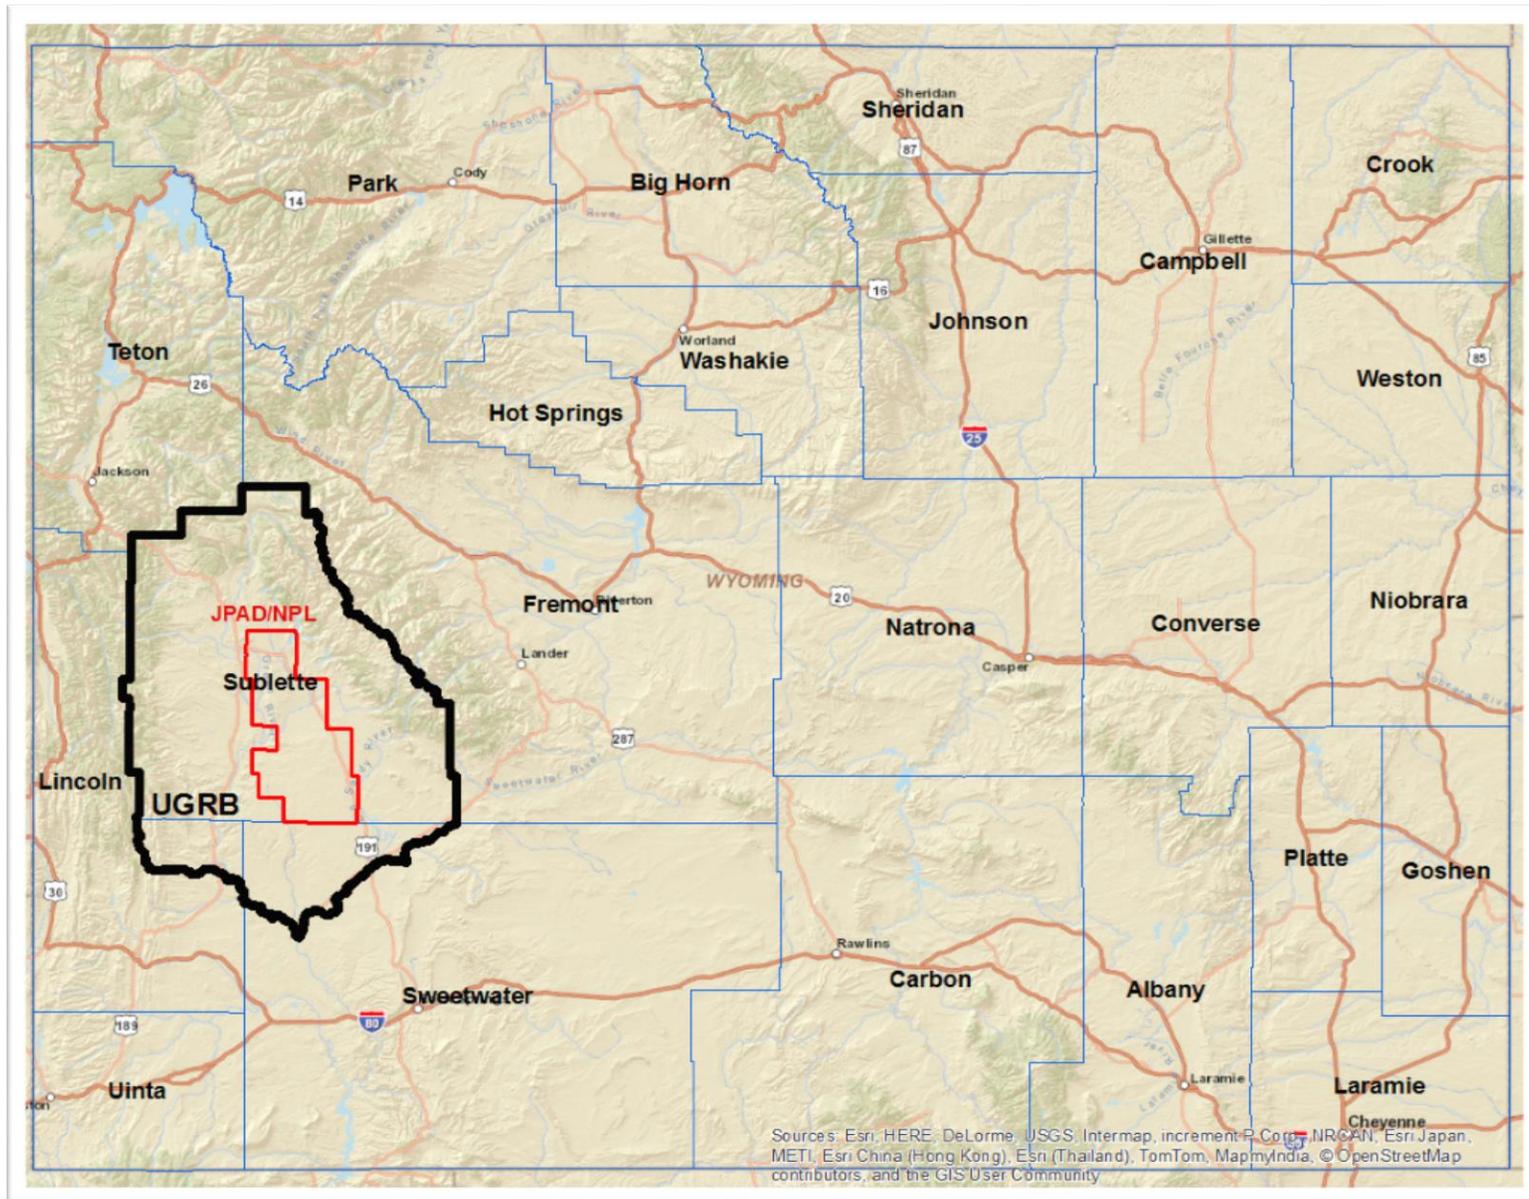

Lincoln County: (part) The area of the county north and east of the boundary defined by a line starting at the point defined by the intersection of the southwest corner Section 30 Range (R) 115 West (R115W) Township (T) 27 North (T27N) and the northwest corner of Section 31 R115W T27N of Sublette County at Sublette County's border with Lincoln County. From this point the boundary moves to the west 500 feet to the Aspen Creek. The boundary follows the centerline of Aspen Creek downstream to the confluence of Aspen Creek and Fontenelle Creek (in R 116 W T26N Section 1). From this point the boundary moves generally to the south along the centerline of Fontenelle Creek to the confluence of Fontenelle Creek and Roney Creek (in R115W T24N Section 6). From the confluence, the boundary moves generally to the east along the centerline of Fontenelle Creek and into the Fontenelle Reservoir (in R112W T24N Section 6). The boundary moves east southeast along the centerline of the Fontenelle Reservoir and then toward the south along the centerline of the Green River to where the Green River in R111W T24N Section 31 crosses into Sweetwater County.

Sweetwater County: (part) The area of the county west and north of the boundary which begins at the midpoint of the Green River, where the Green River enters Sweetwater County from Lincoln County in R111W T24N Section 31. From this point, the boundary follows the center of the channel of the Green River generally to the south and east to the confluence of the Green River and the Big Sandy River (in R109W T22N Section 28). From this point, the boundary moves generally north and east along the centerline of the Big Sandy River to the confluence of the Big Sandy River with Little Sandy Creek (in R106W T25N Section 33). The boundary continues generally toward the northeast along the centerline of Little Sandy Creek to the confluence of Little Sandy Creek and Pacific Creek (in R106W T25N Section 24). From this point, the boundary moves generally to the east and north along the centerline of Pacific Creek to the confluence of Pacific Creek and Whitehorse Creek (in R103W T26N Section 10). From this point the boundary follows the centerline of Whitehorse Creek generally to the northeast until it reaches the eastern boundary of Section 1 R103W T26N. From the point where Whitehorse Creek crosses the eastern section line of Section 1 R103W T26N, the boundary moves straight north along the section line to the southeast corner of Section 36 R103W T27N in Sublette County where the boundary ends.

The **JPAD/NPL** area is defined as:

Sublette County: R109W & R110W in T34N,
R109W & R110W in T33N,
R108W, R109W & R110W in T32N,
R108W, R109W & R110W in T31N,
R107W, R108W & R109W in T30N,
R107W, R108W, R109W, & R110W in T29N,
R107W, R108W, R109W, & R110W in T28N,
and R107W, R108W & R109W in T27N

The **SWA** refers to all other areas in the State excluding the **UGRB** or **JPAD/NPL**.

Presumptive BACT Requirements for SWA Facilities

Flashing

For the purpose of determining flashing emissions all vapor streams containing VOC and/or HAP components from all storage tanks (e.g., oil, condensate, produced water with oil or condensate carryover) and all separation vessels (e.g., gun barrels, production and test separators, production and test treaters, water knockouts, gas boots, flash separators, drip pots, etc.) at a facility, which are or may be vented to the atmosphere shall be considered.

New Facilities

PAD Facilities

Upon First Date of Production (FDOP), VOC and HAP flashing emissions shall be controlled by at least 98%.

Single Well Facilities and Tank Batteries

Within 60 days of FDOP, flashing emissions containing greater than or equal to 6 Tons per Year (TPY) VOC and HAPs shall be controlled by at least 98%.

Modified Facilities

PAD Facilities

Upon modification, all new and existing VOC and HAP flash emissions shall be controlled by at least 98%.

Single Well Facilities and Tank Batteries

Within 60 days of modification, all new and existing flashing emissions containing greater than or equal to 6 TPY VOC and HAPs shall be controlled by at least 98%.

New and Modified Facilities

Condensate and oil tanks that are on site solely for use during emergency or upset conditions, such as spare tanks at facilities connected to liquids gathering systems, are not subject to the 98% control requirements.

The removal of a flashing emissions control device(s) may be allowed upon approval if, after at least one year from the date of installation, VOC and HAP flashing emissions have declined to less than, and are reasonably expected to remain below 4 TPY of VOC and HAPs.

Presumptive BACT Requirements for SWA Facilities (cont.)

Dehydration Units

For the purpose of determining emissions from dehydration units, vapor streams containing VOC or HAP components released from the process vents (reboiler still vents & glycol flash separator vents) of all dehydration units at a facility, which are or may be vented to the atmosphere shall be considered. See page 9 for the definitions of **potential uncontrolled** VOC and HAP emissions and **potential** VOC and HAP emissions.

New Facilities

Upon FDOP, all dehydration units shall be equipped with reboiler still vent condensers. Removal of the condensers will not be allowed.

PAD Facilities

Upon FDOP, all dehydration unit VOC and HAP emissions shall be controlled by at least 98%. After one year, combustion units used to achieve the 98% control may be removed upon approval if

- Total **potential** VOC and HAP emissions from all units are less than 4 TPY and
- All units are equipped with still vent condensers.

Single Well Facilities

Within 60 days of FDOP, if total **potential uncontrolled** VOC and HAP emissions from all units are greater than or equal to 6 TPY, emissions from all units shall be controlled by at least 98%.

After one year, combustion units used to achieve the 98% control may be removed upon approval if

- Total **potential** VOC and HAP emissions from all units are less than 4 TPY and
- All units are equipped with still vent condensers.

Modified Facilities

Requirements are the same as those for PADs and single well facilities except use the date of modification in place of FDOP. Control requirements apply to all existing and new dehydration units.

All Facilities

When a combustion unit is required at a facility for control of dehydration unit emissions, all non-condensable still vent vapors shall be collected and routed to a combustion unit for at least 98% control of VOC and HAP emissions. All glycol flash separator vapors shall be collected and routed to the combustion unit for at least 98% control of VOC and HAP emissions and/or used as fuel for process equipment burners.

Presumptive BACT Requirements for SWA Facilities (cont.)

All Facilities (cont.)

At facilities where a combustion unit is not required for control of flash or dehydration unit emissions, all glycol flash separator vapors shall be collected for use as fuel in process equipment burners. Excess flash vapors that are not used as fuel may be vented to the atmosphere.

Potential Uncontrolled VOC and HAPs emissions shall be determined using GRI-GLYCalc version 4.0 (V4.0) or higher or other method accepted by the Division and shall be based on the projected, year one, average daily dry gas throughput rate, maximum circulation rate for the glycol circulation pump(s) installed, average expected operating parameters for wet gas temperature and pressure, maximum dry gas water content or number of absorber stages and extended hydrocarbon content of the wet gas from a sample of the wet gas taken upstream of the dehydration unit contact tower. Flash separators, still vent condensers, limited operating hours, and limited glycol circulation rates shall not be considered when determining potential uncontrolled emissions.

Still vent condensers shall consist of equipment engineered and designed to achieve maximum condensation of the condensable components in the still vent vapors by providing adequate temperature differentials between the condenser outlet and still vent stream. Still vent pipes shall not be considered condensers.

Potential emissions for determining combustion device removal after one year shall be calculated using GRI-GLYCalc V4.0 or higher or other method accepted by the Division based on the past twelve calendar months of normal gas production rates, actual average wet gas temperature and pressure, actual water content of the dried gas or number of absorber stages.

Actual operating parameters for glycol flash separators may be used upon approval. Limited operating hours and limited glycol circulation rates shall not be considered for control removal.

Presumptive BACT Requirements for SWA Facilities (cont.)

Pneumatic Pumps

New Facilities

PAD Facilities

Upon FDOP, VOC and HAP emissions associated with the discharge streams of all natural gas-operated pneumatic pumps shall be controlled by at least 98% or the pump discharge streams shall be routed into a closed loop system (e.g., sales line, collection line, fuel supply line).

Single Well Facilities and Tank Batteries

Within 60 days of FDOP,

At sites with controls installed for flashing or dehydration unit emissions:

VOC and HAP emissions associated with the discharge streams from natural gas-operated pneumatic pumps shall be controlled by at least 98% or the discharge streams shall be routed into a closed loop system.

At sites without controls installed for flashing or dehydration unit emissions:

Pneumatic pumps (other than heat trace/heat medium/hot glycol circulation) shall be solar, electric or air-driven pumps in lieu of natural gas-operated pneumatic pumps or the discharge streams shall be routed into a closed loop system. Wherever possible, heat trace/heat medium/hot glycol circulation pumps shall be solar-operated, electric or air-driven.

Modified Facilities

Requirements are the same as above except include all new and existing pneumatic pumps and use the date of modification in place of FDOP.

New and Modified Facilities

At sites where pneumatic pump emissions are controlled by a combustion unit used for the control of flashing or dehydration unit emissions, control of the pneumatic pump emissions will be evaluated upon request for removal of the combustion unit. (See Flashing, Page 7)

Presumptive BACT Requirements for SWA Facilities (cont.)

Pneumatic Controllers

New Facilities

Upon FDOP, natural gas-operated pneumatic controllers shall be low bleed or zero bleed controllers or the controller discharge streams shall be routed into a closed loop system.

Modified Facilities

Upon modification, new natural gas-operated pneumatic controllers shall be low or zero bleed controllers or the controller discharge streams shall be routed into a closed loop system.

Within 60 days of modification, existing natural gas-operated pneumatic controllers shall be replaced by or converted to low or zero bleed controllers or the discharge streams of existing natural gas-operated pneumatic controllers shall be routed into a closed loop system.

Truck Loading

New Facilities

Within 60 days of FDOP, loading emissions containing greater than or equal to 6 TPY VOC and HAP emissions shall be controlled. Operators are expected to utilize a vapor collection system or equivalent device for the truck loading operation that is assumed, based on AP-42 Section 5.2, to capture a minimum of 70% of the truck loading vapors. The captured vapors are to be routed to a smokeless combustion device with a reported destruction efficiency of 98%, or routed to an equivalent control.

Modified Facilities

Upon modification, all new and existing VOC and HAP loading emissions containing greater than or equal to 6 TPY VOC and HAP emissions shall be controlled. Operators are expected to utilize a vapor collection system or equivalent device for the truck loading operation that is assumed, based on AP-42 Section 5.2, to capture a minimum of 70% of the truck loading vapors. The captured vapors are to be routed to a smokeless combustion device with a reported destruction efficiency of 98%, or routed to an equivalent control.

New and Modified Facilities

The removal of a control device(s) may be allowed upon approval if after at least one year from the date of installation VOC and HAP loading emissions have declined to less than, and are expected to remain below 4 TPY of VOC and HAPs.

Note: Safety issues associated with the control of truck loading emissions will be taken into consideration by the Division. Applicants will be required to demonstrate that safety issues would preclude the application of controls, and the demonstration will have to be approved by the Division prior to the date that controls would be required under the Guidance.

Presumptive BACT Requirements for SWA Facilities (cont.)

Well Completions

Operators shall submit applications to perform well completions using Best Management Practices. One permit will be issued to each company that drills and completes wells within the State. An example of a well completions or “Green Completions” permit is available on the AQD website, <http://deq.wyoming.gov/aqd/new-source-review> or a copy may be obtained by contacting the Wyoming Air Quality Division at (307) 777-7391.

For existing operators, Green Completion permit applications shall be filed with the Division by January 1, 2017. For new operators, a Green Completion permit application shall be filed with the first application for a production site.

Produced Water Tanks

New Facilities

PAD Facilities

Upon FDOP, VOC and HAP emissions from all active produced water tanks shall be controlled by at least 98%.

Single Well Facilities and Tank Batteries

Within 60 days of FDOP, at sites where flashing emissions must be controlled by at least 98%, VOC and HAP emissions from all active produced water tanks shall be controlled by at least 98%.

Modified Facilities

PAD Facilities

Upon modification, VOC and HAP emissions from all new active produced water tanks shall be controlled by at least 98%.

Within 60 days of modification, existing open-top, active, produced water tanks shall be taken out of service for use as active produced water tanks. All active produced water tanks shall be closed top and shall have VOC and HAP emissions controlled by at least 98%.

New and Modified Facilities

Produced water tanks that are on site solely for use during emergency or upset conditions, such as spare tanks at facilities connected to liquids gathering systems, are not subject to the 98% control requirements.

The removal of a emissions control device(s) may be allowed upon approval if, after at least one year from the date of installation, VOC and HAP flashing emissions have declined to less than, and are reasonably expected to remain below 4 TPY of VOC and HAPs.

Presumptive BACT Requirements for SWA Facilities (cont.)

Blowdown/Venting

Best Management Practices (BMP) and information gathering requirements for new and modified facilities.

BMP: During manual and automated blowdown/venting episodes associated with liquids unloading, wellbore depressurization in preparation for maintenance or repair, hydrate clearing, emergency operations, equipment depressurization, etc., associated VOC and HAP emissions shall be minimized to the extent practicable. During manual blowdown or venting, personnel shall remain on site to ensure minimal gas venting occurs.

Information Gathering: Specific recordkeeping and reporting requirements will be established during the permitting process and will include estimates of associated regulated air pollutants, reasons for episodes, durations of episodes, steps taken to minimize emissions and descriptions of emission estimation methods.

For existing operators, well blowdown and venting permit applications shall be filed with the Division by January 1, 2017. For new operators, a well blowdown and venting permit application shall be filed with the first application for a production site.

Emission Sources without Presumptive BACT requirements

For uncontrolled sources emitting greater than or equal to 6 TPY VOC and HAP emissions, that do not have P-BACT requirements, a BACT analysis shall be filed with the permit application for the associated facility.

INTENTIONALLY LEFT BLANK

Presumptive BACT Requirements for UGRB Facilities

Flashing

For the purpose of determining flashing emissions all vapor streams containing VOC or HAP components from all storage tanks (e.g., oil, condensate, produced water with oil or condensate carryover) and all separation vessels (e.g., gun barrels, production and test separators, production and test treaters, water knockouts, gas boots, flash separators, drip pots, etc.) at a facility, which are or may be vented to the atmosphere shall be considered.

New Facilities

PAD Facilities

Upon FDOP, VOC and HAP flashing emissions shall be controlled by at least 98%.

Single Well Facilities and Tank Batteries

Within 60 days of FDOP, flashing emissions containing greater than or equal to 4 TPY VOC and HAPs shall be controlled by at least 98%.

Modified Facilities

PAD Facilities

Upon modification, all new and existing VOC and HAP flash emissions shall be controlled by at least 98%.

Single Well Facilities and Tank Batteries

Within 60 days of modification, all new and existing flashing emissions containing greater than or equal to 4 TPY VOC and HAPs shall be controlled by at least 98%.

New and Modified Facilities

Condensate and oil tanks that are on site for use during emergency or upset conditions, such as spare tanks at facilities connected to liquids gathering systems, are not subject to the 98% control requirements.

The removal of flashing emissions control devices may be allowed upon approval after one year if VOC flashing emissions have declined to less than, and are reasonably expected to remain below 4 TPY.

Presumptive BACT Requirements for UGRB Facilities (cont.)

Dehydration Units

For the purpose of determining emissions from dehydration units, vapor streams containing VOC or HAP components released from the process vents (reboiler still vents & glycol flash separator vents) of all dehydration units at a facility, which are or may be vented to the atmosphere shall be considered. See page 9 for the definitions of **potential uncontrolled** VOC and HAP emissions and **potential** VOC and HAP emissions.

New Facilities

Upon FDOP, all dehydration units shall be equipped with reboiler still vent condensers. Removal of the condensers will not be allowed.

PAD Facilities

Upon FDOP, all dehydration unit VOC and HAP emissions shall be controlled by at least 98%. After one year, combustion units used to achieve the 98% control may be removed upon approval if

- Total **potential** VOC and HAP emissions from all units are less than 4 TPY and
- All units are equipped with still vent condensers.

Single Well Facilities

Within 60 days of FDOP, if total **potential uncontrolled** VOC and HAP emissions from all units are greater than or equal to 4 TPY, emissions from all units shall be controlled by at least 98%.

After one year, combustion units used to achieve the 98% control may be removed upon approval if

- Total **potential** VOC and HAP emissions from all units are less than 4 TPY and
- All units are equipped with still vent condensers.

Modified Facilities

Requirements are the same as those for PADs and single well facilities except use the date of modification in place of FDOP. Control requirements apply to existing and new dehydration units.

All Facilities

When a combustion unit is required at a facility for control of flash or dehydration unit emissions, all non-condensable still vent vapors shall be collected and routed to the combustion unit for at least 98% control of VOC and HAP emissions and all glycol flash separator vapors shall be collected and routed to the combustion unit for at least 98% control of VOC and HAP emissions and/or used as fuel for process equipment burners.

At facilities where a combustion unit is not required for control of flash or dehydration unit emissions, all glycol flash separator vapors shall be collected for use as fuel in process equipment burners. Excess flash vapors that are not used as fuel may be vented to the atmosphere.

Presumptive BACT Requirements for UGRB Facilities (cont.)

Pneumatic Pumps

New Facilities

Upon FDOP, VOC and HAP emissions associated with the discharge streams of all natural gas-operated pneumatic pumps shall be controlled by at least 98% or the pump discharge streams shall be routed into a closed loop system (e.g., sales line, collection line, fuel supply line).

Modified Facilities

Upon modification, VOC and HAP emissions associated with the discharge streams of all new and existing natural gas-operated pneumatic pumps shall be controlled by at least 98% or the pump discharge streams shall be routed into a closed loop system.

New and Modified Facilities

At sites where pneumatic pump emissions are controlled by a combustion unit used for the control of flash or dehydration unit emissions, control of the pneumatic pump emissions will be evaluated upon request for removal of the combustion unit. (See Flashing, Page 14)

Pneumatic Controllers

New Facilities

Upon FDOP, natural gas-operated pneumatic controllers shall be low or zero bleed controllers or the controller discharge streams shall be routed into a closed loop system.

Modified Facilities

Upon modification, new natural gas-operated pneumatic controllers shall be low or zero bleed controllers or the controller discharge streams shall be routed into a closed loop system.

Within 60 days of modification, existing natural gas-operated pneumatic controllers shall be replaced by or converted to low or zero bleed controllers or the discharge streams of existing natural gas-operated pneumatic controllers shall be routed into a closed loop system.

Presumptive BACT Requirements for UGRB Facilities (cont.)

Fugitives

For new and modified facilities where fugitive emissions are greater than or equal to 4 TPY of VOCs, operators shall submit a Fugitive Emissions Monitoring (FEM) Protocol. The fugitive emission monitoring in the FEM Protocol shall be no less frequent than quarterly, and may consist of Method 21, infrared camera, audio-visual-olfactory (AVO) inspections, or some combination thereof and must be approved by the Division. A proposed FEM Protocol consisting of only AVO inspections will not be accepted by the Division.

Truck Loading

New Facilities

Within 60 days of FDOP, loading emissions containing greater than or equal to 6 TPY VOC and HAP emissions shall be controlled. Operators are expected to utilize a vapor collection system or equivalent device for the truck loading operation that is assumed, based on AP-42 Section 5.2, to capture a minimum of 70% of the truck loading vapors. The captured vapors are to be routed to a smokeless combustion device with a reported destruction efficiency of 98%, or routed to an equivalent control.

Modified Facilities

Upon modification, all new and existing VOC and HAP loading emissions containing greater than or equal to 6 TPY VOC and HAP emissions shall be controlled. Operators are expected to utilize a vapor collection system or equivalent device for the truck loading operation that is assumed, based on AP-42 Section 5.2, to capture a minimum of 70% of the truck loading vapors. The captured vapors are to be routed to a smokeless combustion device with a reported destruction efficiency of 98%, or routed to an equivalent control.

New and Modified Facilities

The removal of a control device(s) may be allowed upon approval if after at least one year from the date of installation VOC and HAP loading emissions have declined to less than, and are expected to remain below 4 TPY of VOC and HAPs.

Note: Safety issues associated with the control of truck loading emissions will be taken into consideration by the Division. Applicants will be required to demonstrate that safety issues would preclude the application of controls, and the demonstration will have to be approved by the Division prior to the date that controls would be required under the Guidance.

Presumptive BACT Requirements for UGRB Facilities (cont.)

Well Completions

Operators shall submit applications to perform well completions using Best Management Practices. One permit will be issued to each company that drills and completes wells within the **UGRB**. The permits will be modeled after those issued to operators completing wells in the Jonah and Pinedale Anticline Development Area. An example of a well completions or “Green Completions” permit is available on the AQD website, <http://deq.wyoming.gov/aqd/new-source-review> or a copy may be obtained by contacting the Wyoming Air Quality Division at (307) 777-7391.

Produced Water Tanks

New Facilities

PAD Facilities

Upon FDOP, VOC and HAP emissions from all active produced water tanks shall be controlled by at least 98%.

Single Well Facilities and Tank Batteries

Within 60 days of FDOP, at sites where flashing emissions must be controlled by at least 98%, VOC and HAP emissions from all active produced water tanks shall be controlled by at least 98%.

Modified Facilities

PAD Facilities

Upon modification, VOC and HAP emissions from all new active produced water tanks shall be controlled by at least 98%.

Within 60 days of modification, existing open-top, active, produced water tanks shall be taken out of service for use as active produced water tanks. All active produced water tanks shall be closed top and shall have VOC and HAP emissions controlled by at least 98%.

Single Well Facilities and Tank Batteries

Within 60 days of modification, at sites where flashing emissions must be controlled by at least 98%, VOC and HAP emissions from all active produced water tanks shall be controlled by at least 98%.

New and Modified Facilities

Open-top or blow down tanks shall not be used as active produced water tanks but may be used for blow down or for temporary storage during emergency or upset conditions, such as spare tanks at facilities connected to liquids gathering systems, and do not have to be tied into 98% control systems.

Removal of produced water tank emissions control may be allowed upon approval. (See Flashing, Page 14)

Presumptive BACT Requirements for UGRB Facilities (cont.)

Blowdown/Venting

Best Management Practices (BMP) and information gathering requirements will be incorporated into permits for new and modified facilities.

BMP: During manual and automated blowdown/venting episodes associated with liquids unloading, wellbore depressurization in preparation for maintenance or repair, hydrate clearing, emergency operations, equipment depressurization, etc., associated VOC and HAP emissions shall be minimized to the extent practicable. During manual blowdown or venting, personnel shall remain on site to ensure minimal gas venting occurs.

Information Gathering: Specific recordkeeping and reporting requirements will be established during the permitting process and will include estimates of associated regulated air pollutants, reasons for episodes, durations of episodes, steps taken to minimize emissions and descriptions of emission estimation methods.

Emission Sources without Presumptive BACT requirements

For uncontrolled sources emitting greater than or equal to 4 TPY VOC that do not have P-BACT requirements, a BACT analysis shall be filed with the permit application for the associated facility.

INTENTIONALLY LEFT BLANK

Presumptive BACT Requirements for [JPAD/NPL Facilities](#)

Flashing

For the purpose of determining flashing emissions all vapor streams containing VOC or HAP components from all storage tanks (e.g., oil, condensate, produced water with oil or condensate carryover) and all separation vessels (e.g., gun barrels, production and test separators, production and test treaters, water knockouts, gas boots, flash separators, drip pots, etc.) at a facility, which are or may be vented to the atmosphere shall be considered.

New Facilities

Upon FDOP, VOC and HAP flashing emissions shall be controlled by at least 98%.

Modified Facilities

Upon modification, all new and existing VOC and HAP flashing emissions shall be controlled by at least 98%.

New and Modified Facilities

Condensate and oil tanks that are on site for use during emergency or upset conditions, such as spare tanks at facilities connected to liquids gathering systems, are not subject to the 98% control requirements.

The removal of flashing emissions control devices may be allowed upon approval after one year if VOC and HAP flashing emissions have declined to less than, and are reasonably expected to remain below 4 TPY.

Dehydration Units

New Facilities

Upon FDOP, all VOC and HAP emissions from dehydration unit process vents shall be controlled by at least 98%. No control removal will be allowed.

Modified Facilities

Upon modification, all VOC and HAP emissions from new and existing dehydration unit process vents shall be controlled by at least 98%. No control removal will be allowed.

Presumptive BACT Requirements for [JPAD/NPL Facilities \(cont.\)](#)

Pneumatic Pumps

New Facilities

Upon FDOP, VOC and HAP emissions associated with the discharge streams of all natural gas-operated pneumatic pumps shall be controlled by at least 98% or the pump discharge streams shall be routed into a closed loop system (e.g., sales line, collection line, fuel supply line).

Modified Facilities

Upon modification, VOC and HAP emissions associated with the discharge streams of all new and existing natural gas-operated pneumatic pumps shall be controlled by at least 98% or the pump discharge streams shall be routed into a closed loop system.

New and Modified Facilities

For pneumatic pump emissions controlled by a combustion unit used to control flash emissions which may be removed, the control method for pump emissions will be evaluated upon request for approval to remove the combustion unit. (See Flashing, Page 20)

Pneumatic Controllers

New Facilities

Upon FDOP, natural gas-operated pneumatic controllers shall be low or zero bleed controllers or the controller discharge streams shall be routed into a closed loop system.

Modified Facilities

Upon modification, new natural gas-operated pneumatic controllers shall be low or zero bleed controllers or the controller discharge streams shall be routed into a closed loop system.

Within 60 days of modification, existing natural gas-operated pneumatic controllers shall be replaced by or converted to low or zero bleed controllers or the controller discharge streams shall be routed into a closed loop system.

Produced Water Tanks

New Facilities

Upon FDOP, VOC and HAP emissions from all active produced water tanks shall be controlled by at least 98%.

Modified Facilities

Upon modification, VOC and HAP emissions from all new active produced water tanks shall be controlled by at least 98%.

Within 60 days of modification, existing open-top, active, produced water tanks shall be taken out of service for use as active produced water tanks. All active produced water tanks shall be closed top and shall have VOC and HAP emissions controlled by at least 98%.

New and Modified Facilities

Open-top or blow down tanks shall not be used as active produced water tanks but may be used for blow down or for temporary storage during emergency or upset conditions, such as spare tanks at facilities connected to liquids gathering systems, and do not have to be tied into 98% control systems.

Removal of water tank emissions control may be allowed upon approval. (See Flashing, Page 20)

Fugitives

For new and modified facilities where fugitive emissions are greater than or equal to 4 TPY of VOCs, operators shall submit a FEM Protocol. The fugitive emission monitoring in the FEM Protocol shall be no less frequent than quarterly, and may consist of Method 21, infrared camera, AVO inspections, or some combination thereof and must be approved by the Division. A proposed FEM Protocol consisting of only AVO inspections will not be accepted by the Division.

Presumptive BACT Requirements for [JPAD/NPL](#) Facilities (cont.)

Truck Loading

New Facilities

Within 60 days of FDOP, loading emissions containing greater than or equal to 6 TPY VOC and HAP emissions shall be controlled. Operators are expected to utilize a vapor collection system or equivalent device for the truck loading operation that is assumed, based on AP-42 Section 5.2, to capture a minimum of 70% of the truck loading vapors. The captured vapors are to be routed to a smokeless combustion device with a reported destruction efficiency of 98%, or routed to an equivalent control.

Modified Facilities

Upon modification, all new and existing VOC and HAP loading emissions containing greater than or equal to 6 TPY VOC and HAP emissions shall be controlled. Operators are expected to utilize a vapor collection system or equivalent device for the truck loading operation that is assumed, based on AP-42 Section 5.2, to capture a minimum of 70% of the truck loading vapors. The captured vapors are to be routed to a smokeless combustion device with a reported destruction efficiency of 98%, or routed to an equivalent control.

New and Modified Facilities

The removal of a control device(s) may be allowed upon approval if after at least one year from the date of installation VOC and HAP loading emissions have declined to less than, and are expected to remain below 4 TPY of VOC and HAPs.

Note: Safety issues associated with the control of truck loading emissions will be taken into consideration by the Division. Applicants will be required to demonstrate that safety issues would preclude the application of controls, and the demonstration will have to be approved by the Division prior to the date that controls would be required under the Guidance.

Well Completions

Operators shall submit applications to perform well completions using Best Management Practices. One permit will be issued to each company that drills and completes wells within the [JPAD/NPL](#). The permits will be modeled after those issued to operators completing wells in the Jonah and Pinedale Anticline Development Area. An example of a well completions or “Green Completions” permit is available on the AQD website, <http://deq.wyoming.gov/aqd/new-source-review> or a copy may be obtained by contacting the Wyoming Air Quality Division at (307) 777-7391.

Presumptive BACT Requirements for [JPAD/NPL Facilities \(cont.\)](#)

Blowdown/Venting

Best Management Practices (BMP) and information gathering requirements will be incorporated into permits for new and modified facilities.

BMP: During manual and automated blow down/venting episodes associated with liquids unloading, wellbore depressurization in preparation for maintenance or repair, hydrate clearing, emergency operations, equipment depressurization, etc., associated VOC and HAP emissions shall be minimized to the extent practicable. During manual blow down or venting, personnel shall remain on site to ensure minimal gas venting occurs.

Information Gathering: Specific recordkeeping and reporting requirements will be established during the permitting process and will include estimates of associated regulated air pollutants, reasons for episodes, durations of episodes, steps taken to minimize emissions and descriptions of emission estimation methods.

Emission Sources without Presumptive BACT requirements

For uncontrolled sources emitting greater than or equal to 4 TPY VOC and HAPs that do not have P-BACT requirements, a BACT analysis shall be filed with the permit application for the associated facility.

INTENTIONALLY LEFT BLANK

Determining P-BACT Flashing Emissions

Flashing losses occur when produced liquids (crude oil or condensate) are exposed to temperature increases or pressure drops as they are transferred from production vessels to other vessels or to atmospheric storage tanks. For purposes of this guidance, the term “**flash emissions**” refers to VOC and HAP pollutants associated with entrained natural gas vapors released to the atmosphere from hydrocarbon liquids in surface production equipment. This production equipment may include gun barrels, separators, treaters, produced water tanks, gas drips, freewater knockouts, etc. In addition to flash emissions, vessels containing hydrocarbon liquids also have emissions associated with **working** and **breathing** (also called standing) losses. These are vapors displaced from oil or condensate due to evaporation and agitating.

Use the following steps to determine projected potential flashing and working/breathing losses:

STEP 1: 30 days after the First Date of Production calculate the **average daily condensate or oil production**.

*Example: Well produced 600 BBL during the first 30 days after the First Date of Production.
average daily condensate/oil production = 600 BBL ÷ 30 days = 20 BPD*

STEP 2: Calculate the **projected first year annualized average daily condensate/oil production** rate by multiplying the average 30-day rate times 0.6. This effectively results in a first year, annualized daily production rate, which is 20% of the initial production rate. Additionally, this effectively accounts for an 80% decline in daily production by the end of the first year. (described in more detail on page 36)

Example:

***projected first year, annualized average daily oil/condensate production** = 20 × 0.6 = 12 BPD*

If the expected decline rate is less than 80%, then the expected decline rate should be used. Using an expected decline rate > 80% requires pre-approval from the Division.

STEP 3: Use an approved flash emissions model or direct measurement of tank emissions to determine **projected first year VOC and HAP emissions associated with the projected first year average daily production rate**.

Actual flash emissions are determined the same as projected potential emissions except that the actual average daily condensate or oil production rate is used rather than a projected production rate.

Determining P-BACT Flashing Emissions (cont.)

Several methods are available to calculate or measure flash emissions with some being more accurate than others. Even though working/breathing/flashing losses are almost always mixed together and exit from a common vent at the same time, some methods only calculate working and breathing losses and some only calculate flashing losses. Some methods will calculate all three types of emissions simultaneously. Each method has specific constraints. For whichever method used, all supporting data used to calculate the emissions, including identification of the calculation method, description of sampling methods and copies of lab sampling analyses shall be provided with the emissions estimate.

| | Method | Emissions Calculated | Comments |
|---|--|---------------------------|---|
| 1 | Direct measurement | working, breathing, flash | Sampling and lab analysis required. Results are relatively accurate. |
| 2 | Process Simulator | flash, working, breathing | i.e. PROMAX, HYSIM, HYSIS Software is expensive but results are accurate when based on site-specific sampling and lab analysis. |
| 3 | API E&P TANKS Software V 2.0 and higher | working, breathing, flash | Requires site specific sampling. Not as accurate as more expensive process simulators and no longer supported by the software producer (American Petroleum Institute). |
| 4 | Laboratory measurement of the Gas-Oil-Ratio (GOR) from a pressurized liquid sample | flash only | This is a direct laboratory analysis of the flash vapors emitted from a pressurized oil/condensate sample. |
| 5 | EPA TANKS 4.0.9d | working, breathing only | Program distributed by the EPA through their website at https://www3.epa.gov/ttn/chief/software/tanks/index.html |

Extended hydrocarbon liquids analyses used for model input shall be no older than **three** years. Composite analyses may be used as input. These are averaged extended hydrocarbon compositions based on samples from at least five wells located in the same geographical area, producing from the same formation and under similar conditions ($\pm 25^\circ$ psig) as the well being permitted. Analyses used as the basis for the average shall be no older than **three** years.

Determining P-BACT Dehydration Unit Emissions

Dehydration units use glycol (TEG, DEG or EG) to absorb water from produced gas before it is introduced into gas sales or collection lines. Upon contact with wet gas, “lean” glycol absorbs water and other liquids. It is then considered “rich”. To remove impurities, or regenerate, the rich glycol is routed through a glycol flash separator and/or a reboiler. During flash separation and reboiling, water and hydrocarbon vapors containing VOC and HAP pollutants are released from the rich glycol. These are then discharged to the atmosphere from the dehydration unit process vents.

Use the following steps to determine projected potential dehydration unit emissions:

STEP 1: Once a new well has produced for 30 days after the First Date of Production, determine the average daily gas production rate.

Example:

*Well produced 100 MMCF during the first 30 days after the First Date of Production
average daily gas production = $100 \text{ MMCF} \div 30 \text{ days} = 3.3 \text{ MMCFD}$*

STEP 2: Calculate the **projected first year, annualized average daily gas production** rate by multiplying the initial average 30-day rate times 0.6. This effectively results in a first year, annualized daily production rate, which is 20% of the initial production rate. Additionally, this effectively calculates an 80% decline in daily production by the end of the first year. (described in more detail on page 36.)

Example:

***projected first year, annualized average daily gas production** = $3.3 \times 0.6 = 2.0 \text{ MMCFD}$*

STEP 3: Use GRI-GLYCalc V4.0 or higher or other method approved by the Division with the projected first year, annualized average daily production rate to determine **potential, annualized uncontrolled VOC and HAP emissions** from the dehydration unit **process vents**. **Process vents** include reboiler still vents, glycol flash separators and still vent condensers.

Model input:

- 1) An extended hydrocarbon analysis of wet gas sampled upstream of the reboiler contact tower. Or, a composite extended hydrocarbon analysis may be used. A composite analysis is the average composition from at least five nearby wells producing from the same formation as the new well and under the same or very similar separator pressure and temperature conditions. Samples shall be no older than three years.
- 2) The projected first year average daily gas production rate (MMCFD).
- 3) Average, actual equipment operational parameters, including wet gas temperature and pressure, dry gas water content, glycol flash separator temperature and pressure, stripping gas source and rate and average operating parameters of emission control equipment.
- 4) The **maximum lean glycol circulation rate** (gpm) for the glycol circulation pump in use. Maximum circulation rates for the most commonly used Kimray Model pumps are listed in **TABLE 1**.

Determining P-BACT Dehydration Unit Emissions (cont.)

TABLE 1

| KIMRAY GLYCOL PUMP RATES | | | | |
|---------------------------------|----------------|------|------------------------|------|
| Model # | Capacity (gpm) | | Working Pressure (psi) | |
| | min | max | min | max |
| 3154 PV | 0.05 | 0.22 | 100 | 1500 |
| 1715 PV | 0.13 | 0.67 | 300 | 1500 |
| 4015 PV | 0.2 | 0.67 | 300 | 1500 |
| 9015 PV | 0.45 | 1.5 | 300 | 1500 |
| 21015 PV | 1.1 | 3.5 | 400 | 1500 |
| 45015 PV | 2.77 | 7.5 | 400 | 1500 |
| 4015 LP | 0.13 | 0.33 | 100 | 500 |
| 2015 SC | 0.13 | 0.33 | 100 | 500 |
| 5015 SC | 0.2 | 0.83 | 100 | 500 |
| 10015 SC | 0.37 | 1.67 | 100 | 500 |
| 20015 SC | 1 | 3.33 | 100 | 500 |

Data from Kimray O&G Equipment and Controls Catalog

Actual dehydration unit emissions are determined the same as projected potential emissions except that the actual average daily gas production rate is used in the GLYCalc model rather than a projected production rate.

BACT for Flashing Emissions

The following control systems or devices are accepted by the Division as meeting BACT for flash emissions:

- 1) A vapor recovery device that is designed and operated and may be demonstrated to reduce the mass content of VOC and total HAP emissions in the vapors vented to the device by at least 98%.
- 2) An enclosed, smokeless combustion device or flare that is designed and operated and may be demonstrated to reduce the mass content of VOC and total HAP emissions in the vapors vented to the device by at least 98%.
- 3) Any other control device or configuration that can be demonstrated to reduce the mass content of total HAP and VOC in the process gases vented to the device or configuration by at least 98%.
- 4) Monitoring and recordkeeping, which will demonstrate continuous and effective emission control are required upon start up of the control system. For a combustion device this may be a thermocouple and continuous recording device or any other equivalent device to detect and record the presence of the pilot flame, or a combustion chamber temperature recorder/monitor. The monitoring/recording requirements become enforceable permit conditions.
- 5) Emissions control equipment, systems or devices, all vent lines, connections, fitting, valves, relief valves, thief hatches or any other appurtenance employed to contain and collect vapors and transport them to the emission control system or device, shall be maintained and operated during any time a well is producing such that the emissions are controlled at all times.

CAUTION: Total emissions from any facility or source shall not exceed major source levels prior to emission control installation. Major source levels are 10 TPY of any single HAP, 25 TPY of any combination of HAP or 100 TPY of any regulated pollutant. Flash emissions prior to control installation will be determined using approved emission models or methods based on actual reported production and operating conditions. Reported production includes that sold during well completion activities, which are reported to the WOGCC. Flash emissions are directly proportional to production rates, provided operational parameters remain consistent, so it is acceptable to prorate emissions based on production.

BACT for Dehydration Unit Emissions

Other emission control systems or devices than those previously discussed may be used upon approval by the Division to meet BACT requirements for emissions from dehydration unit process vents (reboiler still vents and vents from glycol flash separators or glycol flash tanks). In order to be approved, the operator must provide a demonstration certifying the system or device will reduce the mass content of total HAP and VOC in the process gases vented to the device or configuration by at least 98%.

Emissions control equipment, systems or devices, all vent lines, connections, fitting, valves, relief valves, hatches or any other appurtenance employed to contain and collect vapors and transport them to the emission control system or device, shall be maintained and operated during any time a well is producing such that the emissions are controlled at all times.

Monitoring and recordkeeping, which will demonstrate continuous and effective emission control are required upon start up of the control system. For combustion devices this may be a thermocouple and continuous recording device for the pilot flame or any other equivalent device to detect and record the presence of the pilot flame. A temperature recorder/monitor might be used to demonstrate sufficient heat of combustion or a continuous, wind-up chart recorder might be used to demonstrate continual operation by measuring and recording temperature or pressure parameters.

REMINDER: Dehydration units at oil and gas production facilities may be subject to additional NESHAP requirements under 40 CFR part 63, subpart HH. It is the operator's responsibility to comply with all applicable requirements of the NESHAP regulations.

CAUTION: Total emissions from any facility or source shall not exceed major source levels prior to emission control installation. Major source levels are 10 TPY of any single HAP, 25 TPY of any combination of HAP or 100 TPY of any regulated pollutant. Dehydration unit emissions occurring prior to the installation of required controls will be determined using the GRI-GLYCalc model or other method approved by the Division based on the maximum lean glycol circulation rate and the actual reported gas production rate including any gas, which was routed through the dehydration unit during well completion operations.

BACT for Sources without P-BACT Requirements

For emission sources without PRESUMPTIVE BACT requirements, BACT shall be addressed when the uncontrolled source emits greater than or equal to 6 TPY VOC and HAPs for sources located in the **SWA** or 4 TPY VOC and HAPs for sources located in the **UGRB** or **JPAD/NPL**.

For these sources **EITHER** the emission source will be controlled using previously implemented BACT **OR** a BACT cost analysis will be performed and submitted with the application showing either:

control is not technically feasible (i.e., due to physical constraints the emissions cannot be controlled)

OR

control is not economically reasonable (i.e., based on a control cost analysis the “cost to control per ton of pollutant reduced” is uneconomical).

CAUTION: **BACT** may be required at lower levels and for other emissions and emission sources than those stated in this guidance, but as a minimum, **BACT** shall be considered when equal to or above these guidance emission levels. For example, operators installing pumping unit engines according to Guidance might be asked to submit a BACT analysis for the engine.

Multiple pieces of the same type of equipment are considered one emission source for permitting purposes.

For example, there are five oily rag burners at a facility located in the **SWA**. Uncontrolled emissions from the five burners shall be aggregated for permitting purposes. If total uncontrolled VOC emissions from the five burners are less than the development area specific threshold of 6 TPY, BACT requirements are met with no control. If total uncontrolled emissions from the five burners are greater than or equal to 6 TPY VOC and HAPs, emissions from all five burners shall be reduced to less than 6 TPY VOC and HAPs in order to meet BACT requirements or the applicant shall demonstrate controlling the emissions is not economically reasonable nor technically feasible.

Permit Applications

For **JPAD/NPL**, **UGRB** and **SWA** facilities, unless a permit is issued prior to start up, a C6 S2 Oil & Gas Production Facilities permit application shall be filed within 90 days after the First Date of Production for a new facility or Date of Modification of an existing facility. The application notifies the AQD that the new or modified facility has begun operation. It describes the facility process, equipment and associated emissions/emissions controls and serves as a form of certification by the owner that the Presumptive BACT requirements have been met.

Whether the application is being filed after construction under the Presumptive BACT process or prior to construction, the appropriate application forms, depending upon the facility equipment and operating scenario, need to be filled out. A complete application includes the following

- A cover letter stating the purpose of the application
- Equipment list for the facility
- A written process description and process diagram for the facility, including each air emission source and the operational parameters of each source (examples provided on pages 34 & 35)
- The appropriate IMPACT forms
 - Cover Sheet
 - Emission Unit Form for all new or modified equipment
 - Pollutant Emissions Form for each emission unit
 - Release Point Form for each emission unit
 - Control Equipment Form (where applicable)
- The appropriate additional documentation (examples include)
 - Emission Summary
 - BACT cost analysis
- Explanations or demonstrations of all methods used to calculate or estimate emissions for each emission source, including controlled and uncontrolled sources. Emission calculation methods are described later.
- All applicable and required attachments, including:
 - Input and output for emission models/software/process simulations
 - Equipment manufacturer's emissions information
 - Laboratory analyses used for emission models/software/process simulations or calculations including a description of sampling procedures and handling, sampling locations, sampling location parameters (i.e., pressure and temperature at sampling port)
- Any additional attachments or information necessary for complete review of the application

Permit Applications (cont.)

As of September 2, 2014, the New Source Review program is processing all air quality permit applications electronically through the IMPACT System. There are two acceptable methods to submit an application. Please choose just one of the methods below:

- Applications may be submitted through the IMPACT portal (<https://airimpact.wyo.gov>). Submittals through the IMPACT portal are sufficient and paper copies are not required.
- Two paper copies (one with an original signature) of each complete permit application.

The preferred method for filing the application is through the IMPACT portal.

For facilities constructed or modified under the **Presumptive BACT** process a complete C6 S2 application shall be submitted within **90 days** of the **First Date of Production**. In the event that the IMPACT portal is not functioning properly and prevents the submittal of the application within 90 days of First Date of Production, the applicant will need to contact the Division prior to the due date of the application to inform NSR of the issue and the applicant will need to provide documentation in the permit application showing the reason for the delayed submittal. Examples of acceptable documentation include a screen shot showing the issue or a copy of email correspondence between the applicant and the Division discussing the problem.

If not submitting through the IMPACT portal, download IMPACT application forms from the AQD website:

<http://deq.wyoming.gov/aqd/new-source-review/resources/application-forms/>

The oil and gas applications forms are contained in one Microsoft Excel file. The file name for the IMPACT application forms is “01 - AQD - NSR - Application Form”.

If you need assistance with the applications forms, contact the Wyoming Air Quality Division at **(307) 777-7391**.

Address written requests to: Wyoming Department of Environmental Quality
Air Quality Division
(see WDEQ website for current mailing address)
attn: O&G NSR Permitting*

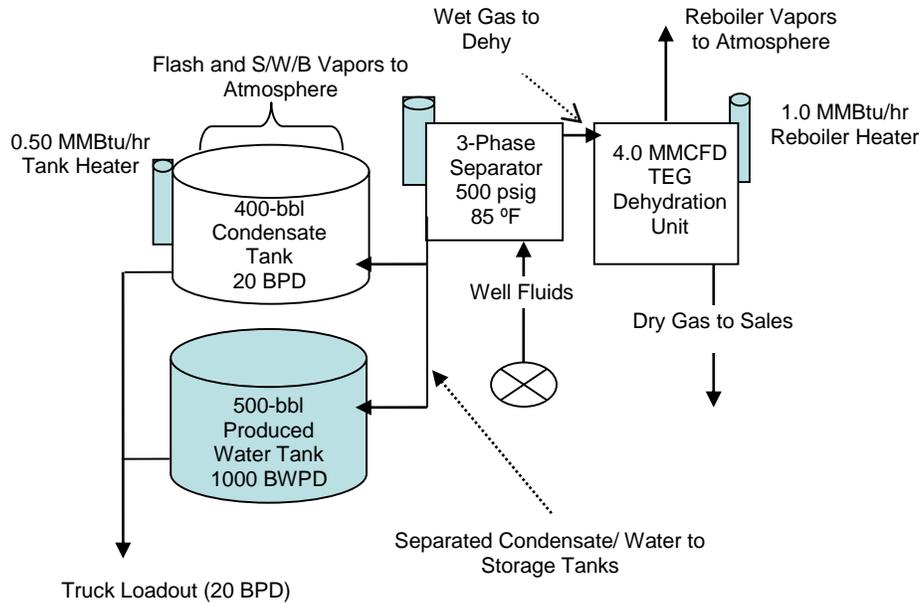

*To assist with the proper routing of the application and application materials, please make sure to address the materials to O&G NSR Permitting.

With the implementation of an electronic permitting system, the NOI process will no longer be utilized for new applications. Minor equipment installations and/or modifications that qualified for a NOI will now submit a complete application with the appropriate information listed on page 32. IMPACT forms and associated information are required for new or modified equipment.

Permit Applications (cont.)

Example Process Diagram & Description

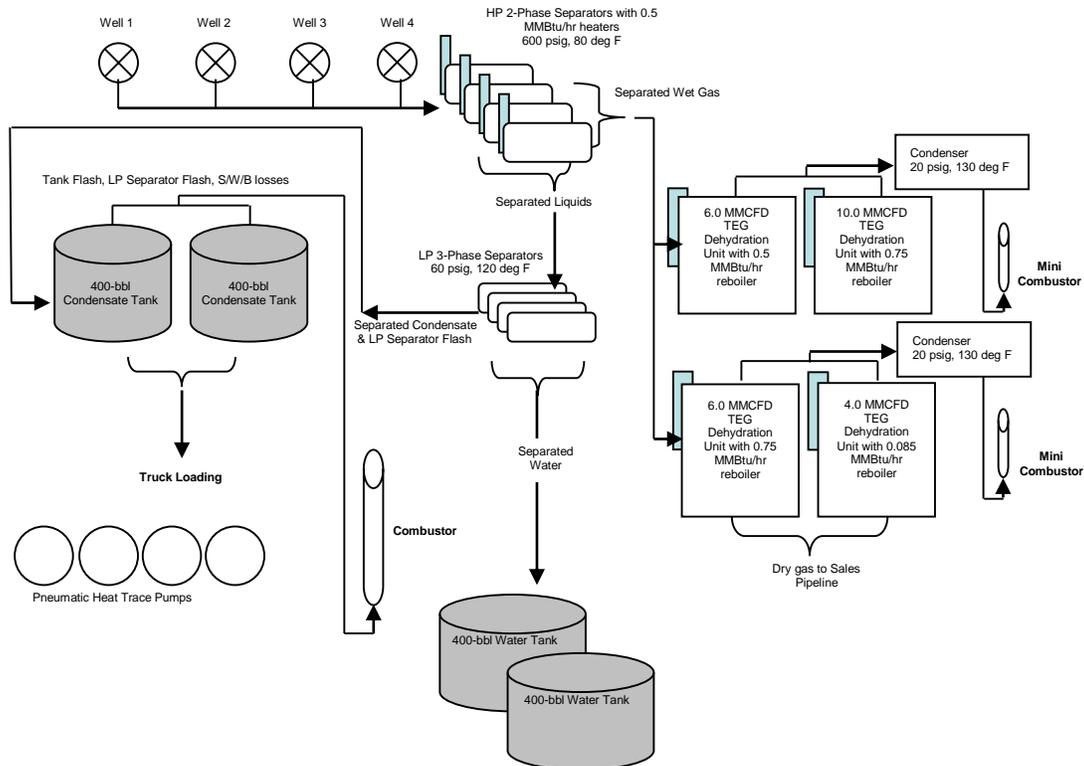

EXAMPLE: Air emission sources in the diagram are the condensate storage tank from which vapors are vented to the atmosphere, the dehydration unit reboiler still vent and the three natural gas-fired process heaters. Produced fluids are directed to the 3-phase separator for separation of condensate/water/gas. Wet gas is directed to the TEG dehydration unit for drying. Separated condensate and water are routed to the appropriate tanks for storage prior to being hauled from location via truck. Produced gas is used as burner fuel. Reboiler vapors and flash emissions are vented to the atmosphere along with S/W/B losses from the condensate tank.

Permit Applications (cont.)

Example Process Diagram & Description

EXAMPLE: Total well fluids from four wells flow to the 2-ph HP separators. Wet gas from the HP separators flows to the four dehydration units. Separated fluids from the 2-ph HP separators flows to the 3-ph LP separators. Separated condensate and water flows from the 3-ph LP separators to the storage tanks. Gas released in the 3-ph separators is routed to the condensate storage tanks. Tank vapors, including tank flash, gas from the 3-ph LP separators and S/W/B vapors are collected and directed to a 30-foot smokeless combustor. The temperature of the combustor is continually monitored and recorded using a SCADA (supervisory control and data acquisition) system. Reboiler still vents vapors flow through condensers. Condensed liquids are pumped to the condensate storage tanks. Non-condensable vapors flow to the 20-foot Mini-Combustors. The temperature of the Mini-combustors is continually monitored and recorded using a SCADA system. Pneumatic heat trace pumps operate 6 months per year using produced gas from the HP separators to operate. Vent lines from the pumps are routed into the condensate dump lines from the LP separators.

The process diagram does not need to be computer generated. A simple hand sketch is sufficient as long as the required information is included. The diagram does not need to be drawn to scale and does not need to represent the exact position of production equipment at the facility as long as the process description and operating scenario are clearly defined.

Permit Applications (cont.)

Upon receipt of a paper application, the Division must input the required application information into an electronic system (IMPACT) for processing. Once the paper application is processed, the Division sends the applicant a receipt letter. For electronic applications received via IMPACT, the Division simply issues a receipt letter after the application is received and a reviewer is assigned. The reviewer has up to 30 days to perform a completeness review to ensure adequate and correct information has been filed. If the application is deemed incomplete the reviewer will notify the applicant and request further information. Upon completeness the reviewer has 60 days to complete a technical review, write an application analysis and make any recommendations. During this process the decision to issue a permit or waiver takes place. If the decision is to issue a permit, the proposed permit, including compliance requirements, is published for a mandatory 30 day public comment period. If no comments are received the permit is issued once the public comment period ends. If comments are received these are addressed by the AQD. It is possible comments will warrant a public hearing. When this is the case, a final permit may be denied or delayed.

A minimum fee (\$464, subject to change) will be charged to each application. An hourly fee (\$58 per hour, subject to change) will be assessed for the time it takes AQD personnel to process the application. A bill will be sent to the applicant when the process is complete. Billing is handled as follows:

Initial billing (permits only) is assessed when a proposed permit is sent to public notice. The initial billing must be paid before AQD can issue a final permit.

Final billing is assessed for waivers and permits after these are issued.

Contact the Division for the current hourly rate.

NOTE: The Presumptive BACT permitting process may not be used for sour gas (H₂S) production facilities unless the only emissions of H₂S will be those associated with fugitive losses from valves, fittings, surface piping and pneumatic devices, etc. If there will be H₂S emissions associated with vented gas or tank vapors or if sour gas will be flared the applicant shall contact the Division for permitting guidance prior to construction.

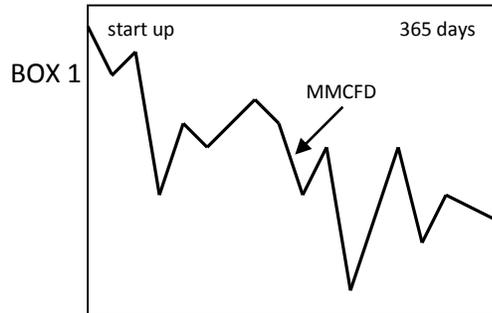

No internal combustion compressor engines or generator engines may be installed under the Presumptive BACT process.

No pumping unit engines greater than 50 Hp may be installed under the Presumptive BACT permitting process. Such engines shall be permitted prior to installation.

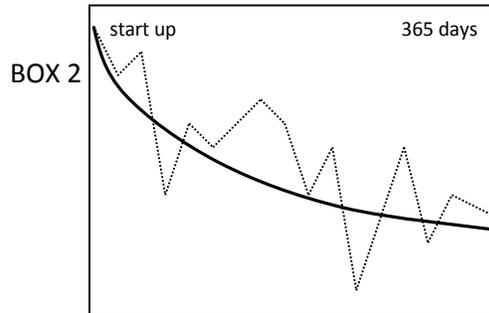

The 0.6 decline factor

The first year daily production rates are represented by the jagged line **BOX 1**. The area under the line represents the total actual production volume for the first year. It is difficult to calculate the total volume under the jagged line so it is smoothed out **BOX 2** using statistical methods.

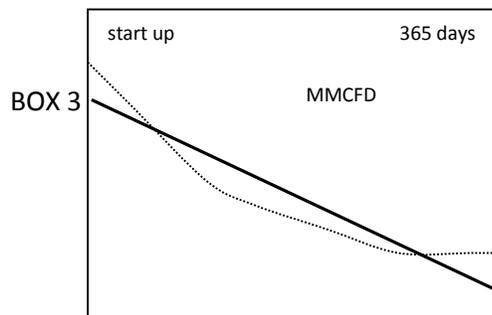

EXAMPLE - actual daily gas production rate vs time

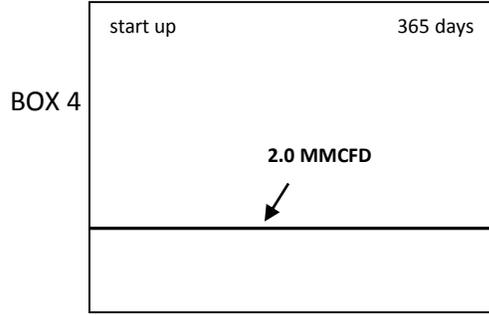

Actual production during the first year is represented by the area under the jagged line which ultimately turns out to be ≈ 730 MMCF.

The jagged line representing daily production is “smoothed” out using statistical methods.

The “smoothed” curve in BOX 2 is “straightened” out using mathematical methods.

“leveled” out, projected daily gas production rate vs time

Total projected production for the first year is represented by the area under the straight line
 $2 \text{ MMCFD} \times 365 \text{ days} = 730 \text{ MMCF}$

First year projected emissions are based on 730 MMCF of produced gas.

The smoothed curve is “straightened” out in **BOX 3**, then “leveled” out in **BOX 4**. Now the total production for the first year is represented by the area under the line in **BOX 4**, which is easily calculated. Production curves from a large sampling of Wyoming wells indicate the average well declines by 80% during the first year. That 80% decline is represented by the level line in **BOX 4** after the first 30-day average production rate is multiplied by 0.6. For the first month the well makes an average 3.333 MMCFD. With 80% decline during the first year, the well will make 0.667 MMCFD at the end of the first year ($3.333 - 0.8(3.333) = 0.667$). Then the average daily production rate over 365 days is $(3.333 + 0.667)/2 = 2.0$ MMCFD, which is the same as $3.333 \times 0.6 = 2.0$.

Pumping Unit Engines

A pumping unit engine is an engine used to provide electrical or mechanical energy to a pump in order to produce a well.

This Guidance does not apply to compressor engines, engines used for vapor recovery, or pumping unit engines greater than 50 Hp.

This Guidance replaces the March 9, 2012 Pumping Unit Engine Emissions Policy.

Historically, AQD has allowed the installation of pumping unit engines at oil & gas production facilities as part of the Guidance. Engines were allowed to be installed prior to permit issuance, provided the engine was site rated for less than 50 Hp and emitted less than 5 TPY of NO_x.

The Guidance does not however preclude the Division from asking the applicant to submit a Best Available Control Technology (BACT) analysis to determine if emissions from the engine are technically feasible and economically reasonable to control. As demonstrated in the March 9, 2012 Pumping Unit Engine Emissions Policy, BACT is a moving target and relying on an emissions threshold of 5 TPY NO_x was no longer considered BACT for pumping unit engines less than 50 Hp. AQD will continue to allow installation of pumping unit engines prior to obtaining a permit provided the engine meets BACT and the requirements listed below.

Installation of pumping unit engines site rated for 50 Hp or less is allowed provided the engine meets NO_x emissions of 2.0 g/hp-hr and CO emissions of 3.0 g/hp-hr.

Initial and/or periodic emissions testing and monitoring of the pumping unit engine may be established in the permit or permit waiver.

APPENDIX A

EMISSION CALCULATIONS

Emissions from processes and equipment, which shall be accounted for and reported by applicants FOR ALL O&G PRODUCTION FACILITIES are:

| Emission Unit or Process | Associated Emissions |
|---|-----------------------------|
| storage tanks (flashing & S/W/B losses) | VOC HAP |
| pressurized vessels (flashing losses) | VOC HAP |
| dehydration units (reboiler still vents & glycol flash tanks) | VOC HAP |
| natural gas fired burners, heaters, flares | VOC NO _x CO |
| natural gas operated pneumatic controllers/pumps | VOC HAP |
| fugitives | VOC HAP |
| natural gas fired engines | NO _x CO VOC |
| truck load out | VOC HAP |

AP-42 EMISSION FACTORS

Throughout this Guidance reference is made to AP-42 emission factors. The complete AP-42 compilation may be downloaded from <https://www3.epa.gov/ttn/chief/ap42/index.html>.

STORAGE TANK EMISSIONS

Flashing and Standing/Working/Breathing (S/W/B) losses are the terms for emissions which occur when hydrocarbon liquids are exposed to temperature and pressure changes (i.e., from separator pressure and temperature to storage tank pressure and temperature) causing hydrocarbon vapors to be released from the liquids. The vapors may contain VOCs, HAPs and H₂S.

Software is available for modeling these emissions. Models accepted by the Air Quality Division are those using Peng-Robinson or S-R-K methods based on widely accepted principals of behavior for hydrocarbon vapors and liquids. Some common software programs for estimating these emissions are PROMAX, HYSIM, HYSYS, K-FLASH, PROSIM and API E&P TANKS (v2.0 and higher). The models require input detailing chemical properties of the fluids handled and physical operating parameters of the system(s) and production equipment. Output from the models includes volumes, rates and chemical components of the individual process streams from tanks and pressurized vessels.

Emissions from storage tanks may also be physically measured. In order to do so all tank valves, hatches, relief devices, leaks, etc. shall be sealed. Tank vapors shall only be allowed to exit the tank through a metered outlet. Usually this requires a meter capable of measuring low volumes. The measurement period shall last long enough to capture a representative tank vapor volume. An extended hydrocarbon analysis of the vapors shall be obtained along with the vapor volume.

MEASURED TANK FLASH EMISSIONS – EXAMPLE CALCULATION

The tons per year of VOC and HAP emissions associated with tank flashing are calculated as follows:

Given: Condensate tank vapors = 1000 scf/day
VOC weight % = 20
HAP weight % = 5
Condensate vapor molecular weight = 20 lb/lb-mol

TPY total flash emissions = $1000 \text{ scf/day} \times (1 \text{ lb-mol}/379 \text{ scf}) \times (20 \text{ lb/lb-mol}) \times (\text{ton}/2000 \text{ lb}) \times (365 \text{ days/year}) = 9.6 \text{ TPY}$

TPY total VOC emissions = $9.6 \text{ TPY} \times (20 \text{ weight \% VOC} / 100) = 1.9 \text{ TPY VOC}$

TPY total HAP emissions = $9.6 \text{ TPY} \times (5 \text{ weight \% HAP} / 100) = 0.5 \text{ TPY HAP}$

S/W/B losses

Not all software programs include tools for estimating S/W/B losses. There is free software available from the EPA named EPA TANKS. The most recent available version of EPA TANKS may be downloaded from the EPA website at <https://www3.epa.gov/ttn/chief/software/tanks/index.html>.

PRESSURIZED VESSELS

Whenever vapors from a pressurized vessel (separator, treater, FWKO, flash separator, gunbarrel, gas boot, etc) are released to the atmosphere, other than during times of emergency or upset conditions, emissions associated with those vapors shall be accounted for.

The same flash emission models mentioned above, for tank flash emissions, are often used to estimate emissions from pressurized vessels. Again, an extended hydrocarbon analysis of the liquids involved and actual operational conditions of the production equipment are necessary as input for the models.

Even when vapors from a pressurized vessel are collected for use as process burner fuel or fuel for an IC engine, for example, emissions associated with the total vapors shall be accounted for when considering potential emissions from a facility. If the volume and rate of vented vapors are known and an extended hydrocarbon analysis is available, associated emissions may be calculated in the same manner as described on Page 39 (calculation of flash emissions). If these are not available, the volumes shall be measured and analyzed in order to perform the calculations and determine associated emissions.

DEHYDRATION UNIT EMISSIONS

Air pollutants, mostly VOCs and HAPs, are associated vapors released from reboiler still vents and glycol flash separators. To estimate these emissions the GRI-GLYCalc v4.0 or higher model or other approved method is used. This relatively inexpensive software was created by the Gas Research Institute (GRI) for determining optimal operating parameters for dehydration units and is available from the Gas Technology Institute (GTI) with a website address of <http://sales.gastechnology.org/>.

Input for the model includes an extended hydrocarbon analysis of wet gas sampled upstream of the contact tower, actual operating parameters of all associated equipment (i.e., reboiler still vent temp., flash separator temp., dry gas flow rate, glycol recirculation rate, condenser, etc) and physical properties of the dry and wet gas streams. The model provides an estimate of individual emission components and the rates of vapor and liquid streams exiting each process vent of a dehydration unit. When submitting a GRI-GLYCalc

model it is only necessary to submit the INPUT SUMMARY, EMISSIONS SUMMARY, CONDENSER VENT OUTPUT (if applicable) and FLASH TANK OUTPUT (if applicable).

NATURAL GAS FIRED HEATERS (external combustion equipment)

NO_x, CO and VOC emissions from process unit heaters should be calculated using the emission factors (EF) below from EPA AP-42, Tables 1.4-1, 1.4-2 and 1.5-1. The following lists these factors:

Emission Factors for Industrial and Commercial Boilers

| Pollutant | Butane Gas ¹ (0.3 to 100 MMBtu/hr heat input) | Propane Gas ² (0.3 to 100 MMBtu/hr heat input) | Natural Gas ³ <100 MMBtu/hr heat input | Natural Gas ³ |
|------------------------------|---|--|--|--------------------------|
| NO _x ⁴ | 15 lb/1000 gal | 13 lb/1000 gal | 0.098 lb/MMBtu | 100 lb/MMcf |
| CO ⁴ | 8.4 lb/1000 gal | 7.5 lb/1000 gal | 0.082 lb/MMBtu | 84 lb/MMcf |
| TOC ^{4,5} | 1.1 lb/1000 gal | 1.0 lb/1000 gal | 0.010 lb/MMBtu | 11 lb/MMcf |

- 1 Based on an average heating value of 102 × 10⁶ Btu/1000 gallons of Butane.
- 2 Based on an average heating value of 91.5 × 10⁶ Btu/1000 gallons of Propane.
- 3 Based on an average heating value of 1020 Btu/SCF of natural gas.
- 4 The emission factors in this table may be converted to other natural gas heating values by multiplying the given emission factors by the ratio of the heating value of the actual gas used to the average heating values listed
 Converted EF = (EF from table above × (actual heat value/heat value in table)).
- 5 VOC emissions may be determined by multiplying the calculated TOC (total organic compounds) emission rate by the weight percent of VOC compounds in the actual fuel gas stream.

HEATER EMISSIONS - EXAMPLE CALCULATION

Given: Separator heater rating = 0.5 MMBtu/hr
 Gas Heating Value = 1300 Btu/scf
 VOC weight % = 20
 Annual operating hours = 8760
 NO_x EF = 100 lb/MMcf
 CO EF = 84 lb/MMcf
 TOC EF = 11 lb/MMcf

NO_x emissions = (0.5 MMBtu/hr) × (100 lb/MMcf) × (1300 Btu/1020 Btu) × (1 scf/1020 Btu) × (8760 hr/yr) × (ton/2000 lb) = 0.27 TPY NO_x

For CO emissions, the same calculation is used except the EF is 84 lb/MMcf.

VOC emissions = 0.5 × 11 × (1300/1020) × 1/1020 × 8760/2000 × (20% VOC/100) = 0.006 VOC TPY VOC ← INSIGNIFICANT at less than 0.1 TPY

FLARES

The NO_x and CO emissions for flares should be based on **0.14 lb NO_x/MMBtu and 0.035 lb CO/MMBtu** (Emission factors from Section 4 of EPA Document “Preferred and Alternative Methods for Estimating Air Emissions from Oil and Gas Field Production and Processing Operations”) and the reported fuel usage based heat input. VOC and HAP emissions from flaring should be based upon the guaranteed destruction efficiency of the flare. Reported flared gases shall include pilot gas with heat content and flared gas with average estimated heat content. The rationale for using these factors as opposed to AP-42 factors for flares is that the flare factors are believed to be only applicable to chemical plant type flares engaged in burning low BTU gases. The gases typically burned in flares in Wyoming contain more than 900 Btu/scf and emissions are expected to be closer to the AP-42 factors for NO_x and CO from gas fired heaters and boilers greater than 10 MMBtu/hr.

FLARE EMISSIONS - EXAMPLE CALCULATIONS – CONDENSATE TANK FLASH

Given: Total waste gas = 125 scf/hr
Gas heating value = 1350 Btu/scf

$$\text{NO}_x \text{ emissions} = (125 \text{ scf/hr}) \times (1350 \text{ Btu/scf}) \times (0.14 \text{ lb NO}_x/\text{MMBtu}) \times (\text{MMBtu}/10^6 \text{ Btu}) \times (8760 \text{ hr/yr}) \times (1 \text{ ton}/2000 \text{ lb}) = 0.1 \text{ TPY NO}_x$$

FLARE PILOT EMISSIONS

Given: Flare pilot gas = 5 scf/min
Gas heating value = 1000 Btu/scf

$$\text{NO}_x \text{ emissions} = (5 \text{ scf/min}) \times (1000 \text{ Btu/scf}) \times (0.14 \text{ lb NO}_x/\text{MMBtu}) \times (\text{MMBtu}/10^6 \text{ Btu}) \times (60 \text{ min/hr}) \times (8760 \text{ hr/yr}) \times (1 \text{ ton}/2000 \text{ lb}) \\ = 0.18 \text{ TPY NO}_x$$

For CO emissions the same calculations are used except the EF for CO is 0.035 lb/MMBtu.

FLARE EMISSIONS EXAMPLE CALCULATION – DEHYDRATION UNITS

Given: Glycol flash separator vapors = 25 scf/min
Reboiler still vent vapors = 5 scf/min
Total waste gas = 30 scf/min (25 scf/min glycol flash vapors + 5 scf/min reboiler still vent vapors)
Gas Heating Value = 1050 Btu/scf (**assume at least 1000 BTU/SCF if the heat content is unknown**)

$$\text{NO}_x \text{ emissions} = (30 \text{ scf/min}) \times (1050 \text{ Btu/scf}) \times (0.14 \text{ lb NO}_x/\text{MMBtu}) \times (\text{MMBtu}/10^6 \text{ Btu}) \times (60 \text{ min/hr}) \times (8760 \text{ hr/yr}) \times (1 \text{ ton}/2000 \text{ lb}) \\ = 1.1 \text{ TPY NO}_x$$

For CO emissions the same calculations are used except the EF for CO is 0.035 lb/MMBtu.

PNEUMATIC PUMPS

If a pneumatic pump uses natural gas as the motive gas, the pump will release VOC and HAP emissions each time it strokes since all motive gas is vented by the pump. To determine emissions from the pump, manufacturer’s information regarding gas usage shall be known as well as the hydrocarbon composition of the motive gas.

PNEUMATIC PUMP EMISSIONS - EXAMPLE CALCULATION

A Texsteam Series MX pump is used to circulate hot glycol in heat trace lines. The pump moves 0.15 gallons per 40 strokes and is currently stroking at 20 strokes per minute (spm). The pump requires 24 scf for each gallon of glycol pumped. The pump motive gas weighs 20 lb/lb-mol and contains 50 wt% VOCs and 30 wt% HAPs.

$$\text{Pump usage/vent rate} = (20 \text{ strokes/min}) \times (0.15 \text{ gallons/40 strokes}) \times (24 \text{ scf/gallon}) = 1.8 \text{ scf/min}$$

$$\text{VOC emissions} = (1.8 \text{ scf/min}) \times (20 \text{ lb/lb-mol}) \times (\text{lb-mol}/379 \text{ scf}) \times (\text{ton}/2000 \text{ lb}) \times (525600 \text{ min/yr}) \times (50 \text{ wt\% VOC}/100) = 12.5 \text{ TPY VOC}$$

PNEUMATIC CONTROLLERS

Emissions from continuous bleed pneumatic controllers shall be based on the manufacturer-certified bleed rates. Emissions from intermittent vent controllers shall be based on the volume of gas required for actuation and the applicant's best engineering estimate of the frequency of actuations.

TRUCK LOADING

VOC emissions from loading oil or condensate into tank trucks should be estimated using the following formula with data from AP-42 tables.

$$L_L = 12.46 \times S \times P \times M/T$$

Where: L_L = loading loss, pound per 1,000 gallons of liquid loaded (lb/1000 gal)

S = a saturation factor (See Table 5.2-1 below)

P = true vapor pressure of liquid loaded (psia)

M = molecular weight of tank vapors (lb/lb-mol)

T = temperature of bulk liquid loaded ($^{\circ}\text{R}$) ($^{\circ}\text{R} = ^{\circ}\text{F} + 460$)

" S " values are obtained from Table 5.2-1.

" M " and " N " values are obtained from Table 7.1-2.

Table 5.2-1 Saturation (S) Factors for Calculating Petroleum Liquid Loading Losses

| Cargo Carrier | Mode of Operation | "S" Factor |
|--------------------------------|--|------------|
| tank trucks and rail tank cars | submerged loading of a clean cargo tank | 0.50 |
| | submerged loading: dedicated normal service | 0.60 |
| | submerged loading: dedicated vapor balance service | 1.00 |
| | splash loading of a clean cargo tank | 1.45 |
| | splash loading: dedicated normal service | 1.45 |
| | splash loading: dedicated vapor balance service | 1.00 |

Table 7.1-2 Properties of Selected Petroleum Liquids

Only crude oil properties are supplied here. The full table of values can be found in AP-42, Table 7.1-2)

| petroleum liquid | vapor molecular weight at 60°F (lb/lb-mol) | condensed vapor density at 60°F (lb/gal) | liquid density at 60°F (lb/gal) | true vapor pressure (psi) at various temperatures in °F | | | | | | |
|------------------|--|--|---------------------------------|---|-----|-----|-----|-----|-----|-----|
| | | | | 40 | 50 | 60 | 70 | 80 | 90 | 100 |
| | "M" | | | "P" | | | | | | |
| Crude Oil RVP 5 | 50 | 4.5 | 7.1 | 1.8 | 2.3 | 2.8 | 3.4 | 4.0 | 4.8 | 5.7 |

TRUCK LOADOUT - EXAMPLE CALCULATION

Given: Condensate loaded = 360 bbl crude/month

S = 0.6

P = 2.3 psi

M = 50 lb/lb-mol

T = 50

$$L_L = \frac{(12.46) \times (0.60) \times (2.3 \text{ psi}) \times (50 \text{ lb/lb-mol})}{(50^\circ\text{F} + 460)} = 1.69 \text{ lb/1000 gal}$$

$$\text{Loading losses (TPY)} = (1.69 \text{ lb/1000 gal}) \times (\text{annual sales of } 360 \text{ bbl/mo}) \times (12 \text{ mo/yr}) \times (42 \text{ gal/bbl}) \times (\text{ton}/2000 \text{ lb}) = 0.15 \text{ TPY}$$

Capture efficiencies are determined on a case-by-case basis for controlled sites.

FUGITIVE EMISSIONS

The easiest way to calculate total hydrocarbon fugitive emissions is to multiply the number of components at a site by the EPA Average Emissions Factors shown in the tables below. The first table lists the average emission rates of **total hydrocarbon** (THC) to be assumed for all components in hydrocarbon service installed at a site. The factors are current as of June 15, 1996 and given in pounds per component - day (lb/component-day). The second table lists speciated rates.

The only information needed for this method is a count or estimate of the number of flanges, connectors (other than flanges), open-ended lines, pumps, valves and "other" components at the site grouped by stream (gas, light oil, heavy oil, water/oil). The number of components can be determined by either counting them in the field or by estimating them.

**EPA Average Emission Factors for Total Hydrocarbon (THC) Emissions
From O&G Production Operations**
(lb/component-day)

| equipment type | equipment service category | | | |
|--------------------|----------------------------|-------------------------|-------------------------|------------------------------|
| | gas | heavy oil (< 20°API) | light oil (> 20°API) | water/light oil ¹ |
| connector | .011 | .0004 | .011 | .0058 |
| flange | .021 | .000021 | .0058 | .00015 |
| open ended line | .11 | .0074 | .074 | .013 |
| other ² | .47 | .0017 | .4 | .74 |
| pump | .13 | not available | .69 | .0013 |
| valve | .24 | .00044 | .13 | .0052 |

SOURCE: US EPA Bulletin Board (Leaks_OG.WP5; 8/9/1995)

¹ The water/light oil emission factors apply to water streams in light oil service with water content between 50% and 99%. For streams with water content > 99% the emission rate is considered negligible.

² The "other" equipment type includes compressor, pressure relief valves, diaphragms, drains, dump arms, hatches, instruments, meters, polished rods and vents.

NOTE: The emission factors in the table above are not intended to be used to represent emissions from components that are improperly designed (e.g., enardo valves over pressurizing, failure of thief hatches to reseal after over pressurizing) or equipment not maintained properly (e.g., thief hatch left open). For example, emissions from an enardo valve on a condensate tank vent line, operating in the full or partially open position due to excessive tank vapor pressure that exceeds the pressure setting of the enardo valve, are not considered to be fugitive emissions.

Speciated hydrocarbon emission rates can be estimated by multiplying the total hydrocarbon emission rates obtained from the table above by actual measured weight fractions. If measured data is not available, contact the Division for further guidance.

FUGITIVE EMISSIONS - EXAMPLE CALCULATION

Given: 25 valves in light oil service

THC emission factor = 0.13 lb/component-day

VOC weight fraction = 0.292

HAP weight fractions = 0.02430 + 0.00027 + 0.00075 + 0.00017 + 0.00036 = 0.0259

VOC emissions = 25 valves × 0.13 lb THC/valves-day × 1 ton/2000 lb × 365 day/hr × 0.292 = 0.17 TPY VOC

HAP emissions = 25 valves × 0.13 lb THC/valves-day × 1 ton/2000 lb × 365 day/yr × 0.0259 = 0.015 TPY total HAPs

INTERNAL COMBUSTION PUMPING UNIT ENGINE EMISSIONS

The method for calculating engine emissions is to use emission factors provided by the engine manufacturer, the maximum site-rated horsepower and the annual operating hours.

PUMPING UNIT ENGINE EMISSIONS - EXAMPLE CALCULATION

Given: Manufacturer's NO_x emission factor = 2 g/hp-hr
Maximum site-rated horsepower = 250 hp
Annual operating hours = 8760

NO_x emissions = (2.0 g/hp-hr) × (250 hp) × (8760 hr/yr) × (ton/2000 lb) × (1 lb/453.6 g) = 4.8 TPY

For CO and VOC emissions the same calculations are used except the manufacturer's EF for CO and VOC are used.

CONVERTING MOLE PERCENT TO WEIGHT PERCENT

Many emission estimation and calculation methods require weight percent to be used, rather than mole percent. Most lab analyses list gas constituents in mole percent, however you can request the lab provide both mole and weight percent.

You may download the Excel spreadsheet to convert mole percent to weight percent, at <http://deq.wyoming.gov/aqd/new-source-review/>.

APPENDIX B

DEFINITIONS

Air Contaminant – Shall mean dust, fumes, mist, smoke, other particulate matter, vapor, gas or any combination of these; but shall not include steam or water vapor.

Air pollutants – Also known as criteria pollutants, Air pollutant emissions which have ambient air standards associated with them. Air pollutants include such emissions as volatile organic compounds (VOC), nitrogen oxides (NO_x), carbon monoxide (CO), sulfur dioxide (SO₂), hazardous air pollutants (HAP) and others.

Average Daily Production – The qualified maximum total production of domestic crude petroleum and petroleum condensates including natural gas liquids produced from a well during a certain period of time (i.e. 1-month, 1-year) divided by the number of calendar days in the certain period during which the well produced. For example, the average 30-daily condensate production rate for well ABC is the qualified maximum total condensate production during the 30-day period $x(\text{BBL}) \div 30(\text{days}) = y(\text{BPD})$. If well ABC only produced 5 days out of the 30-day period, then the average daily condensate production rate for the well is $x(\text{BBL}) \div 5(\text{days}) = y(\text{BPD})$.

Closed System – A vessel (treater, separator), pipeline, sales line, gathering line, collection line, field gas supply or distribution line or any other vessel or line from which no vapors or liquids can exit through open lines, holes, vents or valves unless those lines, holes, vents or valves are connected to another closed system or to a source of continual and complete combustion, unless the vent or valve is a relief device that is designed and intended to open only during emergency situations.

Completion – An oil well shall be considered completed when the first new oil is produced through wellhead equipment into lease tanks from the producing interval after the production string has been run. A gas well shall be considered completed when the well is capable of producing gas through wellhead equipment from the producing zone after the production string has been run.

Condensate – Hydrocarbon liquid separated from natural gas that condenses (becomes liquid) due to changes in temperature, pressure, or both, and remains liquid at standard conditions.

Custody Transfer – The transfer of produced petroleum and/or condensate, after processing and/or treatment in the producing operations, from storage vessels or automatic transfer facilities to pipelines or any other forms of transportation.

Division – The Wyoming Department of Environmental Quality, Air Quality Division.

First Date of Production – The date permanent production equipment is in place and product is consistently flowing to sales lines, gathering lines or storage tanks. Production occurring during well completion activities which is routed to temporary production equipment is considered to occur prior to the First Date of Production. If extended periods of time pass between zone completions but production from initially completed zones is consistently flowing to permanent production equipment, the First Date of Production is the date when production from the initial zones began consistently flowing to the permanent production equipment, even though more zones will be completed later.

Fugitive Emissions (Fugitives) – Air emissions which result from gas vapors escaping through and around seals, packing, gaskets, threads, and other such pressure sealing connections.

Gas – All natural gases and all hydrocarbons not defined as oil.

Gas Well – A well, the principal production of which, at the mouth of the well, is gas, as defined by the Wyoming Conservation Law.

Grandfathered – A facility, installation or site which was built or in service before May 29, 1974 and that has not been physically or operationally changed, causing an increase in any pollutant (to which any state standard applies) or causing the emission of a new pollutant. (Modifications which could eliminate grandfather status are increasing production rate by fracturing, acidizing, recompletion of a zone, change in artificial lift methods, bringing new wells into a central battery or a waterflood response. Also such things as installing an engine, increasing horsepower, change in burner ratings. This list is not all inclusive and judgment should be used to determine appropriate status.)

HAP – Pollutants identified in Section 112(b) of the Clean Air Act. Typical hazardous air pollutants include benzene, toluene, ethyl-benzene, xylene, n-hexane, formaldehyde, methanol and others.

Low bleed pneumatic controller – A continuous bleed or intermittent vent device that emits less than 6 scf/hr. The Division considers controllers that are operated in accordance with manufacturer design specifications and have a manufacturer-designed emission rate that satisfies the 6 scf/hr threshold, to meet the definition of low bleed pneumatic controller.

Major Emitting Facility – A facility which either has the potential to emit 250 TPY or more of any one regulated air pollutant or is a named facility and has the potential to emit 100 TPY or more of any one regulated air pollutant. For a facility located in a non-attainment area, the definition of major emitting facility is subject to change based on the area's classification. See WAQSR Chapter 6, Section 13.

Major Source – A source which emits either 100 TPY or more of a regulated air pollutant, 10 TPY or more of a hazardous air pollutant, or 25 TPY or more of the total hazardous air pollutants.

Modified Facility – An existing facility becomes modified once production streams or production equipment associated with another well or wells is added to or tied into it. The date modification occurs to an existing facility is the First Date of Production for the added well or the date the production streams associated with an additional well or wells are tied into equipment at the existing facility.

Examples of facility modifications not involving new wells or added production from other wells are:

- Increasing the production rate above the average daily condensate/oil or gas production rate for the previous twelve (12) calendar months by fracturing, acidizing, recompletion of a current production zone, change in artificial lift methods, or a CO₂ flood/water flood response.
- Completing in additional production zones resulting in an increase in production above the average daily condensate/oil or gas production rate for the previous twelve (12) calendar months and/or emissions at the facility.
- Existing production equipment is replaced with larger equipment, resulting in increased potential or actual emissions.

Note: When equipment with Presumptive BACT requirements is added to a facility but doesn't trigger the definition of a modified facility, the Presumptive BACT requirements only have to be met for the new equipment (i.e., a pneumatic methanol pump is added, this new pump would have to either be controlled or solar, air or electric).

Oil – Crude petroleum oil and any other hydrocarbons, regardless of gravities, which are produced at the well in liquid form by ordinary production methods, and which are not the result of condensation of gas before or after it leaves the reservoir.

Oil Well – A well, the principal production of which, at the mouth of the well, is oil, as defined by the Wyoming Conservation Law.

PAD – A PAD facility is a location where more than one well and/or associated production equipment are located, where some or all production equipment is shared by more than one well or where well streams from more than one well are routed through individual production trains located at the same or contiguous and adjacent location. If the production streams or production equipment associated with one or more wells is added to an existing single well facility, that location is then considered to be a PAD facility. A single well becomes a multiple well or PAD facility upon the First Date of Production of an additional well at the location or on the day production streams associated with an additional well or wells from separate locations are routed to the single well facility. A tank battery is not considered a PAD facility.

Potential to Emit – The maximum capacity of a stationary source to emit any air pollutant under its physical and operational design. Any physical or operational limitation on the capacity of a source to emit an air pollutant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored or processed, shall be treated as part of its design if the limitation is enforceable by the EPA and the Division.

Recompletion – Any downhole operation in an existing oil or gas well that is conducted to establish production of oil or gas from any geological interval not currently completed or producing in said existing oil or gas well.

Single Well Facility – A single well facility is one where production equipment is associated with only one well. A single well becomes a multiple well or PAD facility upon the First Date of Production of an additional well at the location or on the day production streams associated with an additional well or wells from separate locations are routed to the single well facility.

Spud – The commencement of operations for the first boring of a hole for the drilling of an oil, gas or injection well. This includes setting conductor casing.

Synthetic Minor – “Synthetic Minor” sources are sources that do the following types of things to limit emission rates below 100 TPY: 1) limit operating hours of a source or 2) limit production rates such that source emissions are less than 100 TPY.

Tank Battery – An oil production facility with little to no produced gas that is comprised mainly of separators, heaters, and tanks. The facility does not use dehydration units. The API gravity of the produced oil is no higher than 25°.

VOC – Volatile organic compound means any organic compound which participates in atmospheric photochemical reactions; typically considered C₃⁺ or Non-methane/ethane hydrocarbon vapors.

VOC Weight Percent – This is the weight of the volatile organic compounds, expressed as a percent, as compared to the total weight of the compounds in a gas stream. (This should not be confused with the volume or mole percent of a gas stream, which is usually how it is expressed in a lab analysis of a gas.)

Wildcat Well – Any oil or gas well designated as a wildcat well by the Wyoming Oil and Gas Conservation Commission. Wildcat wells are wells outside known fields or new wells which are determined by the Commission to have discovered oil or gas in a pool not previously proven productive.

Workover – Any downhole operation in an existing oil or gas well that is designed to sustain, restore or increase the production rate or ultimate recovery in a geologic interval currently completed or producing in said existing oil or gas well. Workover includes but is not limited to: acidizing, reperforating, fracture treating, sand/paraffin removal, casing repair, squeeze cementing or setting bridge plugs to isolate water productive zones from oil or gas productive zones or any combination thereof. Workover does not mean the routine maintenance, repair or replacement of downhole equipment such as rods, pumps, tubing, packers or other mechanical devices.

Worst case – A situation allowed in air permitting in the State of Wyoming where a facility, site or source (which is representative of all the facilities, sites or sources within a designated field area) may be used to represent the worst air emissions for the field area sources.

Wyoming Environmental Quality Act – Wyoming Statute, Title 35 “Public Health and Safety”, Chapter 11 “Environmental Quality” which provides the authority for the rules and regulations of the Air Quality Division.

Zero bleed controller – Electric, air-driven, or solar powered controller that does not rely on natural gas to actuate.

General Permit 18.1 Template

Equipment leaks from valves, flanges, pressure relief devices, open end valves or lines, pump seals, compressor seals (except seals regulated under 40 CFR 60.5385 or 5390, or 40 CFR 60.5385a or 5390a) in natural gas service

B. Facility-Wide Terms and Conditions

The following are the terms and conditions for a General PTIO to be issued to a non-Title V facility

1. This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).
 - a) For the purpose of a permit-to-install document, the facility-wide terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.
 - (1) None
 - b) For the purpose of a permit-to-operate document, the facility-wide terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.
 - (1) None
2. The emissions unit contained in this permit must comply with various federal New Source Performance Standards (NSPS). The complete NSPS requirements may be accessed via the internet from the Electronic Code of Federal Regulations (e-CFR) website <http://www.ecfr.gov> or by contacting the appropriate Ohio EPA District Office or local air agency. The permittee must comply with the applicable requirements of 40 CFR Part 60 Subpart OOOO/OOOOa as they apply to the emissions source.
3. Records related to this PTIO may be maintained at an off-site location (e.g. regional office), provided they are made accessible when the need arises, otherwise by the next business day upon Ohio EPA request (or made viewable electronically on-site and submitted to Ohio EPA within 24 hours).

C. Emissions Unit Terms and Conditions

Note: The following are the terms and conditions for a General PTIO to be issued to a non-Title V facility

1. **Emissions Unit Group: Equipment/Pipeline Leaks, F001**

| EU ID | Operations, Property and/or Equipment Description |
|-------|---|
|-------|---|

| EU ID | Operations, Property and/or Equipment Description |
|-------|--|
| F001 | <p>Ancillary equipment¹ and associated equipment: compressors², pumps, piping, pneumatic controllers, inlet separators, gas-water/condensate/oil separators, etc.</p> <p>Equipment/pipeline leaks from valves, flanges, pressure relief devices, open end valves or lines, and pump and compressor seals (except seals regulated under 40 CFR 5380 or 5385 or 40 CFR 5380a or 5385a) in natural gas service.</p> |

a) This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).

(1) For the purpose of a permit-to-install document, the emissions unit terms and conditions in this permit are federally enforceable, with the exception of those listed below, which are enforceable under state law only.

a. None.

(2) For the purpose of a permit-to-operate document, the emissions unit terms and conditions in this permit are enforceable under state law only, with the exception of those listed below, which are federally enforceable.

a. None.

b) Applicable Emissions Limitations and/or Control Requirements

(1) The specific operation(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures are identified below. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|--|--|
| a. | OAC rule 3745-31-05(A)(3) June 30, 2008 | Develop and implement a site-specific leak detection and repair program for ancillary equipment as described in paragraph c)(2). |

¹ "Ancillary Equipment" is defined in 40 CFR Part 63, Subpart HH as "any of the following pieces of equipment: pumps, pressure relief devices, sampling connection systems, open-ended valves, or lines, valves, flanges, or other connectors." The Subpart HH definition is being used for this permit but note that the equipment leak standards found in Subpart HH do not apply for this permit because this permit is for an "area source" and the equipment leak standards do not apply to area sources.

² "Compressor" for the purpose of this permit excludes "Centrifugal compressor" and "Reciprocating compressor" as defined in 40 CFR 60.5430 or 60.5430a as appropriate.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|--|--|
| b. | <p>40 CFR Part 60 Subpart OOOO</p> <p>Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution.</p> <p>40 CFR 60.5390(b)(1)</p> | <p>Every pneumatic controller at a natural gas processing plant must have a natural gas continuous bleed rate of zero.</p> |
| c. | <p>OAC 3745-31-05(E)</p> | <p>Emissions of Volatile Organic Compounds (VOC) shall not exceed 10.0 tons per year from fugitive equipment leaks.</p> |

(2) Additional Terms and Conditions

- a. Proposed amendments to 40 CFR Part 60, Subpart OOOO were published in the Federal Register on September 18, 2015. If final amendments to 40 CFR Part 60, Subpart OOOOa become applicable to this emissions unit, then the permittee shall comply with all applicable provisions of 40 CFR Part 60, Subpart OOOOa and 40 CFR Part 60, Subpart A instead of the associated Subpart OOOO requirements listed in this permit.

c) Operational Restrictions

(2) Ancillary Equipment Leak Detection and Repair Program

The permittee shall develop and implement a leak detection and repair program designed to monitor and repair leaks from ancillary equipment covered by this permit, including each pump, compressor, pressure relief device, connector, valve, flange, vent, cover, any bypass in the closed vent system, and each storage vessel. This program shall meet the following requirements:

- a. Leaks shall be detected by the use of either a "Forward Looking Infra-Red" (FLIR) camera or an analyzer meeting U.S. EPA Method 21 of 40 CFR Part 60, Appendix A.
- b. An initial monitoring shall be completed within 90 days of startup and quarterly thereafter for a period of four consecutive quarters (1 year).
- c. If following the initial four consecutive quarters, less than or equal to 2.0% of the ancillary equipment are determined to be leaking during the most recent quarterly monitoring event, then the frequency of monitoring can be reduced to semi-annual.

- d. If following two consecutive semi-annual periods, less than 2.0% of the ancillary equipment are determined to be leaking during the most recent semi-annual monitoring event, then the frequency of the monitoring can be reduced to annual.
 - e. If more than or equal to 2.0% of the ancillary equipment are determined to be leaking during any one of the semi-annual or annual monitoring events, then the frequency of monitoring shall be returned to quarterly.
 - f. The program shall require the first attempt at repair within five (5) calendar days of determining a leak.
 - g. The program shall require that the leaking component be repaired within 30 calendar days after the leak is detected, except as provided for in (c)(2)h.
 - h. The program shall allow for the delayed repair of a leaking component following the language found in 40 CFR 60.482-9a.
 - i. The program shall follow the Monitoring and Record Keeping requirements described in paragraph 1.d) of this permit.
- (3) In the event that a leak or defect is detected in the cover, closed vent system, process equipment, or control device, the permittee shall make a first attempt at repair no later than 5 calendar days after the leak is detected. Repair shall be completed no later than 30 calendar days after the leak is detected as allowed in 40 CFR 60.5416(c)(4). Any delay of repair of a leak or defect shall meet the requirements of 40 CFR 60.5416(c)(5).

[40 CFR 60.5416(c)(4) and (5)], [40 CFR 60.5415(e)(3)], [40 CFR 60.482-9a], and [ORC 3704.03(T)]

d) Monitoring and/or Recordkeeping Requirements

- (1) The permittee shall perform an inspection each day that an operator is at the facility and the facility is in operation or is pressurized in any of its components, for indications of releases from the pressure relief valves, and any olfactory, visual or auditory indications of equipment leaks. The positive indication of a release or a leak shall be noted in an operations log, along with the following information:
 - a. the name of the inspector;
 - b. the date and time inspected;
 - c. the identification of the pressure relief valve that released and/or piece of equipment that leaked;
 - d. the estimated or calculated duration of the pressure relief valve release and/or equipment leak and the estimated emission totals; and

- e. any corrective actions taken to minimize or eliminate the release or leak.
- (2) The permittee shall maintain records of the maximum scf/m for scheduled maintenance venting.
- (3) Ancillary Equipment Leak Detection and Repair Program Monitoring and Record Keeping for Programs Utilizing FLIR Cameras
- a. Leaks shall be determined by visually observing each ancillary component through the FLIR camera to determine if leaks are visible.
 - b. The following information shall be recorded during each leak inspection:
 - i. the date the inspection was conducted;
 - ii. A description of the manufacturer, model number and serial number of the FLIR camera;
 - iii. the name of the employee conducting the leak check;
 - iv. the identification of any component that was determined to be leaking;
 - v. the date the first attempt to repair the component was made;
 - vi. the reason the repair was delayed following the language found in 40 CFR 60.5416(c)(5);
 - vii. the date the component was repaired and determined to no longer be leaking;
 - viii. the total number of components that are leaking; and
 - ix. the percentage of components leaking, determined as the sum of the number of components for which a leak was detected, divided by the total number of ancillary components capable of developing a leak, and multiplied by 100.
 - c. The permittee shall maintain written records that demonstrate the FLIR camera is operated and maintained in accordance with the manufacturer's operation and maintenance instructions.
 - d. The records from each inspection and the dates each leak is detected and repaired shall be maintained for at least 5 years and shall be made available to the Director or his representative upon oral or written request.

[40 CFR 60.5416(c)] and [ORC 3704.03(T)]

(4) Ancillary Equipment Leak Detection and Repair Program Monitoring and Record Keeping for Programs Utilizing a Method 21 Analyzer

a. Leaks shall be measured by utilizing U.S. EPA Method 21 (40 CFR Part 60, Appendix A). All potential leak interfaces shall be traversed as close to the interface as possible. The arithmetic difference between the maximum concentration indicated by the instrument and the background level is to be compared with 500 ppm or 10,000 ppm (as applicable) for determining compliance.

b. A component is considered to be leaking if the instrument reading is equal to or greater than:

| | |
|--|------------|
| pressure relief device in gas/vapor service | 500 ppm |
| pressure relief device in light liquid service | 10,000 ppm |
| pumps in light liquid service | 2,000 ppm |
| compressor | 500 ppm |
| sampling connection system* | * |
| open ended valves or lines** | ** |
| valves in gas/vapor and light liquid service | 500 ppm |
| closed vent system | 500 ppm |
| connectors in gas/vapor and light liquid service | 500 ppm |
| all other ancillary and associated equipment | 10,000 ppm |

* must be equipped with a closed-purge, closed-loop, or closed-vent system

** must be equipped with a cap, blind flange, plug, or a second valve

c. The following information shall be recorded during each leak inspection:

- i. the date the inspection was conducted;
- ii. the name of the employee conducting the leak check;
- iii. the identification of any component that was determined to be leaking (company ID and component type (flange, pump, etc.);
- iv. the date the first attempt to repair the component was made;

- v. the reason the repair was delayed following the language found in 40 CFR 60.5416(c)(5);
 - vi. the date the component was repaired and determined to no longer be leaking;
 - vii. the total number of components that are leaking; and
 - viii. the percentage of components leaking, determined as the sum of the number of components for which a leak was detected, divided by the total number of ancillary components capable of developing a leak, and multiplied by 100.
- d. The permittee shall maintain records that demonstrate the Method 21 analyzer is operated and maintained in accordance with the manufacturer's operation and maintenance instructions.
- e. In order to calibrate the analyzer, the following calibration gases shall be used:
- i. zero air, which consists of less than 10 ppm of hydrocarbon in air; and
 - ii. a mixture of air and methane or n-hexane at a concentration of approximately, but less than, 10,000 ppm of methane or n-hexane.
- f. The records from each inspection and the dates each leak is detected and repaired shall be maintained for at least 5 years and shall be made available to the Director or his representative upon oral or written request.

[40 CFR 60.5416(c)] and [ORC 3704.03(T)]

e) Reporting Requirements

- (1) The permittee shall submit an annual Permit Evaluation Report (PER) to the Ohio EPA District Office or Local Air Agency by the due date identified in the Authorization section of this permit. The permit evaluation report shall cover a reporting period of no more than twelve months for each air contaminant source identified in this permit. It is recommended that the PER be submitted electronically through the Ohio EPA's "e-Business Center: Air Services" although PERs can be submitted via U.S. postal service or can be hand delivered.

[OAC 3745-15-03(B)(2) and (D)]

- (2) Supplement to the PER for the Ancillary Equipment Leak Detection and Repair Program

For each inspection that occurred during the year, the permittee shall submit the following information with the annual PER from data collected by the ancillary equipment leak detection and repair program:

- a. the date of the inspection;
- b. the number of components determined to be leaking;
- c. the company ID and component type (flange, pump, etc.) of each leaking component;
- d. the total number of components at the site;
- e. the percent of components determined to be leaking;
- f. a list of all components that have not been repaired due to a delay of repair and the reason for the delay; and
- g. a notification indicating if the permittee has changed future inspection frequencies based on the percent of components leaking.

[40 CFR 60.5416(c)] and [ORC 3704.03(T)]

f) Testing Requirements

Compliance with the Emission Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

(1) Emissions Limitation:

Emissions of VOC shall not exceed 10.0 tons per year from fugitive equipment leaks.

Applicable Compliance Method:

The annual VOC limitation is the estimated potential-to-emit based upon the maximum number of components and type of service (gas/vapor and light liquid) expected at this facility. Unless or until more accurate emission factors have been demonstrated or established for the site (e.g. following initial and subsequent monitoring and inspections), the appropriate emissions factors from U.S. EPA's "Protocol for Equipment Leak Emission Estimates," Table 2-4, for Oil and Gas production Operations (EPA-453/R-95-017, November 1995), shall be used to demonstrate compliance with the annual limit, as shown below, with the exception of gas-driven pneumatic controllers, for which emission factors derived from review of recent literature are listed below. The facility's potential emissions from ancillary and associated equipment shall be documented from the summation of the following calculations. Where the maximum mass per cent of VOC and corresponding specific mass of the rich gas stream are known, those values may be substituted in the calculations in lieu of 50% and 0.08097 lb/scf respectively. (note: where

multiplication by % VOC is indicated, it should be understood that multiplication by a decimal fraction is intended, i.e. a divisor of 100 is implicit):

Component Type # of components x emission factor x % VOC* = lb VOC/hr

In Gas/Vapor Service

Number of connectors x 0.000441 lb/hr x 50% VOC = lb VOC/hr

Number of valves x 0.00992 lb/hr x 50% VOC = lb VOC/hr

Number of flanges x 0.00086 lb/hr x 50% VOC = lb VOC/hr

Number of compressor seals** x 0.0194 lb/hr x 50% VOC = lb VOC/hr

(note: the emissions of reciprocating or centrifugal (wet seal or dry seal) compressors, including blowdown and leakage through seals and closed valves, may be subject to capture and control and other permitting requirements appropriate to non-fugitive categories of sources, and may, in that case, not be within the scope of this general permit)

Number of relief valves x 0.01940 lb/hr x 50% VOC = lb VOC/hr

Number of other ancillary and associated units of equipment x 0.01940 lb/hr x 50 % VOC = lb VOC/hr

Number of high bleed (exceeding a 6 scf/hr continuous bleed specification) gas driven pneumatic controllers x (50.8 continuous plus intermittent bleed, scf/hr) x 0.08097*** lb/scf x 50% VOC = lb VOC/hr
(note: these are not allowed under this general permit)

Number of low bleed (conforming to 6 scf/hr continuous bleed specification) gas driven pneumatic controllers x (14.89 continuous plus intermittent bleed, scf/hr) x 0.08097*** lb/scf x 50% VOC*** = lb VOC/hr

Number of zero bleed (i.e., zero continuous bleed) gas driven pneumatic controllers x (13.5 intermittent bleed, scf/hr) x 0.08097*** lb/scf x 50% VOC*** = lb VOC/hr

In Light Liquid Service

Number of connectors x 0.000463 lb/hr x 100% VOC = lb VOC/hr

Number of_valves x 0.00551 lb/hr x 100% VOC = lb VOC/hr

Number of_flanges x 0.00024 lb/hr x 100% VOC = lb VOC/hr

Number of_pump seals x 0.0287 lb/hr x 100% VOC = lb VOC/hr

Number of relief valves x 0.01653 lb/hr x 100% VOC = lb VOC/hr

The total summation of VOC emissions per hour shall be multiplied by 8760 hours per year and divided by 2000 pounds to calculate the tons of estimated annual fugitive VOC emissions.

Compliance with the ton per year limit shall be determined following the first 12 months of operation.

As an alternative to using the above emission factors to calculate VOC emissions, the permittee may use facility specific VOC information for site specific emission factors.

* The default % VOC for Gas/Vapor service was based on the highest percent VOC in gas analyses submitted by representative facilities.

** This emission factor is intended only for compressors not meeting the definition of "Centrifugal compressor" or "Reciprocating compressor" in 40 CFR part 60, Subpart OOOO or OOOOa as appropriate.

*** The conversion of scf/hr to lb/hr is accomplished by assuming a mean molecular weight of 30.74 and corresponding specific volume of 12.35 scf/lb (or specific mass of 0.08097 lb/scf) to be typical of a rich gas stream.

g) Miscellaneous Requirements

- (1) None.

GENERAL PERMIT 12.1 TEMPLATE

High Volume Horizontal Hydraulic Fracturing, OIL AND GAS WELL SITE PRODUCTION OPERATIONS

B. Facility-Wide Terms and Conditions

The following are the terms and conditions for a General PTIO to be issued to a non-Title V facility

1. This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).
 - a) For the purpose of a permit-to-install document, the facility-wide terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.
 - (1) B.6. and B.8.
 - b) For the purpose of a permit-to-operate document, the facility-wide terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.
 - (1) B.9. and B.10.
2. The Ohio EPA has determined that this facility is subject to the requirements of 40 CFR Part 63 Subpart ZZZZ, the National Emission Standards for Hazardous Air Pollutants (NESHAP) for Reciprocating Internal Combustion Engines; and Part 63 Subpart HH, the National Emission Standards for Hazardous Air Pollutants from Oil and Natural Gas Production Facilities . At this time, the Ohio EPA is not accepting delegation for area sources subject to the Maximum Achievable Control Technology NESHAP (MACT) rules. The requirements of these rules, that are applicable to the area source(s) for hazardous air pollutants (HAP) identified in this permit, shall be enforceable by U.S. EPA. The complete requirements of this rule (including the Part 63 General Provisions) may be accessed via the Internet from the Electronic code of Federal Regulations (e-CFR) website <http://www.ecfr.gov/> or by contacting the appropriate Ohio EPA District Office or Local Air Agency.
3. Multiple emissions units contained in this permit must comply with various federal New Source Performance Standards (NSPS) and Maximum Achievable Control Technology (MACT) standards. The complete NSPS and MACT requirements may be accessed via the internet from the Electronic Code of Federal Regulations (e-CFR) website <http://ecfr.gpoaccess.gov> or by contacting the appropriate Ohio EPA District Office or local air agency. The permittee must comply with the applicable requirements of 40 CFR Part 60 Subparts OOOO, JJJJ, and IIII and 40 CFR Part 63 Subparts HH and ZZZZ as they apply to the emissions source.
4. Air contaminant sources that qualify as de minimis under OAC rule 3745-15-05, or are exempt under OAC rule 3745-31-03(A)(1) or (4) are not subject to emission standards established within this permit. Although this permit does not apply to de minimis or exempt sources, emissions from de minimis or exempt sources must be included in the total potential to emit (PTE) calculations for this permit. PTE calculations should include sources such as:
 - a) qualifying non-road engines (exempt per 3745-31-03(A)(1)(pp)),
 - b) emergency diesel generator(s) (exempt per 3745-31-03(A)(1)(nn)),
 - c) micro turbines less than 200 kW (de minimis per OAC rule 3745-15-05), and
 - d) natural gas-fired heaters/boilers of various types that are less than 10 MMBtu/hr heat input (exempt per 3745-31-03(A)(1)(a)).
5. Emissions units permitted under a previously issued PTI/PTIO as portable sources shall be subject to the requirements of this General Permit during the time they are located at this site, provided that the emission unit(s) meets the qualifying criteria.

6. The requirements of this permit do not supersede any Ohio Department of Natural Resources requirements.
7. It is the permittee's responsibility to determine if any air pollution emitting equipment not covered by this permit needs a separate air permit.
8. Modeling to demonstrate compliance with the "Toxic Air Contaminant Statute", ORC 3704.03(F)(4)(b), is not necessary if/when the maximum annual emissions for each toxic air contaminant, as defined in OAC rule 3745-114-01, is less than 1.0 ton per year (or are subject to a standard under 40 CFR Part 63). OAC Chapter 3745-31 requires permittees to apply for and obtain a new or modified PTIO prior to making a "modification" as defined by OAC rule 3745-31-01. The permittee is hereby advised that changes in the composition of the materials or use of new materials that would cause the emissions of any toxic air contaminant to increase to above 1.0 ton per year may require the permittee to apply for and obtain a new PTIO.
9. The permittee remains subject to all applicable federal law and regulations and all applicable provisions of the Ohio State Implementation Plan as approved by the Administrator of the U.S. EPA. The provisions of the Ohio State Implementation Plan are independently enforceable by the U.S. EPA.
10. If the determination that the facility is not a major source is based on actual emissions of 5 tons per year or more of any single HAP or 12.5 tons per year or more of a combination of HAP, the permittee shall update the facility's major source determination within 1 year of the prior determination and each year thereafter, using gas composition data measured during the preceding 12 months of operation. Only HAP emissions from glycol dehydration units and storage vessels shall be aggregated for major source determination at the production field facility (facility located prior to the point of custody transfer).
[40 CFR 63.760(c)] and [40 CFR 63.761]
11. Emission units and any required control and monitoring equipment shall be operated in a manner consistent with safety and good air pollution control practices for minimizing emissions.
[40 CFR 63.764(j)], [40 CFR 60.4243(b)], and [40 CFR 60.4211(g)]

C. Emissions Unit Terms and Conditions

1. Emissions Unit: Dehydration System, P001

Operations, Property and/or Equipment Description:

| | |
|------|--|
| P001 | Up to two glycol dehydration unit(s) (includes contact tower or absorption column and glycol dehydration unit reboiler) and gas-condensate-glycol (GCG) separator (flash separator), which may be vented to a condenser or BTEX (benzene, toluene, ethyl benzene, xylene) elimination system with condenser, and/or flare (less than 10 MMBtu/hr) or a facility-wide flare (see P004). |
|------|--|

a) This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).

(1) For the purpose of a permit-to-install document, the emissions unit terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.

a. 1.b)(1)d.

(2) For the purpose of a permit-to-operate document, the emissions unit terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.

b. 1.b)(1)e. and 1.b)(1)f.

b) Applicable Emissions Limitations and/or Control Requirements

(1) The specific operation(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures are identified below. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|--|---|
| a. | OAC rule 3745-31-05(A)(3), as effective 11/30/01 | <p>For Total Organic Compounds (TOC), total hazardous air pollutants (total HAP), or benzene, compliance with the applicable control requirements of 40 CFR Part 63, Subpart HH.</p> <p>Emissions from a flare used to control emissions from the glycol dehydration unit shall not exceed:</p> <p>0.25 ton Nitrogen Oxides (NOx) per month averaged over a 12-month rolling period;</p> <p>0.23 ton VOC per month averaged over a 12-month rolling period; and</p> |

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|---|--|
| | | 0.15 ton Sulfur dioxide (SO ₂) per month averaged over a 12-month rolling period. See b)(2)a. |
| b. | OAC rule 3745-31-05(A)(3)(a)(ii) | See b)(2)b. |
| c. | ORC 3704.03(T) | Carbon Monoxide (CO) emissions from a flare used as a control device for the dehydrator shall not exceed 1.35 tons CO per month averaged over a 12-month rolling period. |
| d. | OAC rule 3745-31-05(E) | See b)(2)b. |
| e. | Part 63, Subpart HH, National Emission Standards for hazardous air pollutants (NESHAP) from Oil and Natural Gas Production Facilities | Compliance with the applicable portions of 40 CFR Part 63, Subpart HH. Any final amendments to this rule will supersede any previous Subpart HH requirement(s) in this permit. |
| f. | 40 CFR 63.11(b)(4) | No visible emissions except for 5 minutes during any 2 consecutive hours. |

(2) Additional Terms and Conditions

- a. The permittee has satisfied the Best Available Technology (BAT) requirements pursuant to OAC paragraph 3745-31-05(A)(3), as effective November 30, 2001, in this permit. On December 1, 2006, paragraph (A)(3) of OAC rule 3745-31-05 was revised to conform to ORC changes effective August 3, 2006 (S.B. 265 changes), such that BAT is no longer required by State regulation for NAAQS pollutant less than ten tons per year. However, that rule revision has not yet been approved by U.S. EPA as a revision to Ohio's State Implementation Plan (SIP). Therefore, until the SIP revision occurs and the U.S. EPA approves the revision to OAC rule 3745-31-05, the requirement to satisfy BAT still exists as part of the federally-approved SIP for Ohio. Once U.S. EPA approves the December 1, 2006 version of 3745-31-05, then BAT no longer applies.
- b. These rules apply once U.S. EPA approves the December 1, 2006 version of OAC rule 3745-31-05 as part of the State Implementation Plan:
 - i. This permit takes into account the following voluntary restrictions (including the use of any applicable air pollution control equipment) for the purpose of avoiding Best Available Technology (BAT) requirements under OAC rule 3745-31-05(A)(3):
 - (a) Emissions of Volatile Organic Compounds (VOC) (excludes methane and ethane) shall not exceed 5.0 tons/year;
 - (b) Use of a dehydration system flash separator that captures flash vapors; and

d) Monitoring and/or Recordkeeping Requirements

- (1) The permittee shall maintain records of the annual facility natural gas or hydrocarbon liquid throughput or a record of the maximum potential annual throughput rate attainable, based on the physical and operational design of the unit, in accordance with 40 CFR 63.760(a).
- (2) Where a flare is used to control the dehydration still vent, the permittee must:
 - a. continuously monitor the presence of the flame;
 - b. record all periods during which the automatic flare ignition system (pilot flame or electronic arc ignition system) or thermocouple was not working; and
 - c. record all periods during which there was gas being vented to the flare but the flare was not lit.
- (3) Where a condenser (or BTEX elimination system) is used to control the dehydration still vent, the permittee must:
 - a. continuously monitor and record the vapor outlet temperature of the condenser; and
 - b. record all periods of time when the condenser is not operating correctly to control the emissions from the dehydration still vent.
- (4) For each triethylene glycol (TEG) dehydration unit, the permittee shall document the method of compliance as follows:
 - a. if the permittee is using the exemption for the annual average flow rate of natural gas to the TEG dehydration unit, the permittee shall either install and operate a monitoring instrument to directly measure and record the natural gas flow rate to the glycol dehydration unit or demonstrate to the Director's satisfaction that the actual annual average natural gas flow rate to the dehydration unit is less than 85,000 scm/day, in accordance with 40 CFR 63.772(b)(1); or
 - b. if the permittee is using the exemption for the actual average benzene emissions from the TEG dehydration unit, the permittee shall keep the record of the determination (including the test methods and data used to support it) using either the GRI-GLYCalc™ model or by directly measuring benzene using the appropriate methods identified in 40 CFR 63.772(a)(1), in accordance with 40 CFR 63.772(b)(2); or
 - c. if the permittee does not meet one of the exemptions identified in 40 CFR 63.764(e) and is not located in a Urbanized Area (UA) plus offset and Urban Cluster (UC) boundary (as defined in 40 CFR 63.761), the permittee may (instead of meeting the control requirements) keep the record of the calculation for the optimal circulation rate (or alternate circulation rate as allowed using GRI-GLYCalc™ model) and records documenting this circulation rate is not exceeded in accordance with 40 CFR 63.764(d)(2); or

- d. if the permittee does not meet one of the exemptions identified in 40 CFR 63.764(e) and is located in a Urban Area (UA) plus offset and Urban Cluster (UC) boundary (as defined in 40 CFR 63.761), the permittee shall comply with the control requirements specified in 40 CFR 63.765 and the monitoring and recordkeeping requirements identified in 40 CFR 63.764(d)(1) to demonstrate compliance.

e) Reporting Requirements.

- (1) The permittee shall submit an annual Permit Evaluation Report (PER) to the Ohio EPA District Office or Local Air Agency by the due date identified in the Authorization section of this permit. The permit evaluation report shall cover a reporting period of no more than twelve months for each air contaminant source identified in this permit. It is recommended that the PER is submitted electronically through the Ohio EPA's "e-Business Center: Air Services" although PERs can be submitted via U.S. postal service or can be hand delivered.

[OAC 3745-15-03(B)(2) and (D)]

- (2) The permittee shall identify in the PER:
 - a. the annual facility natural gas or hydrocarbon liquid throughput for the year of the report, in accordance with 40 CFR 63.760(a);
 - b. identification of the kind of liquid glycol used in the dehydrator during the year of the report, e.g., ethylene glycol, diethylene glycol, or triethylene glycol*;
 - c. if the permittee is using triethylene glycol and meeting the exemption for the flow rate of natural gas to the TEG dehydration unit, the actual annual average natural gas flow rate to the TEG dehydration unit; and either the calculations and/or method of measurement of this flow rate or a statement that this flowrate was based on the maximum design capacity of the unit;
 - d. if the permittee is using triethylene glycol and meeting the exemption for benzene emissions, the actual annual average emissions of benzene from the TEG dehydration unit; and if these emissions were determined using the GRI-GLYCalc™ model, the method used to determine the benzene concentration entered into the model, and/or identification of the method used for direct measurement;
 - e. if the permittee is using triethylene glycol and the area source is not located in an UA plus offset and UC boundary and does not meet one of the exemptions identified in 40 CFR 63.764(e), the calculation for the optimal circulation rate and the method of measurement for the gas flowrate (MMscf/day) and inlet/outlet water content (lbs/MMscf), and a statement as to whether or not the optimal circulation rate was exceeded, to include the date, duration, and the non-compliant circulation rate measured;
 - f. if the permittee is using triethylene glycol and the area source is located in an UA plus offset and UC boundary and does not meet one of the exemptions identified in 40 CFR 63.764(e), the method of control that was used to demonstrate

compliance, the results of the compliance demonstration, and a statement as to whether or not the selected compliance option was met;

- g. where a flare is used to control the dehydration still vent, all periods of time during which the automatic flare ignition system was not functioning properly or the flare was not maintained as required in this permit, to include the date, time, and duration of each such period of time;
- h. where a condenser (or BTEX elimination system) is used to control the dehydration still vent, all periods of time when the continuous temperature monitoring device for the condenser vapor outlet temperature is not working or is not continuously recording the vapor outlet temperature when process gas is being vented to the condenser; and
- i. where the triethylene glycol dehydrator does not meet one of the exemptions in 40 CFR 63.764(e) or is not demonstrating compliance by documenting and maintaining the optimum glycol circulation rate as required in 40 CFR 63.764(d)(2), the flare or condenser used to demonstrate compliance shall meet all of the requirements of Part 63 Subpart HH.

* if not using triethylene glycol, the information in “c” through “i” is not required

[40 CFR 63.764(d) and (e)], [40 CFR 63.765], and [40 CFR 63.772(a) and(b)]

f) **Testing Requirements**

Compliance with the Emission Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

(1) Emissions Limitation:

For total TOC, total HAP, or benzene, compliance with the applicable control requirements of 40 CFR Part 63, Subpart HH.

Applicable Compliance Method:

The permittee may determine the annual total TOC (excludes methane and ethane), total HAP, or benzene emissions using the appropriate methods identified in 40 CFR 63.772 and/or GRI-GLYCalc™ model, Version 3.0 or higher, and the procedures presented in the associated GRI-GLYCalc™ Technical Reference Manual. Inputs to the model shall be representative of actual operating conditions of the glycol dehydration unit(s) and may be determined using the procedures documented in the Gas Research Institute (GRI) report entitled “Atmospheric Rich/Lean Method for Determining Glycol Dehydrator Emissions” (GRI-95/0368.1);

Potential TOC, total HAP, and/or benzene emissions estimates shall be based on the maximum glycol circulation rate(s), in gallons per minute (gpm); the worst case pollutant concentrations from representative extended gas analyses of the inlet wet gas; and the maximum natural gas flow rate, as determined by 40 CFR 63.772(b)(1)(i); or for a new unit, potential emissions shall be estimated in accordance with 40 CFR 63.760(a) and increased by a factor of 1.2. The permittee may also determine the estimated annual

VOC emission through direct measurement using Method M25A or Method 18, both from Appendix A of Part 60.

[40 CFR 63.765(b)(1) and/or (c)(3)], [40 CFR 63.771(c) and (d)], [40 CFR 63.772], [40 CFR 63.773(d)], and [OAC rule 3745-31-05(E)]

(2) Emission Limitation from a flare used to control the dehydrator:

1.35 tons of CO per month averaged over a 12-month rolling period

Applicable Compliance Method:

The emissions limitation for CO is based on using the AP-42 emission factor of 0.37 lb CO/MMBtu from Chapter 13.5 for Industrial Flares, Table 13.5-1, "Emission Factors for Flare Operations" and using the estimated burner rating of 10.0 MMBtu/hr. Estimated CO emissions shall be determined by the following calculations:

$$0.37 \text{ lb CO/MMBtu} \times 10.0 \text{ MMBtu/hr} = 3.7 \text{ lbs CO/hr}$$

$$3.7 \text{ lbs CO/hr} \times 8760 \text{ hrs/yr} \times 1 \text{ ton/2000 lbs} = 16.2 \text{ tons CO/year}$$

$$16.2 \text{ tons CO} \div 12 \text{ months} = 1.35 \text{ tons CO/month averaged over a 12-month rolling period}$$

Compliance with the tons/month averaged over a 12-month rolling period shall be determined following the first 12 months of operation.

(3) Emission Limitation from a flare used to control the dehydrator:

0.23 ton of VOC per month averaged over a 12-month rolling period

Applicable Compliance Method:

The emissions limitation for VOC is based on using the AP-42 emissions factor of 0.14 lb of hydrocarbon/MMBtu from Chapter 13.5 for Industrial Flares, Table 13.5-1 "Emission Factors for Flare Operations" excluding emissions of methane (55% per Table 13.5-2 "Hydrocarbon Composition of Flare Emissions") and using the estimated burner rating of 10 MMBtu/hr. Estimated VOC emissions shall be determined by the following calculation:

$$0.14 \text{ lb VOC/MMBtu} \times 45\% \times 10.0 \text{ MMBtu/hr} = 0.63 \text{ lb VOC/hr}$$

$$0.63 \text{ lb VOC/hr} \times 8760 \text{ hr/yr} \times 1 \text{ ton/2000 lbs} = 2.8 \text{ tons VOC/year}$$

$$2.8 \text{ tons VOC} \div 12 \text{ months} = 0.23 \text{ ton VOC/month averaged over a 12-month rolling period}$$

Compliance with the tons/month averaged over a 12-month rolling period shall be determined following the first 12 months of operation.

(4) Emission Limitation from a flare used to control the dehydrator:

0.25 ton of NOx per month averaged over a 12-month rolling period

Applicable Compliance Method:

The emissions limitation for NO_x is based on using the AP-42 emission factor of 0.068 lb NO_x/MMBtu from Chapter 13.5 for Industrial Flares, Table 13.5-1, "Emission Factors for Flare Operations" and using the estimated burner rating of 10 MMBtu/hr. Estimated NO_x emissions shall be determined by the following calculation:

$$0.068 \text{ lb NO}_x/\text{MMBtu} \times 10.0 \text{ MMBtu/hr} = 0.68 \text{ lb NO}_x/\text{hr}$$

$$0.68 \text{ lb NO}_x/\text{hr} \times 8760 \text{ hrs/yr} \times 1 \text{ ton}/2000 \text{ lbs} = 3.0 \text{ tons NO}_x/\text{year}$$

$$3.0 \text{ tons NO}_x \div 12 \text{ months} = 0.25 \text{ ton NO}_x/\text{month} \text{ averaged over a 12-month rolling period}$$

Compliance with the tons/month averaged over a 12-month rolling period shall be determined following the first 12 months of operation.

(5) Emission Limitation from a flare used to control the dehydrator:

0.15 ton of SO₂ per month averaged over a 12-month rolling period

Applicable Compliance Method:

The SO₂ emissions limitation is based on a fuel gas with a maximum H₂S content of 250 ppmv for sour gas.

Compliance with the ton per year SO₂ emissions limitation shall be determined by the following calculations:

$$10 \text{ MMBtu/hr} \times 1 \text{ scf}/1020 \text{ Btu} \times 1 \text{ lb-mole}/379.5 \text{ scf} \times 250 \text{ ppm H}_2\text{S} \times 64 \text{ lb SO}_2/\text{lb-mole} = 0.41 \text{ lb SO}_2/\text{hr}$$

$$0.41 \text{ lb SO}_2/\text{hr} \times 8760 \text{ hrs/year} \times 1 \text{ ton}/2000 \text{ lbs} = 1.8 \text{ tons SO}_2/\text{year}$$

$$1.8 \text{ tons SO}_2 \div 12 \text{ months} = 0.15 \text{ ton SO}_2/\text{month} \text{ averaged over a 12-month rolling period}$$

Compliance with the tons/month averaged over a 12-month rolling period shall be determined following the first 12 months of operation.

(6) Emission Limitation:

Where the flare is used to demonstrate compliance with Part 63, Subpart HH, there shall be no visible emissions from the flare, except for periods not to exceed a total of 5 minutes during any 2 consecutive hours.

Applicable Compliance Method:

Compliance with the visible emissions limitation shall be determined in accordance with U.S. EPA Method 22 in Appendix A of 40 CFR Part 60.

[40 CFR 63.11(b)(4)]

g) Miscellaneous Requirements

Permit Number: [Permit Number]

Facility Name: [Facility Name]

Facility ID: [Facility ID]

Working Copy of a Permit in Progress

(1) None

2. Emissions Units: Spark Ignition Internal Combustion Engines, P002

Operations, Property and/or Equipment Description:

| | |
|------|--|
| P002 | <p>One or multiple stationary natural gas-fired spark ignition (SI) internal combustion engines (ICE) with a combined total horsepower (HP) of no more than 1,800 HP for the site.*</p> <p>Includes 2007 and later model year engines manufactured after the applicable effective date identified in 40 CFR 60.4230(a)(3); and engines manufactured before the effective date of the NSPS, where compliance with the Part 60 Subpart JJJJ emissions standards for the same size engine can be met by retrofitting the engine with a control device and demonstrated through stack testing.</p> |
|------|--|

* In order to maintain the carbon monoxide (CO) emissions below major source thresholds and nitrogen oxides (NOx) emissions below state significant impact levels, where the sum of the total horsepower (HP) of the spark ignition (SI) engines exceeds 1,300 HP, the SI engines rated at or over 100 HP may be required to meet more stringent standards for CO and NOx than is applicable to the engine.

- a) This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).
 - (1) For the purpose of a permit-to-install document, the emissions unit terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.
 - (a) None.
 - (2) For the purpose of a permit-to-operate document, the emissions unit terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.
 - (a) 2.b)(1)a.
- b) Applicable Emissions Limitations and/or Control Requirements
 - (1) The specific operation(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures are identified below. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|-------------------------------|---|
| a. | 40 CFR Part 60, Subpart JJJJ | Engines shall either be certified to the applicable Part 60 Subpart JJJJ emission standards and/or the exhaust emissions shall not exceed the |

| | | |
|----|---|---|
| | <p>In accordance with 40 CFR 60.4230, the engines in this emissions group are subject to the New Source Performance Standards (NSPS) for Stationary Spark Ignition (SI) Internal Combustion Engines (ICE).</p> <p>40 CFR 60.4233(e)</p> <p>40 CFR 60.4231(a), (d), and (e)-mfg.</p> <p>Table 1 to Part 60, Subpart JJJJ</p> | <p>following emission limitations:</p> <p>the applicable emission standards for nitrogen oxides (NOx), carbon monoxide (CO), and volatile organic compounds (VOC) as identified in Table 1 to Part 60, Subpart JJJJ; or</p> <p>for engines less than or equal to 25 HP, the applicable standards from 40 CFR Part 90 or Part 1054; or</p> <p>for engines greater than 25 HP and less than 100 HP, the applicable standards from Part 1048.</p> <p>Where the total summation of the SI ICE HP is equal to or less than 1,300 HP, the natural gas engine emissions together shall not exceed the worst-case emission standards for engines of 100 HP or greater from Table 1 to the subpart¹:</p> <p>2.0 grams of NOx per horsepower hour (2.0 g NOx/HP-hr);</p> <p>4.0 grams of CO per horsepower hour (4.0 g CO/HP-hr); and</p> <p>1.0 gram of VOC per horsepower hour (1.0 g VOC/HP-hr);</p> <p>In order to maintain CO emissions below major source thresholds and NOx emissions below state significant impact levels, where the total summation of the SI ICE HP is greater than 1,300 HP, the natural gas engine emissions together shall not exceed the following:</p> <p>1.45 grams of NOx per horsepower hour (1.45 g NOx/HP-hr);</p> <p>3.0 grams of CO per horsepower hour (3.0 g CO/HP-hr); and</p> <p>1.0 gram of VOC per horsepower hour (1.0 g VOC/HP-hr).</p> <p>See b)(2)c., d. and e.</p> |
| b. | <p>OAC rule 3745-17-11(B)(5)</p> <p>ORC 3704.03(T)</p> | <p>Particulate Emissions (PE) shall not exceed 0.310 lb/MMBtu for stationary small internal combustion engines rated less than or equal to 600 HP and 0.062 lb/MMBtu for stationary large</p> |

¹ Note: Each engine shall be required to meet the applicable emission standards under 40 CFR Part 60, Subpart JJJJ, based on the manufacture date and size engine, or where required, shall meet the Subpart JJJJ Table 1 standards or the limits identified in this permit by retrofitting pre-NSPS engines with a control device.

| | | |
|----|--|---|
| | | internal combustion engines rated over 600 HP. |
| c. | OAC rule 3745-17-07(A)(1) | Visible particulate emissions from the exhaust stack serving this emissions unit shall not exceed 20 percent opacity, as a six-minute average, except as specified by rule. |
| d. | OAC rule 3745-18-06(G) | Pursuant to OAC rule 3745-18-06(A), this stationary internal combustion engine is exempt from the sulfur dioxide (SO ₂) emission limitation specified by this rule during any calendar day in which natural gas is the only fuel burned. |
| e. | ORC 3704.03(T) | Compliance with the applicable g/HP-hr limits from 40 CFR Part 60, Subpart JJJJ for NO _x , CO and VOC. |
| f. | OAC rule 3745-31-05(A)(3), as effective 11/30/01 | See b)(2)a. |
| g. | OAC rule 3745-31-05(A)(3)(a)(ii), as effective 12/01/06 | See b)(2)b. |
| h. | 40 CFR Part 60 Subpart JJJJ 40 CFR 60.4233 and OAC 3745-31-05(F) | All SI ICE shall meet all applicable NSPS requirements where the model year is subject to these emission standards and all older model year engines shall be fitted with a control device (where required) and shall be demonstrated to meet the NSPS emission standards as applicable to 2007 and later model year engines of the same size/power. |
| i. | OAC 3745-31-05(F) | 5.75 lbs NO _x /hr from all SI engines combined. |

(2) Additional Terms and Conditions

- a. The permittee has satisfied the Best Available Technology (BAT) requirements pursuant to OAC rule 3745-31-05(A)(3), as effective November 30, 2001, in this permit. On December 1, 2006, paragraph (A)(3) of OAC rule 3745-31-05 was revised to conform to the Ohio Revised Code (ORC) changes effective August 3, 2006 (Senate Bill 265 changes), such that BAT is no longer required by State regulations for National Ambient Air Quality Standard (NAAQS) pollutant(s) less than ten tons per year. However, that rule revision has not yet been approved by U.S. EPA as a revision to Ohio's State Implementation Plan (SIP). Therefore, until the SIP revision occurs and the U.S. EPA approves the revisions to OAC rule 3745-31-05, the requirement to satisfy BAT still exists as part of the federally-approved SIP for Ohio. Once U.S. EPA approves the December 1,

2006 version of OAC rule 3745-31-05 these emission limitations/control measures no longer apply.

- b. This rule applies once U.S. EPA approves the December 1, 2006 version of OAC rule 3745-31-05 as part of the State Implementation Plan.

The Best Available Technology (BAT) requirements under OAC rule 3745-31-05(A)(3) do not apply to the SO₂ emissions from this air contaminant source since the potentials to emit for SO₂ are less than ten tons per year.

- c. The stationary spark ignition (SI) internal combustion engine(s) (ICE) are subject to and shall be operated in compliance with the requirements of 40 CFR Part 60, Subpart JJJJ, standards of performance for stationary SI ICE.

[40 CFR 60.4230(a)]

- d. The owner/operator of all SI ICE shall demonstrate compliance with the emissions standards identified in 40 CFR 60.4233 of Part 60, Subpart JJJJ in accordance with 40 CFR 60.4243(b).

[40 CFR 60.4233] and [40 CFR 60.4243(b)]

- e. The gram per horsepower-hour emissions limitations are based on the emission standards from Table 1 of NSPS JJJJ for natural gas-fired engines. In order to maintain the carbon monoxide (CO) emissions below major source thresholds and nitrogen oxide (NOx) emissions below state significant impact levels, where the sum of the total horsepower (HP) of the spark ignition (SI) engines exceeds 1,300 HP, the SI engines rated at or over 100 HP shall meet the CO and NOx limits identified in the Testing Section of this permit. However, each engine installed at the natural gas production site and subject to a more stringent standard, based on the model year and engine's size, must be demonstrated to comply with the applicable emissions standard established in 40 CFR 60.4233.

c) **Operational Restrictions**

- (1) The stationary SI ICE shall be installed, operated, and maintained according to the manufacturer's recommendations or in accordance with the operator's Operation and Maintenance (O&M) Plan and in a manner consistent with good air pollution control practice for minimizing emissions. The permittee shall operate and maintain the stationary SI ICE to achieve the emission standards identified in 40 CFR 60.4233 over the entire life of the engine(s). The air-to-fuel ratio controllers shall be set by the operator according to the manufacturer's operations manual, to ensure proper operation of the engines and their control device (catalytic converter) and to minimize emissions.

[40 CFR 60.4234], [40 CFR 60.4243(b)], and [40 CFR 60.4243(g)]

d) **Monitoring and/or Recordkeeping Requirements**

- (1) The following records shall be maintained for each spark ignition engine operating at the well site:
 - a. all notifications submitted to comply with and all documentation supporting compliance with Part 60 Subpart JJJJ;

- b. all notifications submitted to comply with and all documentation supporting compliance with Part 63 Subpart ZZZZ;
- c. records of all maintenance conducted on the engines;
- d. for certified engines less than or equal to 100 HP, the certification from the manufacturer, documenting that the engine(s) meet(s) the emission standards identified in 40 CFR 60.4231 or for uncertified engines, the testing results from the initial and subsequent performance tests, as applicable, conducted to meet the requirements of 40 CFR 60.4243(b)(2)(i) or (ii); and
- e. the information identified in 40 CFR Parts 90, 1048, 1054, and/or 1060 that is required to be provided by the manufacturer to the operator/owner, as applicable to the model year and horsepower of the engines.

The permittee or owner/operator (if leased) of the engines shall keep the above records and a maintenance plan for the engines, and shall maintain documentation that the engine is maintained and operated according the manufacturer's emission-related instructions.

[40 CFR 60.4245(a)] and [40 CFR 60.4243(a) and (b)]

e) Reporting Requirements

- (1) The permittee shall submit an annual Permit Evaluation Report (PER) to the Ohio EPA District Office or Local Air Agency by the due date identified in the Authorization section of this permit. The permit evaluation report shall cover a reporting period of no more than twelve months for each air contaminant source identified in this permit. It is recommended that the PER is submitted electronically through the Ohio EPA's "e-Business Center: Air Services" although PERs can be submitted via U.S. postal service or can be hand delivered.

[OAC 3745-15-03(B)(2) and (D)]

- (2) The permittee shall identify in the PER:
 - a. each SI engine located (and operated) at the production site during the year, identified by the model year, horse power, and the date of manufacturer of each engine;
 - b. a statement as to whether each engine was purchased certified by the manufacturer, in accordance with the Subpart JJJJ, i.e., the manufacturer has provided a warranty for the emissions when the engine was first sold;
 - c. a statement as to whether each engine was operated and maintained in accordance with the manufacturers emission-related instructions;
 - d. the date each uncertified SI engine was tested for compliance with the applicable emission standards identified in Part 60 Subpart JJJJ; and
 - e. identification of each engine that did not meet the applicable emission standards identified in 40 CFR 60.4233 and/or this permit, the number of hours each such

engine was in operation while not in compliance, the pollutant limitation(s) that were exceeded, and information on the date and resolution of compliance.

- (3) For each natural gas SI ICE not certified to the applicable emission standards identified in 40 CFR Part 60 Subpart JJJJ, and subject to the performance testing requirements of 40 CFR 60.4243(b)(2), the permittee shall submit a copy of the results of each performance test conducted to demonstrate compliance within 60 days after the test has been completed.

[40 CFR 60.4245(d)]

f) Testing Requirements

Compliance with the Emission Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods.

- (1) The SI engines shall meet the applicable emissions standards identified in 40 CFR 60.4233 and/or the applicable emission limits required in this permit. Engines greater than 100 HP shall not exceed the emission standards identified in Table 1 to Subpart JJJJ and engines less than 100 HP shall not exceed the applicable standards identified in 40 CFR 60.4231, as required per 40 CFR 60.4233, all as applicable to each engine's horsepower and model year. In order to maintain the facility below major source thresholds and significant impact levels, older engines that were manufactured before the effective date of the NSPS shall be retrofitted with controls that can demonstrate the emission limits established in this permit are met.

- (2) For each natural gas engine purchased without an EPA certificate of conformity (most engines >25 HP), the permittee shall conduct or have conducted an initial performance test to demonstrate compliance with the NSPS standards for NO_x, CO, and VOC; and for each engine greater than 500 HP, subsequent performance tests shall be conducted every 8,760 hours or 3 years, whichever comes first.

[40 CFR 60.4243(b)(2)]

- (3) Emission Limitation:

Visible particulate emissions from the exhaust stack serving this emissions unit shall not exceed 20% opacity, as a six-minute average, except as specified by rule.

Applicable Compliance Method:

If required, compliance shall be determined through visible emission observations performed in accordance with U.S. EPA Reference Method 9 in 40 CFR, Part 60, Appendix A.

[OAC rule 3745-17-07(A)(1)]

- (4) Emissions Limitations:

Particulate Emissions (PE) shall not exceed 0.310 lb/MMBtu for small engines ≤ 600 HP; and 0.062 lb/MMBtu for large engines > 600 HP

Applicable Compliance Method:

If required, the permittee shall demonstrate compliance with the emission limitations through exhaust emission tests performed in accordance with 40 CFR Part 60, Appendix A, Methods 1 through 5.

[OAC 3745-17-11(B)(5)]

(5) Emissions Limitations:

2.0 grams NO_x /HP-hr for engines ≥ 100 HP; or

1.45 grams NO_x /HP-hr for engines ≥ 100 HP where the total engine power is greater than 1,300 HP; and/or

the combination of SI engines shall be calculated to not exceed 5.75 lbs NO_x/hour, based on the summation of the emission stack test results and/or the pound per hour emissions calculated from the emission rate certified by the manufacturer.

Applicable Compliance Method:

The emission limitations are based on the exhaust emission standards identified in 40 CFR 60.4231(e). Compliance with the applicable g/HP-hr NO_x standard shall be demonstrated through performance/stack testing, if not certified to the standard. The g/HP-hr limitations above are based on the emission standards from Table 1 to Part 60 Subpart JJJJ for engines 100 HP or larger. Compliance with the short term and ton per year NO_x emissions limitation shall be determined for each non-emergency spark ignition engine located on the site using the applicable compliance methods identified in Part 60 Subpart JJJJ. The combination of SI engines together shall be calculated to not exceed 5.75 lbs NO_x/hour, based on the summation of the emission stack test results and/or the pound per hour NO_x emissions calculated from the emission rate certified by the manufacturer.

Where the sum of the total HP of the facility SI ICE is no greater than 1,300 HP, the following calculations establish the pound per hour emissions of NO_x from the spark ignition engines covered in this permit:

$$2.0 \text{ g NO}_x/\text{HP-hr} \times 1,300 \text{ HP} \times 1\text{lb}/454 \text{ g} = 5.73 \text{ lbs NO}_x/\text{hr}$$

Where the sum of the total HP of the SI ICE exceeds 1,300 HP, an average NO_x limit between 2.0 grams/HP-hr and 1.45 grams/HP-hr shall be required in order to meet the 5.75 lbs/hour NO_x limitation established in this permit. The average emissions of NO_x (in grams/HP-hr) shall be calculated as follows:

$$\text{Average g NO}_x/\text{HP-hr} = \sum_{n=1}^n [\text{g/HP-hr} \times \text{HP}] / \text{total HP}$$

Where:

g/HP-hr = the standard to which each natural gas engine is certified

HP = the horsepower of each individual natural gas engine

total HP = the total horsepower or summation of the horsepower of each natural gas engine

n = number of natural gas engines at the well site

The following calculations establish the maximum pound per hour emissions of NOx from the spark ignition engines covered in this permit where the summation of the horsepower exceeds 1,300 HP, and where the average emissions of NOx is maintained at or below 1.45 grams/HP-hr:

$$1.45 \text{ g NOx/HP-hr} \times 1,800 \text{ HP} \times 1\text{lb}/454 \text{ g} = 5.75 \text{ lbs NOx/hr}$$

When required, the permittee shall demonstrate compliance with the NOx limitation according to the requirements of 40 CFR 60.4244, using the applicable test methods in Table 2 to Part 60 Subpart JJJJ.

[40 CFR 60.4233(e)], [40 CFR 60.4243(b)(2)]. [40 CFR 60.4244], and [Table 1 to Part 60 Subpart JJJJ]

(6) Emissions Limitations:

4.0 grams CO/HP-hr for engines \geq 100 HP; or

3.0 grams CO/HP-hr for engines \geq 100 HP where the total engine power is greater than 1,300 HP; and/or

the combination of SI engines shall be calculated to not exceed 11.9 lbs CO/hour, based on the summation of the emission stack test results and/or the pound per hour CO emissions calculated from the emission rate certified by the manufacturer.

Applicable Compliance Method:

The emission limitations are based on the exhaust emission standards identified in 40 CFR 60.4231(e). Compliance with the applicable g/HP-hr CO standard shall be demonstrated through performance/stack testing, if not certified to the standard. The g/HP-hr limitations above are based on the emission standards from Table 1 to Part 60 Subpart JJJJ for engines 100 HP or larger. Compliance with the short term and ton per year CO emissions limitation shall be determined for each non-emergency spark ignition engine located on the site using the applicable compliance methods identified in Part 60 Subpart JJJJ. The combination of SI engines together shall be calculated to not exceed 11.9 lbs CO/hour, based on the summation of the emission stack test results and/or the pound per hour CO emissions calculated from the emission rate certified by the manufacturer.

Where the sum of the total HP of the facility SI ICE is no greater than 1,300 HP, the following calculations establish the pound per hour emissions of CO from the spark ignition engines covered in this permit:

$$4.0 \text{ g CO/HP-hr} \times 1,300 \text{ HP} \times 1\text{lb}/454 \text{ g} = 11.5 \text{ lbs CO/hr}$$

Where the sum of the total HP of the SI ICE exceeds 1,300 HP, an average CO limit between 4.0 grams/HP-hr and 3.0 grams/HP-hr shall be required in order to meet the 11.9 lbs/hour CO limitation established in this permit. The average emissions of CO (in grams/HP-hr) shall be calculated as follows:

$$\text{Average g CO/HP-hr} = \sum_{n=1} [\text{g/HP-hr} \times \text{HP}] / \text{total HP}$$

Where:

g/HP-hr = the standard to which each natural gas engine is certified

HP = the horsepower of each individual natural gas engine

total HP = the total horsepower or summation of the horsepower of each natural gas engine

n = number of natural gas engines at the well site

The following calculations establish the maximum pound per hour emissions of CO from the spark ignition engines covered in this permit where the summation of the horsepower exceeds 1,300 HP, and where the average emissions of CO is maintained at or below 3.0 grams/HP-hr:

$$3.0 \text{ g CO/HP-hr} \times 1,800 \text{ HP} \times 1\text{lb}/454 \text{ g} = 11.9 \text{ lbs CO/hr.}$$

When required, the permittee shall demonstrate compliance with the CO limitation according to the requirements of 40 CFR 60.4244, using the applicable test methods in Table 2 to Part 60 Subpart JJJJ.

[40 CFR 60.4233(e)], [40 CFR 60.4243(b)(2)]. [40 CFR 60.4244], and [Table 1 to Part 60 Subpart JJJJ]

(7) Emissions Limitations:

1.0 gram VOC/HP-hr for engines \geq 100 HP

Applicable Compliance Method:

The emission limitations are based on the exhaust emission standards identified in 40 CFR 60.4231(e). Compliance with the applicable g/HP-hr VOC standard shall be demonstrated through performance/stack testing, if not certified to the standard. The g/HP-hr limitations above are based on the emission standards from Table 1 to Part 60 Subpart JJJJ for engines 100 HP or larger. Compliance with the short term and ton per year VOC emissions limitation shall be determined for each non-emergency spark ignition engine located on the site using the applicable compliance methods identified in Part 60 Subpart JJJJ.

The following calculations establish the pound per hour emissions of VOC from the spark ignition engines covered in this permit:

$$1.0 \text{ g VOC/HP-hr} \times 1,800 \text{ HP} \times 1\text{lb}/454 \text{ g} = 4.0 \text{ lbs VOC/hr}$$

When required, the permittee shall demonstrate compliance with the VOC limitation according to the requirements of 40 CFR 60.4244, using the applicable test methods in Table 2 to Part 60 Subpart JJJJ.

[40 CFR 60.4233(e)], [40 CFR 60.4243(b)(2)]. [40 CFR 60.4244], and [Table 1 to Part 60 Subpart JJJJ]

g) Miscellaneous Requirements

(1) Replacement of or Installation of Additional Engines

The permittee may install additional stationary engines or replace existing engines at any time during the life of this permit as long as the following are met:

- a. at any given time, the total horsepower of all natural gas engines in service at the site is no more than 1,800 HP;
- b. all natural gas engines in service at the site meet the applicable NSPS emission standards as identified in the NSPS and this permit, and all applicable State or Federal rules;
- c. the permittee maintains a list of all stationary natural gas engines used at the site; and
- d. the permittee continues to meet the qualifying criteria associated with the natural gas engines for this general permit.

(2) Stack Height of Stationary Natural Gas Engines

- a. Any engine with greater or equal to 250 HP shall be equipped with an exhaust stack that is at least 20' above ground level.
- b. Any engine with less than 250 HP shall be equipped with an exhaust stack that is at least 12' above ground level.

3. Emissions Unit: Compression Ignition Engines, P003

Operations, Property and/or Equipment Description:

| | |
|------|---|
| P003 | One or multiple stationary diesel-fired compression ignition (CI) (diesel) internal combustion engines (ICE) with a combined total horsepower (HP) of no more than 250 HP for the site ² , and that are either certified to meet the Tier 3 emission standards (from 40 CFR 60.89.112 Table 1) for diesel engines or retrofitted with a control device that demonstrates each engine meets the Tier 3 standards. |
|------|---|

a) This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).

(1) For the purpose of a permit-to-install document, the emissions unit terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.

(a) None.

(2) For the purpose of a permit-to-operate document, the emissions unit terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.

(a) 3.b)(1)a.

b) Applicable Emissions Limitations and/or Control Requirements

(1) The specific operation(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures are identified below. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|--|---|
| a. | 40 CFR Part 60, Subpart IIII 40 CFR 60.4204(b) 40 CFR 60.4201(a) Table 1 to 40 CFR 89.112, Tier 3 | The exhaust emissions from any compression ignition (CI) internal combustion engine (ICE) shall not exceed the appropriate Tier 3 emission standards identified in Table 1 to 40 CFR 89.112. The emission limitations are based on the following worst-case Tier 3 emission standards for engines greater than or equal to 50 HP: |

² This emissions unit includes stationary diesel engines used for production. It does not include various portable engines that are temporarily used on the site nor does it include engines that are exempt from permitting. For instance, any engines qualifying for the non-road exemption found in Ohio Administrative Code (OAC) paragraph 3745-31-03(A)(1)(pp) would not be covered by this permit.

² Note: The worst case emission standards for diesel-fired engines less than 300 HP were used to establish the emissions limitation. However, each engine shall be required to meet the applicable Tier 3 emission standards (or Tier 2 standards for engines <50 HP) from Table 1 of 40 CFR 89.112.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|---|---|
| | | 0.40 gram PM/kW-hr; 4.7 grams NOx + NMHC/kW-hr; and 5.0 grams CO/kW-hr. See b)(2)c. |
| b. | 40 CFR 60.4207(b) 40 CFR 80.510(b) | The sulfur content of the diesel fuel burned in this engine shall not exceed 15 ppm or 0.0015% sulfur by weight. See b)(2)c., c)(2), d)(1), and e)(2). |
| c. | 40 CFR 89.113 | Engine(s) subject to Part 60, Subpart IIII shall be certified by the manufacturer to the following opacity standards: 20% opacity during the acceleration mode; 15% opacity during the lugging mode; and 50% opacity during the peaks in either the acceleration or lugging modes. |
| d. | OAC rule 3745-18-06 | The SO ₂ limitation established per this rule is less stringent than the limitation established in 40 CFR 80.510(b). |
| e. | OAC rule 3745-17-07(A)(1) | Visible particulate emissions from the exhaust stack serving this engine shall not exceed 20% opacity, as a six-minute average, except as specified by rule. |
| f. | OAC rule 3745-31-05(A)(3), as effective 11/30/01 | Compliance with the applicable gram/kW-hr limits found in 40 CFR Part 60, Subpart IIII for PM, NOx + NMHC, and CO. See b)(2)a. |
| g. | OAC rule 3745-31-05(A)(3)(a)(ii), as effective 12/01/06 | See b)(2)b. |
| h. | OAC rule 3745-17-11(B)(5) | The emission limitation specified by this rule is less stringent than the emission limitation established for PM pursuant to 40 CFR Part 60, Subpart IIII. |
| i. | 40 CFR Part 60 Subpart IIII 40 CFR 60.4202 | All CI ICE shall meet all applicable NSPS requirements where the model year is subject to these standards and older engines shall be fitted |

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|--|-------------------------------|---|
| | | with a control device that demonstrates the Tier 3 standards are met. |

(2) Additional Terms and Conditions

a. The permittee has satisfied the Best Available Technology (BAT) requirements pursuant to OAC rule 3745-31-05(A)(3), as effective November 30, 2001, in this permit. On December 1, 2006, paragraph (A)(3) of OAC rule 3745-31-05 was revised to conform to the Ohio Revised Code (ORC) changes effective August 3, 2006 (Senate Bill 265 changes), such that BAT is no longer required by State regulations for National Ambient Air Quality Standard (NAAQS) pollutant(s) less than ten tons per year. However, that rule revision has not yet been approved by U.S. EPA as a revision to Ohio's State Implementation Plan (SIP). Therefore, until the SIP revision occurs and the U.S. EPA approves the revisions to OAC rule 3745-31-05, the requirement to satisfy BAT still exists as part of the federally-approved SIP for Ohio. Once U.S. EPA approves the December 1, 2006 version of OAC rule 3745-31-05 these emission limitations/control measures no longer apply.

b. This rule applies once U.S. EPA approves the December 1, 2006 version of OAC rule 3745-31-05 as part of the State Implementation Plan.

The Best Available Technology (BAT) requirements under OAC rule 3745-31-05(A)(3) do not apply to the PM, NOx, CO, and VOC emissions from this air contaminant source since the uncontrolled potential to emit for PM, NOx, CO, and VOC are less than ten tons per year.

c. The stationary compression ignition (CI) internal combustion engine (ICE) is subject to and shall be operated in compliance with the requirements of 40 CFR Part 60, Subpart IIII, the standards of performance for stationary CI ICE.

[40 CFR 60.4200(a)]

d. The stationary CI ICE has been or shall be purchased certified by the manufacturer to emission standards as stringent as those identified in 40 CFR 60.4201(a) and found in Tier 3 of 40 CFR 89.112, Table 1, for engines greater than or equal to 50 horsepower (37 kilowatt) and less than or equal to 250 horsepower (186 kilowatt), and to the opacity standards found in 40 CFR 89.113.

[40 CFR 60.4204(b)], [40 CFR 60.4201(a)], [40 CFR 60.4203], and [40 CFR 60.4211(c)]

e. The quality of the diesel fuel burned in this engine shall meet the following specifications on an "as received" basis:

i. a sulfur content which is sufficient to comply with the allowable sulfur dioxide emission limitation of 0.0015 pound sulfur dioxide/MMBtu actual heat input; and 15 ppm sulfur or 0.0015% sulfur by weight;

- ii. a minimum cetane index of 40 or a maximum aromatic content of 35 volume percent; and
- iii. a heating value greater than 135,000 Btu/gallon.

Compliance with the above-mentioned specifications shall be determined by using the analytical results provided by the permittee or oil supplier for each shipment of oil.

[40 CFR 60.4207(b)] and [40 CFR 80.510(b)]

c) **Operational Restrictions**

- (1) The stationary CI ICE shall be installed, operated, and maintained according to the manufacturer's emission-related written instructions over the entire life of the engine; and the permittee shall only change those emission-related settings that are allowed by the manufacturer. The CI ICE must also be installed and operated to meet the applicable requirements from 40 CFR Part 89, Control of Emissions from New and In-use Non-road CI ICE and Part 1068, the General Compliance Provisions for Engine Programs. The permittee shall operate and maintain the stationary CI ICE to achieve the Tier 3 emission standards in Table 1 to 40 CFR 89.112, as required per 40 CFR 60.4204.

[40 CFR 60.4206] and [40 CFR 60.4211(a)]

- (2) Diesel fuel burned in the CI, ICE shall not exceed the standards for sulfur as specified by 40 CFR 80.510(b), i.e., the maximum sulfur content of diesel fuel shall not exceed 15 ppm or 0.0015% sulfur by weight.

[40 CFR 60.4207(b)] and [40 CFR 80.510(b)]

- (3) If the stationary CI internal combustion engine is equipped with a diesel particulate filter to comply with the emission standards in 40 CFR 60.4204, the diesel particulate filter must be installed with a backpressure monitor that notifies the permittee when the high backpressure limit of the engine is approached.

[40 CFR 60.4209(b)]

- (4) The summation of engine power from all the diesel engines installed at the production facility site (following well completion) shall not exceed 250 HP.

d) **Monitoring and/or Recordkeeping Requirements**

- (1) For each shipment of oil received for burning in this engine, the permittee shall maintain records of the total quantity of the diesel oil received and the oil supplier's (or permittee's) analyses for sulfur content, in parts per million (40 CFR 80.510) or percent by weight. The permittee shall perform or require the supplier to perform the analyses for sulfur content and heat content in accordance with 40 CFR 80.580, using the appropriate ASTM methods. These records shall be retained for a minimum of 5 years and shall be available for inspection by the Director or his/her representative.

[for 40 CFR 60.4207(b)]

- (2) The permittee shall maintain the manufacturer's certification or compliant test data for non-certified engines, to the applicable Tier 3 emission standards in Table 1 of 40 CFR 89.112 at a central location for all facility ICE and it shall be made available for review upon request. If the manufacturer's certification is not kept on site, the permittee shall maintain a log for the location of each ICE and it shall identify the agency-assigned emissions unit number, the manufacturer's identification number, and the identification number of the certificate. The permittee or owner/operator (if leased) of the engines shall keep a maintenance plan and records of the maintenance conducted on each engine, to include documentation that the engine is maintained and operated according to the manufacturer's emission-related instructions.

[40 CFR 60.4211]

- (3) The permittee shall maintain a record of the diesel fuel burned in each ICE during each calendar year. The diesel fuel usage shall be calculated using the best method available to estimate the annual fuel consumption of each engine, which might include, but are not be limited to: a flow meter installed on the engine, records of the volume of diesel fuel oil received with each delivery, the fuel oil levels recorded from the diesel storage tank, and/or the recorded or estimated hours of operation along with the manufacturer's documentation of the estimated fuel flow rate.

- (4) If the stationary CI internal combustion engine is equipped with a diesel particulate filter to comply with the emission standards in 40 CFR 60.4204, the permittee shall keep records of the date, time, and any corrective action(s) taken in response to the notification from the backpressure monitor, that the high backpressure limit of the engine has been approached or exceeded.

[40 CFR 60.4214(c)]

- (5) The permittee shall maintain a record of visible emission checks for the stack of diesel engines. The record shall be documented during maintenance operations.

e) Reporting Requirements

- (1) The permittee shall submit an annual Permit Evaluation Report (PER) to the Ohio EPA District Office or Local Air Agency by the due date identified in the Authorization section of this permit. The permit evaluation report shall cover a reporting period of no more than twelve months for each air contaminant source identified in this permit. It is recommended that the PER is submitted electronically through the Ohio EPA's "e-Business Center: Air Services" although PERs can be submitted via U.S. postal service or can be hand delivered.

[OAC 3745-15-03(B)(2) and (D)]

- (2) The permittee shall identify in the PER:
- a. each CI engine located (and operated) at the production site during the year, to include the year of manufacture and/or year rebuilt, the horse power;
 - b. a statement as to whether each engine was purchased certified by the manufacturer, in accordance with the Subpart IIII, i.e., the manufacturer has provided a warranty for the emissions when the engine was first sold;

- c. a statement as to whether each engine was operated and maintained in accordance with the manufacturers emission-related instructions;
- d. the date each uncertified SI engine was tested for compliance with the Tier 3 emission standards from 40 CFR 89.112;
- e. identification of any uncertified engine that did not meet the applicable Tier 3 emission standards, to include the horse power and year of manufacture and/or year rebuilt; and
- f. any period of time that the quality of oil burned in each engine did not meet the requirements established in 40 CFR 80.510(b), based upon the required fuel records, to include the amount burned, the engine combusting it, the date(s), and the date the non-compliant fuel was purchased*.

* if the fuel oil is purchased before 10/1/10, the amendments of 1/30/13 allow the fuel to be used until depleted

[40 CFR 60.4207(b)] and [40 CFR 80.510(b)]

- (3) If the stationary CI internal combustion engine is equipped with a diesel particulate filter to comply with the emission standards in 40 CFR 60.4204, the permittee shall include in the PER any records of the date, time, and any corrective action(s) taken in response to the notification from the monitor that the backpressure has been approached or exceeded.

[for 40 CFR 60.4214(c)]

f) **Testing Requirements**

Compliance with the Emission Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

(1) Emission Limitation:

Manufacturer's certification requirements related to opacity include:

20% opacity during the acceleration mode;

15% opacity during the lugging mode; and

50% opacity during the peaks in either the acceleration or lugging modes.

Applicable Compliance Method:

The CI ICE subject to the standards in 40 CFR Part 60, Subpart IIII shall be purchased certified by the manufacturer to the opacity standards of 40 CFR 89.113.

[40 CFR 60.4204(b)], [40 CFR 60.4201(a)], and [40 CFR 89.113]

(2) Emission Limitation:

Visible particulate emissions from the exhaust stack serving this engine shall not exceed 20 %opacity, as a six-minute average, except as specified by rule.

Applicable Compliance Method:

Visible emission checks shall be conducted following the completion of maintenance operations. Compliance shall be determined through visible emission observations performed in accordance with U.S. EPA Reference Method 9 in 40 CFR, Part 60, Appendix A.

[OAC rule 3745-17-07(A)(1)]

(3) Emission Limitation:

0.40 gram PM/kW-hr

Applicable Compliance Method:

Compliance with the applicable g/kW-hr emissions standard shall be based on the manufacturer's certification to the standards applicable to each engine and by maintaining the engine according to the manufacturer's specifications. The g/kW-hr standard above is the worst-case Tier 3 exhaust emission standards from Table 1 of 40 CFR 89.112 for diesel engines between 50 and 300 horsepower (37 and 225 kilowatts). An uncertified engine shall either be stack tested following installation or test data shall be submitted to demonstrate compliance with the appropriate limit based on the horsepower.

If required, the permittee shall demonstrate compliance with the emission limitations through performance tests conducted in accordance with the provisions in f)(8)below.

[40 CFR 60.4204(b)], [40 CFR 60.4201(a)], [40 CFR 60.4211(c)], and [40 CFR 60.4212(a) and (c)]

(4) Emissions Limitations:

4.7 grams NO_x + NMHC/kW-hr

Applicable Compliance Method:

Compliance with the applicable g/kW-hr emissions standard shall be based on the manufacturer's certification to the standards applicable to each engine and by maintaining the engine according to the manufacturer's specifications. The g/kW-hr standard above is the worst-case Tier 3 exhaust emission standards from Table 1 of 40 CFR 89.112 for diesel engines between 50 and 300 horsepower (37 and 225 kilowatts). An uncertified engine shall either be stack tested following installation or test data shall be submitted to demonstrate compliance with the appropriate limit based on the horsepower.

For the purpose of reporting emissions, where the limitation is for NO_x + NMHC, the NO_x and VOC limitations shall be calculated using a ratio of 74.6% NO_x to 25.4% VOC:*

4.7 g NO_x+NMHC/kW-hr x 74.6% NO_x* = 3.5 grams NO_x/kW-hr.

If required, the permittee shall demonstrate compliance with the emission limitations through performance tests conducted in accordance with the provisions in f)(8)below.

[40 CFR 60.4204(b)], [40 CFR 60.4201(a)], [40 CFR 60.4211(c)], and [40 CFR 60.4212(a) and (c)]

(5) Emissions Limitations:

5.0 grams CO/kW-hr

Applicable Compliance Method:

Compliance with the applicable g/kW-hr emissions standard shall be based on the manufacturer's certification to the standards applicable to each engine and by maintaining the engine according to the manufacturer's specifications. The g/kW-hr standard above is the worst-case Tier 3 exhaust emission standards from Table 1 of 40 CFR 89.112 for diesel engines between 50 and 300 horsepower (37 and 225 kilowatts). An uncertified engine shall either be stack tested following installation or test data shall be submitted to demonstrate compliance with the appropriate limit based on the horsepower.

If required, the permittee shall demonstrate compliance with the emission limitations through performance tests conducted in accordance with the provisions in f)(8)below.

[40 CFR 60.4204(b)], [40 CFR 60.4201(a)], [40 CFR 60.4211(c)] and [40 CFR 60.4212(a) and (c)]

(6) Emissions Limitations:

4.7 grams NO_x + NMHC/kW-hr

Applicable Compliance Method:

Compliance with the emission limitations shall be based on the manufacturer's certification and by maintaining the engine according to the manufacturer's specifications. The g/kW-hr limitation is the worst-case Tier 3 exhaust emission standards from Table 1 of 40 CFR 89.112 for diesel engines between 50 and 300 horsepower (37 and 225 kilowatts). An uncertified engine shall either be stack tested following installation or test data shall be submitted to demonstrate compliance with the appropriate limit based on the horsepower.

For the purpose of reporting emissions, where the limitation is for NO_x + NMHC, the NO_x and VOC limitations shall be calculated using a ratio of 74.6% NO_x to 25.4% VOC*:

$4.7 \text{ g NO}_x\text{+NMHC/kW-hr} \times 25.4\% \text{ NMHC}^* = 1.19 \text{ gram VOC/kW-hr.}$

If required, the permittee shall demonstrate compliance with the emission limitations through performance tests conducted in accordance with the provisions in f)(8)below.

[40 CFR 60.4204(b)], [40 CFR 60.4201(a)], [40 CFR 60.4211(c)], and [40 CFR 60.4212(a) and (c)]

*This ratio is based upon the linear relationship of NO_x to NMHC from Table 1 of Subpart IIII, Table 1 from 40 CFR 89.112, to Tables 4, 5, and 6 from 40 CFR 1039.102.

(7) Emissions Limitation:

Sulfur content 15 ppm or \leq 0.0015% by weight sulfur

Applicable Compliance Method:

Compliance shall be demonstrated through the record keeping requirements for the sulfur content of each shipment of diesel oil received. If meeting the standards in 40 CFR 80.510(b), this calculates to approximately 0.0015 lb SO₂/MMBtu.

[40 CFR 60.4207(b)] and [40 CFR 80.510(b)]

- (8) If it is determined by Ohio EPA that a compliance demonstration is required through performance testing, i.e., the engine is not certified or not operated in accordance with the manufacturer's emission-related instructions, it shall be conducted using one of the following test methods or procedures:

- a. in accordance with 40 CFR 60.4212, conduct the exhaust emissions testing using the in-use testing procedures found in 40 CFR Part 1039, Subpart F, measuring the emissions of the regulated pollutants as specified in 40 CFR Part 1065; or
- b. in accordance with 40 CFR 60.4213, conduct exhaust emissions testing using the test methods identified in Table 7 to Subpart IIII of Part 60.

If demonstrating compliance through the in-use testing procedures in 40 CFR Part 1039, Subpart F, exhaust emissions from the stationary CI ICE shall not exceed the "not to exceed" (NTE) numerical requirements, rounded to the same number of decimal places as the applicable standard in 40 CFR 89.112, determined from the following equation:

$$\text{NTE requirement for each pollutant} = 1.25 \times \text{STD}$$

Where:

STD = The standard specified for the pollutant in 40 CFR 89.112.

[40 CFR 60.4212(a) and (c)]

g) Miscellaneous Requirements

- (1) Replacement of or Installation of Additional Engines

- a. The permittee may install additional stationary compression ignition engines or replace existing stationary compression ignition engines at any time during the life of this permit as long as the following are met:
 - i. at any given time, the total horsepower of all stationary compression ignition engines in service at the site is no more than 250 HP;
 - ii. all stationary compression ignition engines in service at the site meet all applicable NSPS emission standards identified in the NSPS and this permit, and all applicable State or Federal rules;
 - iii. the permittee maintains a list of all stationary compression ignition engines used at the site; and

- iv. the permittee continues to meet the qualifying criteria associated with the stationary compression ignition engines for this general permit.

(2) Stack Height of Stationary Compression Ignition Engines

- a. Each stationary compression ignition engine shall be equipped with an exhaust stack that is at least 12' above ground level.

4. Emissions Unit: Enclosed or Open Flare/Combustion Device, P004

Operations, Property and/or Equipment Description:

| | |
|------|---|
| P004 | Enclosed or Open Flare(s)/Combustion Device(s) with a maximum combined capacity heat input of no more than 250 MMBtu/hr and operated at no more than 10 MMBtu per hour combined heat input from all the sources vented to the combustion device(s), except during an emergency ³ |
|------|---|

- a) This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).
 - (1) For the purpose of a permit-to-install document, the emissions unit terms and conditions in this permit are federally enforceable, with the exception of those listed below, which are enforceable under state law only.
 - a. None.
 - (2) For the purpose of a permit-to-operate document, the emissions unit terms and conditions in this permit are enforceable under state law only, with the exception of those listed below, which are federally enforceable.
 - a. 4.b)(1)d. and 4.b)(1)e.
- b) Applicable Emissions Limitations and/or Control Requirements
 - (1) The specific operation(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures are identified below. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|-------------------------------|--|
| a. | ORC 3704.03(T) | For VOC and where applicable, compliance with the applicable control requirements of 40 CFR Part 60, Subpart OOOO, by having a designed minimum control efficiency of 95% for an enclosed flare/combustor. Carbon monoxide (CO) emissions shall not exceed 1.35 tons per month averaged over a 12-month rolling period. |
| b. | OAC rule 3745-31-05(A)(3), as | Nitrogen Oxide (NOx) emissions shall not |

³ This emissions unit applies when a facility chooses to use a flare/combustion device to control VOCs emitted from the entire facility (including, but not limited to, flash vessel/storage tanks, truck loading for water and/or petroleum liquids, and the dehydrator). If a separate flare is used to control dehydrator emissions, then the flare requirements found in the dehydrator emissions unit terms govern the dehydrator flare.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|--|--|
| | effective 11/30/01 | <p>exceed 0.25 ton per month averaged over a 12-month rolling period.</p> <p>Sulfur Dioxide (SO₂) emissions shall not exceed 0.15 ton per month averaged over a 12-month rolling period.</p> <p>See b)(2)a.</p> |
| c. | OAC rule 3745-31-05(A)(3)(a)(ii), as effective 12/01/06 | See b)(2)b. |
| d. | <p>Part 63, Subpart HH, National Emission Standards for hazardous air pollutants (NESHAP) from Oil and Natural Gas Production Facilities</p> <p>Control/operational requirements applicable to area source TEG dehydration units not meeting one of the exemptions found in 40 CFR 63.764(e).</p> | <p>For a triethylene glycol dehydration unit subject to the standards, compliance with the applicable portions of 40 CFR Part 63, Subpart HH. Design and operate the enclosed flare/combustion device in accordance with the requirements of 40 CFR 63.771(d)(1), i.e., reduce the mass content of either TOC or total HAP, in the gases vented to it (from the closed vent system), by 95% by weight or greater; or reduce the concentration of TOC or total HAP to less than or equal to 20 ppm by volume on a dry basis corrected to 3% oxygen, in accordance with 40 CFR 63.772(e); or design the open flare in accordance with 40 CFR 63.11(b).</p> |
| e. | <p>Part 60, Subpart OOOO, Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution</p> <p>Control requirements applicable to each storage vessel constructed, modified, or reconstructed after 8/23/11 with potential VOC emissions equal to or greater than 6 tons/year.</p> | <p>For a storage vessels subject to the standards, compliance with the applicable portions of 40 CFR Part 60, Subpart OOOO. By the applicable compliance date, design and operate an enclosed combustion device in accordance with the requirements of 40 CFR 60.5412(d)(1) to reduce the mass content of VOC by 95% by weight or greater; or install a combustion control device that's model has been tested by the manufacturer in accordance with 40 CFR 60.5413(d); or install an open flare designed in accordance with 40 CFR 60.18(b).</p> |
| f. | 40 CFR 60.5412(d)(1)(iii) | <p>If required to install controls in accordance with 40 C FR 60.5393, an enclosed combustion device must be operated with no visible emissions except for periods not to exceed a total of 1 minute in any 15 minute period, conducting Method 22 once every calendar month.</p> |

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|--|-------------------------------|--|
| | 40 CFR 60.5413(e)(3) | If demonstrating compliance using a combustion control device that is performance tested by the manufacturer, in accordance with 40 CFR 60.5413(d), the combustion device must be operated with no visible emissions except for periods not to exceed a total of 2 minutes in any 1 hour of operation, conducting Method 22 once per calendar quarter. |

(2) Additional Terms and Conditions

- a. The permittee has satisfied the Best Available Technology (BAT) requirements pursuant to OAC rule 3745-31-05(A)(3), as effective November 30, 2001, in this permit. On December 1, 2006, paragraph (A)(3) of OAC rule 3745-31-05 was revised to conform to the Ohio Revised Code (ORC) changes effective August 3, 2006 (Senate Bill 265 changes), such that BAT is no longer required by State regulations for National Ambient Air Quality Standard (NAAQS) pollutant(s) less than ten tons per year. However, that rule revision has not yet been approved by U.S. EPA as a revision to Ohio's State Implementation Plan (SIP). Therefore, until the SIP revision occurs and the U.S. EPA approves the revisions to OAC rule 3745-31-05, the requirement to satisfy BAT still exists as part of the federally-approved SIP for Ohio. Once U.S. EPA approves the December 1, 2006 version of OAC rule 3745-31-05 these emissions limitations/control measures no longer apply.
- b. This rule applies once U.S. EPA approves the December 1, 2006 version of OAC rule 3745-31-05 as part of the State Implementation Plan.

The Best Available Technology (BAT) requirements under OAC rule 3745-31-05(A)(3) do not apply to the PE, NO_x, and SO₂ emissions from this air contaminant source since the uncontrolled potential to emit for PE, NO_x, and SO₂ are less than ten tons per year.
- c. Pit flaring is prohibited.

c) Operational Restrictions

- (1) The flare or combustion device shall be operated with a flame present at all times when gases are vented to it.
- (2) An automatic flame ignition system shall be installed to meet one of the following requirements:
 - a. If using a pilot flame ignition system, the presence of a pilot flame shall be monitored using a thermocouple or other equivalent device to detect the presence of a flame. A pilot flame shall be maintained at all times in the flare's pilot light burner. If the pilot flame goes out and does not relight, then an alarm shall sound; or

- b. If using an electric arc ignition system, the arcing of the electric arc ignition system shall pulse continually and a device shall be installed and used to continuously monitor the electric arc ignition system.
- (3) The flare, its auto ignition system, and its recorder shall be installed, calibrated, operated, and maintained in accordance with the manufacturer's recommendations, instructions, and operating manuals.
 - (4) If the dehydrator does not qualify for one of the exemptions found in 40 CFR Part 63.764(e) or if it has been determined that any storage vessel emits 6 tons or more of VOC per year, the enclosed flare/combustion device must be designed and operated to reduce VOC, TOC, or total HAP, as applicable, by 95% by weight; or the concentration of TOC or Total HAP, as applicable, to 20 ppm by volume on a dry basis and corrected to 3% oxygen, in accordance with the applicable rule; or the open flare shall be designed and operated in accordance with 40 CFR 63.11(b) or 40 CFR 60.18(b).
 - (5) This flare/combustion device shall operate at no more than 10 MMBtu/hr heat input at all times except:
 - a. when a malfunction occurs, e.g., when excess gas must be safely disposed of by venting it to the flare/combustion device; or
 - b. for repair pressure blow-downs; or
 - c. when another well is being drilled or fractured and the gas must be safely disposed of by venting it to the flare/combustion device.
- d) **Monitoring and/or Recordkeeping Requirements**
- (1) If the permittee is using the flare/combustion device to demonstrate compliance with 40 CFR 63.771(d) for the TEG dehydrator or to demonstrate compliance with 40 CFR 60.5412(d) for each storage vessel calculated to have VOC emission equal to or exceeding 6 tons per year, the permittee shall maintain the appropriate records to demonstrate that the enclosed flare/combustion device is designed and operated to reduce VOC, TOC, or total HAP by 95% by weight; or the concentration of TOC or Total HAP to 20 ppm by volume on a dry basis and corrected to 3% oxygen, all in accordance with the applicable rules; or shall maintain the records required to demonstrate that the open flare is designed and operated in accordance with 40 CFR 63.11(b) or 40 CFR 60.18(b), as applicable per federal rules.
 - (2) The permittee shall:
 - a. continuously monitor the presence of the flame;
 - b. record all periods during which the automatic flare ignition system (pilot flame or electronic arc ignition system) or thermocouple was not working and gas was being vented to the flare/combustion device; and
 - c. record all periods of time during which gas was being vented to the flare/combustion device and there was no flame

- (3) The permittee shall maintain a record of all periods of time (date and number of hours) during which the flare/combustion device is burning collected gases at a heat input greater than 10 MMBtu per hour, along with a description of the emergency and/or the reason the heat input was greater than 10 MMBtu/hr.

e) Reporting Requirements

- (1) The permittee shall submit an annual Permit Evaluation Report (PER) to the Ohio EPA District Office or Local Air Agency by the due date identified in the Authorization section of this permit. The permit evaluation report shall cover a reporting period of no more than twelve months for each air contaminant source identified in this permit. It is recommended that the PER is submitted electronically through the Ohio EPA's "e-Business Center: Air Services" although PERs can be submitted via U.S. postal service or can be hand delivered.

[OAC 3745-15-03(B)(2) and (D)]

- (2) If the permittee is using an enclosed flare/combustion device to demonstrate compliance with 40 CFR 63.771(d) for the TEG dehydrator or to demonstrate compliance with 40 CFR 60.5412(d)(1) for each storage vessel calculated to have VOC emission equal to or exceeding 6 tons per year, the permittee shall submit the results of the compliance demonstration, conducted in accordance with the applicable subpart, in the PER.
- (3) If the permittee is using an open flare to demonstrate compliance, the permittee shall submit all visible emission readings, heat content determinations, flowrate measurements, and exit velocity determinations made during the compliance or reporting period, as applicable by rule.
- (4) The permittee shall identify in the PER:
 - a. all periods of time when the pilot flame or electronic arc ignition system is not working when process gas is being vented to it, including the date, time, and duration of each such period; and
 - b. all periods of time during which the flare/combustion device was operated at greater than 10 MMBtu per hour heat input rate, including the date, time, and duration of each such period, and a description of the reason why the heat input exceeded 10 MMBtu per hour.

f) Testing Requirements

Compliance with the Emission Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

- (1) Emission Limitation:

1.35 tons CO/month averaged over a 12-month rolling period

Applicable Compliance Method:

The emissions limitation for CO is based on using the AP-42 emission factor of 0.37 lb CO/MMBtu from Chapter 13.5 for Industrial Flares, Table 13.5-1, "Emission Factors for

Flare Operations” and using the normal operation rate of 10 MMBtu/hr. Estimated CO emissions shall be determined by the following calculations:

$$0.37 \text{ lb CO/MMBtu} \times 10 \text{ MMBtu/hr} = 3.7 \text{ lbs CO /hr}$$

$$3.7 \text{ lbs CO/hr} \times 8760 \text{ hrs/yr} \times 1 \text{ ton}/2000 \text{ lbs} = 16.2 \text{ tons CO/year}$$

$$16.2 \text{ tons CO} \div 12 \text{ months} = 1.35 \text{ tons CO/month averaged over a 12-month rolling period}$$

Compliance with the tons/month averaged over a 12-month rolling period shall be determined following the first 12 months of operation.

(2) Emission Limitation:

For VOC and where applicable, compliance with the applicable control requirements of 40 CFR Part 60, Subpart OOOO, by having a designed minimum control efficiency of 95% for an enclosed flare/combustor.

Applicable Compliance Method:

See the compliance method described in the flash vessel/storage vessel(s) emissions unit (T001).

(3) Emission Limitation:

$$0.25 \text{ ton NOx/month averaged over a 12-month rolling period}$$

Applicable Compliance Method:

The emissions limitation for NOx is based on using the AP-42 emission factor of 0.068 lb NOx/MMBtu from Chapter 13.5 for Industrial Flares, Table 13.5-1, “Emission Factors for Flare Operations” and using the normal operation rate of 10 MMBtu/hr. Estimated NOx emissions shall be determined by the following calculation:

$$0.068 \text{ lb NOx/MMBtu} \times 10 \text{ MMBtu/hr} = 0.68 \text{ lb NOx /hr}$$

$$0.68 \text{ lb NOx/hr} \times 8760 \text{ hrs/yr} \times 1 \text{ ton}/2000 \text{ lbs} = 3.0 \text{ tons NOx/year}$$

$$3.0 \text{ tons NOx} \div 12 \text{ months} = 0.25 \text{ ton NOx/month averaged over a 12-month rolling period}$$

Compliance with the tons/month averaged over a 12-month rolling period shall be determined following the first 12 months of operation.

(4) Emission Limitations:

$$0.15 \text{ ton SO}_2\text{/month averaged over a 12-month rolling period}$$

Applicable Compliance Method:

The SO₂ emissions limitation is based on a fuel gas with a maximum H₂S content of 250 ppmv for sour gas.

Compliance with the ton per year SO₂ emissions limitation shall be determined by the following calculations:

$$10 \text{ MMBtu/hr} \times 1 \text{ scf/1020 Btu} \times 1 \text{ lb-mole/379.5 scf} \times 250 \text{ ppm H}_2\text{S} \times 64 \text{ lb SO}_2/\text{lb-mole} = 0.41 \text{ lbs SO}_2/\text{hr}$$

$$0.41 \text{ lb SO}_2/\text{hr} \times 8760 \text{ hrs/year} \times 1 \text{ ton/2000 lbs} = 1.8 \text{ tons SO}_2/\text{year}$$

$$1.8 \text{ tons SO}_2 \div 12 \text{ months} = 0.15 \text{ ton SO}_2/\text{month} \text{ averaged over a 12-month rolling period}$$

Compliance with the tons/month averaged over a 12-month rolling period shall be determined following the first 12 months of operation.

(5) Visible Emissions Limitation for an enclosed combustion control device used to demonstrate compliance with Part 60 Subpart OOOO:

An enclosed combustion device used to demonstrate compliance must be operated with no visible emissions except for periods not to exceed a total of 1 minute in any 15 minute period, conducting Method 22 once every calendar month.

[40 CFR 60.5412(d)(1)(iii)]

OR

If demonstrating compliance using a combustion control device that is performance tested by the manufacturer, in accordance with 40 CFR 60.5413(d), the combustion device must be operated with no visible emissions except for periods not to exceed a total of 2 minutes in any 1 hour of operation, conducting Method 22 once per calendar quarter.

[40 CFR 60.5413(e)(3)]

Applicable Compliance Method:

Compliance with the visible emissions limitation shall be determined in accordance with U.S. EPA Method 22 in Appendix A of 40 CFR Part 60.

[40 CFR 60.5412(d)(1)(iii)] [40 CFR 60.5413(e)(3)] and [40 CFR 60.5413(a)(1)]

g) **Miscellaneous Requirements**

- (1) Any final amendments to Part 63 Subpart HH and/or Part 60 Subpart OOOO will supersede any previous Subpart HH or Subpart OOOO requirement(s) in this permit.

5. Emissions Unit Group: Equipment/Pipeline Leaks, F001

| EU ID | Operations, Property and/or Equipment Description |
|-------|---|
| F001 | <p>Ancillary equipment⁴ and Associated equipment: compressors, pumps, piping, pneumatic controllers, inlet separators, gas-water/condensate/oil separators, etc.</p> <p>Equipment/pipeline leaks from valves, flanges, pressure relief devices, open end valves or lines, and pump and compressor seals in VOC or wet gas service.</p> |

- a) This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).
 - (1) For the purpose of a permit-to-install document, the emissions unit terms and conditions in this permit are federally enforceable, with the exception of those listed below, which are enforceable under state law only.
 - a. None.
 - (2) For the purpose of a permit-to-operate document, the emissions unit terms and conditions in this permit are enforceable under state law only, with the exception of those listed below, which are federally enforceable.
 - a. 5.b)(1)b.
- b) Applicable Emissions Limitations and/or Control Requirements
 - (1) The specific operation(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures are identified below. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|---|---|
| a. | ORC 3704.03(T) | Develop and implement a site-specific leak detection and repair program for ancillary equipment as described in paragraph 5.c)(2). |
| b. | 40 CFR Part 60 Subpart OOOO Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution. | Each natural gas-driven pneumatic controller designed and operated to have a bleed rate less than or equal to 6 standard cubic feet per hour (scf/hr) and maintained in accordance with the manufacturer’s instructions, shall not be considered an affected facility, subject to Part 60 Subpart |

⁴ “Ancillary Equipment” means the same as defined in 40 CFR Part 63, Subpart HH. The Subpart HH definition is being used for this permit but note that the equipment leak standards found in Subpart HH do not apply for this permit because this permit is for an “area source” and the equipment leak standards do not apply to area sources.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|--|--|
| | 40 CFR 63.5365(d); 40 CFR 60.5390; and 40 CFR 60.5410(d) | OOOO. Each pneumatic controller constructed, modified, or reconstructed on or after 10/15/13, located between the wellhead and a natural gas processing plant, and designed to have a bleed rate equal to or greater than 6 scf/hr is an affected facility subject to the requirements of Part 60 Subpart OOOO. Each pneumatic controller affected facility that is constructed after 8/23/11 and is subject to these standards shall be tagged with the month and year of installation. |
| c. | OAC 3745-31-05(F) | Emissions of Volatile Organic Compounds (VOC) shall not exceed 10.56 tons per year from fugitive equipment leaks. |

(2) Additional Terms and Conditions

a. None

c) Operational Restrictions

(1) Pneumatic Controller Restrictions

Unless it can be demonstrated that the pneumatic controller needs to have a higher bleed rate based on functional needs in accordance with 40 CFR 60.5390(a), each natural gas-driven pneumatic controller affected facility installed, modified, or reconstructed on or after 10/15/13 and located between the wellhead and the point of custody transfer to an oil pipeline or a natural gas transmission line or storage facility, must be designed and operated with a bleed rate less than or equal to 6 standard cubic feet per hour (6 scf/hr).

[40 CFR 60.5390(c)(1), (d), and (e)], [40 CFR 60.5365(d)], [40 CFR 60.5410(d)], and [40 CFR 60.5415(d)(1)]

(2) Ancillary Equipment Leak Detection and Repair Program

The permittee shall develop and implement a leak detection and repair program designed to monitor and repair leaks from ancillary equipment covered by this permit, including each pump, compressor, pressure relief device, connector, valve, flange, vent, cover, any bypass in the closed vent system, and each storage vessel. This program shall meet the following requirements:

a. Leaks shall be detected by the use of either a “Forward Looking Infra Red” (FLIR) camera or an analyzer meeting U.S. EPA Method 21 of 40 CFR Part 60, Appendix A.

- b. An initial monitoring shall be completed within 90 days of startup and quarterly thereafter for a period of four consecutive quarters (1 year).
 - c. If following the initial four consecutive quarters, less than or equal to 2.0% of the ancillary equipment are determined to be leaking during the most recent quarterly monitoring event, then the frequency of monitoring can be reduced to semi-annual.
 - d. If following two consecutive semi-annual periods, less than 2.0% of the ancillary equipment are determined to be leaking during the most recent semi-annual monitoring event, then the frequency of the monitoring can be reduced to annual.
 - e. If more than or equal to 2.0% of the ancillary equipment are determined to be leaking during any one of the semi-annual or annual monitoring events, then the frequency of monitoring shall be returned to quarterly.
 - f. The program shall require the first attempt at repair within five (5) calendar days of determining a leak.
 - g. The program shall require that the leaking component is repaired within 30 calendar days after the leak is detected.
 - h. The program shall allow for the delayed repair of a leaking component following the language found in 40 CFR 60.5416(c)(5).
 - i. The program shall following the Monitoring and Record Keeping requirements described in paragraph 5.d) of this permit.
- (3) In the event that a leak or defect is detected in the cover, closed vent system, process equipment, or control device, the permittee shall make a first attempt at repair no later than 5 calendar days after the leak is detected. Repair shall be completed no later than 30 calendar days after the leak is detected as allowed in 40 CFR 60.5416(c)(4). Any delay of repair of a leak or defect shall meet the requirements of 40 CFR 60.5416(c)(5).

[40 CFR 60.5416(c)(4) and (5)], [40 CFR 60.5415(e)(3)], and [ORC 3704.03(T)]

d) Monitoring and/or Recordkeeping Requirements

(1) Pneumatic Controller Monitoring and Record Keeping

- a. Each natural gas-driven pneumatic controller affected facility installed or reconstructed on or after 8/23/11, located between the wellhead and natural gas processing plant shall be tagged with the month and year of installation, reconstruction, or modification and with information that can identify or trace the records for the manufacturer's design specifications.
- b. The following records shall be maintained for each natural gas-driven pneumatic controller installed at the facility after 8/23/11:
 - i. records of the date installed or reconstructed, the location and/or equipment each controller is servicing, and the manufacturer specifications;

- ii. if applicable, the records needed to demonstrate why the operations require the use of a pneumatic controller with a bleed rate greater than 6 scf/hr and the functional basis for requiring the higher bleed rate; or
 - iii. if installed on or after 10/15/13, records of the manufacturer's specification indicating that the pneumatic controller is designed to have a natural gas bleed rate less than or equal to 6 scf/hr; or
 - iv. if the pneumatic controller has been installed on or after 8/23/11 and before 10/15/13, the manufacturer's designed bleed rate; and
 - v. where a higher bleed rate has not been demonstrated to be needed, the records of any deviations from the 6 scf/hr bleed rate for each pneumatic controller installed on or after 10/15/13.
- c. Once a gas-driven pneumatic controlled has been documented to have a bleed rate less than or equal to 6 scf/hr, it is no longer subject to the requirements of Part 60 Subpart OOOO. The manufacturer's specifications for the pneumatic controller and/or other records demonstrating compliance or exemption from the requirements should be maintained until the well site is closed.

[40 CFR 60.5390(c) and (f)], [40 CFR 60.5410(d)], [40 CFR 60.5415(d)(3)], [40 CFR 60.5420(c)(4)], and [40 CFR 60.5365(d)]

(2) Ancillary Equipment Leak Detection and Repair Program Monitoring and Record Keeping for Programs Utilizing FLIR Camera's

- a. Leaks shall be determined by visually observing each ancillary component through the FLIR camera to determine if leaks are visible.
- b. The following information shall be recorded during each leak inspection:
 - i. the date the inspection was conducted;
 - ii. the name of the employee conducting the leak check;
 - iii. the identification of any component that was determined to be leaking;
 - iv. the date the first attempt to repair the component was made;
 - v. the reason the repair was delayed following the language found in 40 CFR 60.5416(c)(5);
 - vi. the date the component was repaired and determined to no longer be leaking;
 - vii. the total number of components that are leaking; and
 - viii. the percentage of components leaking, determined as the sum of the number of components for which a leak was detected, divided by the total number of ancillary components capable of developing a leak, and multiplied by 100.

- c. The permittee shall maintain records that demonstrate the FLIR camera is operated and maintained in accordance with the manufacturer's operation and maintenance instructions.
- d. The records from each inspection and the dates each leak is detected and repaired shall be maintained for at least 5 years and shall be made available to the Director or his representative upon verbal or written request.

[40 CFR 60.5416(c)] and [ORC 3704.03(T)]

(3) Ancillary Equipment Leak Detection and Repair Program Monitoring and Record Keeping for Programs Utilizing a Method 21 Analyzer

- a. Leaks shall be measured by utilizing U.S. EPA Method 21 (40 CFR Part 60, Appendix A). All potential leak interfaces shall be traversed as close to the interface as possible. The arithmetic difference between the maximum concentration indicated by the instrument and the background level is compared with 500 ppm or 10,000 ppm (as applicable) for determining compliance.
- b. A component is considered to be leaking if the instrument reading is equal to or greater than:

| | |
|---|------------|
| pressure relief device in gas/vapor service | 10,000 ppm |
| pressure relief device in light liquid service | 10,000 ppm |
| pumps in light liquid service | 10,000 ppm |
| compressor | 500 ppm |
| sampling connection system* | * |
| open ended valves or lines** | ** |
| valves in gas/vapor and light liquid service | 10,000 ppm |
| closed vent system | 500 ppm |
| connectors | 10,000 ppm |
| all other ancillary and associated equipment in VOC service | 10,000 ppm |

* must be equipped with a closed-purge, closed-loop, or closed-vent system

** must be equipped with a cap, blind flange, plug, or a second valve

- c. The following information shall be recorded during each leak inspection:
 - i. the date the inspection was conducted;
 - ii. the name of the employee conducting the leak check;
 - iii. the identification of any component that was determined to be leaking (company ID and component type (flange, pump, etc.);

- iv. the date the first attempt to repair the component was made;
 - v. the reason the repair was delayed following the language found in 40 CFR 60.5416(c)(5);
 - vi. the date the component was repaired and determined to no longer be leaking;
 - vii. the total number of components that are leaking; and
 - viii. the percentage of components leaking, determined as the sum of the number of components for which a leak was detected, divided by the total number of ancillary components capable of developing a leak, and multiplied by 100.
- d. The permittee shall maintain records that demonstrate the Method 21 analyzer is operated and maintained in accordance with the manufacturer's operation and maintenance instructions.
- e. In order to calibrate the analyzer, the following calibration gases shall be used:
- i. zero air, which consists of less than 10 ppm of hydrocarbon in air; and
 - ii. a mixture of air and methane or n-hexane at a concentration of approximately, but less than, 10,000 ppm of methane or n-hexane.
- f. The records from each inspection and the dates each leak is detected and repaired shall be maintained for at least 5 years and shall be made available to the Director or his representative upon verbal or written request.

[40 CFR 60.5416(c)] and [ORC 3704.03(T)]

e) Reporting Requirements

- (1) The permittee shall submit an annual Permit Evaluation Report (PER) to the Ohio EPA District Office or Local Air Agency by the due date identified in the Authorization section of this permit. The permit evaluation report shall cover a reporting period of no more than twelve months for each air contaminant source identified in this permit. It is recommended that the PER is submitted electronically through the Ohio EPA's "e-Business Center: Air Services" although PERs can be submitted via U.S. postal service or can be hand delivered.

[OAC 3745-15-03(B)(2) and (D)]

- (2) Supplement to the PER for the Ancillary Equipment Leak Detection and Repair Program
- For each inspection that occurred during the year, the permittee shall submit the following information with the annual PER from data collected by the ancillary equipment leak detection and repair program:
- a. the date of the inspection;
 - b. the number of components determined to be leaking;

- c. the company ID and component type (flange, pump, etc.) of each leaking component;
- d. the total number of components at the site;
- e. the percent of components determined to be leaking;
- f. a list of all components that have not been repaired due to a delay of repair and the reason for the delay; and
- g. a notification indicating if the permittee has changed future inspection frequencies based on the percent of components leaking.

[40 CFR 60.5416(c)] and [ORC 3704.03(T)]

(3) **Pneumatic Controller Reporting**

The permittee shall submit an initial annual report, for each natural gas-driven pneumatic controller installed at the facility after 8/23/11, within 90 days after the end of the initial compliance period as determined according to 40 CFR 60.5410. Subsequent annual reports are due on the same date each year following the initial report. The annual reports may contain multiple facilities if each pneumatic controller is clearly identified along with its location, and the report includes the following information from 40 CFR 60.5420 for each natural gas-driven pneumatic controller:

- a. company name and address of the affected facility;
- b. identification of each affected facility included in the annual report*;
- c. beginning and ending dates of the reporting period;
- d. the identification of each pneumatic controller and the equipment it controls;
- e. the month and year each pneumatic controller was installed, reconstructed, or modified;
- f. a statement as to whether the manufacturer's specifications indicate the controller is designed to maintain a natural gas bleed rate less than or equal to 6 scf/hour; or the explanation of why the bleed rate needs to be operated to exceed this and the manufacturer's specifications for the bleed rate;
- g. records of any deviations from the appropriate natural gas bleed rate; and
- h. certification of the responsible official of truth, accuracy, and completeness.

* One report for multiple affected facilities may be submitted provided the report contains all of the information required and is clearly separated and identified for each well site.

[40 CFR 60.5410(d)], [40 CFR 60.5420(b)(1) and (5) and (c)(4)], [40 CFR 60.5390(f)], and [40 CFR 60.5415(d)(2)]

f) **Testing Requirements**

Compliance with the Emission Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

(1) Emissions Limitation:

Emissions of VOC shall not exceed 10.56 tons per year from fugitive equipment leaks.

Applicable Compliance Method:

The annual VOC limitation is the estimated potential-to-emit based upon the maximum number of components and type of service (gas/vapor and light liquid) expected at the natural gas production site. Unless or until more accurate emission factors have been demonstrated or established for the site (e.g. following initial and subsequent monitoring and inspections), the appropriate emissions factors from U.S. EPA's "Protocol for Equipment Leak Emission Estimates", Table 2-4, for Oil and Gas production Operations (a conservative estimate), shall be used to demonstrate compliance with the annual limit. The facility's potential emissions from ancillary and associated equipment shall be documented from the summation of the following calculations:

Component Type # of components x emission factor x % VOC* = lb VOC/hr

In Gas/Vapor Service

Number of connectors x 0.000441 lb/hr x 50% VOC = lb VOC/hr

Number of valves x 0.00992 lb/hr x 50% VOC = lb VOC/hr

Number of flanges x 0.00086 lb/hr x 50% VOC = lb VOC/hr

Number of compressor seals x 0.01940 lb/hr x 50% VOC = lb VOC/hr

Number of relief valves x 0.01940 lb/hr x 50% VOC = lb VOC/hr

Number of high bleed pneumatic controllers x 0.0194 lb/hr x 50% VOC = lb VOC/hr

In Light Liquid Service

Number of connectors x 0.000463 lb/hr x 100% VOC = lb VOC/hr

Number of valves x 0.00551 lb/hr x 100% VOC = lb VOC/hr

Number of flanges x 0.00024 lb/hr x 100% VOC = lb VOC/hr

Number of pump seals x 0.0287 lb/hr x 100% VOC = lb VOC/hr

Number of relief valves x 0.01653 lb/hr x 100% VOC = lb VOC/hr

Number of high bleed pneumatic controllers x 0.01653 lb/hr x 100% VOC = lb VOC/hr

The total summation of VOC emissions per hour shall be multiplied by 8760 hours per year and divided by 2000 pounds to calculate the estimated annual fugitive VOC emissions.

Compliance with the ton per year limit shall be determined following the first 12 months of operation.

As an alternative to using the above emission factors to calculate VOC emissions, the permittee may use facility specific VOC information for site specific emission factors.

* The % VOC for Gas/Vapor service was based on the highest percent VOC in gas analyses submitted by representative facilities.

(2) Emission Limitation:

Each natural gas-driven pneumatic controller installed after 10/15/13 shall be operated with a bleed rate less than or equal to 6 scf/hr, unless it can be demonstrated that the pneumatic controller needs to have a higher bleed rate based on functional needs.

Applicable Compliance Method:

Natural gas shall be used as a surrogate for VOC. If required, the detection of leaks of natural gas into the ambient air from the pneumatic controller(s) may be determined using Method 21 from 40 CFR 60 Appendix A; however, compliance is demonstrated through maintaining the manufacturer's design specifications, showing that the controller is designed to operate with a bleed rate less than 6 scf/hr. If required, Method 21 may be used during inspections of the facility.

[40 CFR 60.5390(a) or (c)(1)], [40 CFR 60.5410(d)], and [40 CFR 60.5415(d)(1)], with [ORC 3704.03(T)]

g) **Miscellaneous Requirements**

- (1) Any amendment to Part 60, Subpart OOOO shall supersede the Subpart OOOO compliance limitations and/or options contained in this permit.

6. Emissions Unit: Flash Vessel/Storage Vessels and truck loading for produced water, crude oil, condensate, and/or petroleum liquids: T001

Operations, Property and/or Equipment Description:

| | |
|------|--|
| T001 | One or multiple vertical fixed roof flash vessel/storage vessel(s) with a combined capacity of no more than 252,000 gallons (6,000 barrels), where each flash vessel/storage vessel has an individual capacity of no more than 39,894 gallon (950 barrel). |
|------|--|

a) This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).

(1) For the purpose of a permit-to-install document, the emissions unit terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.

(a) None.

(2) For the purpose of a permit-to-operate document, the emissions unit terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.

(a) 6.b)(1)c.

b) Applicable Emissions Limitations and/or Control Requirements

(1) The specific operation(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures are identified below. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|-------------------------------|--|
| a. | ORC 3704.03(T) | <p>Total VOC emissions (including breathing losses, working losses, and flashing losses) from all storage vessels combined at the site shall not exceed 4.28 tons per month averaged over a 12-month rolling period.</p> <p>In order to comply with the tons per month emission limit, utilize one or more of the following controls:</p> <p>Use of add-on control (vapor recovery, flare or equivalent) to control emissions from storage vessels as needed to comply with the annual VOC emission limitations. If a flare is used, it must meet the requirements</p> |

| | | |
|----|---|--|
| | | detailed in emissions unit P004. |
| b. | OAC Rule 3745-21-09(L) | See b)(2)a. |
| c. | Part 60, Subpart OOOO Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution | <p>The facility must calculate the potential for VOC emissions for each single storage vessel using an accepted model or calculation methodology, based on the maximum average daily throughput determined for a 30-day period of production prior to 10/15/13 for Group 1 storage vessels*, or determined for a 30-day period of production prior to 4/15/14 or 30 days after startup for Group 2 storage vessels**.</p> <p>Where these potential VOC emissions are calculated to equal or exceed 6 TPY, the permittee must either maintain the uncontrolled actual VOC emissions at less than 4 TPY and maintain monthly emission calculations in accordance with 40 CFR 60.5395(d)(2); or install a control device, closed vent system, and covers designed and operated to reduce VOC emissions by 95.0%, and by 4/15/14 or 60 days after startup for Group 2 storage vessels or by 4/15/15 for Group 1 storage vessels.</p> <p>Conduct monthly inspections of collection and control equipment.</p> <p>Any final amendments to this rule will supersede the requirement(s) in this permit.</p> <p>See b)(2) b. through f.</p> |
| d. | 40 CFR 60.5413(d) | Option to demonstrate compliance with Part 60 Subpart OOOO through the use a control device model tested by the manufacturer. |
| e. | 40 CFR 60.5412(d)(1)(iii) 40 CFR 60.5413(e)(3) | <p>If required to install controls in accordance with 40 CFR 60.5395, an enclosed combustion device must be operated with no visible emissions except for periods not to exceed a total of 1 minute in any 15 minute period, conducting Method 22 once every calendar month.</p> <p>If demonstrating compliance using a combustion control device that is performance tested by the manufacturer, in accordance with 40 CFR 60.5413(d), the combustion device must be operated with no</p> |

| | | |
|----|--|---|
| | | visible emissions except for periods not to exceed a total of 2 minutes in any 1 hour of operation, conducting Method 22 once per calendar quarter. |
| f. | 40 CFR 60.5365(e) OAC 3745-31-05(F) | The permittee accepts a voluntarily limit to restrict the potential VOC emissions from each storage vessel to less than 6 tons per year. |

(2) Additional Terms and Conditions

- a. The permittee shall not place, store, or hold in these fixed roof tanks any petroleum liquid other than crude oil and condensate where there is no custody transfer, unless such tank is designed or equipped in accordance with the requirements of paragraph (L)(1) of OAC rule 3745-21-09 with an internal floating roof or equivalent control approved by the Director, prior to storing such petroleum liquids.

[OAC rule 3745-21-09(L)]

- b. Any storage vessel subject to and controlled in accordance with the requirements for storage vessels in 40 CFR Part 60 Subpart Kb, or 40 CFR Part 63 Subparts G, CC, HH, or WW are not subject to Part 60 Subpart OOOO.

[40 CFR 60.5395(h)]

- c. If the storage vessel affected facility is installed with a floating roof to reduce VOC emissions, it must meet the requirements of 40 CFR 60.112b(a)(1) or (2) and the relevant monitoring, inspection, recordkeeping, and reporting requirements in Part 60, Subpart Kb.

[40 CFR 60.5395(e)(2)]

- d. The permittee shall calculate the potential for VOC emissions for each single storage vessel (defined in 40 CFR 60.5430) using an accepted model or calculation methodology. Emissions of VOC shall be based on the maximum average daily throughput determined for:

- i. a 30-day period of production prior to 10/15/13 for storage vessels installed after 8/23/11 and on or before 4/12/13, i.e., Group 1 storage vessels; and/or
- ii. a 30-day period of production prior to 4/15/14 or 30 days after startup for storage vessels installed after 4/12/13, i.e., Group 2 storage vessels.

[40 CFR 60.5410(h)] and [40 CFR 60.5365(e)]

- e. Unless meeting the requirements of 40 CFR 60.5395(d)(2), where the uncontrolled actual VOC emissions can be demonstrated to be less than 4 tons per year, or where it has been demonstrated that the potential VOC emissions are less than 6 TPY, the VOC emissions from each storage vessel affected facility shall be reduced by 95.0 percent by April 15, 2014, or within 60 days after

startup, for Group 2 storage vessels; or by April 15, 2015 for Group 1 storage vessels.

[40 CFR 60.5395] and [40 CFR 60.5415(e)(3)]

- f. Any vapors from storage vessels that are recovered and routed to a vapor recovery unit (VRU) system meeting the cover and closed vent system requirements specified in 40 CFR 60.5411(b) and (c) are not required to be included in the determination of VOC potential to emit for purposes of determining affected facility status for NSPS Subpart OOOO. However, if the VRUs are removed or if the system fails to meet the cover and closed vent system requirements of Subpart OOOO, the potential VOC emissions from each such storage vessel shall be calculated within 30 days of the removal or non-compliant operations of the VRU system.

[40 CFR 60.5365(e)]

c) Operational Restrictions

- (1) Total capacity of all storage vessels storing condensate and/or condensed water shall not exceed 252,000 gallons (6000 barrels) combined, excluding any exempt or de minimis vessels.
- (2) Each storage vessel subject to the control requirements of Part 60 Subpart OOOO shall be equipped with a cover that meets the requirements of 40 CFR 60.5411(b); and the storage vessel shall be connected through a closed vent system designed and operated with no detectable emissions, as determined using olfactory, visual and auditory inspections, and in accordance with 40 CFR 60.5411(c) to either: 1. an enclosed combustion control device, designed and operated in accordance with 40 CFR 60.5412(d) or 40 CFR 60.5413(d); 2. an open flare meeting the requirements identified in this permit; or 3. to a process. The collection and control systems shall be operated at all times when gases, vapors, and fumes are vented from the subject storage vessels to a control device; and where routing emissions to a process it must be operational 95% or more of the year.

[40 CFR 60.5365(e)], [40 CFR 60.5395], [40 CFR 60.5410(h)], [40 CFR 60.5411(b) and (c)(1) and (2)], and [40 CFR 60.5412(d)] or [40 CFR 60.5413(d)], and [40 CFR 60.5415(e)(3)]

- (3) In the event that a leak or defect is detected in the cover or closed vent system that is used to demonstrate compliance, the permittee shall make a first attempt at repair no later than 5 calendar days after the leak is detected. Repair shall be completed no later than 30 calendar days after the leak is detected in accordance with 40 CFR 60.5416(c)(4) and (5). A record of the leak detected and repairs must be maintained for a period of five years.

[40 CFR 60.5416(c)(4) and (5)] and [40 CFR 60.5415(e)(3)]

- (4) Where the closed vent system (used to demonstrate compliance) contains one or more bypass devices that could be used to divert all or a portion of the gases, vapors, or fumes from entering the control device or a process, the requirements identified in 40 CFR 60.5416(c)(3) shall be met.

[40 CFR 60.5416(c)(3)], [40 CFR 60.5411(c)(3)] and [40 CFR 60.5415(e)(3)]

- (5) Each enclosed combustion device, used to meet the emission reduction standard in 40 CFR 60.5395(d), shall be installed and operated in accordance with 40 CFR 60.5412(d) and 40 CFR 60.5417(h). As an alternative, a combustion control device may be installed whose model has been tested by the manufacturer in accordance with 40 CFR 60.5413(d), and the facility can instead meet the criteria in 40 CFR 60.5413(d)(11) and 40 CFR 60.5413(e).

[40 CFR 60.5410(h)], [40 CFR 60.5412(d)], [40 CFR 60.5417(d)(1)(iii) and (h)], and [40 CFR 60.5415(e)(3)]

d) Monitoring and/or Recordkeeping Requirements

- (1) The permittee shall maintain the following records documenting the facility's determination of emissions from each storage vessel:

- a. the maximum average daily throughput determined for a 30-day period of production prior to 10/15/13 for Group 1 storage vessels and prior to 4/15/14 or 30 days after startup for Group 2 storage vessels;
- b. the content of each storage vessel;
- c. the lab analyses, calculations, and process simulation model results documenting the annual emissions from breathing, working, and flashing losses; and
- d. the records for the content and annual throughput (in gallons per year) for each storage vessel.

These records shall be maintained for at least 5 years and shall be made available to the Director or his representative upon verbal or written request.

[40 CFR 60.5365(e)] and [40 CFR 60.5410(h)]

- (2) Where using vapor recovery unit(s) (VRU) for compliance, the permittee shall maintain records that document the VRU system is operated in compliance with the cover and closed vent system requirements of 40 CFR 60.5411(b) and 40 CFR 60.5411(c).

[40 CFR 60.5365(e)]

- (3) Where required, the permittee shall conduct monthly inspections for each closed vent system, each cover, and the combustion control device used to demonstrate compliance in accordance with 40 CFR 60.5416(c) and 40 CFR 60.5417(h); and shall maintain the records identified in 40 CFR 60.5420(c).

[40 CFR 60.5416(c)], [40 CFR 60.5417(h)], [40 CFR 60.5411(b) and (c)], [40 CFR 60.5415(e)(3)], and [40 CFR 60.5420(c)]

- (4) Where the facility is using an enclosed combustion device for compliance, the permittee shall maintain the appropriate records to demonstrate that the control device is designed and operated to reduce VOC by 95.0% by weight and is operated and maintained in accordance with 40 CFR 60.5412(d); or if the model device has been performance tested by the manufacturer in accordance with 40 CFR 5413(d), the device shall be monitored, operated and maintained in accordance with 40 CFR 5413(e).

[40 CFR 60.5410(h)], [40 CFR 60.5412(d)] or [40 CFR 60.5413(d) and (e)]

- (5) Where using an open flare for compliance, the permittee shall maintain the records required to demonstrate that the open flare is designed and operated in accordance with Part 60 Subpart OOOO and the requirements of this permit.
- (6) Where the permittee has accepted a voluntarily limit to restrict the potential VOC emissions to less than 6 tons per year and less than 0.50 tons per month averaged over a 12-month rolling period, the records documenting the maximum monthly potential VOC emissions (calculated in accordance with 40 CFR 60.5365(e)) shall be maintained and made readily available upon request.

[40 CFR 60.5365(e)] and [OAC 3745-31-05(F)]

e) Reporting Requirements

- (1) The permittee shall submit an annual Permit Evaluation Report (PER) to the Ohio EPA District Office or Local Air Agency by the due date identified in the Authorization section of this permit. The permit evaluation report shall cover a reporting period of no more than twelve months for each air contaminant source identified in this permit. It is recommended that the PER is submitted electronically through the Ohio EPA's "e-Business Center: Air Services" although PERs can be submitted via U.S. postal service or can be hand delivered.

[OAC 3745-15-03(B)(2) and (D)]

- (2) The permittee shall submit an initial annual report within 90 days after the end of the initial compliance period for each storage vessel determined to have potential VOC emissions equal or greater than 6 tons per year. Subsequent annual reports are due no later than the same date each year following the initial report. The reports shall include the information identified in 40 CFR 60.5420(b).

[40 CFR 60.5420(b)] and [40 CFR 60.5410(h) and (i)]

f) Testing Requirements

Compliance with the Emission Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

- (1) Emissions limitation:

Total VOC emissions from all storage vessels (including breathing losses, working losses, and flashing losses) shall not exceed 4.28 tons per month averaged over a 12-month rolling period.

Compliance with the tons/month averaged over a 12-month rolling period shall be determined following the first 12 months of operation.

For each storage vessels not meeting the collection and control requirements of Part 60 Subpart OOOO, the potential annual VOC emissions must be documented to be less than 6 tons/year; or the uncontrolled actual VOC emissions shall be calculated to be less than 4 tons/year in accordance with 40 CFR 60.5395(d)(2) through monthly determinations.

For each storage vessel with potential emissions equal to or greater than 6 tons VOC/year, reduce VOC emissions by 95.0% by installing a closed vent system designed and operated with no detectable emissions, that routes all gases, vapors, and fumes to a process or a combustion control device meeting the requirements of 40 CFR 60.5412(d) or 40 CFR 60.5413(d).

Applicable Compliance Method, documenting emissions:

Annual emissions from breathing, working, and flashing losses from each storage vessel shall be calculated based on the maximum average daily throughput determined for a 30-day period of production prior to 10/15/13 for Group 1 storage vessels and/or prior to 4/15/14 or 30 days after startup for Group 2 storage vessels.

Flashing losses shall be calculated using a generally accepted model or process simulation software program(s) and/or calculation methodology such as, but not limited to, E&P Tank, HYSIM, HYSIS, VMG, or ProMax, to calculate the VOC emissions.

Pressurized samples shall be taken after the separator and at the same time from the flash gas and condensate/oil lines for flash gas analyses; and the data from these lab analyses shall be used in the process simulation software to document emissions from flashing.

Instead of taking pressurized samples from the separator(s) or from the storage vessels, the permittee may utilize pressurized samples acquired from another similar facility operating under similar conditions, or choose to take a representative reservoir sample from a well in another part of the play. If the permittee chooses to use pressurized samples from another facility, the flash gas analyses shall be submitted along with documentation demonstrating that the facility's pressurized condensate/oil and gases would have similar chemical compositions and would be under similar pressures; and provide evidence that if pressurized samples were taken and lab analyses were conducted, the results would provide equivalent or lower emissions. "Similar", in this case, means that the chemical composition, pressures, and operating parameters/conditions of the similar facility are close enough to this facility's condensate/oil and gas composition, pressures, and operations, that the expected emissions would be equivalent to or less than the emissions calculated from the flash gas analyses obtained from the similar facility. If the permittee chooses to use a representative reservoir sample, the analyses must be incorporated into an approved process simulation modeling program utilizing site-specific operating parameters. "Representative", in this case, means having an API gravity no more than 3 degrees below the API gravity of the condensate detected at the facility being permitted. A representative sample with a higher API gravity results in a more conservative emissions estimate and is, therefore, not a concern. If changes to the operating conditions and/or liquid composition are such that the emissions would be expected to exceed those determined with the representative analyses, the permittee shall either submit site-specific analyses using pressurized samples from the separator (with the highest pressures, if more than one), or submit emissions estimates using another representative analyses. The Director reserves the right to require the owner/operator to obtain samples from the facility in order to verify compliance.

Working and breathing losses may be calculated using E&P Tank, EPA Tanks 4.0 software, or other accepted calculation methodology; and/or the working/loading emissions may be calculated using the "Loading Loss Equation" from AP-42, Section

5.2, for Transportation and Marketing of Petroleum Liquids, which is based on multiplying a loading loss factor (L^*) by the annual petroleum liquid throughput in gallons per year, as follows:

$$*L = 12.46 \text{ SPM/T}$$

For uncontrolled loading, the VOC emissions shall be calculated by multiplying an uncontrolled loading loss factor (L_{UC}) by the rolling, 12-month summation of the throughput of condensate and petroleum liquids (in gallons) and dividing by 2000 lbs/ton. The result will be added to the breathing and flashing emission estimates.

$$L_{UC} = 12.46 \text{ SPM/T}$$

For controlled loading, the VOC emissions shall be calculated by multiplying a controlled loading loss factor (L_C) by the rolling, 12-month summation of the throughput of condensate and petroleum liquids (in gallons) and dividing by 2000 lbs/ton. The result will be added to the breathing and flashing emission estimates.

$$L_C = 12.46 \text{ SPM/T} [1 - \text{Efficiency}/100]$$

Where:

$$\text{Capture Efficiency} = 97\%$$

$$\text{Destruction Efficiency} = 98\%$$

$$\text{Control Efficiency} = 97\% \times 98\% = 95\%$$

Where:

L = loading loss, pounds per 1000 gallons loaded (Q)

S = saturation factor

P = vapor pressure of liquid loaded, pounds per square inch absolute

M = molecular weight of vapor

T = temperature of bulk liquid ($^{\circ}\text{R}$)

Applicable Compliance Method, through design of collection and controls:

Initial compliance with the Part 60, Subpart OOOO standards for storage vessel affected facilities shall be demonstrated by complying with the applicable portions of 40 CFR 60.5411(b) and (c), and 40 CFR 60.5412(d) or 40 CFR 60.5413(e) if the control device is tested by the manufacturer.

Continuous compliance with the Part 60, Subpart OOOO standards for storage vessel affected facilities shall be demonstrated by complying with the applicable portions of 40 CFR 60.5415(e), 40 CFR 60.5416(c), and 40 CFR 60.5417(d) or (h).

Group 1 storage vessels (installed between 8/24/11 and 4/12/13) must be in compliance by April 15, 2015; and Group 2 storage vessels (installed after 4/12/13) must be in

compliance by 4/15/14 or within 60 days after startup. In the event an amendment to NSPS Subpart OOOO requires a performance test for the combustion control device to demonstrate compliance, the permittee shall schedule such performance test as required by the amended rules.

[40 CFR 60.5365(e)], [40 CFR 60.5395], [40 CFR 60.5410(h)], [40 CFR 60.5411(b) and (c)], [40 CFR 60.5412(d) or 40 CFR 60.5413(d)], [40 CFR 60.5415(e)(3)], and [ORC 3704.03(T)]

(2) Visible Emissions Limitation for an enclosed combustion control device used to demonstrate compliance with Part 60 Subpart OOOO:

An enclosed combustion device used to demonstrate compliance must be operated with no visible emissions except for periods not to exceed a total of 1 minute in any 15 minute period, conducting Method 22 once every calendar month.

[40 CFR 60.5412(d)(1)(iii)]

OR

If demonstrating compliance using a combustion control device that is performance tested by the manufacturer, in accordance with 40 CFR 60.5413(d), the combustion device must be operated with no visible emissions except for periods not to exceed a total of 2 minutes in any 1 hour of operation, conducting Method 22 once per calendar quarter.

[40 CFR 60.5413(e)(3)]

Applicable Compliance Method:

Compliance with the visible emissions limitation shall be determined in accordance with U.S. EPA Method 22 in Appendix A of 40 CFR Part 60.

[40 CFR 60.5412(d)(1)(iii)] [40 CFR 60.5413(e)(3)] and [40 CFR 60.5413(a)(1)]

g) **Miscellaneous Requirements**

- (1) Any amendment to Part 60, Subpart OOOO shall supersede the Subpart OOOO compliance limitations and/or options contained in this permit.

Concepts for Proposed General Permit for Well Pads and Proposed GP-5 Modifications

Oil and Gas Technical Advisory Board Meeting
March 31, 2016

Background

- On January 19, 2016 Governor Tom Wolf announced a four-point methane emission reduction strategy for Oil and Gas operations.
 - DEP will develop a new general permit for new unconventional well pad operations.
 - DEP will revise its current general permit (GP-5) updating the permitting requirements.
 - DEP will develop a regulation for existing sources for consideration by the Environmental Quality Board.
 - DEP will establish best management practices, including leak detection and repair programs to reduce emissions along production, gathering, transmission and distribution lines.

Key Concepts for the proposed New GP for Well Pad Operations

- Currently, natural gas compressor stations are permitted under general plan approval and/or general operating permit number 5 (GP-5).
- Oil and natural gas wells may be exempted from permitting requirements provided the owner or operator complies with the conditions set forth in plan approval exemption #38.
- As part of the Department's Methane Emission Reduction Strategy, the Department is in the process of developing a new general permit to replace exemption #38 and revising the current GP-5.

Key Concepts for the proposed New GP for Well Pad Operations

- Most of the substantive requirements for exemption #38 are expected to be included in the new general permit.
- The Department is exploring the possibility of requiring that diesel-fired engines used on drill rigs meet the EPA's Tier 4 standards.
- The requirement for leak detection and repair (LDAR) may be similar to the current GP-5, including quarterly LDAR inspections using optical gas imaging system and monthly Audio Video Olfactory (AVO) inspections.

Key Concepts for the proposed New GP for Well Pad Operations

- The first attempt at leak repair must be done within five (5) calendar days of leak detection. If purchase of parts is necessary, the leak must be repaired within 15 calendar days, after the purchase of parts.
- VOC emissions from storage tanks must be controlled by at least 95%.
- Permitting requirements addressing fugitive dust control measures may be included.

Concepts for the proposed New GP for Well Pad Operations

- The Department is exploring the requirement for no-bleed and/or low-bleed pneumatic controllers and pumps.
- Emissions from pumps may also be controlled through routing pump discharge streams into a closed loop system or a vapor recovery unit.
- The permit may require the operation of pig launchers without venting hydrocarbons into the atmosphere.

Concepts for the proposed New GP for Well Pad Operations

- The Department is considering that plunger lifts or flaring be required to reduce methane emissions from wellbore liquid unloading.
- The permit may explicitly address the emission from produced water impoundment tanks. The Department is exploring the feasibility of add-on controls on enclosed storage tanks or a closed loop system for an efficient reuse of produced water.
- Annual compliance certifications may be required to be submitted to the Department by the responsible official, as is the case with the current GP-5.

Concepts for GP-5 Modifications

- The applicability of GP-5 may be extended to natural gas transmission operations.
- The Department may require no-bleed and/or low-bleed pneumatic controllers.
- The first attempt at leak repair must be done within five (5) calendar days of leak detection. If purchase of parts is necessary, the leak must be repaired within 15 calendar days, after the purchase of parts.

Concepts for GP-5 Modifications

- The Department is exploring the requirement that owners and operators prevent venting of VOCs and methane during all compressor maintenance and operational activities.
- The Department is considering a requirement that storage tanks must control air contaminant emissions by at least 95%.
- The permit may require the operation of pig launchers without venting hydrocarbons into the atmosphere.

Concepts for GP-5 Modifications

- The Department is considering the requirement to use electric pumps or routing pumps discharged to closed systems when electricity is not available.
- Emissions from pneumatic pumps driven by natural gas may also be controlled through routing pump discharge streams into a closed loop system or a vapor recovery unit, or the pumps may be replaced with zero bleed pumps.
- The use of dry seals or control of wet seal venting of methane from each compressor by 95%.

DEPARTMENT OF ENVIRONMENTAL PROTECTION

Bureau of Air Quality

Krishnan Ramamurthy
Chief, Division of Permits
717-783-9476
kramamurth@pa.gov

**COMMONWEALTH OF PENNSYLVANIA
DEPARTMENT OF ENVIRONMENTAL PROTECTION
AIR QUALITY PROGRAM**

**GENERAL PLAN APPROVAL AND/OR GENERAL OPERATING PERMIT
BAQ-GPA/GP-5**

Natural Gas Compression and/or Processing Facilities

SECTION A. GENERAL CONDITIONS

1. Statutory/Regulatory Authority and General Description

In accordance with Section 6.1(f) of the Air Pollution Control Act (“APCA”), 35 P.S. § 4006.1(f) and 25 *Pa. Code* Chapter 127, Subchapter H (relating to general plan approvals and general operating permits), the Department of Environmental Protection (hereinafter referred to as “Department” or “DEP”) hereby issues this General Plan Approval and/or General Operating Permit (“General Permit” or “GP-5”) for natural gas, compression and/or processing facilities (hereinafter referred to as “facility”) constructed or operating in this Commonwealth.

2. Definitions

Words and terms that are not otherwise defined in this General Permit shall have the meanings set forth in Section 3 of the APCA (35 P.S. § 4003) and Title 25, Article III including 25 *Pa. Code* § 121.1 (relating to definitions) unless the context indicates otherwise. The meanings set forth in applicable definitions codified in the Federal Code of Regulations including 40 CFR Part 60 Subparts Kb, KKK, LLL, JJJJ, KKKK, and OOOO or 40 CFR Part 63 Subparts HH and ZZZZ shall also apply to this General Permit.

Coal bed methane – Methane that is released from the coal and surrounding rock strata.

Natural gas compression and/or processing facility – A facility that produces, compresses and/or processes natural gas, coal bed methane, or gob gas starting with gas dehydration, compression, fractionation, and storage.

3. Applicability/Scope

- (a) This General Permit authorizes the construction, modification, and/or operation of natural gas compression and/or a gas processing facility. The applicability of this General Permit may include any of the following:
 - (i) Natural gas-fired spark ignition internal combustion engines (hereinafter referred to as “engine”).
 - (ii) Natural gas-fired simple cycle turbines (hereinafter referred to as “turbine”).

- (iii) Centrifugal compressors.
 - (iv) Storage vessels/tanks.
 - (v) Glycol dehydration units and associated equipment including Gas-Condensate-Glycol (“GCG”) separators (Flash tank separators).
 - (vi) Natural gas fractionation process units (such as De-propanizer, De-ethanizer, De-butanizer).
 - (vii) Equipment leaks.
 - (viii) Pneumatic controllers.
 - (ix) Sweetening units.
- (b) If a source is exempted from plan approval requirements under 25 *Pa. Code* § 127.14 (relating to exemptions), the authorization to use this GP-5 may be requested for the operation of the source.
- (c) If any source located at the natural gas, compression and/or processing facility cannot be regulated under this General Permit, a plan approval and/or an operating permit issued in accordance with 25 *Pa. Code*, Chapter 127, Subchapter B (relating to plan approval requirements) and/or Subchapter F (relating to operating permit requirements) will be required.

4. Prohibited Use of GP-5

GP-5 may not be used for the construction, modification or operation of any of the following air contamination sources:

- (a) A proposed source located at a Title V facility.
- (b) A proposed source that is subject to Title V permitting requirements specified in 25 *Pa. Code* Chapter 127, Subchapters F and G, prevention of significant deterioration and nonattainment new source review requirements specified in 25 *Pa. Code* Chapter 127, Subchapters D (relating to prevention of significant deterioration) or E (relating to new source review).
- (c) Any engine or turbine that is used as a “peak shaving engine generator” or source participating in an Emergency and Economic Load Response Program.
- (d) Any engine or turbine that is used on a natural gas transmission line. Transmission line means a pipeline, other than a gathering line, that transports gas from a gathering line or storage facility to a distribution center, storage facility, or large volume customer that is not downstream from a distribution center.

5. General Plan Approval Best Available Technology Requirement

This General Permit establishes Best Available Technology (“BAT”) requirements and authorizes the construction or modification of a natural gas compression and/or processing facility and any air cleaning devices that meet the BAT requirements established under 25 *Pa. Code* §§ 127.1 and 127.12(a)(5).

The owner or operator of any existing facility for which a plan approval was previously issued pursuant to 25 *Pa. Code* § 127.11 (relating to plan approval requirements) shall continue to comply with the BAT requirements established in the previously issued plan approval if they are more stringent than the BAT requirements established in this General Permit.

6. General Operating Permit Requirements

Any facility or air contamination source that is constructed or modified under this General Permit may be operated on a temporary basis to facilitate shakedown of sources and air cleaning devices provided that the owner or operator notifies the Department in accordance with Section A, Condition 11 (relating to notice requirements) of this General Permit.

7. Municipal Notifications

A facility owner or operator proposing to use this General Permit shall notify the local municipality and county where the air pollution source is to be located that the applicant has applied for an authorization to use GP-5. The notification shall clearly describe the proposed sources and/or modifications. The owner or operator shall also submit to the Department proof of submittal of the municipal notification along with a copy of the Application for Authorization to Use GP-5.

8. Application for Use

Pursuant to 25 *Pa. Code* § 127.621 (relating to application for use of general plan approvals and general operating permits), any person proposing to construct, operate or modify a natural gas compression and/or processing facility listed in Condition 3 in Section A, under this General Permit shall submit to the Department the Application for Authorization to Use GP-5. This application shall be accompanied by the Compliance Review Form required under 25 *Pa. Code* §§ 127.12a (relating to compliance review) and § 127.412 (relating to compliance review forms), appropriate application fees specified in Section A, Condition 13 of this General Permit, proof of the municipal notification and any additional forms and information requested by the Department. This General Permit authorizes the specific sources and the specific location of the facility as described in the application.

9. Compliance Requirements

- (a) The owner or operator authorized to use this General Permit shall comply with the specifications in the application and terms and conditions of this General Permit.
- (b) All sources and associated air pollution control equipment located at a natural gas compression and/or processing facility shall be:
 - (i) Operated in such a manner as to not cause air pollution, as that term is defined in 25 *Pa. Code* § 121.1;

- (ii) Operated and maintained in accordance with the manufacturer's specifications, procedures, recommended maintenance schedule, and the specifications in the Application for Authorization to Use GP-5, or an alternate procedure approved by the Department that achieves equal or greater emission reductions;
 - (iii) Operated and maintained in such a manner that no owner or operator may permit the emission into the outdoor atmosphere of any malodorous air contaminants from any source such that the malodors are detectable outside the property of the owner or operator on whose land the facility is being operated in accordance with *25 Pa. Code* § 123.31 (relating to odor emissions); and
 - (iv) Operated and maintained in accordance with the fugitive emission requirements of *25 Pa. Code* § 123.1 (relating to prohibition of certain fugitive emissions) and *25 Pa. Code* § 123.2 (relating to fugitive particulate matter).
- (c) The emissions from all sources and associated air pollution control equipment located at a natural gas compression and/or processing facility shall not equal or exceed any of the following on a 12-month rolling sum basis:
- (i) Nitrogen oxides (NO_x) – 100 tons.
 - (ii) Carbon monoxide (CO) – 100 tons.
 - (iii) Sulfur oxides (SO_x) – 100 tons.
 - (iv) Particulate matter with an aerodynamic diameter less than 10 microns (PM₁₀) – 100 tons.
 - (v) Particulate matter with an aerodynamic diameter less than 2.5 microns (PM_{2.5}) – 100 tons.
 - (vi) Volatile organic compounds (VOCs) – 50 tons.
 - (vii) Any individual hazardous air pollutant (HAP) – 10 tons.
 - (viii) Total hazardous air pollutants (HAPs) – 25 tons.
 - (ix) Greenhouse gases, expressed as carbon dioxide equivalent (CO₂e) – 100,000 tons.
 - (x) In addition, the emissions from all sources and associated air pollution control equipment located at a natural gas compression and/or processing facility in Bucks, Chester, Delaware, Montgomery, or Philadelphia counties shall not equal or exceed any of the following on a 12-month rolling sum basis:

- (A) Nitrogen oxides (NO_x) – 25 tons.
- (B) Volatile organic compounds (VOCs) – 25 tons.

10. Modification, Suspension, Revocation of GP-5 and Authorizations to Use the General Permit

- (a) The Department may modify, suspend, or revoke and reissue this General Permit if it is determined that GP-5 does not comply with the Clean Air Act, Air Pollution Control Act or regulations adopted under these acts.
- (b) This General Permit may be modified, suspended, or revoked if the Department determines that the natural gas compression and/or processing facilities cannot be adequately regulated under this General Permit.
- (c) An authorization to construct and/or operate a natural gas compression and/or processing facility under this General Permit may be suspended or revoked if the Department determines that, at any time, the owner or operator has failed to construct and/or operate the facility in compliance with the terms and conditions of this General Permit or information identified in the Application for Authorization to Use GP-5, or supplemental material included with the application that the Department used to determine if the proposed sources will comply with the GP-5.
- (d) Upon suspension or revocation of authorization to construct and/or operate a natural gas compression and/or processing facility under this General Permit, the owner or operator shall cease construction immediately of the facility. The owner or operator of the facility shall not restart the construction and/or operation prior to receipt of written approval from the Department.

11. Notice Requirements

- (a) The applications and notifications required by 25 *Pa. Code* § 127.621 and Section A, Condition 5 of this General Permit shall be submitted to the appropriate DEP Regional Office responsible for issuing authorizations to use general permits in the county in which the natural gas compression and/or processing facility is or will be located.
- (b) As required under 25 *Pa. Code* § 127.621(b), the application shall be either by hand delivery or courier (i.e., Federal Express, United Parcel Service, United States Postal Service, etc.) to the Department or sent by certified mail, return receipt requested.
- (c) The owner or operator shall notify the Department, in writing, no later than five (5) business days after the following activities:
 - (i) Initial commencement date of construction of the source(s) authorized under this General Permit.

- (ii) Final completion date of construction.
 - (iii) Any lapse in construction activity of eighteen (18) months or more that may take place in between the initial and start-up dates in (a) and (b) above.
- (d) At least five (5) business days prior to commencing operation of the source or facility, the owner or operator shall provide a written notification to the Department of the intent to commence operation of the natural gas compression and/or processing facility authorized by this General Permit . When multiple sources at the facility are subject to different commencement of operation schedules, written notice shall be submitted to DEP prior to the commencement of operation of each source.
- (e) *Malfunctions.* The owner or operator shall notify the Department by telephone within twenty-four (24) hours of the discovery of any malfunction at a natural gas compression and/or processing facility operating pursuant to this General Permit, or any malfunction of pollution control equipment associated with a facility, which results in, or may possibly be resulting in, the emission of air contaminants in excess of any applicable limitation specified herein. Following the telephone notification, a written notice also be submitted to DEP as specified below.
- (i) If the owner or operator is unable to provide notification by telephone to the appropriate Regional Office within twenty-four (24) hours of discovery of a malfunction due to a weekend or holiday, the notification shall be made to the Department by no later than 4 p.m. on the first business day for the Department following the weekend or holiday.
 - (ii) Any malfunction that poses an imminent danger to the public health, safety, welfare, or environment shall be reported by telephone to the Department and the County Emergency Management Agency immediately after the discovery of an incident. The owner or operator shall submit a written report of instances of such malfunctions to the Department within three (3) business days of the telephone report.
 - (iii) Unless otherwise required by this General Permit, any other malfunctions shall be reported to the Department, in writing, within five (5) business days of malfunction discovery.

12. Term of Authorization to Use General Permit

The authorization to construct and/or operate a natural gas compression and/or processing facility under this General Permit is granted for a fixed period of five (5) years except that the authorization to construct a facility will expire eighteen (18) months from the date of the Department authorization if the owner or operator fails to commence construction. If construction commences within eighteen (18) months of the date of receipt of authorization from the Department, but it is not yet completed, the authorization to construct the facility under this General Permit is automatically extended, provided there is no subsequent lapse in construction

activity of eighteen (18) months or more, up to a maximum of five (5) years from the date of Department authorization. If the construction, modification or installation is not commenced within eighteen (18) months of the authorization of this GP-5 or if there is more than an 18-month lapse in construction, modification or installation, a new application for authorization of GP-5 shall be submitted. The Department may extend the 18-month period upon a satisfactory showing that an extension is justified.

13. General Permit Fees

Each applicant seeking authorization to use GP-5 shall submit the applicable fees required under this condition to the appropriate DEP regional office. The following fees schedule applies to this General Permit:

- (a) General Plan Approval application fee:
One thousand and seven hundred dollars (\$1,700)
- (b) General Operating Permit fee:
Three hundred and seventy-five dollars (\$375)
- (c) Annual operating permit administration fee, payable by March 1st for the previous calendar year:
Three hundred and seventy-five dollars (\$375)
- (d) The Department may increase the applicable fees for this General Plan Approval/General Permit in accordance with the applicable fee schedules in 25 Pa. Code Chapter 127, Subchapter I (relating to plan approval and operating permit fees) following notice in the *Pennsylvania Bulletin*.

14. Recordkeeping and Reporting Requirements

The owner or operator of the facility shall maintain records that clearly demonstrate to the Department that the facility is not a Title V facility. In addition, the owner or operator of the facility shall keep records to verify compliance with the facility-wide emission limitations. These records shall be maintained at a minimum on a monthly basis and the emissions shall be calculated on a 12-month rolling sum. These records shall be retained for a minimum of five (5) years and shall be made available to the Department upon request. The Department reserves the right to request additional information necessary to determine compliance with this General Permit.

15. Annual Source Reporting Requirements

In accordance with 25 Pa. Code § 135.3, the owner or operator of natural gas compression and/or natural gas processing facilities shall submit to the Department by March 1st each year a source report for the preceding calendar year for all sources regulated under this General Permit. The report shall include all emissions information for all previously reported sources and new sources which were first operated during the preceding calendar year. Emissions data including, but not limited to the following, shall be reported: carbon monoxide,

oxides of nitrogen (“NO_x”), particulate matter less than 10 micrometers in diameter (PM₁₀), particulate matter less than 2.5 micrometers in diameter (PM_{2.5}), sulfur dioxide, volatile organic compounds, total hazardous air pollutants (“HAP”), speciated individual HAP emissions, and greenhouse gases, expressed as CO_{2e}.

16. Public Records and Confidential Information

- (a) As required under Section 13.2 of the APCA, 35 P.S. § 4013.2, the records, reports or information obtained by the Department under this General Permit shall be available to the public, except as provided in paragraph (b) of this condition.
- (b) Upon cause shown by the owner or operator that the records, reports or information, or a particular portion thereof, but not emission data, to which the Department has access under the APCA, if made public, would divulge production or sales figures or methods, processes or production unique to that person or would otherwise tend to affect adversely the competitive position of that person by revealing trade secrets, including intellectual property rights, the Department will consider the record, report or information, or particular portion thereof confidential in the administration of the APCA.

17. Circumvention

- (a) The owner or operator of a natural gas compression and/or processing facility may not circumvent the new source review requirements of 25 Pa. Code Chapter 127, Subchapter E by causing or allowing a pattern of ownership or development, including the phasing, staging, delaying or engaging in incremental construction over a geographic area of a facility which, except for the pattern of ownership or development, would otherwise require a permit or submission of a plan approval application.
- (b) No person may permit the use of a device, stack height that exceeds good engineering practice stack height, dispersion technique or other technique that without resulting in reduction of the total amount of air contaminants emitted, conceals or dilutes an emission of air contaminants that would otherwise be in violation of this plan approval, the Air Pollution Control Act or the regulations promulgated thereunder, except that with prior written approval of the Department, the device or technique may be used for control of malodors.

18. NSPS and NESHAP Submittals

- (a) The owner or operator of a natural gas compression and/or processing facility shall submit to the appropriate DEP Regional Air Quality Office requests, reports, applications, submittals and other communications concerning applicable New Source Performance Standards and National Emissions Standards for Hazardous Air Pollutants.

- (b) In accordance with 40 CFR § 60.4 (relating to address) and 40 CFR § 63.10 (relating to recordkeeping and reporting requirements) copies of all requests, reports, applications, submittals and other communications shall also be submitted to the EPA Region III Office. Copies submitted to EPA shall be sent to the following address:

Office of Air Enforcement and Compliance Assistance (3AP20)
United States Environmental Protection Agency
Region III
1650 Arch St.
Philadelphia, PA 19103-2029

19. Emission Limitations and/or Operating Requirements Previously Established for Best Available Technology and/or to Restrict Operations

- (a) This General Permit cannot be used to relax best available technology or other emission limitations or requirements previously established through the air quality permitting process.
- (b) An owner or operator of a natural gas compression and processing facility may apply to the Department for a plan approval for any air contamination source in lieu of seeking authorization to use the general plan approval for natural gas compression and/or processing facilities.

20. Transfer of Ownership

The authorization to use GP-5 may not be transferred from the owner or operator of a natural gas compression and processing facility except when the change of ownership is demonstrated to the satisfaction of the Department and the Department approves the transfer of the authorization in writing. Within thirty (30) days after a change of ownership of the facility, the new owner or operator shall submit to the Department a GP-5 Application, compliance review form, and applicable fees in accordance with Condition 13 of this General Permit.

21. Expiration and Re-authorization of the Use of GP-5

- (a) The authorization granted by the Department to construct and/or operate under this General Permit shall terminate on the date of expiration of the authorization unless a complete application for the use of GP-5 is submitted to the Department at least thirty (30) days prior to the expiration date of the authorization.
- (b) Upon receipt by the Department of a timely and administratively and technically complete application for re-authorization to operate under this General Permit, the owner or operator may continue to operate the natural gas compression and/or processing facility subject to final action by the Department on the GP-5 application provided that the facility is operated in compliance with all terms and conditions of this General Permit. The authorization to use GP-5 shall cease to exist if the owner or operator fails to

submit, by the deadline specified by the Department, any additional information requested by the Department to process the application.

22. Source Test Requirements

The owner or operator of any source subject to performance testing requirements in this General Permit shall comply with the following:

- (a) Within one hundred eighty (180) days after the initial startup of the engine or turbine, the owner or operator shall demonstrate compliance with the applicable emission limits and furnish the Department a written report of the result of such performance test.
- (b) At least thirty (30) calendar days prior to commencing an emission testing program to demonstrate compliance required by this General Permit, a Test Protocol shall be submitted to the Department's Division of Source Testing and Monitoring and the appropriate Regional Office for review and approval. The Test Protocol shall meet all applicable requirements specified in the most current version of the Department's Source Testing Manual. The emissions testing shall not commence prior to receipt of a protocol acceptance letter from the Department.
- (c) At least fifteen (15) calendar days prior to commencing an emission testing program to demonstrate compliance required by this General Permit, written notification of the date and time of testing shall be provided to the Department's appropriate Regional Office. Notification, in writing, shall also be sent to the Department's Bureau of Air Quality, Division of Source Testing and Monitoring, so that an observer may be present. The Department is under no obligation to accept the results of any testing performed without adequate advance written notice to the Department of such testing.
- (d) Within fifteen (15) calendar days after completion of the on-site testing portion of an emission test program to demonstrate compliance required by this General Permit, if a complete test report has not yet been submitted, an electronic notification shall be sent to the Department's Division of Source Testing and Monitoring and the appropriate Regional Office indicating the completion date of the on-site testing.
- (e) A complete test report shall be submitted to the Department's Division of Source Testing and Monitoring and the appropriate Regional Office no later than sixty (60) calendar days after completion of the on-site testing portion of an emission test program required by this General Permit.
- (f) The complete test report shall include a summary of the emission results at the beginning of the report indicating if each pollutant measured is within permitted limits and a statement of compliance or non-compliance with all applicable permit conditions. The summary results will include, at a minimum, the following information:

- (i) A statement that the owner or operator has reviewed the report from the emissions testing company and agrees with the findings;
 - (ii) Permit number(s) and condition(s) that are the basis for the evaluation;
 - (iii) Summary of results with respect to each applicable permit condition;
and
 - (iv) Statement of compliance or non-compliance with each applicable permit condition.
- (g) All submittals with the exception of periodic monitoring data shall meet all applicable requirements specified in the most current version of the Department's Source Testing Manual.
- (h) All testing with the exception of periodic monitoring shall be performed in accordance with any applicable federal regulations (such as New Source Performance Standards), 25 *Pa. Code*, Chapter 139, and the current revision of the Department's Source Testing Manual or an alternative test method as approved by the Department. The owner or operator of the facility shall use the following federal reference methods or alternative test methods approved, in writing, by the Department to demonstrate compliance:
- 40 CFR Part 60, Appendix A, Method 5 and EPA Test Method 202 shall be used to determine the Total Particulate Matter emissions.
- 40 CFR Part 60, Appendix A, Method 7E shall be used to determine the nitrogen oxide (NO_x) emissions.
- 40 CFR Part 60, Appendix A, Method 10 shall be used to determine the carbon monoxide (CO) emissions.
- 40 CFR Part 60 Methods 25A and 18 or 40 CFR Part 60 Method 25A and 40 CFR Part 63 Method 320 shall be used to determine the NonMethane Non-Ethane Hydrocarbon (NMNEHC) emissions.
- 40 CFR Part 63 Appendix A, Method 320 or Method 328 shall be used to determine the Formaldehyde (HCHO) emissions.
- (i) Reports, protocols and test completion notification with the exception of periodic monitoring data shall be submitted through PSIMS*Online available through <https://www.depgreenport.state.pa.us/ecommm/Login.jsp>. If internet submittal is not feasible, copies of the submittal shall be sent to the appropriate Pennsylvania Department of Environmental Protection Regional Office and to the attention of the Department's Bureau of Air Quality, Division of Source Testing and Monitoring, 400 Market Street, 12th Floor Rachel Carson State Office Building, Harrisburg, PA 17105-8468, with deadlines verified through document postmarks.

- (j) The owner or operator shall ensure that all applicable federal reporting requirements are followed, including timelines more stringent than those contained herein. In the event of an inconsistency or any conflicting requirements between federal and state laws and regulation, the owner or operator shall comply with the most stringent provision, term, condition, method or rule.
- (k) If, at any time, the Department has notified the owner or operator that the air contaminant emissions from the source operating under this General Permit are, or may be, in excess of any applicable air contaminant emission limitation, the owner or operator shall conduct source tests deemed necessary by the Department to determine the actual air contaminant emission rate. The testing shall be conducted in accordance with the applicable provisions of *25 Pa. Code*, Chapter 139 (relating to sampling and testing) as well as in accordance with any additional requirements or conditions established by the Department at the time the owner or operator is notified, in writing, of the need to conduct testing.

23. Applicable Laws

Nothing in this General Permit relieves the facility owner or operator from the obligation to comply with all applicable Federal, state and local laws and regulations including *25 Pa. Code* Article III (relating to air resources). Applicable Federal regulations include, but are not limited to, the following New Source Performance Standards codified at 40 CFR Part 60 (incorporated by reference in *25 Pa. Code* § 122.3) and National Emission Standards for Hazardous Air Pollutants codified at 40 CFR Part 63 (incorporated by reference in *25 Pa. Code* § 127.35):

- (a) 40 CFR Part 60, Subpart Kb – Standards of Performance for Volatile Organic Liquid Storage Vessels (Including Petroleum Liquid Storage Vessels) for Which Construction, Reconstruction, or Modification Commenced after July 23, 1984.
- (b) 40 CFR Part 60, Subpart KKK – Standards of Performance for Equipment Leaks of VOC from Onshore Natural Gas Processing Plants.
- (c) 40 CFR Part 60, Subpart LLL – Standards of Performance for Onshore Natural Gas Processing: SO₂ Emissions
- (d) 40 CFR Part 60, Subpart JJJJ – Standards of Performance for Stationary Spark Ignition Internal Combustion Engines.
- (e) 40 CFR Part 60, Subpart KKKK – Standards of Performance for Stationary Combustion Turbines.
- (f) 40 CFR Part 60, Subpart OOOO– Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution.

- (g) 40 CFR Part 63, Subpart HH – National Emissions Standards for Hazardous Air Pollutants from Oil and Natural Gas Production Facilities.
- (h) 40 CFR Part 63, Subpart ZZZZ – National Emission Standards for Hazardous Air Pollutants for Reciprocating Internal Combustion Engines.

SECTION B. REQUIREMENTS FOR NATURAL GAS-FIRED SPARK IGNITION INTERNAL COMBUSTION ENGINES

1. Emission Standards for Existing Engines

In accordance with 25 *Pa. Code* §§ 127.1 and 127.12(a)(5), any existing engine operating under GP-5 authorizations approved by the Department prior to the issuance of this General Permit shall continue to comply with the emissions standards and other requirements in Condition 1(a) or 1(b) of this section.

- (a) The engine shall be operated or equipped with air cleaning devices to meet the following emission levels:
 - (i) Oxides of Nitrogen (“NO_x”) (as NO₂) at rated brake horsepower (bhp) and operating at rated speed of two (2.0) grams per bhp-hour (gm/bhp-hr).
 - (ii) Non Methane Hydrocarbon excluding formaldehyde (NMHC) (as propane) at rated bhp and operating at rated speed of two (2.0) gm/bhp-hr.
 - (iii) Carbon Monoxide (“CO”) at rated bhp and operating at rated speed of two (2.0) gm/bhp-hr.
- (b) At operating conditions less than rated capacity, internal combustion engines shall, on a pounds-per-hour basis, emit no more than they emit at rated bhp and rated speed.
- (c) In accordance with 25 *Pa. Code* §§ 127.1 and 127.12(a)(5), visible emissions shall not exceed either of the following limitations:
 - (i) Equal to or greater than 10 percent for a period or periods aggregating more than three (3) minutes in any one hour.
 - (ii) Equal to or greater than 30 percent at any time.
- (d) The owner or operator of the engine shall comply with the applicable Standards of Performance (“NSPS”) for Stationary Spark Ignition Internal Combustion Engines specified in 40 CFR Part 60, Subpart JJJJ, and/or the National Emission Standards for Hazardous Air Pollutants (“NESHAP”) for Stationary Spark Ignition Internal Combustion Engines specified in 40 CFR Part 63, Subpart ZZZZ.

2. Emission Standards for New Stationary Engines

- (a) In accordance with 25 Pa. Code §§ 127.1 and 127.12 (a) (5), a new engine for which construction or reconstruction commenced after the effective date of this General Permit shall not exceed the emissions standards specified in the following table:

| Engine Type | Rated bhp | NO _x | CO | NMNEHC as propane (excluding HCHO) | HCHO |
|-----------------------------|--------------|-----------------|--|------------------------------------|---|
| NG-fired Lean and Rich burn | ≤100 | 2.0 gm/bhp-hr | 2.0 gm/bhp-hr | - | - |
| NG-fired Lean-burn | >100 to ≤500 | 1.0 gm/bhp-hr | 2.0 gm/bhp-hr | 0.70 gm/bhp-hr | - |
| NG-fired Lean-burn | >500 | 0.50 gm/bhp-hr | 47 ppmvd @ 15% O ₂ or 93% reduction | 0.25 gm/bhp-hr | 0.05 gm/bhp-hr |
| NG-fired Rich-burn | >100 to ≤500 | 0.25 gm/bhp-hr | 0.30 gm/bhp-hr | 0.20 gm/bhp-hr | |
| NG-fired Rich-burn | >500 | 0.20 gm/bhp-hr | 0.30 gm/bhp-hr | 0.20 gm/bhp-hr | 2.7 ppmvd @ 15% O ₂ or 76% reduction |

- (b) The owner or operator of the engine shall also comply with all other applicable NSPS requirements established in 40 CFR Part 60, Subpart JJJJ, Subpart OOOO, and the NESHAP requirements in 40 CFR Part 63, Subpart ZZZZ.
- (c) In accordance with 25 Pa. Code §§ 127.1 and 127.12(a)(5), visible emissions from the engine shall not exceed either of the following limitations:
- (i) Equal to or greater than 10 percent for a period or periods aggregating more than three (3) minutes in any one (1)-hour; and
 - (ii) Equal to or greater than 30 percent at any time.

3. Start-up and Shut-down Exception for Engines

The emission limitations specified in Section B, Conditions 1 and 2 of this General Permit shall apply at all times except during periods of start-up and shut-down provided that the duration of start-up and shut down does not exceed 30 minutes per occurrence. The owner or operator shall operate the engine in a manner consistent with good air pollution control practices for minimizing emissions at all times, including periods of startup and shutdown. The emissions from start-up and shut-down shall be included in the 12-month rolling sum of emissions. The owner

or operator of the engine shall comply with all applicable start-up and shut-down requirements in accordance with 40 CFR Part 60, Subpart JJJJ, and 40 CFR Part 63, Subpart ZZZZ.

4. Performance Testing Requirements for Engines

- (a) For a new or reconstructed engine which has a rated capacity less than or equal to 500 brake horsepower, vendor guarantees or Department-approved data from test conducted within 12-months on an identical engine for NO_x, CO, and NMHC or NMNEHC shall be sufficient to verify emissions rates. However, the Department reserves the right to require additional information to verify any emission rates that may include source testing in accordance with applicable provisions of 25 *Pa. Code* Chapter 139 (relating to sampling and testing). The vendor guarantees shall not be construed to satisfy the engine certification requirements specified in 40 CFR § 60.4243.
- (b) For a new or reconstructed engine which has a rated capacity greater than 500 brake horsepower, within one hundred eighty (180) days after initial start-up or re-authorization of this General Permit, the owner or operator shall perform source testing on each affected engine in accordance with applicable provisions of 25 *Pa. Code* Chapter 139 (relating to sampling and testing) on each affected engine for NO_x, CO, HCHO, and NMHC or NMNEHC and furnish the Department a written report of the result of such performance test. Engine testing load conditions shall be representative to within 10 percent of 100% peak or the highest achievable load. The source testing shall be conducted in accordance with the requirements specified in Conditions 21 and 22 in Section A of this General Permit.
- (c) In addition to the source testing required by Condition 4(b) of Section B, every 2,500 hours of operation and no sooner than forty-five (45) days from the previous test, the owner or operator shall perform periodic monitoring for NO_x and CO emissions to verify continued compliance upon each of the respective engines which has a rated capacity greater than 500 brake horsepower and subject to the BAT as specified in Section B, Conditions 1 and 2 of this General Permit. A Department-approved test that has been performed within 45 days prior to the scheduled periodic monitoring may be used in lieu of the periodic monitoring for that time period. A portable gas analyzer may be used to satisfy the requirements of this condition utilizing three test runs of twenty (20) minutes for each test run. The Department may alter the frequency of portable analyzer tests based on the test results. The frequency of portable gas analyzer tests may be altered with written Departmental approval. The portable gas analyzer shall be used and maintained according to the manufacturer's specifications and the procedures specified in ASTM D 6522 or equivalent as approved by the Department.
- (d) Within thirty (30) calendar days after the completion of periodic monitoring, the owner or operator shall submit the results to the appropriate DEP Regional Office. The Department reserves the right to require source tests in

accordance with EPA reference methods should the data from the portable analyzer warrant such tests.

5. Work Practice and Monitoring Requirements for Engines

- (a) In accordance with 25 Pa. Code §§ 127.1 and 127.12(a)(5), the owner or operator of a new or reconstructed natural gas-fired engine shall install, maintain, and operate each engine and associated air pollution control equipment in accordance with manufacturer's specifications.
- (b) The owner or operator shall maintain comprehensive accurate records of number of hours per month that each engine operated using a non-resettable hour meter, the amount of each fuel type that is used per month in each engine, the date the GP-5 authorization was issued, the date construction began, the date of initial startup, the date testing is required, parameters required to be tested, and the date testing was performed for each engine.
- (c) In accordance with 25 Pa. Code §§ 127.1 and 127.12(a)(5), the owner or operator of an engine shall comply with the monitoring requirements specified in 40 CFR §§ 60.4237 and 63.6625.

6. Notification, Recordkeeping and Reporting Requirements for Engines

- (a) The owner or operator of an engine shall also comply with the applicable notification, reporting, and recordkeeping requirements specified in 40 CFR §§ 60.4245 and 63.6645.
- (b) Submittal of reports in accordance with the requirements and schedules outlined in this General Permit.
- (c) These records shall be retained for a minimum of five (5) years and shall be made available to the Department upon request.

SECTION C. REQUIREMENTS FOR NATURAL GAS-FIRED SIMPLE CYCLE GAS TURBINES

1. Emissions Standards for Turbines

The owner or operator of a new or reconstructed turbine with a rated capacity equal to or greater than 1000 bhp or 10.7 gigajoules per hour (10 MMBtu/ per hour), based on the higher heating value (HHV) of the fuel that commenced construction, modification, or reconstruction after February 18, 2005, shall comply with applicable requirements specified in 40 CFR Part 60, Subpart KKKK.

- (a) In accordance with 25 Pa. Code §§ 127.1 and 127.12(a)(5), the owner or operator of a new or reconstructed turbine shall not exceed the following emissions standards:

| Turbine Size (BHP) | NO _x ppmvd corrected at 15% O ₂ | CO ppmvd corrected at 15% O ₂ | NMNEHC (as Propane) ppmvd corrected at 15% O ₂ | Total Particulate Matter Lbs/MMBtu |
|--------------------|---|--|---|------------------------------------|
| ≥1,000 and <5,000 | 25 | 25 | 9 | 0.03 |
| ≥5,000 and <15,000 | 15 | 25 | 9 | 0.03 |
| ≥15,000 | 15 | 10 ppm or 93% reduction | 5 ppm or 50% reduction | 0.03 |

- (b) Compliance with the emissions standards in this section shall be considered compliance with the NSPS emissions standards specified in 40 CFR Part 60, Subpart KKKK and 25 Pa. Code Chapter 122 (relating to national standards of performance for new stationary sources).

2. Start-up and Shut-down Exception for Turbines

The emission limitations specified in Section C, Condition 1 of this General Permit shall apply at all times except during periods of start-up and shut-down, provided, however, that the duration of start-up and shut-down do not exceed thirty (30) minutes per occurrence. The turbine shall be operated in a manner consistent with good air pollution control practices for minimizing emissions, at all times, including periods of startup, shutdown, and malfunction. The emissions from start-up and shut-down shall be included in the 12-month rolling sum of emissions. The owner or operator of a turbine shall comply with all applicable start-up and shut-down requirements in accordance with 40 CFR Part 60, Subpart KKKK.

3. Performance Testing Requirements for Turbines

- (a) For a new or reconstructed turbine, within one hundred eighty (180) days after initial start-up or re-authorization of this General Permit, the owner or operator shall perform source testing on each affected turbine for NO_x, CO, NMNEHC, Total Particulate Matter, and furnish the Department a written report of the results of such performance testing. Turbine testing load conditions shall be within 10 percent of the 100% peak or the highest achievable load. The source testing shall be conducted in accordance with the requirements specified in Conditions 21 and 22 of Section A in this General Permit.
- (b) In addition to the source testing required by this condition, every 2,500 hours of operation and no sooner than forty-five (45) days from the previous test, the owner or operator shall perform periodic monitoring for NO_x and CO emissions to verify that each turbine is in compliance with the BAT requirements established in Section C, Condition 1 of this General Permit for turbines. If a Department-approved test has been performed within 45 days prior to the scheduled periodic monitoring, this test may be used in lieu of the periodic monitoring for that time period.

A portable gas analyzer may be used to satisfy the requirements of this condition utilizing three 20-minute test runs. The Department may alter the frequency of portable analyzer tests based on the results. The portable gas analyzer shall be maintained according to the manufacturer's specifications and the procedures specified in ASTM D 6522 or equivalent as approved by the Department. The Department may also waive all or parts of this requirement if the owner or operator demonstrates compliance, in lieu of testing, through alternate means satisfactory to the Department.

- (c) Within thirty (30) calendar days after the completion of periodic monitoring, the owner or operator shall submit the results to the appropriate DEP Regional Office. The Department reserves the right to require source tests in accordance with EPA reference methods should the data from the portable analyzer warrant such tests.

4. Work Practice and Monitoring Requirements for Turbines

- (a) In accordance with 25 Pa. Code §§ 127.1 and 127.12(a)(5), the owner or operator of a new or reconstructed turbine shall install, maintain, and operate the turbine and associated air pollution control equipment in accordance with manufacturer's specifications.
- (b) The owner or operator shall maintain comprehensive, accurate records of number of hours per month that each turbine operated using a non-resettable hour meter, amount of each fuel type that is used per month in each, date GP-5 issued, date construction began, date of initial startup, date testing is required, parameters required to be tested, and date testing was performed for each turbine.
- (c) The owner or operator of any turbine shall comply with the applicable monitoring requirements specified in 40 CFR §§ 60.4335 through 60.4370.

5. Notification, Recordkeeping and Reporting Requirements for Turbines

- (a) The owner or operator of a turbine shall comply with the notification, reporting, and recordkeeping requirements specified in 40 CFR §§ 60.4245 and 63.6645.
- (b) Submittal of reports in accordance with the requirements and schedules outlined in this General Permit.
- (c) These records shall be retained for a minimum of five (5) years and shall be made available to the Department upon request.

SECTION D. REQUIREMENTS FOR CENTRIFUGAL COMPRESSORS

The owner or operator of centrifugal compressors shall also comply with the applicable requirements specified in 40 CFR Part 60, Subpart OOOO.

SECTION E. REQUIREMENTS FOR STORAGE VESSELS / STORAGE TANKS

The owner or operator of each storage vessel / storage tank shall also comply with the applicable requirements specified in 40 CFR Part 60, Subparts Kb and OOOO and 40 CFR Part 63, Subpart HH (relating to national emission standards for hazardous Air pollutants from oil and natural gas production facilities).

1. In accordance with 25 *Pa. Code* §§ 127.1 and 127.12(a)(5), the owner or operator of each storage tank with a capacity greater than 40,000 gallons shall also comply with the requirements specified in 25 *Pa. Code* § 129.56.
2. In accordance with 25 *Pa. Code* §§ 127.1 and 127.12(a) (5), the owner or operator of each storage tank with a capacity less than or equal to 40,000 gallons shall also comply with the requirements in 25 *Pa. Code* § 129.57.

SECTION F. REQUIREMENTS FOR GLYCOL DEHYDRATORS

1. The owner or operator of each glycol dehydrator located at natural gas compression and/or processing facility shall comply with the applicable requirements established in 40 CFR Part 63, Subpart HH. The owner or operator of each glycol dehydrator located at natural gas compression, and/or processing facility shall also comply with the visible emissions and malodor requirements in Conditions 2 (d) and (e) of this section.
2. The owner or operator of any existing glycol dehydrator, which has a total uncontrolled potential emission rate of VOC in excess of ten (10) tons per year, and authorized to operate under previously issued GP-5, shall continue to comply with the emissions standards and other requirements in paragraph (a) through (j) of this condition and any applicable requirements established in 40 CFR Part 63, Subpart HH.
 - (a) The VOC emissions from the glycol dehydrator still vent stream shall be controlled either by at least 85% with a condenser, a flare or other air cleaning device, or any alternative methods as approved by the Department. This control efficiency requirement must be demonstrated to the satisfaction of the Department.
 - (b) A glycol dehydrator using a condenser as an air cleaning device shall daily achieve an average final exhaust temperature of less than 110 degrees Fahrenheit (110 °F).
 - (c) A glycol dehydrator using a flare as an air cleaning device shall ensure destruction of VOC emissions to the flare stack by maintaining the heat content of the flare gas above 300 Btu/scf. The owner or operator shall document daily visual observations of the continuous presence of a flame. Alternatively, the owner or operator may equip the flare with a heat sensing monitoring device with a continuous recorder that indicates the continuous ignition of the pilot flame. The flare shall be designed and operated in accordance with the applicable requirements in 40 CFR § 60.18.

- (d) Visible emissions from a glycol dehydrator using a flare shall not exceed either of the following limitations:
 - (i) Equal to or greater than 10% for a period or periods aggregating more than 3 minutes in any one hour.
 - (ii) Equal to or greater than 30% at any time.
 - (e) A glycol dehydrator shall not emit malodorous air contaminants in such a manner that the malodors are detectable outside the facility property.
 - (f) The owner or operator of a glycol dehydrator shall maintain records of the results of any testing conducted to determine compliance with paragraphs (a) through (e) of this condition.
 - (g) If a condenser is installed as an air cleaning device on a glycol dehydrator, the owner or operator shall maintain records of final exhaust temperature and time observed twice per week on different days during daylight hours.
 - (h) If a flare is used as an air cleaning device for the glycol dehydrator, the owner or operator shall maintain a record of daily visual observations of the continuous presence of a flame or a record of the continuous recorder that indicates the continuous ignition of the pilot flame.
 - (i) The owner or operator of the glycol dehydrator shall maintain records of the date of any maintenance and repair of the required air cleaning device and duration of uncontrolled emissions during such activities.
 - (j) The owner or operator of a glycol dehydrator shall maintain the following records:
 - (i) VOC emissions using GRI-GLYCalc computer software or an alternative method as approved by the Department.
 - (ii) A record of actual throughput per day and the glycol circulation rate.
- 3.** The owner or operator of a new glycol dehydrator, which is not subject to the requirements established in 40 CFR Part 63, Subpart HH and has a total uncontrolled potential emission rate of VOC in excess of five (5) tons per year shall be controlled either by at least 95% with a condenser, a flare or other air cleaning device, or any alternative methods as approved by the Department. This control efficiency requirement must be demonstrated to the satisfaction of the Department. The owner or operator of a new glycol dehydrator shall also comply with the requirements in Condition 2 (b) through (j) of this section.
- 4.** The owner or operator of a new glycol dehydrator, which is not subject to the requirements established in 40 CFR Part 63, Subpart HH and has a total uncontrolled potential VOC emission rate of equal to or less than five (5) tons per

year shall comply with the requirements in Condition 2 (d), (e), and (j) of this section.

SECTION G. REQUIREMENTS FOR ONSHORE NATURAL GAS PROCESSING PLANTS

In accordance with 25 Pa. Code §§ 127.11 and 127.12(a)(5), the owner or operator of a fractionation unit located at an onshore natural gas processing plant shall comply with 40 CFR Part 60, Subpart KKK – Standards of Performance for Equipment Leaks of VOCs from Onshore Natural Gas Processing Plants.

SECTION H. REQUIREMENTS FOR EQUIPMENT LEAKS

1. The owner or operator of the natural gas compression and/or processing facility shall, at a minimum, on a monthly basis perform a leak detection and repair program that includes audible, visual, and olfactory (“AVO”) inspections.
2. Within 180 days after the initial startup of a source, the owner or operator of the facility shall, at a minimum on a quarterly basis, use forward looking infrared (“FLIR”) cameras or other leak detection monitoring devices approved by the Department for the detection of fugitive leaks. The Department may grant an extension for use of FLIR camera upon receipt of a written request from the owner or operator of the facility documenting the justification for the requested extension.
3. If any leak is detected, the owner or operator of the facility shall repair the leak as expeditiously as practicable, but no later than fifteen (15) days after the leak is detected, except as provided in 40 CFR § 60.482-9. The owner or operator shall record each leak detected and the associated repair activity. These records shall be retained for a minimum of five (5) years and shall be made available to the Department upon request.

SECTION I. REQUIREMENTS FOR PNEUMATIC CONTROLLERS

The owner or operator of each pneumatic controller affected facility shall also comply with the applicable requirements specified in 40 CFR Part 60, Subpart OOOO.

SECTION J. REQUIREMENTS FOR SWEETENING UNITS

In accordance with 25 Pa. Code §§ 127.11 and 127.12(a)(5), the owner or operator of a sweetening unit shall also comply with the applicable requirements of 40 CFR Part 60, Subparts KKK and OOOO.

S Supporting Information

ABSTRACT: Oil and gas (O&G) well pads with high hydrocarbon emission rates may disproportionately contribute to total methane and volatile organic compound (VOC) emissions from the production sector. In turn, these emissions may be missing from most bottom-up emission inventories. We performed helicopter-based infrared camera surveys of more than 8000 O&G well pads in seven U.S. basins to assess the prevalence and distribution of high-emitting hydrocarbon sources (detection threshold $\sim 1\text{--}3\text{ g s}^{-1}$). The proportion of sites with such high-emitting sources was 4% nationally but ranged from 1% in the Powder River (Wyoming) to 14% in the Bakken (North Dakota). Emissions were observed three times more frequently at sites in the oil-producing Bakken and oil-producing regions of mixed basins ($p < 0.0001$, χ^2 test).

However, statistical models using basin and well pad characteristics explained 14% or less of the variance in observed emission patterns, indicating that stochastic processes dominate the occurrence of high emissions at individual sites. Over 90% of almost 500 detected sources were from tank vents and hatches. Although tank emissions may be partially attributable to flash gas, observed frequencies in most basins exceed those expected if emissions were effectively captured and controlled, demonstrating that tank emission control systems commonly underperform. Tanks represent a key mitigation opportunity for reducing methane and VOC emissions.

Hydrocarbon emissions from a storage tank observed with an infrared camera

■ INTRODUCTION

Hydrocarbon emissions from oil and gas (O&G) facilities pose multiple risks to the environment and human health. Methane, the primary constituent of natural gas, is a short-lived greenhouse gas with 28–34 and 84–86 times the cumulative radiative forcing of carbon dioxide on a mass basis over 100 and 20 years, respectively.¹ Burning natural gas instead of other fossil fuels may increase net radiative forcing for some time, even if carbon dioxide emissions decline, depending on the loss rate of methane across the O&G supply chain.² O&G hydrocarbon emissions also include volatile organic compounds (VOCs), which are defined by the United States Environmental Protection Agency (U.S. EPA) as photochemically reactive organic compounds excluding methane and ethane. VOCs contribute to regional ozone formation and have been linked to elevated ozone levels in several O&G producing regions.^{3,4} Certain VOCs such as benzene are toxic and may be connected to increased risk of cancer and respiratory disease in some areas with O&G development.^{5,6}

Hydrocarbons (HC) can be emitted from vented, fugitive, or combustion sources. Vented HC emissions are intentional releases of natural gas from blowdowns (releasing gas to depressurize equipment for maintenance or safety) or sources that emit as part of routine operations such as pneumatic controllers. Fugitive HC emissions are unplanned releases from equipment leaks or malfunctioning equipment. Combustion HC emissions include uncombusted hydrocarbons in the exhaust of combustion sources such as compressor engines and flares. HC emissions can also occur from storage tanks for oil, natural gas condensate, and produced water. Tanks can be the source of both vented emissions, such as flashing losses when liquids are dumped from high-pressure separators to atmospheric pressure tanks, and fugitive emissions caused by

malfunctioning separators or control devices. Unlike emissions of raw natural gas, which are primarily composed of methane, oil and condensate tank flashing emissions tend to be dominated by heavier alkanes such as propane and butane.⁷

Recent studies have used two broad approaches to estimate methane or VOC emissions: top-down methods that quantify emissions at the regional or larger scale at one or more points in time, and bottom-up methods that use activity data and emission factors to scale up component- or facility-level measurements to generate emission inventories. Generally, top-down estimates of methane emissions have been greater than bottom-up estimates.^{8,9} In the Barnett Shale, a coordinated campaign with simultaneous top-down and bottom-up methods was able to reconcile aircraft mass balance estimates of regional O&G methane emissions with a custom emission inventory based on local and national facility-level measurements.^{10,11} Compared to traditional bottom-up inventories, the coordinated campaign inventories estimated higher emissions due to more comprehensive activity data and the inclusion of high emission “supermitter” sites in the development of emission factors.^{11,12}

Many types of O&G facilities have highly skewed emission distributions with a small fraction of sites contributing the majority of emissions.^{13–17} These high emission facilities, often referred to as supermitters, may include some sites with persistent emissions and others with intermittent episodes of large releases.¹⁸ High emission rates are likely due to both fugitive emissions caused by malfunctions and vented emissions such as tank flashing or blowdowns. The identification and mitigation of high emission sites is critical to reducing regional emissions since these facilities contribute a large portion of total O&G emissions.^{18,19} If the identity of these sites can be predicted, then it would be effective to focus mitigation efforts on sites with characteristics most often associated with high emissions. However, if the occurrence of high emissions is stochastic, then the only viable mitigation solution would be frequent or continuous monitoring of all sites in order to quickly identify and mitigate those with excess emissions.

A common method to detect HC leaks at O&G facilities is optical gas imaging, which has been proposed by U.S. EPA as a regulatory requirement for new and modified sources.²⁰ Since methane and other HC emissions are invisible to the naked eye, infrared (IR) cameras are used to visualize HC plumes.²¹ IR cameras can not differentiate individual HC species nor quantify emissions under field conditions, but their ability to identify the exact location of an emission source is highly valuable for mitigation. A skilled technician on the ground can use an IR camera to quickly survey thousands of components at an O&G facility for leaks.²² Helicopter-based IR camera surveys have been used by operators and regulatory agencies to inspect large numbers of sites for high emission rate sources that may indicate equipment issues or noncompliance with environmental regulations.²³

In this study, we use data collected during helicopter-based IR camera optical gas imaging surveys of more than 8000 O&G well pads to assess the prevalence and distribution of high-emitting HC sources in seven U.S. O&G basins. Survey data were analyzed to determine patterns and statistical relationships of observed emissions with well pad and operator parameters. In turn, observed frequencies of high emission sources were compared to predicted frequencies of observable tank flashing emissions with and without controls to assess if detected

emission sources indicate the presence of malfunctioning emission control systems.

METHODS

Survey areas were selected by stratified random sampling in seven U.S. O&G basins accounting for 33% and 39% of U.S. oil and gas production, respectively: Bakken (North Dakota/Montana), Barnett (north central Texas), Eagle Ford (south Texas), Fayetteville (Arkansas), Marcellus (Appalachian Basin), Powder River (Wyoming/Montana), and Uintah (Utah). Subregions in each basin were selected on the basis of their suitability for helicopter surveys (<1500 m above sea level, unrestricted airspace) and subdivided into 10 × 10 km grid cells. Due to their large size, subregions in the Bakken, Marcellus, and Powder River were centered on areas with active drilling in northwest North Dakota, southwest Pennsylvania, and eastern Wyoming, respectively. Data on well pad characteristics for each of these subregions were obtained for wells with an active status from the production database Drillinginfo, which contains data compiled and cleaned from state databases.²⁴

One or two defining characteristics were identified for each region that best characterized the heterogeneity of the basin's O&G production and could be the basis for stratified sampling. The selected strata were gas-oil ratio (GOR) in produced fluids (Barnett and Uintah), well age (Bakken), a combination of well age and GOR (Marcellus), and well type of oil, gas, or coal-bed gas (Powder River). These strata were chosen to reflect the distinguishing characteristics in each region (e.g., GOR does not vary greatly in the Bakken, so no meaningful stratification is possible along that dimension). Parameter thresholds separating strata were selected independently for each basin to divide grid cells into two or three quantiles of average parameter values. After assigning grids to strata based on their average parameters, a list of grids in each stratum was randomly selected for survey. In two basins, this design was not followed. In the Fayetteville, a single 20 × 20 km area was selected due to limited survey time and homogeneous production across the basin (dry gas without oil). In the Eagle Ford, two unstratified 40 × 15 km survey areas that each covered the basin's broad range in GOR were selected to facilitate efficient measurements by additional research aircraft. A map of surveyed basins is shown in Figure S1.

Survey area boundaries were provided to a professional firm with extensive experience performing leak detection surveys of O&G sites from a helicopter using optical gas imaging (Leak Surveys, Inc.).²⁵ Flights occurred from June to October 2014 using an R44 helicopter. The survey team identified O&G well pads, compressor stations, and small gas processing plants in the survey areas; for this paper, only data from active well pads are included in the analysis. Camera operators used a FLIR GasFindIR infrared camera to visually survey sites for detectable hydrocarbon plumes at an elevation of approximately 50 m above ground level. At each site with detected emissions, the survey team reported the site's latitude/longitude and the number and equipment type of each observed emission source. Additionally, an IR video was recorded at each site with detected emissions, typically by circling the site and focusing on observed emission sources for 20 to 80 s. Videos were reviewed by the lead author to verify the number and type of detected sources.

Two independent methods were used to estimate the minimum detection limit of optical gas imaging with an IR

camera deployed from the survey helicopter. First, an operator in the Fayetteville performed a controlled release of dry natural gas (97% CH₄) from a pipeline pig receiver at a midstream facility while being observed by the helicopter survey team from a typical survey position during cloudy conditions. A variable orifice was used to release natural gas at three rates. These rates were quantified by the bagging method at ~3, 8, and 27 g s⁻¹, respectively. The helicopter survey team recorded observable plumes from all three controlled release tests with the lowest release rate producing only faint images that appeared to represent the detection threshold under test conditions. Second, an aircraft with a methane analyzer used the atmospheric budget method to quantify methane emissions at 19 well pads and compressor stations within 1 h of detection by the helicopter survey team (See the [Supporting Information](#) for methodological details). Measured site emission rates ranged from 1 to 24 g CH₄ s⁻¹ with 84% of central estimates above 3 g CH₄ s⁻¹ (Table S1). Additionally, the helicopter survey team qualitatively ranked the size of emission sources based on the apparent size and density of plumes, but there was no correlation between the qualitative magnitude of emission sources estimated from experienced camera operators and the quantified methane emission rates; potential reasons are discussed in the [Supporting Information](#). Variability in the IR camera's sensitivity to different hydrocarbons (HC) is expected to impact the detection limit. The GasFindIR camera can detect at least 20 different HCs with differing functionality and has the highest sensitivity to alkanes; the reported minimum detectable emission rate under controlled conditions is 2–4 times lower for propane than methane under controlled conditions.²¹ While there may be differences in the ratio of minimum detectable emissions rates in the field compared to controlled conditions, a ratio of 3 was chosen as representative of the increased sensitivity of the camera to higher molecular weight HCs. Therefore, the helicopter survey detection limit was assumed to be ~3 g HC s⁻¹ for dry gas sources with emissions composed primarily of methane and ~1 g HC s⁻¹ for sources such as tanks with emissions composed primarily of higher HCs such as propane. The detection limit of the IR camera is also affected by wind speed. We assessed the average wind speed during surveys based on hourly data during daytime hours from local weather stations. Average wind speed ranged from 2.7 m s⁻¹ in the Uintah to 6.4 m s⁻¹ in the Powder River (Table S2). On the basis of the power law relationship between wind speed and detection limit reported in Benson et al., the difference in wind speed would cause the average detection limit to be 3–4 times higher in the Powder River compared to the Uintah.²¹ Therefore, variability in wind speed contributes uncertainty to the detection limit of a similar magnitude as variable gas composition.

Because survey results were reported for unique well pads rather than by individual well (i.e., many sites had multiple wells), the latitude/longitude of individual wells in surveyed areas were used to aggregate wells into pads by spatially joining all active wells within a 50 m buffer distance.¹⁸ For each pad, well-level data were used to determine the operator, well production type (oil, gas, oil and gas, coal bed methane), well drill type (vertical, horizontal, directional), number of wells, pad age (months since initial production of newest well), gas production, hydrocarbon liquid production, and water production.²⁴ Hydrocarbon liquid production includes both crude oil and natural gas condensate; for this analysis, the term "oil" is used to refer to all hydrocarbon liquids. Water

production data were not available for individual wells in the Fayetteville or Marcellus basins. Parameters were specific to the same survey month for all basins except the Marcellus, for which only annual and semiannual data were available for conventional and unconventional wells, respectively. In addition to pad-specific parameters, operator-specific parameters were calculated for each basin based on operators' full population of wells in each basin. Surveyed sites with detected emissions were matched to individual pads in the survey area using the reported latitude/longitude as well as Google Earth imagery.

The helicopter-based team surveyed 8220 well pads located throughout an area of 6750 km². Average well pad characteristics by basin and strata are summarized in Table S3. The average number of wells per pad ranged from 1.1 in the Uintah to 2.7 in the Fayetteville. Well pads were newest in the Fayetteville (average age of newest well on each pad of 4.1 years) and oldest in the Barnett (13.4 years). Average gas production ranged from 65 Mcf pad⁻¹ day⁻¹ in the Uintah to 1438 Mcf pad⁻¹ day⁻¹ in the Fayetteville. Average oil production ranged from 0 bbl pad⁻¹ day⁻¹ in the Fayetteville to 312 bbl pad⁻¹ day⁻¹ in the Eagle Ford. For the basins with oil production, GOR was lowest in the Bakken (1.2 Mcf bbl⁻¹) and highest in the Marcellus (153 Mcf bbl⁻¹). To assess the representativeness of surveyed sites, we compared these parameters between surveyed sites and the total population of active wells in each basin in 2014 (Table S4). For almost all parameters, surveyed sites had statistically different distributions than the entire basin (Kolmogorov–Smirnov $p > 0.05$) but the percent difference for most values was <25% from the basin mean and almost always within 50%. In all basins, surveyed wells were younger than the full population; in the Bakken, Barnett, Eagle Ford, Marcellus, and Powder River, surveyed wells had higher gas production and/or oil production than the basin average. These slight biases likely resulted from selecting subregions with active drilling to include young sites in our survey areas. Overall, our sampled strata account for the full range of diversity within and across basins and are appropriate for assessing patterns in high emissions.

Pearson's correlation coefficients (r) were used to assess correlation between the presence (nondetect = 0, detect = 1) or number of detected emissions by source type and pad or operator parameters. Binomial generalized linear models (GLM), also known as logistic regression models, were used to predict the probability of detected emissions at a well pad (P_{detect}) from site and operator parameters. Analysis of variance models and Tukey's Honest Significance Difference test were used to assess significant differences in P_{detect} among basins, strata, well type, and drill type. Poisson GLMs were used to predict the number of detected sources by emission type at each pad. For the full data set and individual basins, several single parameter and multiparameter GLMs were evaluated on the basis of their simplicity, Akaike Information Criteria, Pearson's r , and Hosmer-Lemeshow goodness of fit between observed and predicted values to select models meaningful for explaining the effects of parameters on emissions. An alpha level of 0.05 was used to determine statistical significance in all tests. For statistical analyses, percent energy from oil was used as a surrogate for GOR since it has a discrete range and is more normally distributed; this metric was calculated from oil and gas production using an assumed energy content of 5.8 MMBtu bbl⁻¹ for oil and 1.05 MMBtu Mcf⁻¹ for natural gas.²⁶

Table 1. Infrared Camera Survey Results by Basin and Strata^a

| basin | strata | detected sources | | | | well pads with detected sources | |
|--------------|-----------------------|------------------|--------------|----------------|-----------------|---------------------------------|---------------------|
| | | number | % tank vents | % tank hatches | % other sources | number | % of pads |
| Bakken | young | 109 | 9% | 83% | 7% | 57 | 14.9% ^a |
| | old | 61 | 10% | 85% | 5% | 37 | 12.4% ^a |

^aFor the percentage of pads with detected emissions (P_{detect}), letters indicate statistically significant differences among strata within each basin (a–c) and among basins (w–z) as determined by Analysis of Variance models and Tukey's HSD ($p < 0.05$). For example, within the Barnett, P_{detect} in the low GOR strata is statistically different than the high GOR and medium GOR strata; the overall Barnett P_{detect} is statistically different than overall P_{detect} of the Bakken, Marcellus, Powder River, and Uintah.

Table 2. Correlation of Well Pad and Operator Parameters with P_{detect} (the Detection of Emissions at a Site; Nondetect = 0, Detect = 1) or the Number of Detected Sources by Type^a

| parameters | | P_{detect} | total sources | tank vents | tank hatches | nontank sources |
|------------------------------|-------------------|---------------------|---------------|------------|--------------|-----------------|
| well pad parameters | well count | 0.15 | 0.16 | 0.15 | 0.10 | |
| | well age | −0.12 | −0.10 | −0.08 | −0.07 | −0.03 |
| | gas production | 0.12 | 0.11 | 0.15 | 0.04 | |
| | oil production | 0.20 | 0.28 | 0.24 | 0.19 | |
| | water production | 0.06 | 0.06 | 0.04 | 0.06 | |
| | % energy from oil | 0.19 | 0.16 | 0.10 | 0.12 | 0.06 |
| operator regional parameters | well count | −0.11 | −0.09 | −0.06 | −0.06 | −0.05 |
| | gas production | −0.05 | −0.03 | −0.03 | | −0.04 |
| | oil production | 0.09 | 0.10 | 0.06 | 0.08 | |
| | water production | −0.06 | −0.06 | −0.04 | −0.03 | −0.06 |
| | % energy from oil | 0.17 | 0.14 | 0.08 | 0.12 | 0.06 |

^aWell pad parameters represent the individual site. Operator parameters represent all regional well pads operated by the same company as each surveyed site. Reported values are Pearson correlation coefficients (r) that are significantly different than zero ($p < 0.05$).

RESULTS AND DISCUSSION

A total of 494 unique high emissions sources at 327 well pads were detected by the helicopter survey team out of 8220 surveyed well pads in seven basins. The percentage of total well pads with detected HC emissions (P_{detect}) was 4% but ranged from 1% in the Powder River to 14% in the Bakken (Table 1). There were statistically significant differences in P_{detect} by basin with the Bakken higher than all other basins (see Table 1 for full pairwise comparisons). Emissions were more often

observed in oil-producing areas with an average P_{detect} of 13% in the Bakken and low gas-to-oil ratio strata of mixed production basins ($p < 0.0001$, χ^2 test). For example, in the Barnett, 21% of well pads in the low GOR strata showed detectable emissions compared to <1% of sites in the high GOR strata (Table 1). There were also significant differences in P_{detect} by well production type (oil and gas > oil > gas > coal bed methane) and well drill type (horizontal > directional and vertical).

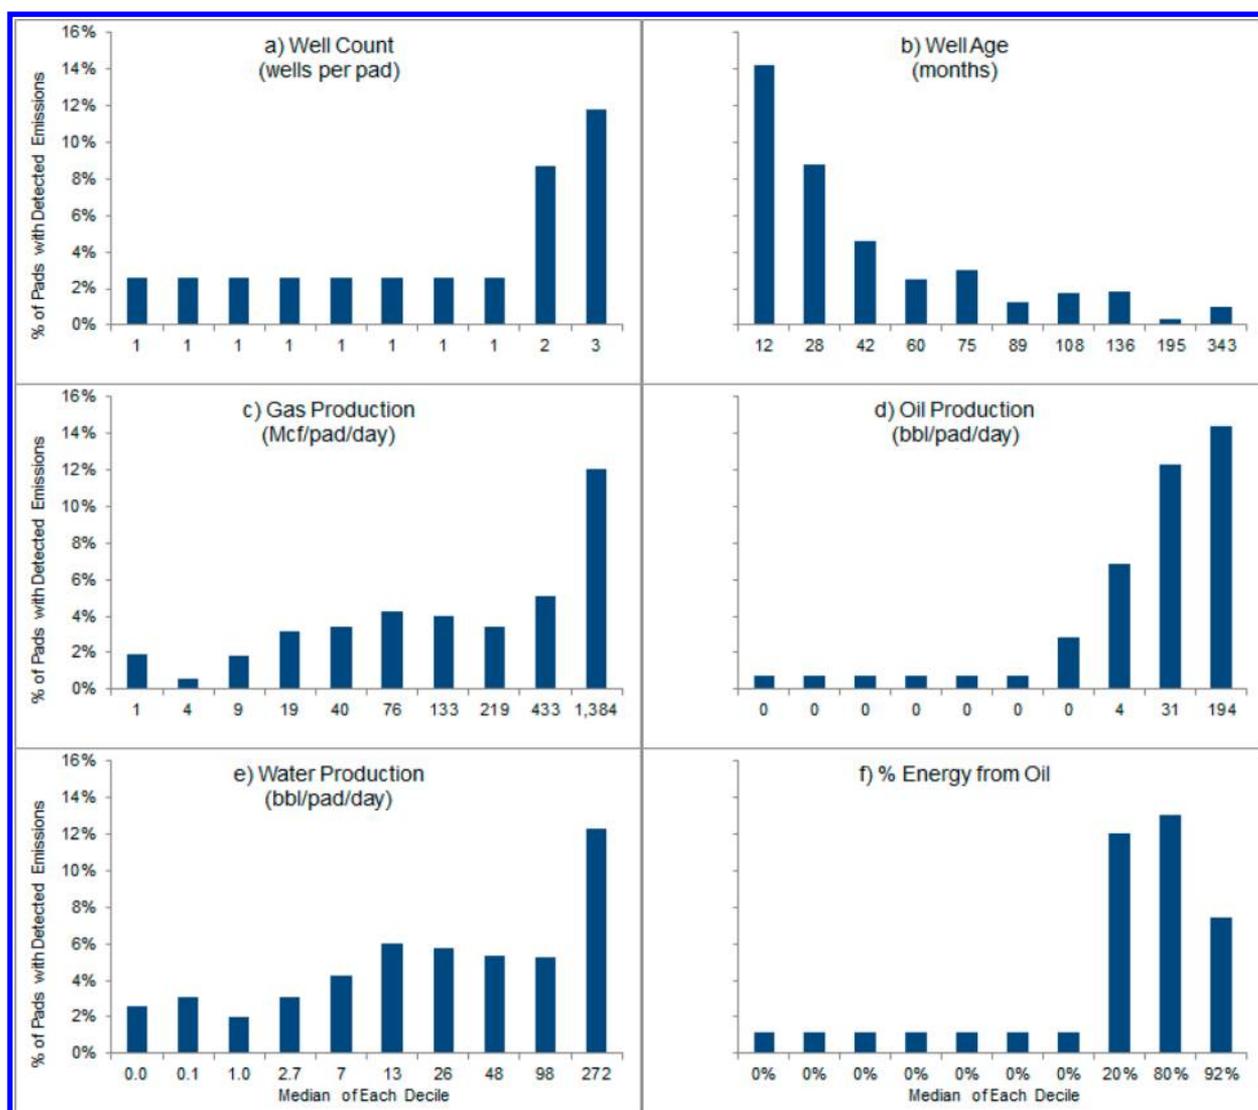

Figure 1. Percentage of well pads with detected emissions by deciles of well pad parameters: (a) well count (wells per pad), (b) well age (months since initial production of newest well), (c) gas production (Mcf/day), (d) oil production (bbl/day), (e) water production (bbl/day), and (f) % energy from oil. The median values of each decile are displayed on the x-axes.

Tank hatches and tank vents were the most common source type of detected emissions, comprising 92% of observed sources (Table 1). The remaining 8% of detected emission sources were dehydrators, separators, trucks unloading oil from tanks, and unlit or malfunctioning flares. Detected emission sources represent individual release points with HC emission rates exceeding the survey's estimated detection limit of approximately 3 g s^{-1} for CH_4 or 1 g s^{-1} for heavier HC. Given this detection limit, no emissions were observed from equipment leaks, pneumatic controllers, or chemical injection pumps, consistent with two recent studies that observed a maximum emission rate of $1.5 \text{ CH}_4 \text{ g s}^{-1}$ at over 1000 such measured sources.^{27,28}

There are several factors that may account for differences among basins in P_{detect} including operational practices, emission control regulations, and the mix of produced hydrocarbons. The effect of weather conditions on the detection limit may also have impacted the frequency of observed emissions. In particular, the higher average wind speed in the Powder River may have contributed to the low frequency of observations.

Statistical Analyses. There were statistically significant but relatively weak positive correlations between detection and numerous well pad parameters: well count, gas production, oil production, water production, and percent energy from oil (Table 2; $r = 0.06$ to 0.20). Detection was negatively correlated with well age ($r = -0.12$), meaning that newer wells were more likely to have detected emissions. The average P_{detect} by decile of analyzed pad parameters is shown in Figure 1. One binomial generalized linear model, GLM A4, predicted detection that was not significantly different than that observed (Hosmer-Lemeshow >0.05); this multiparameter model used basin, the numerical pad parameters well count, well age, gas production, oil production, and percent energy from oil, and the interactions of basin with each numerical parameter, to explain 14% of the variance in P_{detect} ($r^2 = 0.14$). Three other multiparameter GLMs had observed and predicted detections that were statistically different and explained 3–8% of the variance: A1, using basin only; A2, using numerical parameters only; and A3, using basin and the numerical parameters but not their interactions (Table S5, $r^2 = 0.03$, 0.07 , and 0.08 , respectively). The increase in predictive power indicates that

the effect of well pad numerical parameters on P_{detect} varies by basin. For example, in the Marcellus, Powder River, Barnett, and Uintah basins, which have a mix of produced hydrocarbons with a wide range of GOR, there was a significant positive effect of percent energy from oil on predicted P_{detect} , while there was no significant effect of this parameter in the basins with more homogeneous production.

The most predictive GLM, A4, only explained 14% of the variance, which indicates that the presence of high emissions was primarily stochastic or driven by operational characteristics not included in this analysis. Therefore, statistical models have limited utility for predicting the occurrence of individual high emission sources. However, the relatively weak, statistically significant correlation of several parameters with P_{detect} does provide some insights into factors affecting the likelihood of high emissions. To assess the effects of well pad characteristics on detection, we evaluated single parameter GLMs for the full data set and individual basins (Table S6). For the full data set, the GLMs with the best fit between observed and predicted detection were based on well age ($r^2 = 0.04$), oil production ($r^2 = 0.03$), and percent energy from oil ($r^2 = 0.03$). The relative strength of the effects of parameters on the likelihood of detection can be assessed by the ratio of GLM predicted P_{detect} at the 97.5th and 2.5th percentile of parameter distributions. For example, predicted probability of detection for a pad at the 97.5th percentile of well count ($P_{\text{detect}} = 0.11$; 5 wells per pad) is 3.2 times higher than for a pad at the 2.5th percentile ($P_{\text{detect}} = 0.03$; 1 well per pad). For individual basins, single parameter GLMs with statistically significant fits had the same directional effects as the full data set but varied in their relative strength. The best fit GLMs were based on well count in the Bakken and Marcellus, well age in the Powder River and Uintah, and oil production in the Barnett and Eagle Ford. In the Fayetteville, no single parameter GLM had a statistically significant fit. Detailed parameters for GLM A4 and single parameter GLMs are reported in Tables S16 and S17.

Other studies have reported a weak positive correlation between gas production and methane emissions.^{13,28,29} In a prior study of the Barnett Shale, the top 7% of well pads by gas production were estimated to contribute 29% of total methane emissions; this was attributed to higher absolute emissions yet lower proportional loss rates of produced gas at high production sites.¹⁸ The positive correlation between oil production and emission detection may be related to a higher frequency of tank flashing with increased oil production. Brantley et al. reported that oil production was negatively correlated with methane emissions as part of a multivariate linear regression model, which the authors attributed to lower methane content relative to heavier HCs in gas from oil producing wells.¹³ In this study, the opposite effect would be expected since the IR camera detects all HCs with higher sensitivity to heavier HCs. The positive relationship between the number of wells per pad and P_{detect} may be due to greater complexity and potential emission sources at multiwell pads. The negative effect of well pad age, the parameter with the strongest predictive power, is likely related to the inverse relationship between well age and oil and gas production, although all parameters remain significant in multiparameter GLMs. Pads with a well in its first two months of production had over five times the frequency of detected emissions than older pads ($p < 0.001$). Due to the steep decline in production rates of unconventional wells with age, equipment and control devices may be undersized for handling this period of maximum

production. Although older sites would be expected to have a greater likelihood of malfunctions caused by equipment wear, young sites may have initial issues caused by poor setup that have yet to be detected and repaired.

Similar statistical analyses were performed for basin-specific operator characteristics; there were several statistically significant but weak correlations between P_{detect} and these parameters (Table 2) with the strongest positive and negative correlations for an operator's regional percent energy from oil ($r = 0.17$) and regional well count ($r = -0.11$). Binomial GLMs predicting P_{detect} from operator parameters are described in the Supporting Information. Relationships between the number of detected emissions by source type and well pad or operator characteristics were also evaluated (Table 2). For tank vents and hatches, the number of detected sources at a pad was most strongly correlated with oil production ($r = 0.24$ and 0.19). For nontank sources, correlations were weaker ($r = -0.06$ to 0.06). Poisson GLMs predicting the number of detected sources by type from pad parameters are described in the Supporting Information.

Potential Causes of Observed Emissions. High-emitting sources detected by the survey team may have been caused by both malfunctions and normal operations. For nontank sources, IR videos provide evidence that most sources were the result of malfunctions or intentional releases. There were 14 observations of malfunctioning flares that were unlit or operating with poor combustion efficiency. Emissions were detected from the pressure relief valves of four separators; although these pressure relief valves may have been functioning properly for safety purposes, the overpressurization that triggered their release indicates abnormal operations. Eight emission sources were observed from vents associated with trucks unloading oil from tanks, which may be intentional to relieve pressure of gas that is released as oil is pumped into trucks. Fifteen dehydrators were observed to have HC emissions, primarily from still vents that remove water vapor from the water-saturated glycol solution. On the basis of pad gas production and HC emission factors, no more than three of these dehydrators would be expected to have still vent emissions close to the 1 g s^{-1} detection limit.³⁰ Therefore, most observed emissions from dehydrators were likely the result of abnormal operations that allowed excess HC to slip through the vent. In addition to the IR videos of individual sources, the very weak fit between observed and predicted emissions suggests that nontank emission sources are strongly driven by stochastic processes such as malfunctions.

Attributing tank vent and hatch emissions to malfunctions or normal operations is more difficult due to the many potential causes of tank emissions. As part of normal operations, uncontrolled tanks emit HCs from working, breathing, and flashing losses. Tank working and breathing losses generally are expected to be less than 1 g HC s^{-1} , but emissions in excess of this rate can occur from tank flashing after a separator dumps liquids into a tank.^{13,31} As discussed below, the emission rate and frequency of tank flashing emissions can be predicted on the basis of parameters including oil production.

Another routine cause of tank emissions is when wells are vented to unload liquids accumulated in the wellbore, which also releases gas. Emissions from well unloadings can be very large; the average emission rate of over 100 measured unloading events was $111 \text{ g CH}_4 \text{ s}^{-1}$.³² U.S. EPA Greenhouse Gas Reporting Program (GHGRP) data were used to estimate the percentage of wells expected to be venting at any one time in surveyed basins.³³ Assuming the duration of unloading events was 1 h, 0.24% and 0.15% of wells in the Fayetteville

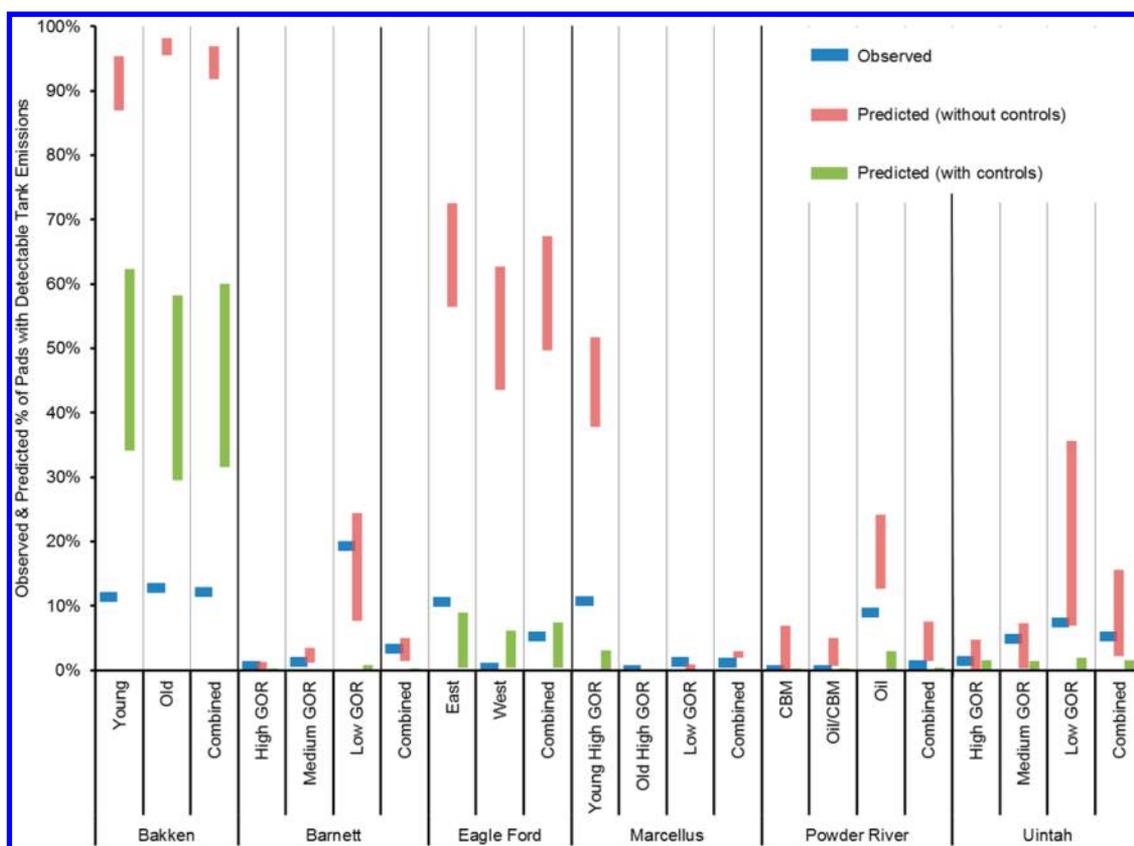

Figure 2. Comparison of the observed and predicted frequencies of well pads with detected tank hydrocarbon emissions assuming an observation threshold of 1 g s^{-1} and basin-level data from the EPA O&G Estimation Tool. Two sets of predicted estimates are provided: red bars reflect predicted frequencies based on potential emissions without controls; green bars reflect the application of controls to the highest emitting tanks (see text for details). Predicted frequencies are shown as a range reflecting different temporal profiles of tank flashing emissions. For several basins and strata, observed frequencies are lower than frequencies predicted without controls but higher than predicted with controls. For example, the combined Uintah observation of 5.8% is within the range predicted for potential emissions but greater than the maximum of 1.5% predicted if all tank control systems were functioning effectively.

(Arkoma) and Uintah basins would have been venting due to liquids unloading at any one time, respectively; all other surveyed basins are predicted to have had less than 0.1% of wells venting from unloading. Therefore, liquids unloading events likely could be detected by the helicopter survey but only can explain a small fraction of observed tank sources.

Finally, abnormal emissions can occur if a separator dump valve fails to properly close and allows produced gas to flow through the tank instead of the sales line. These sources can have very large emission rates, theoretically up to a well's entire gas production if the valve is stuck fully open. In 2014, operators reported over 7000 malfunctioning dump valves to the U.S. EPA GHGRP.³³ On the basis of the reported number of hydrocarbon tanks, approximately 5% of GHGRP tanks was associated with stuck dump valves. Operators do not report the duration of stuck dump valves, but a median duration of 7 days can be back calculated from other GHGRP data. Consequently, less than 0.1% of tanks are expected to have emissions from stuck dump valves at any one time.

Influence of Flashing Emissions by Basin. To determine if flashing could account for the observed P_{detect} of tank emission sources, potential HC emissions from tank flashing were estimated for surveyed well pads. Flash emission rates per unit of liquids production vary by parameters such as separator pressure and API gravity (a measure of HC liquid density). Since these values were not known for individual sites, basin-

level data were obtained from the U.S. EPA O&G Emission Estimation Tool 2014 version 1, which includes a compilation of best available data from several sources including state regulatory agencies.³⁴ The tool provides separate emission factors for produced water, condensate, and crude oil (Table S11). For hydrocarbon liquids, a weighted average emission factor was derived from basin-level oil and condensate production. If tanks at a well pad are manifolded together with a common vent, then flash emissions will occur when any well's separator dumps to the tank battery. Therefore, site-level production was used as a conservatively high estimate of flashing emissions. The temporal variability of flash emissions depends on the frequency and duration of separator dumps and duration of subsequent flash gas venting. Brantley et al. reported that a tank at a Denver-Julesburg well pad producing 29 bbl d^{-1} condensate flashed ten times in 20 min; the duration of flash events in the study ranged from 30 to 120 s.³¹ This indicates that, although individual flash events are short-lived, some sites may have near continuous tank flashing emissions due to frequent venting from separator dumps. To estimate the percentage of sites expected to have flash emissions $\geq 1 \text{ g HC s}^{-1}$ detection limit at any one time, the frequency and emission rate of flash emissions were calculated using two sets of assumptions: continuous emissions at a constant rate or intermittent emissions at the detection limit. Both these estimates use the same daily average emission rate but serve

as lower and upper bounds for the fraction of sites with concurrent emissions at or above the detection limit. The effects of these assumptions were tested with a sensitivity analysis including alternative emission factors and a 3 g HC s^{-1} detection limit (Tables S12–S15). In all basins, the range of predicted frequencies of sites with uncontrolled tank flashing emissions $\geq 1 \text{ g HC s}^{-1}$ included or exceeded observed frequencies (Figure 2; Fayetteville was excluded due to lack of reported liquids production). This indicates that tank flashing could explain observed emissions in the absence of tank emission control devices.

There are several state and federal regulations that require some oil and condensate storage tanks to control VOC emissions, including in North Dakota, Pennsylvania, Utah, and Wyoming.^{35,36} For example, during the time of the survey, U.S. EPA New Source Performance Standard Subpart OOOO required all tanks that began construction after April 12, 2013 and had a potential to emit ≥ 6 tons per year VOC to install control devices with at least 95% control effectiveness within 60 days of initial production.³⁷ Tank emission control devices include flares, combustors (enclosed flares), and vapor recovery units. The improper design, construction, or maintenance of tank control devices can reduce the capture or control efficiency of tank control devices.³⁸ Combustion devices can fail to ignite or have poor combustion efficiency, which causes HC emissions from the combustor stack. Emissions may not be fully captured if control systems are undersized or if condensed liquids in vent lines restrict the flow of gas, which can lead to tank overpressurization that triggers the release of gas from a pressure relief valve or tank hatch. Additionally, tank hatches that are left open accidentally or improperly sealed can allow some portion of vented flash gas to circumvent control devices. To determine if the frequency of observed tank emissions indicates failure of tank control systems, we estimated the percentage of sites expected to be equipped with tank controls by applying basin-level control data from the U.S. EPA O&G Emission Estimation Tool (Table S11).³⁴ For every surveyed well pad, potential emissions from oil, condensate, and water flashing were estimated with basin-level emission factors. Well pads were ranked by potential emissions, and then, controls were assumed to be equipped at a fraction of sites equal to the percentage of tanks with flares reported in the tool (28–86%). Emissions were assumed to be controlled at the reported basin-level capture efficiency (100%) and control efficiency (91–98%).³⁴ If these assumptions were true, then no emissions should be observed from hatches or vents of controlled tanks since all emissions are captured by the control device, but emissions could be observed exiting control devices if uncombusted HC in flare exhaust exceeds the detection limit.

In the Barnett, Powder River, Marcellus, and Uintah Basins, the observed frequency of well pads with detected tank emissions exceeded the maximum predicted frequency based on controlled tank flashing emissions, while in the Bakken the observed frequency was lower than expected (Figure 2). U.S. EPA recently issued a compliance alert that reports inspectors frequently observe emissions from tank hatches and pressure relief valves.³⁸ After an inspection of almost a hundred tanks in Colorado found numerous instances of ineffective control systems caused by design issues such as undersized control devices, an O&G operator entered a consent decree with U.S. EPA and the State of Colorado to evaluate and improve their control systems.³⁹ In the Bakken and Barnett, we inspected Google Earth imagery to assess the presence of tank control

devices at well pads with observed tank emissions; 86% and 56% of well pads with extant imagery, respectively, had apparent control devices. This study's observation that tank hatches and vents were the origin of the majority of detected large emission sources, even at controlled sites, suggests that the U.S. EPA O&G Emission Estimation Tool's assumption of 100% capture efficiency is inaccurate and incomplete capture of emissions by tank control systems is a widespread issue.

Policy Implications. There are several strategies for reducing emissions from tanks, such as installing vapor recovery towers or stabilizers to reduce the vapor pressure of liquids entering tanks, properly sizing control equipment, and maintaining pressure relief valves and tank hatches to prevent leaks. Since this study found a higher frequency of detected emissions at sites within the first few months of production, controlling tank emissions as soon as a site enters production could reduce overall emissions. U.S. EPA New Source Performance Standard Subpart OOOO allows the installation of control devices to be delayed up to 60 days after startup, despite this being a period of maximum production, especially for unconventional wells characterized by rapid production decline.³⁷ The use of properly sized control devices as soon as production is initiated would address a substantial source of emissions. For example, the average Bakken site produces oil about twice the rate in the first two months as it does during the rest of the first year of production.²⁴ Given the evidence reported in this study that the frequency of observed tank emissions is greater than what would be expected if control systems were functioning effectively, it is clear that identifying anomalous emissions through regular or continuous monitoring of hydrocarbon emissions and/or equipment status, such as leak detection and repair programs, would be an effective strategy to reduce emissions.

Currently, U.S. EPA estimates total annual emissions from all oil and gas production sources of 3.1 Tg VOC and 2.9 Tg CH_4 with $0.6 \text{ Tg CH}_4 \text{ yr}^{-1}$ attributed to oil and condensate tanks.^{40,41} The qualitative nature of the IR survey data precludes an accurate estimate of hydrocarbon or methane emissions, but with knowledge of the detection limit of the technology deployed, our observations can be used to estimate a lower bound for tank emissions. Our observation of more than 450 detected tank sources with emission rates $\geq 1 \text{ g HC s}^{-1}$ represent at least 450 g HC s^{-1} (a more likely estimate is $\sim 1575 \text{ g HC s}^{-1}$ based on the median aircraft quantified well pad emission rate of $3.5 \text{ g CH}_4 \text{ s}^{-1}$). While these emissions likely include both intermittent and continuous sources, the assumption of a relatively constant emission rate across a large number of sites is robust and yields an emission rate of at least $14.2 \text{ Gg HC yr}^{-1}$. Since our observations were limited to summer/fall and daylight hours, we were not able to assess how annual average prevalence may be affected by seasonal or diurnal trends such as higher tank breathing losses during warmer conditions. The 8220 surveyed well pads include 1.1%, 3.7%, and 4.5% of U.S. active wells, gas production, and oil production, respectively. There is uncertainty in scaling up emissions from our sample given that the representativeness of surveyed wells to the U.S. national population of O&G wells has not been assessed and there are only weak correlations between the prevalence of high emissions and these parameters. However, scaling up by the best fit parameter, oil production, yields a minimum national HC emission rate of 0.32 Tg yr^{-1} from high emission tank sources. This national emission estimate of tank emissions represents a lower bound for high-

emitting tanks and excludes common, lower emission rate sources such as tank working and breathing losses. This study provides evidence that the cause of some observed emissions is anomalous conditions rather than routine, intermittent tank flashing. U.S. EPA may be underestimating emissions from O&G tanks by overestimating control effectiveness and failing to comprehensively include abnormal, high emission sources. It is reasonable to assume that tanks are a major contributor to the gap between top-down and bottom-up estimates of O&G CH₄ emissions reported by several studies, as well as to the fat-tail emissions observed in a previous study of the Barnett that closed the gap.¹¹

Even though this study found statistically significant correlations between the presence of detected emissions and several well pad and operator parameters, these relationships were weak and GLM models were able to explain less than 15% of the variance. This low degree of predictability indicates that these large emission sources are primarily stochastic and the frequent and widespread inspection of sites to identify and repair high emission sources is critical to reducing emissions. In addition to helicopter-based IR surveys, continuous site-based and mobile leak detection systems may be valuable for quickly identifying these large sources.^{13,14,42–44} Tank vents and hatches account for the vast majority of high emission sources detected at well pads across the U.S. Although routine tank flashing may be responsible for some of these emission sources, there is evidence that substantial emissions are caused by abnormal conditions such as ineffective tank control systems. Installing tank control devices on existing sources combined with maintenance and monitoring to ensure control systems are operating effectively would be an important step for reducing emissions of methane and VOCs. Tanks and other high emission sources are an important contributor to total hydrocarbon emissions from oil and gas well pads and offer a promising opportunity to reduce emissions, but further reductions targeting the numerous emission sources that are individually smaller but collectively large will also be necessary to minimize the health and climate impacts of oil and gas production.

ABSTRACT: Equipment- and site-level methane emissions from 45 compressor stations in the transmission and storage (T&S) sector of the US natural gas system were measured, including 25 sites required to report under the EPA greenhouse gas reporting program (GHGRP). Direct measurements of fugitive and vented sources were combined with AP-42-based exhaust emission factors (for operating reciprocating engines and turbines) to produce a study onsite estimate. Site-level methane emissions were also concurrently measured with downwind-tracer-flux techniques. At most sites, these two independent estimates agreed within experimental uncertainty. Site-level methane emissions varied from 2–880 SCFM. Compressor vents, leaky isolation valves, reciprocating engine exhaust, and equipment leaks were major sources, and substantial emissions were observed at both operating and standby compressor stations. The site-level methane emission rates were highly skewed; the highest emitting 10% of sites (including two superemitters) contributed 50% of the aggregate methane emissions, while the lowest emitting 50% of sites contributed less than 10% of the aggregate emissions. Excluding the two superemitters, study-average methane emissions from compressor housings and noncompressor sources are comparable to or lower than the corresponding effective emission factors used in the EPA greenhouse gas inventory. If the two superemitters are included in the analysis, then the average emission factors based on this study could exceed the EPA greenhouse gas inventory emission factors, which highlights the potentially important contribution of superemitters to national emissions. However, quantification of their influence requires knowledge of the magnitude and frequency of superemitters across the entire T&S sector. Only 38% of the methane emissions measured by the comprehensive onsite measurements were reportable under the new EPA GHGRP because of a combination of inaccurate emission factors for leakers and exhaust methane, and various exclusions. The bias is even larger if one accounts for the superemitters, which were not captured by the onsite measurements. The magnitude of the bias varied from site to site by site type and operating state. Therefore, while the GHGRP is a valuable new source of emissions information, care must be taken when incorporating these data into emission inventories. The value of the GHGRP can be increased by requiring more direct measurements of emissions (as opposed to using counts and emission factors), eliminating exclusions such as rod-packing vents on pressurized reciprocating compressors in standby mode under Subpart-W, and using more appropriate emission factors for exhaust methane from reciprocating engines under Subpart-C.

INTRODUCTION

The growing production and utilization of natural gas in the United States (US) has raised questions about methane emissions from the natural gas system.^{1,2} Methane, a greenhouse gas (GHG), is the primary component of natural gas. The US Environmental Protection Agency (EPA) estimates that the natural gas system contributed about 23% of annual US methane emissions in 2012 by relying heavily on data collected

in the 1990s.³ Recent studies have suggested that the EPA and other emissions inventories may underestimate US national methane emissions from all sources by 25–75%.^{4–6}

Accepted: January 21, 2015

Published: February 10, 2015

The 2012 EPA Greenhouse Gas Inventory (GHGI) attributes one-third of methane emissions from the US natural gas system to the transmission and storage (T&S) sector.³ This sector comprises about 2000 compressor stations distributed along approximately 300,000 miles of pressurized pipelines, underground storage facilities, and associated equipment.³ The EPA GHGI for the T&S sector is largely based on emission factors from a 1996 GRI/EPA study.⁷ During the past two decades, there have been substantial changes in the natural gas system, which warrants a re-examination of methane sources and emission rates, e.g. Allen et al.⁸ Two more recent studies reported emissions data from 13 T&S compressor stations,^{9,10} two fewer than the GRI/EPA study. The lack of methane emissions data was identified as a critical issue for assessing the environmental impacts of natural gas use.¹¹

Starting in 2011, T&S facilities that emit more than 25,000 t of carbon dioxide equivalent (MT-CO₂e) report their emissions under the EPA Greenhouse Gas Reporting Program (GHGRP; 40 CFR §98, Subpart C and Subpart W) using a combination of onsite emission measurements and emission factors. In 2012, 495 transmission and underground storage facilities reported methane emissions under this program, about one-quarter of the total facilities in the T&S sector.³ The EPA GHGI does not yet use the GHGRP emissions or activity data, but the EPA GHGRP represents a potentially important new data source for the next generation of natural gas system emissions inventories. However, the use of leak counts and emission factors for certain equipment types, the exclusion of emissions from sources in certain operating modes, and the use of a single emission factor for all unburned methane emissions in engine exhaust regardless of prime mover type (turbine or reciprocating engine) raise questions over the GHGRP's completeness as a basis for emissions inventories.

This paper presents methane emissions measurements made at 45 compressor stations in the T&S sector, more than the three previous studies combined.^{7,9,10} At each site, two independent yet complementary measurement methodologies were employed—comprehensive onsite emissions measurements and downwind dual-tracer flux. Results from the two independent methodologies are compared to investigate uncertainties in site-level emission estimates, EPA GHGI, and EPA GHGRP. Zimmerle et al.¹² use these results, industry-reported activity and emissions data from the GHGRP, and other data to estimate the 2012 national methane emissions for the T&S sector.

METHODOLOGY

Measurements were performed to characterize the methane emissions from 45 compressor stations in the T&S sector during the summer and fall of 2013. The measurements were made in collaboration with six major natural gas pipeline operators. Two independent yet complementary measurement methodologies were employed. Onsite emissions measurements provide a “bottom-up” estimate of site-level methane emissions by direct measurement of individual emission sources, which are then combined to provide a site-level estimate. Tracer flux techniques provide a “top-down” estimate of site-level emissions derived from measured methane and tracer gas concentrations in downwind plumes. The two approaches were deployed on the same day(s) to facilitate direct comparison of the two independent estimates of the site-level methane emissions, to evaluate site-level closure between

the top-down and bottom-up approaches, and to increase confidence in the results.

Study Sites. Methane emissions were measured at 36 compressor stations in the transmission system and nine compressor stations associated with underground storage facilities operated by six partner companies. The stations were located in 16 states across the South, Mid-Atlantic, Northeast, Midwest, and the Mountain West. The stations were equipped with two types of compressors: reciprocating compressors driven by natural gas-fired reciprocating engines, and centrifugal compressors driven by gas-fired turbines (though a few are driven by electric motors). Nineteen stations were equipped with only reciprocating compressors; the average number of compressors at these sites was 4.8 with an average capacity of 2335 hp per compressor. Twenty-one stations were equipped with only centrifugal compressors; the average number of compressors at these sites was 2.4 with an average capacity of 11,741 hp per compressor. Five sites were “mixed” sites with both compressor types. At least one compressor was operating at 20 sites. Twenty-five sites reported to the EPA GHGRP in 2012. Additional site details are summarized in Tables S1 and S2 in the Supporting Information.

Site selection was performed by the study team from lists of sites provided by the six partner companies. Site selection was not random but instead was based on a number of factors: geographic location, technology, partner company greenhouse survey team schedules, and site suitability for tracer flux measurements. We sought to achieve broad geographic coverage, while we also acknowledged the travel schedule of the field teams. Sites were selected to span a range of technologies (centrifugal versus reciprocating compressors; wet versus dry seal centrifugal compressors), operating states (operating, standby depressurized, and standby pressurized), and GHG reporting status (reporter if required to report under GHGRP, otherwise nonreporter). The majority of the measurements were performed in partnership with partner company GHG onsite survey teams, which required schedule coordination. Finally, local road access and meteorological conditions were evaluated to determine the suitability of each site for tracer flux measurements.

The overall goal of the site selection process was to develop a site list that was broadly representative of the partner company fleets, which comprise ~56% of the interstate transmission facilities reported to the US Federal Energy Regulatory Commission (FERC) under Form 2.¹² Comparisons indicate that this objective was largely achieved. For example, the study sites had 187 compressors, of which 69% were reciprocating compressors; this is slightly lower than the census of reciprocating compressors at all partner-company stations (75% of 3052 compressors). Analysis of the GHGRP or equivalent data for 2012 indicates that the methane emissions from the study sites are representative of the broader company fleets; details are provided in the Supporting Information. Briefly, GHGRP-equivalent annual methane emissions data were available for 2012 from 343 Partner sites. This includes 29 study sites. A two-sample Kolmogorov–Smirnov (K–S) goodness-of-fit hypothesis test indicates that these two sets of 2012 methane emissions data were drawn from the same underlying distribution at 95% confidence (Figure S1, Supporting Information.)

Onsite Measurements. The onsite emissions measurements involved comprehensive leak detection followed by

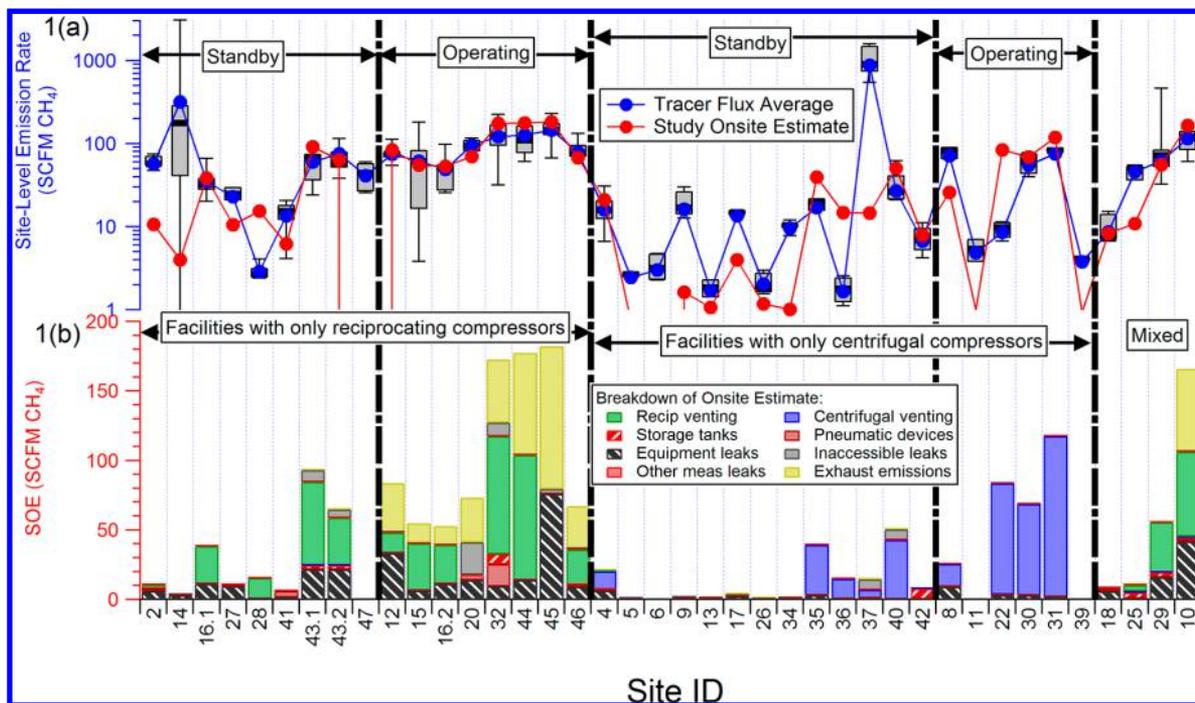

Figure 1. (a) Tracer flux-based site-level methane emission rates for the 40 sites for which both tracer flux and onsite emissions data are available in the same operating state. The boxes represent the 25th and 75th percentiles of the tracer flux data at a site; whiskers represent the 95th and 5th percentiles. The blue line represents the average tracer flux emissions rate, while the red line is the SOE. (b) The SOE broken down by source categories (Table S3, Supporting Information). Sites 18, 25, and 29 were on standby and had both reciprocating and centrifugal compressors (“mixed” sites). Mixed site 10 had one turbine and two reciprocating compressors on standby and four operating reciprocating compressors.

direct measurement of all safely accessible sources of nonengine exhaust methane emissions. Equipment leaks from valves, flanges, connectors, open ended lines, etc. were identified using infrared imaging. The methane emissions from all identified leaks and vented sources (reciprocating compressor rod-packing, blowdown vents, centrifugal wet seals, etc.) were then directly quantified using Bacharach Hi-Flow samplers, anemometers, turbine flow meters, or calibrated bags; in one case, a rotameter was used. Additional details of the onsite emissions measurement protocol are described in the Supporting Information.

A total of 1398 individual onsite methane emissions measurements were collected in this study (Table S5, Supporting Information). For each site, all measured onsite data were combined to create a bottom-up estimate of the site-level methane emissions, called the study onsite estimate (SOE), which is as comprehensive as possible to maximize comparability with the tracer flux measurements of site-level methane emissions. The SOE uses emission estimates in only two situations: (1) inaccessible sources (identified leaks or vents that could not be safely accessed) were estimated using “study factors”; (2) unburned methane in engine/turbine exhaust, not measured in this study, was estimated using AP-42 emission factors (see Supporting Information for details). Study factors are the average of all study measurements for the same component or leak type (Table S10, Supporting Information).

At 34 stations, the onsite methane emissions measurements were made by either the partner company or a partner-supported third-party contractor as part of the company’s ongoing, EPA-mandated GHGRP reporting activities. At 11 stations, the onsite emissions measurements were made by a project-supported contractor (URS Corporation). No significant differences were seen between the partner- and study-

funded onsite contractor data sets when compared against the corresponding downwind tracer flux measurements. At 13 of these stations (Table S2, Supporting Information), the partner contractor only performed a less comprehensive GHGRP-compliant onsite survey, not the more complete study onsite protocol; however, this does not appear to have made a significant difference except at one superemitter site discussed below. Differences between the two protocols are discussed in the Supporting Information.

Downwind Tracer Flux. Downwind tracer flux (or just “tracer flux”) is a technique developed to quantify the aggregate, site-level emissions of methane (or other species) from large, often complex sites with multiple leak points.^{13–15} The dual tracer flux method used here is described in detail by Roscioli et al.¹⁶ Briefly, two tracer gases (nitrous oxide and acetylene) were released at known emission rates from the target site. Each tracer was released from a single point onsite. The release points for the two tracers were separated from each other by up to 750 feet orthogonal to the wind direction so as to bracket the expected sources. The concentrations of the two tracers, methane, ethane, and other species were measured 0.5–3 km downwind of the site using high time-resolution instrumentation (1-Hz or faster, Aerodyne QC-TILDAS and/or Picarro cavity ring-down spectroscopy) deployed on a mobile sampling laboratory. Plume profiles were obtained for each facility by driving the mobile laboratory at a constant speed on a road roughly perpendicular to the wind direction. This process was repeated to obtain multiple plume transects downwind of each site; an average of eight plumes per site met study quality criteria.

The facility-level methane emission rate was calculated for each downwind plume based on the known tracer release rate and the background-corrected methane-to-tracer concentration

ratios.¹⁶ Modeling of pollutant dispersion is not required—this complexity is empirically captured by the tracers. Roscioli et al.¹⁶ describes the different types of plumes and data analysis procedures. Method assumptions and uncertainties are discussed in the Supporting Information. Each plume represents the site-wide emissions in the 1–3 min duration of each transect. While the study plan called for dual-tracer measurements at every site, instrument detection limits and malfunctions on certain days resulted in both dual-tracer and traditional single-tracer plume measurements. Multiple downwind plumes were obtained at each station providing multiple measures of the site-level emissions. The average methane emission rate for each site was calculated by averaging results from each plume weighted by plume-type-specific uncertainty ($1/\sigma^2$; see Supporting Information). The uncertainty of the site average emission rate is calculated as the unbiased sample variance of the mean (using Bessel's correction).

RESULTS

The site-level emissions data are summarized in Figure 1, panel a. The tracer flux measurements indicate that the methane emissions varied by almost three orders of magnitude across the 45 study sites. The methane emission rate from the lowest emitting site was 1.7 ± 0.2 SCFM versus 880 ± 120 SCFM for the highest emitting site (SCFM = standard cubic feet per minute at 1 atm and 15.6 °C; 1 SCFM = 19.2 g CH₄/min). The box-and-whisker plots show the distribution of emissions measured for each plume transect. At most sites, the plume-to-plume differences were small (coefficient of variation less than 20% at 35 sites, Table S9, Supporting Information), which indicates that emissions were relatively invariant in time. Therefore, the variation in emissions at a given site was much lower than variation across sites.

The ethane/methane ratio has been shown to effectively distinguish thermogenic (natural gas) methane from biogenic methane.¹⁷ Figure 2 shows excellent agreement between the ethane/methane ratio measured in the downwind plumes and gas composition data provided by the partner companies (slope 0.94 ± 0.02 , $R^2 = 0.97$, excluding one outlier). This demonstrates that the background-corrected methane measured in each plume is associated with the target facility and not some other source(s). The one outlier in this comparison (site 24) had a significant off-site source of natural gas methane that interfered with the downwind tracer flux measurements; that site is excluded from the subsequent analysis.

Although the tracer flux technique characterizes site-level emissions, it does not identify the specific sources that drive the emissions. The onsite data can address this shortcoming. However, a potential concern with onsite surveys is systematic bias due to inaccessible sources and leaks not detected, especially at large and complex compressor stations with hundreds of valves, vents, and other potential emission points. Therefore, before the onsite data are examined, we compare the SOE calculated from the onsite measurements to the tracer flux data.

Comparison of Tracer Flux and SOE. Figure 3 compares the SOE and tracer flux estimates of the site-level methane emissions at the 40 sites where valid tracer flux and onsite data were collected at the same site in the same operating state on the same day(s). The sites are grouped by compressor type and operational state; if at least one compressor was running, the site is classified as “operating.” The inset of Figure 3 shows the comparison for all 40 sites with simultaneous tracer flux and

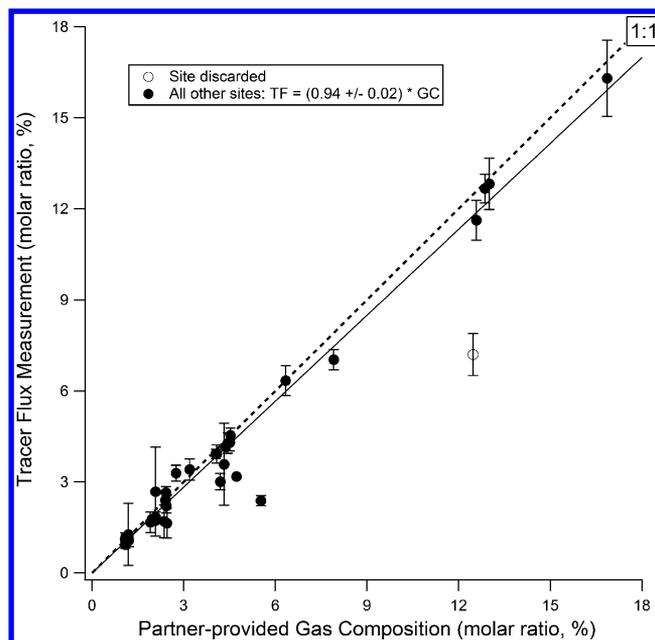

Figure 2. Comparison of ethane/methane molar ratios from partner-company-provided gas composition data with the downwind tracer flux measurements. Disregarding the one site with a known off-site interfering methane source, the two sets of data are strongly correlated ($R^2 = 0.97$).

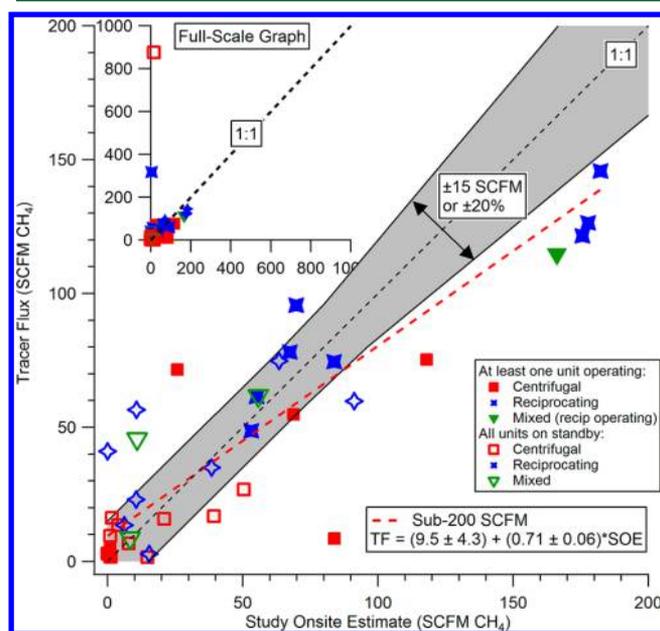

Figure 3. Comparison of the site-level tracer flux average and SOE methane emissions. The main panel shows 38 sites with emissions less than 200 SCFM, while the inset shows the full data set of 40 sites. Open symbols indicate sites where all compressors were in standby mode; solid symbols indicate sites where at least one compressor was running. Gray-shaded area indicates ± 15 SCFM or $\pm 20\%$ uncertainty bars (whichever is larger). Red dashed line is a linear fit (Deming regression) to sub-200 SCFM data.

onsite data, while the main panel shows data for the 38 sites that emitted less than 200 SCFM.

At most sub-200 SCFM sites, there is reasonable agreement between the two independent measures of site-level emissions. For example, Figure 3 shows that the onsite and tracer flux data

for the 38 sub-200 SCFM sites are scattered about the one-to-one line. At 24 of these sites, the two independent measurements agree to within ± 15 SCFM or $\pm 20\%$ (whichever is greater), and data for five other sites are within $\pm 40\%$. The average 95% confidence interval of the tracer flux data is $\pm 29\%$ (Table S9, Supporting Information). Therefore, the data from well over half the sites agree within this bound before even accounting for uncertainty in the SOE. Unfortunately, the dominant uncertainty of the SOE is likely nonparametric uncertainty of uncharacterized emissions (undetected or identified but inaccessible) rather than parametric uncertainty associated with individual measurements or instruments. This nonparametric uncertainty applies to every site (operating and standby) but is impossible to quantify. We expect that the uncertainty of the SOE at most sites to be comparable to that of the tracer flux data. Hence, the site-level emissions at essentially all the sub-200 SCFM sites likely agree within measurement uncertainty.

There appears to be a systematic trend between the two data sets for the sub-200 SCFM sites—a Deming regression yields an intercept of 9.5 SCFM and a slope of 0.71. Therefore, for this subset of sites, the tracer flux method systematically measured somewhat higher methane emission rates than the SOE at lower-emitting sites, while SOE was higher than tracer flux at higher emitting sites. No single common factor explains the discrepancies between the two data sets. Potential explanations include identified but inaccessible sources, estimated engine exhaust emissions, and potential biases in both tracer flux and onsite measurement techniques. For example, the four highest SOE sites had operating reciprocating engines (#10, #32, #44, and #45). At these sites, engine exhaust emissions estimated with AP-42 emission factors contributed 27–57% of SOE. The AP-42 emission factors may overestimate engine methane emissions at these sites; it is also possible that the downwind measurement did not fully capture lofted exhaust emissions.¹⁶ Emissions from identified but unmeasured leaks (when the emission point was not safely accessible) may be greater than the study factors used to estimate them. At some sites, the onsite team followed a GHGRP-compliant protocol (Table S2, Supporting Information) and did not measure all onsite leaks; the tracer flux data was higher than SOE at many of these sites. These and other potential factors are described in more detail in the Supporting Information.

The inset of Figure 3 indicates that the tracer flux estimate was almost two orders of magnitude larger than the SOE at two sites. At both of these sites, there were known issues with the onsite survey. Site 37 had one standby pressurized centrifugal compressor and two standby depressurized centrifugal compressors. The SOE at this site was 15 SCFM versus 880 ± 120 SCFM for the tracer flux. One of the station isolation valves at this site was frosted over and hissing, indicating a very significant leak. The onsite survey team followed a GHGRP-compliant survey and used an acoustic measurement device (VPAC) to characterize the leak at this valve, reporting a leak of only 3 SCFM. Although acoustic devices are approved by EPA to measure leaks across valves, they have been shown to substantially underestimate leak rates.¹⁰ This appears to have occurred at site 37. The other site with a very large discrepancy was site 14, a large storage facility. The SOE at this site was 4 SCFM versus 320 ± 160 SCFM for the tracer flux. This site was undergoing maintenance, during which there was significant venting of isolation valves on a pipeline from the storage field to the compressor station. However, this vent could not be

safely measured by the onsite team. Therefore, its emissions were estimated using the open ended line study factor, which likely substantially underestimated the actual venting. The partner company reported that the venting occurred for 15–20 h. The data for these two sites (37 and 14) highlight the challenges of safely performing onsite measurements of large emission sources.

DISCUSSION

Superemitters and Skewed Distributions. Figure 4, shows that the cumulative distributions of the site-level

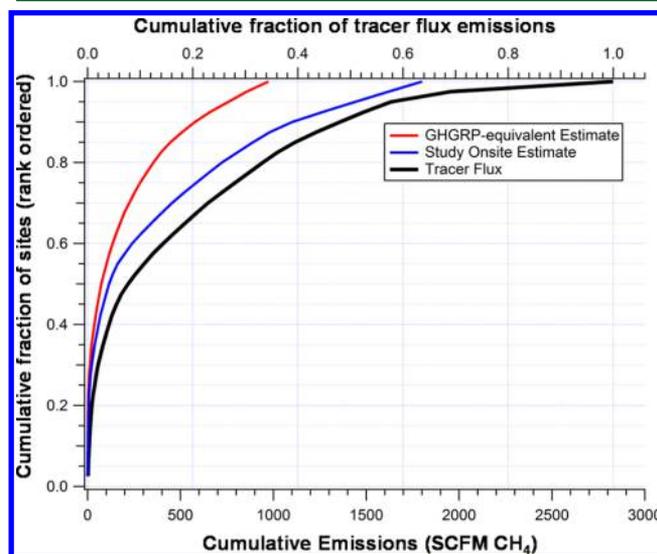

Figure 4. Cumulative distributions of site-level methane emissions from the 40 sites with both tracer flux and onsite emissions measurements obtained in the same operating state. Two different onsite estimates are shown: the SOE, which includes all measured emissions, and the GHGRP-equivalent estimates, which are based on EPA GHGRP protocols (see text for details).

methane emissions measured by this study are highly skewed with a small number of sites contributing disproportionately to the total overall emissions. For example, the highest emitting 10% of the sites contribute over 50% of the aggregate tracer flux emissions across all sites; conversely, the lowest emitting 50% of the sites contributed less than 10% of the aggregate emissions. A large fraction of this is driven by the two superemitters (sites 14 and 37) that were captured by tracer flux but not by onsite measurements. However, the SOE distribution is only modestly less skewed than the tracer flux data, with just 15% of the tested sites responsible for 50% of the cumulative SOE. Not capturing the two superemitters results in the SOE underestimating the total emissions from all sites by 35% relative to the tracer flux technique. The component-level emissions data are similarly skewed.¹²

The skewness of T&S methane emissions, which is quantified here for the first time, appears similar to other natural gas sectors. For example, 10% of the gas wells contributed nearly 70% of the emissions from 250 Texas gas wells measured as part of the Fort Worth study.^{1,9} Highly skewed emissions dominated by a small number of sites have important implications for the construction of emission inventories.⁶

Major Onsite Sources of Fugitive and Vented Emissions. Although there are differences between the tracer

flux and SOE for the 38 nonsuperemitter sites, the difference in the cumulative emissions measured by the two techniques across this subset of sites is small (9%). This means that the comprehensive onsite measurements performed by this study did not systematically miss important emission sources for this subset of sites, and that the onsite measurements can be used to identify major methane sources at these sites.

Figure 1, panel b shows the SOE for each site broken down into major source categories (data are in Tables S9 and S10, Supporting Information). The relative importance of each source category varied from site to site, and no one category was associated with every high emitting site. Compressor venting was the most important source category and contributed almost 50% of the aggregate SOE across all sites. All but two of the sites with above-average emissions had substantial compressor vent emissions. For reciprocating-only stations on standby, comprehensive onsite measurements showed significant compressor rod-packing vent emissions when at least one compressor was in the standby pressurized mode; no compressor vent emissions were observed at sites where every reciprocating compressor was depressurized. Only 14 facilities had natural-gas-driven pneumatic devices; these were not a major source of methane. There was no correlation of methane emissions with site size (as measured by either total horsepower or number of compressors). Additional discussion of the onsite data is in the Supporting Information.

The onsite measurements indicate clear trends in the study-average emissions if one controls for compressor technology (reciprocating-only versus centrifugal-only stations) or operating state (standby versus operating). Figure 1, panel b shows that sites with at least one compressor operating generally emitted more methane than sites completely on standby. Figure 5 shows that these differences are due to emissions from compressor vents and components. However, the onsite data did not capture the superemitter emissions; both superemitter sites were on standby. There are not enough data from this study to conclude whether superemitters are more commonly found in standby or operating modes.

For sites on standby, Figure 5, panel a shows that there are greater per-compressor emissions from reciprocating compressors than from centrifugal compressors, with rod-packing vent emissions from standby pressurized reciprocating compressors the main contributor to this difference. For operating sites, the emissions from centrifugal-only and reciprocating-only sites were comparable on a per-compressor basis. However, centrifugal compressors had five times the horsepower rating of reciprocating compressors in this study; therefore, centrifugal compressors have much lower methane emissions than reciprocating compressors when normalized to horsepower rating or throughput capacity. Zimmerle et al.¹² show that over the past 20 years, centrifugal compressors have become much more common in the T&S sector; therefore, these differences in methane emissions based on compressor technology have important implications for the national inventory.

Operation of reciprocating engines emitted considerably more engine exhaust methane than centrifugal compressors (Figure 1b). The study-average AP-42-based exhaust emissions for reciprocating engines were 13 SCFM/compressor versus only 0.5 SCFM/compressor for turbines.

Emissions are often expressed as a loss rate relative to the methane throughput.^{2,4,6} However, 25 of the study sites were on standby, so they had zero throughput. Figure 2 indicates that substantial (>20 SCFM) methane emissions were

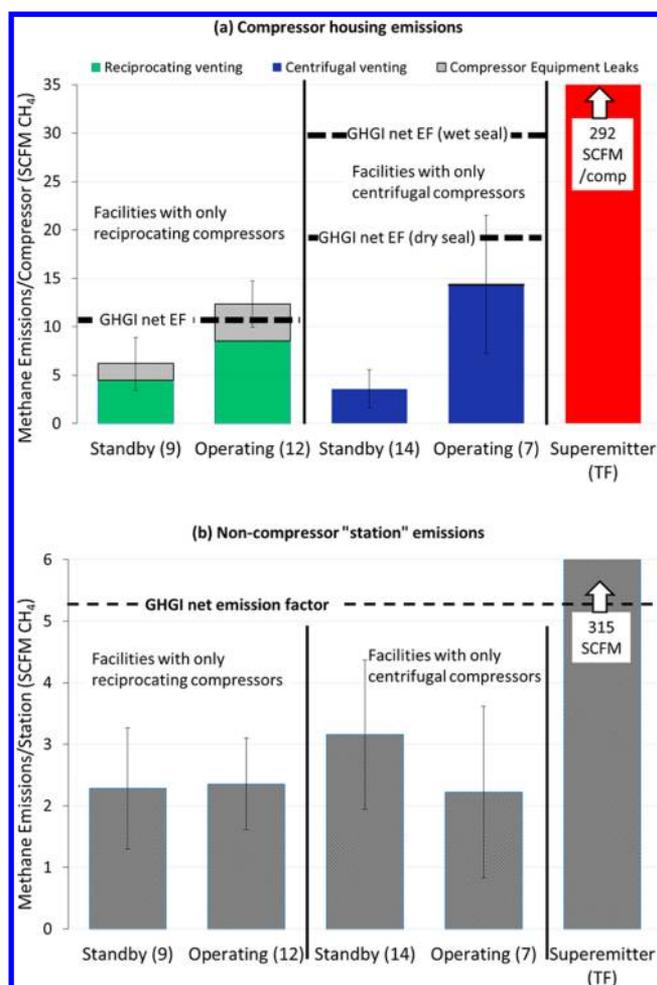

Figure 5. Study-average onsite methane emissions compared to GHGI net emission factors (EFs) for transmission compressor stations: (a) compressor housing, and (b) noncompressor sources. The left four bars in each panel are averages of onsite measurements (numbers in parentheses on the x-axis labels indicate the number of sites in each average), which did not capture the superemitter emissions. The right-most bars show tracer flux data for the two superemitter sites; these two bars extended well beyond the y-axis scales to the value listed on each panel. GHGI net emission factors for compressor stations at storage sites (not shown) are comparable or even higher than those used for transmission.¹² Both dry and wet seal centrifugal compressors were sampled in this study but are combined into one category for simplicity. GHGI net emission factors are a composite of all operating conditions, as discussed in the text. Error bars are one standard of error.

measured at about half of these sites; in fact, the two superemitter sites (site 37 and 14) were on standby. Figure 1, panel b indicates that emissions from standby sites are associated with leaky isolation valves, rod-packing vents on standby pressurized reciprocating compressors, and miscellaneous leaks from other pressurized equipment. T&S stations are often on standby in the summer when the demand for natural gas is lower. Station utilization has also been influenced by the development of new shale gas plays, such as the Marcellus, which have reduced the need to transport gas from the southeast/Texas to the northeast US.

Implications for the EPA GHG Inventory. The EPA GHG inventory for methane categorizes emissions from T&S compressor stations into compressor housing emissions,

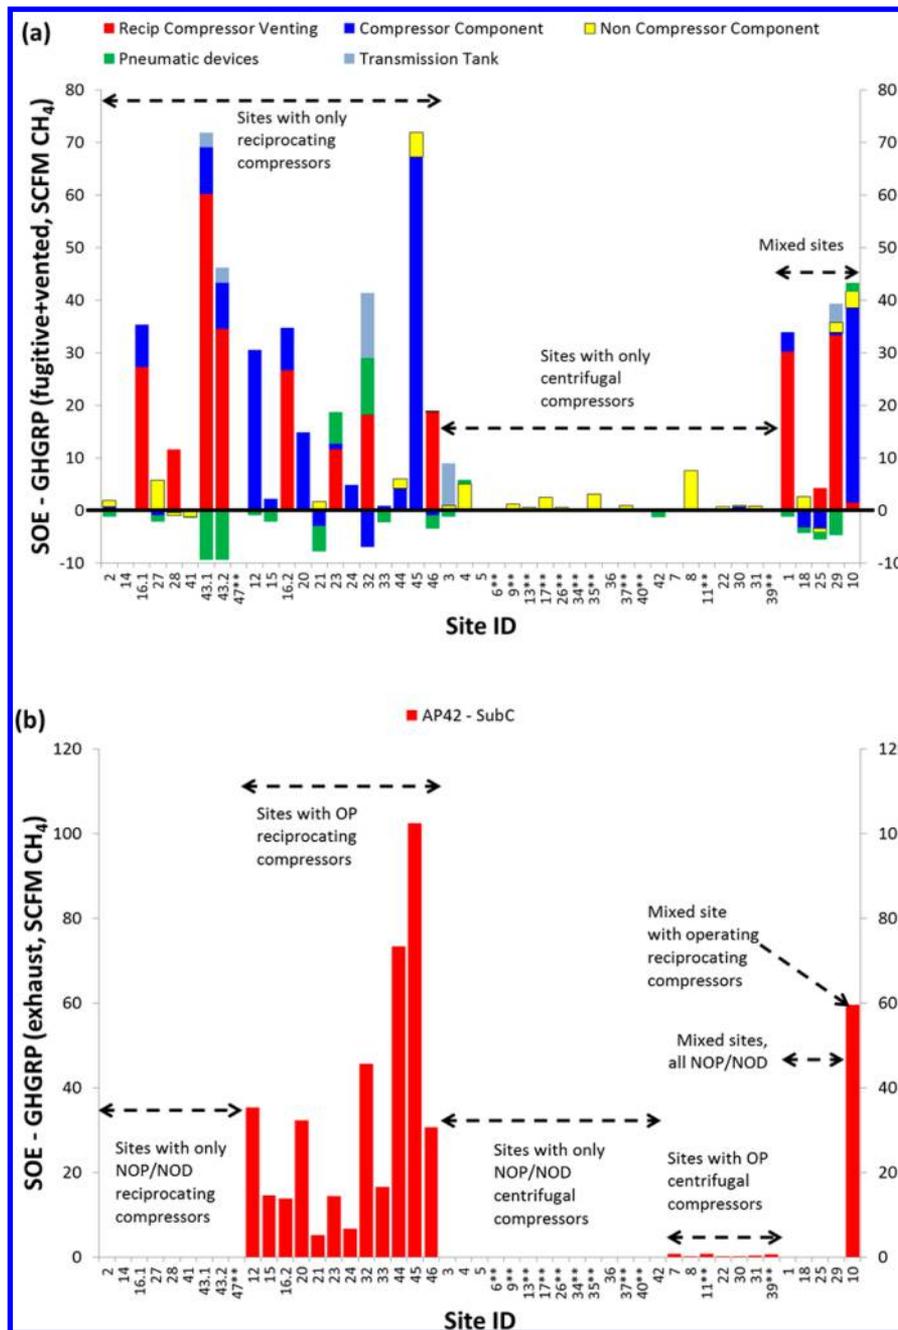

Figure 6. Differences by source category (Table S3, Supporting Information) between the SOE and the GHGRP-equivalent estimate for (a) fugitive and vented emissions and (b) turbine/engine exhaust emissions. Centrifugal compressor vents are minor (less than 0.02 SCFM per site) and therefore excluded for visual clarity in panel a. The SOE uses AP-42-based emission factors to estimate the exhaust emissions of methane, while the GHGRP exhaust emissions are based on Subpart-C. Site IDs with two asterisks indicate that the GHGRP-compliant onsite protocol was used at that site.

noncompressor “station” emissions, exhaust emissions, blow-downs, and emissions from pneumatic devices. The onsite data from this study can be used to evaluate two of these categories: compressor housing and station emissions. The EPA GHGI compressor housing emission factors are a composite of emissions from rod-packing vents (or wet seal or dry seal vents for centrifugal compressors), blowdown and isolation valves, and other compressor equipment (excluding exhaust emissions), weighted by time in operating and standby modes, by mostly using component counts and emissions measurements from the 1990s. Unfortunately, the weighting factors

used by the EPA GHGI are not well documented. This complicates making direct comparisons with the study data.

To make comparisons with our data, effective or net GHGI emission factors were derived from the 2012 GHGI by normalizing the reported net annual emissions (potential less EPA-estimated reductions) in each category by the corresponding GHGI activity. For example, in the transmission sector, GHGI estimates that 7235 reciprocating compressors emit 772.6 Gg/year of methane (activity count in Table A-129, net emissions in Table A-141 of ref 3). Therefore, the net GHGI emission factor is 107 Mg/year for each reciprocating compressor, or 10.6 SCFM (assuming 8760 h/year). The

same calculation was performed for centrifugal compressors. The EPA GHGI does not break out reductions into all categories, so reductions were proportionally distributed across the unspecified categories.¹²

To make more meaningful comparisons with the GHGI, we calculated average emissions from the study onsite data for four types of sites: reciprocating-only sites with all compressors on standby; reciprocating-only sites with one or more compressors operating; centrifugal-only sites with all compressors on standby; and centrifugal-only sites with one or more compressors operating. We also separated the study data into two categories that correspond to those used by the GHGI: compressor housing (compressor vents, valves, and other components, but not engine or turbine exhaust emissions) and station/noncompressor components (storage tanks and non-compressor housing equipment leaks). Before averaging, the compressor housing emissions from each site were normalized by the number of compressors at that site.

Figure 5, panel a compares the different study averages calculated from the onsite data for compressor components to the EPA GHGI net emission factors for reciprocating and centrifugal compressors from the transmission sector. Since the GHGI net emission factor is an annualized composite of operating and nonoperating compressors, it should be bounded by the study-average emission rates for operating and nonoperating compressors. This occurs for sites with only reciprocating compressors, which indicates that there is reasonable agreement between these two data sets for this type of compressor. However, the GHGI methane emission factors for both dry and wet seal centrifugal compressors are larger than the study-average results based on the onsite emissions measurements. The GHGI net emission factors for wet seal and dry seal centrifugal compressors are both larger than the study average of the onsite measurements at sites with operating compressors by a factor of two and 34%, respectively; the difference is even larger for study sites on standby.

Figure 5, panel b shows that study-average noncompressor methane emissions based on the onsite data are comparable across all four categories of stations, independent of compressor type as might be expected. However, the study-average data are about half the EPA GHGI noncompressor emission factor for transmission stations and one-sixth the GHGI net emission factor for storage facilities. The differences between the GHGI and study onsite data shown in Figure 5 are probably, at least partially due to technology improvements and other factors that have occurred over the past two decades.¹²

Although the comparisons with onsite data shown in Figure 5 suggest that the EPA GHGI may overestimate emissions from certain source categories, these comparisons exclude the contribution of the superemitter emissions, which were only measured by the tracer flux method. The superemitter emissions are shown using separate bars in Figure 5. Figure 5, panel a shows tracer flux data from site 37, since the high emissions at this site were likely from the compressor housing; Figure 5, panel b shows tracer flux data from site 14, where the superemitter venting was yard piping ("station" emissions). Average emissions based on this study would likely exceed the EPA GHGI net emission factors if these superemitter emissions were included in the analysis. For example, that could happen if superemitter emissions similar to those shown in Figure 5 occurred at a few percent of sites nationally. However, we lack the data to determine whether the magnitude and frequency of

the superemitters encountered in this study are representative of the entire T&S sector.

Implications for the EPA GHG Reporting Program. In 2011, the EPA started requiring compressor stations in the T&S sector that emit more than 25,000 MT-CO₂e to report their methane emissions under the EPA GHGRP, which is by far the largest effort to date to collect methane emissions data from the T&S sector. These publically available data will likely be a critical input for the next generation of methane emission inventories. The comprehensive onsite measurements in this study can be used to construct a GHGRP-equivalent estimate for the methane emissions from each study site to evaluate the GHGRP protocols.

The GHGRP-equivalent estimate uses the Subpart-W methodology for onsite fugitives and venting and Subpart-C emission factors for engine/turbine exhaust emissions. Briefly, Subpart-W estimates emissions from leaking components are based on leaker counts and emission factors; it excludes emissions from sources in certain operational modes, specifically rod-packing vent emissions from standby pressurized reciprocating compressors. Subpart-C uses a single emission factor for all engines/turbines irrespective of the prime mover type, unlike AP-42, which has specific emission factors depending on engine type (rich burn or lean burn, two-stroke or four-stroke reciprocating engines, and turbines). Methodological differences between the GHGRP-equivalent estimate of site-level emissions and SOE are summarized in Table S3 of the Supporting Information.

Figure 6 shows the source-category-by-source-category differences between the SOE and the GHGRP-equivalent estimate across all study sites. The aggregate SOE for the 45 sites was 2097 SCFM versus only 1148 SCFM for the aggregate GHGRP-equivalent estimate. Since only 25 sites exceed the annual 25,000 MT-CO₂e GHGRP reporting threshold (which is largely determined by fuel combustion CO₂, not methane), the aggregate GHGRP-equivalent methane emissions drop further to 790 SCFM. Therefore, only 38% of the aggregate SOE would be reported under the current EPA GHGRP rules. In addition, the onsite measurements did not capture the two superemitters, so the bias is even larger relative to the total emissions. Only 27% of the aggregate tracer flux methane emissions would be reported under the current GHGRP due to a combination of the GHGRP rules, the GHGRP reporting threshold, and gaps (superemitters) in the onsite measurements.

The 45% difference between the aggregate GHGRP-equivalent estimate and the aggregate SOE for all study sites was almost evenly divided between fugitive/vented emissions and exhaust emissions. Figure 6, panel b indicates that there are very large differences between the AP-42 and Subpart-C methane emission factors for reciprocating engines (0.8 SCFM for Subpart-C versus 451 SCFM using AP-42 emission factors). Therefore, Subpart-C significantly underestimates the unburned methane in reciprocating engine exhaust emissions. Reciprocating engines, in particular two-cycle engines, can emit significant methane due to cyclic combustion, piston ring blow-by, etc.,¹⁸ while modern turbine combustors operate with 99% or higher combustion efficiency.¹⁹

Figure 6, panel a shows large differences between the GHGRP-equivalent estimate and the SOE for fugitive/vented emissions. A major cause of this difference is that the EPA GHGRP does not (as of 2014) require reporting of rod-packing vent emissions from standby pressurized reciprocating

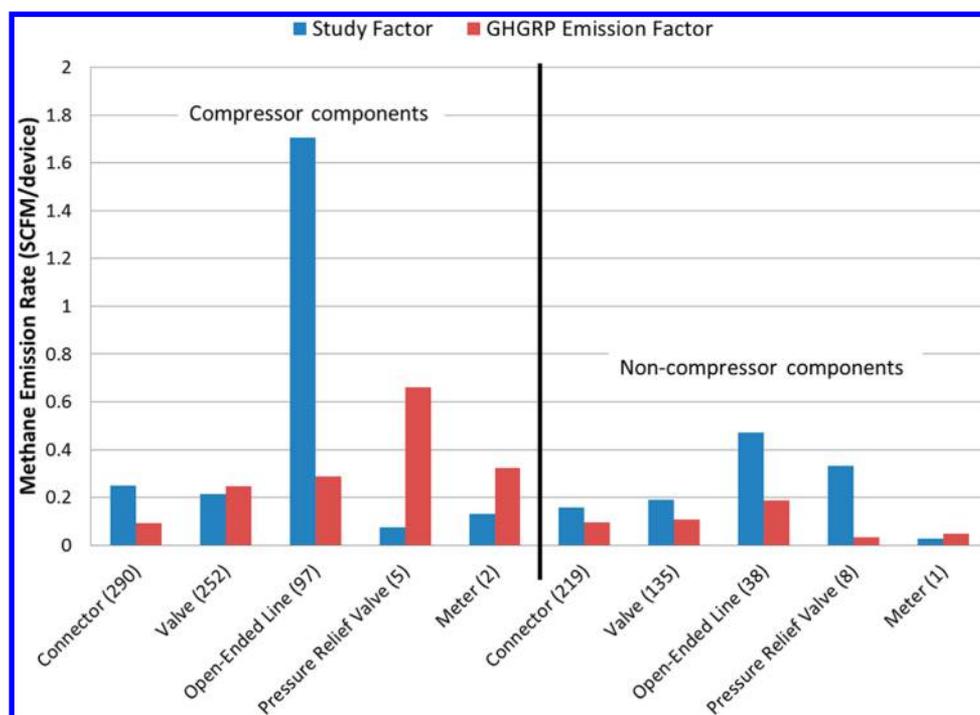

Figure 7. Comparison of the study-average emissions factors (study factors) with the EPA GHGRP emission factors for compressor and noncompressor component sources. Numbers in parentheses on the *x*-axis labels indicate number of study measurements in each category.

compressors. These vents contributed 273 SCFM (13%) to the aggregate SOE and therefore represent an important gap in the GHGRP protocol. Outdated GHGRP emission factors for component leaks account for most of the remaining gap between the measured fugitive/vented emissions and the emissions reportable under GHGRP. For example, Figure 7 indicates that the study-average emission factor for compressor connectors is three times the GHGRP emission factor; the study-average emission factor for open-ended lines is six times larger than the GHGRP emission factor. The study average measurements of leaks from noncompressor connectors and open-ended lines are also larger than the corresponding GHGRP emission factors.

The EPA GHGI does not yet utilize the information in the GHGRP database. This database provides valuable new information on the T&S sector in terms of compressor types, component counts, and other activity factors that are relevant to an emissions inventory. However, before using the GHGRP for inventory calculations, one must account for all the biases and uncertainties in the emissions data shown in Figures 4 and 6; this is done by Zimmerle et al.¹² The value of the GHGRP data for emissions inventory development would be improved by requiring more direct measurements of emissions (as opposed to using counts and emission factors), avoiding the use of acoustic devices, eliminating exclusions such as rod-packing vents on standby pressurized reciprocating compressors, and using more appropriate emission factors for exhaust methane from reciprocating engines.

S Supporting Information

ABSTRACT: Facility-level methane emissions were measured at 114 gathering facilities and 16 processing plants in the United States natural gas system. At gathering facilities, the measured methane emission rates ranged from 0.7 to 700 kg per hour (kg/h) (0.6 to 600 standard cubic feet per minute (scfm)). Normalized emissions (as a % of total methane throughput) were less than 1% for 85 gathering facilities and 19 had normalized emissions less than 0.1%. The range of methane emissions rates for processing plants was 3 to 600 kg/h (3 to 524 scfm), corresponding to normalized methane emissions rates <1% in all cases. The distributions of methane emissions, particularly for gathering facilities, are skewed. For example, 30% of gathering facilities contribute 80% of the total emissions. Normalized emissions rates are negatively correlated with facility throughput. The variation in methane emissions also appears driven by differences between inlet and outlet pressure, as well as venting and leaking equipment. Substantial venting from liquids storage tanks was observed at 20% of gathering facilities. Emissions rates at these facilities were, on average, around four times the rates observed at similar facilities without substantial venting.

■ INTRODUCTION

Methane is the primary component of natural gas; it is also a potent greenhouse gas (GHG). The Environmental Protection Agency (EPA) estimates that the natural gas system contributes 23% of U.S. anthropogenic methane emissions.¹ However, there are discrepancies between recent studies and EPA GHG inventories in some natural gas producing areas.^{2–4} The EPA GHG inventories largely rely on data collected in the early 1990s⁵ and may not reflect recent changes in technology, operations, and regulation. New measurements are needed to characterize methane emissions from the natural gas system.

This study investigates the methane emissions from natural gas gathering and processing (G&P) facilities, which, collectively, gather natural gas from production wells, remove impurities, and deliver it to inter- and intrastate pipeline networks. We define gathering and processing as the equipment and pipeline network between the sales points at well pads and downstream delivery points. This includes gathering pipelines, and the equipment at gathering facilities: compressors (driven by electric motors (“motors”) and/or natural gas-fired internal combustion engines (“engines”) or turbines), dehydration

systems to remove water, and treatment systems to remove hydrogen sulfide and/or carbon dioxide. Processing plants often house this equipment on a larger scale, acting as central nodes in a system of smaller gathering facilities. Processing plants also separate natural gas liquids (NGLs) (such as ethane, propane, butane, and heavier hydrocarbons) from methane. For this study, processing plants are defined as the facilities that meet the 40 CFR Part 60 Subpart KKK definition of “natural gas processing plant” based on the presence of NGL extraction. Facilities that only fractionate NGLs were not included in this study.

This paper presents facility-level measurements of methane emission rates at 130 G&P facilities (114 gathering and 16 processing). A mobile laboratory was used to perform downwind tracer flux measurements, which is an established technique to estimate the total emissions of methane (or other

species) from complex facilities with multiple emission points.^{6–8} Onsite observations with an infrared camera were used to identify emission sources. Companion papers describe the downwind tracer flux methodology and its application to this study⁹ and scaling of these data to estimate emissions for all U.S. G&P facilities.¹⁰

2. METHODS

Downwind tracer flux measurements were conducted at 136 G&P facilities between October 2013 and April 2014. Measurements were successful at 130 G&P facilities. These facilities are located in top gas producing states (including all of the top ten) and basins (Figure 1). The sampled facilities were operated by five natural gas midstream “partner” companies, which provided access and facility data to the study team. The project only investigated emissions from G&P facilities, not the gathering pipeline network that connects these facilities.

2.1. Selection of G&P Facilities for Measurement. The sampling strategy sought to obtain methane emissions data from a wide range of G&P facilities, which vary by age (reflecting technological and regulatory changes), inlet gas composition/pressure, regulatory environment, and regional/local and/or corporate design and operations. In most states, the basic census data needed to design a sampling program that systematically captures variation among G&P facilities are lacking. Therefore, the study team sought to replicate the diversity among G&P facilities owned by the five partner companies. They operate more than 700 gathering facilities and 27 processing plants in all regions of the country—roughly one-quarter and 5%, respectively, of all gathering and processing facilities nationally (Supporting Information (SI) A). All of these facilities were considered by the study team in developing the project sampling plan. This plan sought to (1) sample at the maximum number of processing plants, (2) maximize the number of successful measurements in the top gas producing

regions and across all major gas types (e.g., shale, coal bed methane, etc.), and (3) sample a distribution of facility types representative of the partner company assets.

Details of the facility selection procedures are in SI A. Briefly, the study team was provided a list of all partner company G&P assets (>700 facilities). The study team performed desktop screening of the facilities using aerial imagery (Google Earth) to remove facilities with limited road access on their periphery (desired range of 0.5–2 km) or facilities that were located near obvious potential sources of methane interference. The list of prescreened facilities was then shared with partner companies, with a request for additional feedback regarding potential issues with road access or nearby nonpartner facilities, as needed. Over the course of the field campaign, fewer than ten facilities were removed from the prescreened lists by request of the partner companies. Reasons for removal included issues such as commissioning, decommissioning, transactions (sale of asset), construction, or litigation. Final selection for most gathering facilities was made by the study team from the prescreened list the evening before or the day of sampling, considering road access, wind forecasts, and logistics. Sampling at processing plants was scheduled in advance to align with operator and operations schedules.

The tracer teams were usually escorted to the target facilities by a company representative who was instructed to continue normal operations of the facility. At 14 facilities the study team onsite observer noted that the company personnel adjusted processes or fixed equipment during the sampling, presumably these changes were performed as part of normal operations (SI E). At only one facility (#44) did a tracer team note changes in facility operation that were likely not normal practice as the changes were undone after measurements had been completed. Company representatives were notified. All indications are that this was an isolated occurrence.

Partner company gathering assets were classified based on three equipment-specific functions in gathering systems

Table 1. Summary of Sampled Facilities and Partner Assets (total and %) by Facility Type^a

| | facility type | | | | | | | | | | | |
|----------------|---------------|-----|-----|-----|-------|----|----|----|-----|----|----|-----|
| | C | | C/D | | C/D/T | | D | | D/T | | P | |
| sampled | 34 | 26% | 66 | 51% | 8 | 6% | 5 | 4% | 1 | 1% | 16 | 12% |
| partner assets | 267 | 36% | 379 | 51% | 16 | 2% | 23 | 3% | 28 | 4% | 27 | 4% |

^aC, compression only; C/D, compression and dehydration; C/D/T, compression, dehydration, and treatment; D, dehydration only; D/T, dehydration and treatment; and P, processing.

(compression (“C”), dehydration (“D”), and treatment (“T”)) into five facility types (C, C/D, C/D/T, D, and D/T). Table 1 summarizes facility types sampled by the tracer teams compared to all partner company G&P assets as of August 2013. The distribution of facility types sampled in this study closely resembles the partner assets. The study facilities are also similarly proportioned to lower-48 U.S. gas production:¹¹ Fifty-two percent of the study facilities handled shale gas, 32% conventional, 8% coal-bed methane, 6% tight sands, and 2% offshore.

Detailed information on all 130 G&P facilities is included in SI B, Tables S1–S3. Sampling was conducted at 34 C facilities, which had reciprocating and/or centrifugal compressors. Engines were the primary driver at 31 of the C facilities. Scrubbers, strainers, filter separators, and/or coalescing filters were usually installed upstream of compressors. Produced water and condensate removed from the gas stream were stored in tanks onsite. Air and/or gas pneumatic devices (e.g., liquid level controllers) were also present at all G&P facilities.

Sampling was conducted at 66 C/D facilities, which had dehydration equipment installed downstream of compressor(s) to remove vapor-phase water from the pressurized gas stream, reducing problems with hydrate formation and corrosion.¹² These were typically glycol dehydration systems which operate by contacting the gas stream (via absorbers) with a hydroscopic solvent (usually triethylene glycol), which is regenerated (by heating) and reused.¹³

Sampling was performed at five D only facilities, which represent 4% of partner gathering assets. These removed vapor-phase water from gas produced at nearby wells that had sufficient pressure to move downstream without compression.

Treatment (T) equipment was installed at gathering facilities that handle a raw gas stream rich in acidic gases, carbon dioxide (CO₂) and/or hydrogen sulfide (H₂S). Acid gas removal is based on absorption with one or more amine variants, separation, and regeneration of the amine solution. Treatment equipment were utilized at 6% of partner facilities. Eight C/D/T facilities and one D/T facility were sampled, representing 6% and 1% of study facilities, respectively.

Processing plants (P) are central nodes in most producing areas. They are generally much larger than the typical gathering facilities and are staffed by operators 24 h a day. Compression, dehydration, and treatment equipment are typical for processing plants. These plants also include equipment to separate natural gas liquids from the methane gas stream, such as cryogenic turboexpander and refrigeration skids. These plants will sometimes use fractionation processes to further separate high-value natural gas liquids into separate components of ethane, butane, propane, and hydrocarbons larger than pentane. The study team ruled out conducting measurements at 11 (out of 27) processing plants mainly due to the presence of interfering natural gas facilities (usually other processing plant(s)) owned by a different company.

Figure S1 (SI C) compares facility throughput, inlet and outlet pressure, and total horsepower for C, C/D, C/D/T, and P facilities. The C facilities included in this study had generally lower throughput, inlet and outlet pressures, and horsepower than the other types of facilities with compressors. Methane content ranged from 59% to 98% (mol/mol) across all facilities, but was not related to facility type. Gas composition data are summarized in SI C, Figure S2.

Despite efforts to prescreen facilities, the study team conducted measurements at 29 facilities that were either collocated (e.g., on the same pad or side-by-side) with nonpartner equipment or adjacent to other natural gas facilities. Nonpartner equipment was generally associated with gas production (e.g., wellheads, produced water and/or condensate tanks, flares, etc.). Both infrared camera surveys and proximal mobile lab measurements (immediately downwind of equipment) were performed to assess potential contribution of nonpartner equipment. At most facilities with nonpartner equipment, the methane contribution from such equipment appeared to be negligible in comparison to partner-operated equipment. Therefore, methane emissions estimates have not been modified to account for potential emissions from collocated nonpartner equipment. Facilities with collocated equipment and information on this equipment are summarized in SI D, Table S4.

2.2. Tracer Flux Measurements and Facility Survey.

Roscoli et al.⁹ describes the tracer flux methodology used by this study in detail. Briefly, at each facility, two tracer gases (nitrous oxide and acetylene; both chosen based on their availability and ability to be measured at high time-resolution) were released at known flow rates from points configured to bracket the target facility’s emissions relative to prevailing wind direction (SI G, Figure S3). Concentrations of methane, ethane, acetylene, nitrous oxide, carbon monoxide, and carbon dioxide were measured using a mobile laboratory equipped with high time resolution instrumentation (1-Hz or faster, Aerodyne QC-TILDAS and/or Picarro cavity ring-down spectroscopy).⁹ Measurements were made immediately upwind of each target facility to check for background contamination. Methane plumes were measured approximately 0.5–3 km downwind from the target facility. Multiple plume profiles, each about 30–120 s long, were obtained for each facility by driving the mobile laboratory at a constant speed on a road roughly perpendicular to the wind direction. When the winds were highly variable, plumes were sometimes measured while the mobile lab was stationary. Downwind measurements in the mobile lab were performed over 1–5 h period at most facilities.

While tracer flux measurements were being performed, a dedicated member of the study team served as an “onsite observer,” who documented the initial operating state of the facility and any changes or repairs that were made (SI E, Table S5). The onsite observer also performed a comprehensive survey of the facility, including recording an equipment census (operational state and characteristics such as horsepower), and

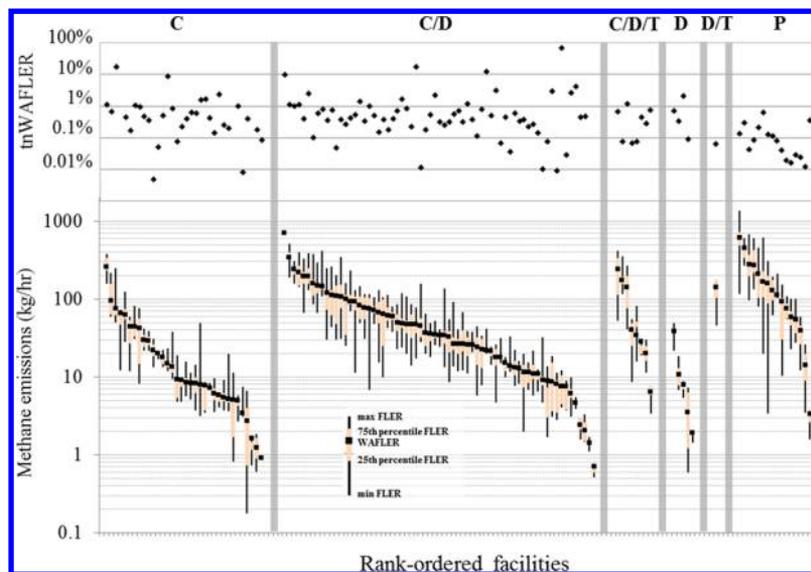

Figure 2. Tracer flux-based facility-level methane emission rates (FLER) for 130 G&P facilities. Facilities are sorted by type (C, D, C/D, etc.) and then rank ordered by WAFLER (square) within each facility type. Emissions are presented in log scale. The vertical boxes represent the 25th and 75th percentiles of FLER data at a facility; whiskers represent the min and max. Throughput-normalized methane emissions rates (tmWAFLER) for 124 facilities (as % CH₄ throughput on the day of sampling) are presented in the top panel in log scale.

readings of facility throughput, inlet and outlet gas pressure (SI B, Tables S1–S3). At 108 of the gathering facilities, the onsite observer also performed an infrared camera survey of all equipment to identify and document potential sources noncombustion methane emissions (SI F, Table S6). Gas composition data (% methane, ethane, etc.) were obtained from company records (SI B, Table S1).

2.3. Analysis of Tracer Flux Data. The tracer flux data were analyzed systematically to quantify the methane emission rate, ensure proper attribution of methane emissions to target facility, and validate codispersion of tracer(s) with methane. The methane facility-level emission rate (FLER) was calculated for each downwind plume based on tracer release rate and the background-corrected methane-to-tracer concentration ratios.⁹ No modeling of pollutant dispersion is required—that complexity is empirically captured by the tracers. Therefore, the FLER is an estimate of the aggregate (or total) methane emissions from the target facility during a 30–120 s period (the typical duration of a plume transect). Roscioli et al.⁹ describes the types of plumes measured, the acceptance criteria, and the process used to analyze each plume.

Multiple downwind plumes were obtained at each facility and the FLER was estimated for each plume. The weighted-average FLER (WAFLER) was calculated by weighting each FLER estimate by its estimated plume-specific uncertainty ($1/\sigma^2$), providing more weight to the plume types meeting the most stringent acceptance criteria.⁹ The weighted sample variance of WAFLER was divided by a correction factor $[1 - ((\sum_{i=1}^n w_i^2) / (\sum_{i=1}^n w_i)^2)]$ to obtain the unbiased weighted sample variance, where w_i represents the weight of each plume. Complete results, including number of accepted plumes, distance downwind, 25th, 75th, minimum and maximum FLER, WAFLER, and the unbiased standard deviation of WAFLER are in SI H, Tables S7–S8. All emissions results are presented as grams CH₄ (19.26 g per standard cubic foot CH₄ at 15.6 °C and 1 atm¹⁴).

Sampling occurred at one gathering facility in two distinct operating states, before and after substantial venting from a

pipe at the top of a tank storing liquids was stopped. The venting was stopped by closing a dump valve on the first stage scrubber that was stuck open. Two WAFLER estimates are reported for this facility (#s 35 and 59), based on the before and after measurements, respectively.

The tracer flux method assumes that the tracer gases codisperse with the methane being emitted from the target facility. Since the tracer release points were set up to bracket the facility, the use of two tracers provides a stringent test on the horizontal dispersion of the emissions. 75% of accepted plumes were dual tracer, covering 112 facilities (83% of the gathering facilities and 100% of the processing plants). Codispersion of tracer gases with methane emissions from elevated vents, flares, and exhaust stacks in the vertical plane is more difficult to verify. Roscioli et al.⁹ modeled tracer codispersion with the exhaust of natural gas-powered engines and turbines using Gaussian dispersion modeling with Briggs plume rise equations.^{9,15} Exhaust is discharged at high temperatures (up to 540 °C) and high velocities (up to 45 m/s). A conservative, worst-case analysis suggests the potential bias in WAFLER from low recovery of methane emissions in engine or turbine exhaust is small (<30%) for almost four-fifths of the G&P facilities in this study (SI J). Processing plants (but typically not gathering facilities) can also have elevated flares, vents, or other emissions sources; the potential bias due to partial recovery of methane from these sources was not examined in this study.

3. RESULTS

The study team recorded more than 1400 plumes which passed the acceptance criteria⁹ and therefore provided a valid measure of the facility-level emission rate (FLER) of methane. Roscioli et al.⁹ provides plots of example plume profiles. Within a plume, methane concentrations are tens to thousands of ppbv above background. The average number of plumes per facility is 11 with a range of 2–42. Each plume provides a short snapshot of the facility-level emissions over the duration of the plume transect (30–120 s). The plume-to-plume differences in the

FLER values provide a measure of the variability of the methane emissions at a given facility.

Figure 2 presents box-and-whisker plots of the accepted plumes for all 130 facilities (131 WAFLEs). The facilities have been sorted by type (C, D, C/D, etc.) and then rank ordered by WAFLE within each facility type. Methane (CH₄) throughput (tonnes/h) was calculated from natural gas throughput (tonnes/h) recorded onsite and the inlet gas composition data provided by the companies. The CH₄ throughput-normalized WAFLE (tnWAFLE), ratio of WAFLE to the CH₄ throughput, is also plotted in Figure 2 for 124 facilities (125 tnWAFLE estimates; five facilities had zero throughput and no throughput data were recorded at one facility).

Across all 114 gathering facilities, WAFLE ranged from 0.7 to 700 kg/h, while tnWAFLE ranged from 0.004% to 70% for the subset of the facilities with nonzero/known CH₄ throughput ($n = 108$). The WAFLE estimates varied widely within and across facility types. However, in general, the plume-to-plume variability in FLER estimates at a given facility is relatively small; the median relative standard deviation or coefficient of variation (CV) is 0.36 and more than two-thirds of the facilities had CVs less than 0.5. This suggests that the emissions from most facilities were relatively stable over the several hour measurement period. The CV at 11 facilities is >0.8. Large CVs may be associated with intermittent sources (e.g., pressure relief valves) and/or changes in facility operation. For example, FLER estimates at Facility #102 (CV 0.62) were much higher after the onsite observer documented increased flame height and smoke production at the flare as well as significant flashing events at the condensate tank batteries. This facility was shut down for maintenance after measurements were completed. At five facilities, a brief methane release event was observed which was associated with specific operations such as a compressor blowdown or startup. All of these events that were measured are cataloged in SI Table S9. They only occurred for a small fraction of the overall measurement period and therefore were not included in the WAFLE calculations.

WAFLE estimates for C/D and C/D/T are higher than those C and D facilities. For example, the median WAFLE for C and D facilities are 8.8 and 7.8 kg/h, respectively, while those of C/D and C/D/T facilities were 35 and 37 kg/h, respectively. However, across the gathering facility types there are no systematic trends in the tnWAFLE because C/D and C/D/T facilities also have higher throughputs. Median tnWAFLE for C, C/D, C/D/T, and D facilities are 0.46, 0.45, 0.36, and 0.51% of CH₄ throughput, respectively.

Figure 2 indicates that methane emissions are generally a small fraction of CH₄ throughput. tnWAFLE is less than 1% at 85 (out of 108) gathering facilities and less than 0.1% at 19 of them. tnWAFLE exceeded 5% at six gathering facilities (two C and four C/D). Five of these had very low CH₄ throughput (<0.5 tonnes/h). The exception is facility #35 (throughput: 7.7 tonnes/h), which was venting a substantial amount of gas when sampling started. At facility #94, which had the highest tnWAFLE (70%) and the lowest throughput (1.4 × 10⁻² tonnes/h), a substantial leak from a pipe union was observed.

Median WAFLE and tnWAFLE of the 16 processing plants are 120 kg/h and 0.079%, respectively. With one exception, the processing plants were high CH₄ throughput facilities, averaging 250 tonnes/h on the day of measurements (range 1.6–780 tonnes/h; SI B, Table S2). WAFLE at processing plants ranged from 3 to 600 kg/h. tnWAFLE for

processing plants were lower than for gathering facilities, ranging from 0.012% to 0.62% of CH₄ throughput.

Partial recovery of lofted emissions is a concern at processing plants, most of which had high flares as well as elevated exhaust stacks, vents, and other components that may emit methane. Using previously mentioned dispersion modeling, we estimate that, under conservative, worst case assumptions, only two (out of 16) processing plants may have >30% bias in WAFLE due to low recovery of uncombusted methane in engine and/or turbine exhaust (facility #'s 123 and 126, SI J). The potential bias due to low recovery of exhaust methane at processing plants is lower than gathering facilities because the majority of the compression power at processing plants in this study was provided by turbines or motors, which have much lower exhaust methane emissions than engines.^{16,17} For example, all of the compressors at four other processing plants were driven by either turbines (facility #'s 118, 127, and 129) or motors (facility #125). Therefore, low recovery of exhaust methane for these plants is a small issue despite the fact that all of the tracer flux measurements were performed <0.5 km downwind from these plants, which was not optimal for codispersion of lofted methane and tracers. A larger concern may be methane emissions associated with high flares and elevated vents or leaks, but these have not been investigated by this study.

The cumulative methane emissions rate summed across all 114 gathering facilities in this study was 6300 kg/h with a cumulative tnWAFLE (\sum WAFLE/ \sum CH₄ throughput) of 0.20%. Cumulative methane emissions from all 16 processing plants was 2,700 kg/h, with a cumulative tnWAFLE of 0.075%. Accounting for potential biases in WAFLE due to uncombusted methane emissions from gas-driven engines and turbines only has a small impact on cumulative emissions (SI J). For example, adding the conservative, worst-case estimate of unrecovered exhaust methane to WAFLE would lead to cumulative methane emissions from all gathering facilities to 7400 kg/h, versus 6300 kg/h previously, and increase the cumulative tnWAFLE from 0.2% to 0.24%. Unrecovered exhaust methane emissions from processing plants would increase from 2700 kg/h to 3100 kg/h, and cumulative tnWAFLE would increase from 0.075% to 0.085%. While recovery of methane emissions from high flares or elevated sources common at processing plants is uncertain, it seems unlikely that such emissions could be large enough to significantly alter normalized emissions at high-throughput processing plants.

Five gathering facilities (#4, 28, 32, 100, and 101) had zero throughput, but were still emitting methane (65, 5.1, 1.6, 1.4, and 0.7 kg/h, respectively). The highest WAFLE (65 kg/h) at a zero-throughput facility was attributed to atmospheric venting from two liquids storage tanks via infrared camera survey. Unlike the other zero-throughput facilities, facility #4 was flowing gas before measurements began. Emissions at the other zero throughput facilities were observed from various sources, including venting from a liquids storage tank and an engine fuel purge (facility #28) and a broken hose leading to a nonoperational pressurized (NOP) compressor (facility #32). The only sources of methane emissions observed at facility #101 with the infrared camera were collocated nonpartner equipment (a dehydration unit and a fuel scrubber).

4. DISCUSSION

4.1. Comparison to Existing G&P Emissions Data.

Relatively little data have been published on methane emissions

from G&P facilities. One of the GRI/EPA studies reported methane emissions at seven processing plants in the TX/LA and West regions.^{8,18} More recent measurements, using comprehensive onsite measurements (including exhaust methane), have been made at nine processing plants.^{19,20} The reported methane emissions rates ranged from 45 to 840 kg/h (this study: 3–600 kg/h CH₄). The cumulative throughput-normalized methane emissions rate was 0.16% versus 0.075% for the 16 plants reported here. Higher normalized emission rates were reported in the GRI/EPA study, which also used the tracer flux method. The cumulative methane emissions rate normalized by cumulative plant capacity (throughput data were not given) for the GRI/EPA data was 0.38%. This is likely a lower bound estimate because processing plants may operate below rated capacity.

Even fewer data are available for gathering facilities. The GRI/EPA study measured methane emissions from two gathering facilities of 86 and 120 kg/h (this study: <1 to 700 kg/h CH₄). No throughput or capacity data were reported for GRI/EPA facilities, precluding comparison of normalized emission rates. Measurements were performed at seven gathering facilities between 2004 and 2005, but only summary data were reported.²⁰ The raw data from previous studies are reproduced and additional comparisons are made in SI K.

All of the processing plants included in this study have reported methane emissions to the EPA greenhouse gas reporting program (GHGRP, 40 CFR 98, Subpart W and Subpart C). Valid comparisons of WAFLER to GHGRP are not possible due to a range of issues in how emissions are calculated under GHGRP. For example, GHGRP does not require reporting of all onsite methane emissions sources (including tanks, acid gas removal units, and gas-driven pneumatics); it excludes other sources in certain operating modes, such as rod-packing vents from NOP reciprocating compressors; and it includes blowdown emissions.²¹ Furthermore, combustion emissions reported under Subpart-C may not provide a realistic characterization of uncombusted methane from operating engines.²²

4.2. Sources of Methane Emissions. Figure 3 indicates that there is some relationship between WAFLER and tnWAFLER and facility natural gas throughput. The absolute methane emissions are generally higher at facilities with larger throughput, but the normalized methane emissions rates (tnWAFLER) generally decrease with increasing natural gas throughput. The opposite relationship of WAFLER and tnWAFLER with throughput (Figure 3) indicates that some of the methane emissions are likely independent of throughput. A leak, for example, may emit the same amount of methane whether the facility is at full or partial capacity.

One-third of the variance ($r^2 = 0.38$) in WAFLER is explained by linear regression with throughput, Figure 3(a). Although throughput explains some of the trend in the emissions data, WAFLERs vary by about an order of magnitude at facilities handling similar volumes of gas. This underscores that there are many factors influencing emissions. Numerous noncombustion emissions sources were documented by the onsite observer via infrared camera survey, which was conducted at 108 gathering facilities (infrared cameras were not used at processing plants, which are subject to regular leak detection and repair (LDAR) for regulatory compliance). Observable emissions sources (leaking and/or venting) were noted at 71 out of 108 gathering facilities (SI F, Table S6). This included venting (flashing and off-gassing) from liquids storage

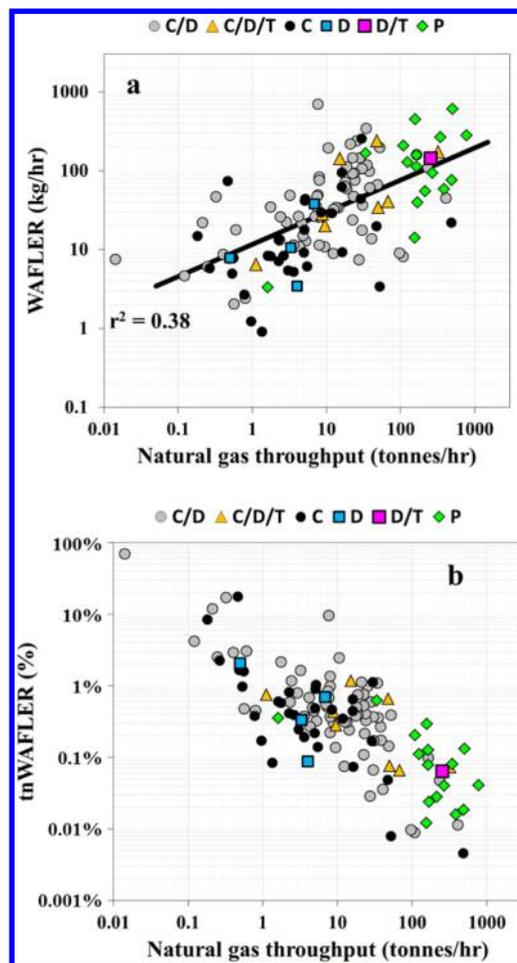

Figure 3. (a) WAFLER and (b) tnWAFLER (% CH₄ throughput) versus reported natural gas throughput on the day sampling was conducted in log–log scale. The line in (a) is a linear regression of the data.

tanks at 48 facilities, leaking or venting from compression equipment at 42 facilities, and gas pneumatics at 28 facilities.

On the basis of the infrared camera videos and other onsite information, a subset of the observed noncombustion emission sources have been classified as substantial (SI M, Tables S17 and S18). These specific sources appeared to be emitting substantially more methane than other sources of the same type (e.g., valves and vents). Since the infrared camera only provides a qualitative indication of the magnitude of the emissions, classification of a source as substantial also involved discussion with company representatives and, if possible, proximal methane measurements using the mobile laboratory. The onsite observer and/or company representative was often able to identify the substantial emission sources without the aid of an infrared camera.

Venting from liquids storage tanks was the most common noncombustion source classified by the onsite observer. It is normal for some flashing or off-gassing from stored liquids to occur. Tank venting, however, may not have always been caused by an issue with the liquids storage tanks themselves, but to a problem elsewhere on the facility (e.g., the stuck dump valve mentioned earlier) that was connected to the tanks. Of the 48 gathering facilities with observable venting from liquids storage tanks, substantial venting from tanks was observed at 23 (SI M). Abnormal process conditions were identified at six of

the 23 facilities. Through the strategic placement of the tracer release locations, the methane emissions rates from liquids storage tanks were estimated at five facilities with substantial venting. These tank-related methane emissions ranged from around 10 to 650 kg/h (SI Table S17). At three gathering facilities (#38, 61, and 76) a company representative made adjustments that had a noticeable impact on tank venting (SI Table S5). Other substantial sources included leaking valves and pipe unions, venting from the dehydrator, and compressor crank case/rod packing vents (SI Table S18). Some of the issues observed in the field (e.g., stuck valves or open thief hatches) that were causing substantial methane venting were addressed by the company representative without interrupting operations. At a few facilities, emissions sources had already been tagged (usually a ribbon) by prior inspections but the issue had not yet been addressed.

Multiple linear least-squares regressions were performed to quantify the contribution of different factors to the WAFLER at gathering facilities (SI M). Only gathering facilities with positive throughput were included in the regression. Variables describing engine and turbine horsepower, facility throughput, and pressure were significant in all models tested. The independent variables in the final regression model were natural log of throughput, delta pressure, and dummy variables for facilities with turbine-driven compressors ($n = 7$) and facilities classified with substantial venting from liquids storage tanks ($n = 22$; one facility with substantial tank venting had zero throughput). Horsepower was not included in the final model because it was highly correlated with throughput, which made the individual contribution of these variables difficult to resolve. The adjusted r^2 of this model is 0.67 and the Root Mean Square Error is 0.754 (diagnostic plots in SI M, Figures S8–S11).

For the 22 gathering facilities flagged by the onsite observer for substantial methane emissions from liquids storage tanks, the average WAFLER is 300% higher than nonflagged facilities. In other words, facilities classified as having substantial methane emissions from liquids storage tanks (~20% of gathering facilities) have around four times the methane emissions than similar, nonflagged facilities.

The regression model also indicates that the WAFLER at facilities with turbine-powered compressors was, on average, 75% lower than at facilities with only engine-powered compressors. The cumulative \ln WAFLER among the seven facilities with turbines is <0.01% of CH_4 throughput. It is not known if the lower emissions at these facilities were due solely to the use of turbines, which have much less exhaust methane than engines, or if it is indicator for some other characteristics of facilities equipped with turbines. Lower methane emissions were also observed from turbine equipped facilities in the transmission and storage sector.²²

Finally, the regression model indicates that the WAFLER increased with the pressure difference across the facility. The magnitude of some fugitive leaks scale with pressure. The number of stages of compression also increases with delta pressure.

4.3. Distribution of Methane Emissions. Figure 4 presents cumulative distributions of WAFLER (as a percentage of the total methane emissions) separately for the gathering (C, C/D, C/D/T, D, D/T) facilities and processing plants. Distributions are presented on two bases: facility number (Figure 4(a)) and cumulative CH_4 throughput (Figure 4(b)).

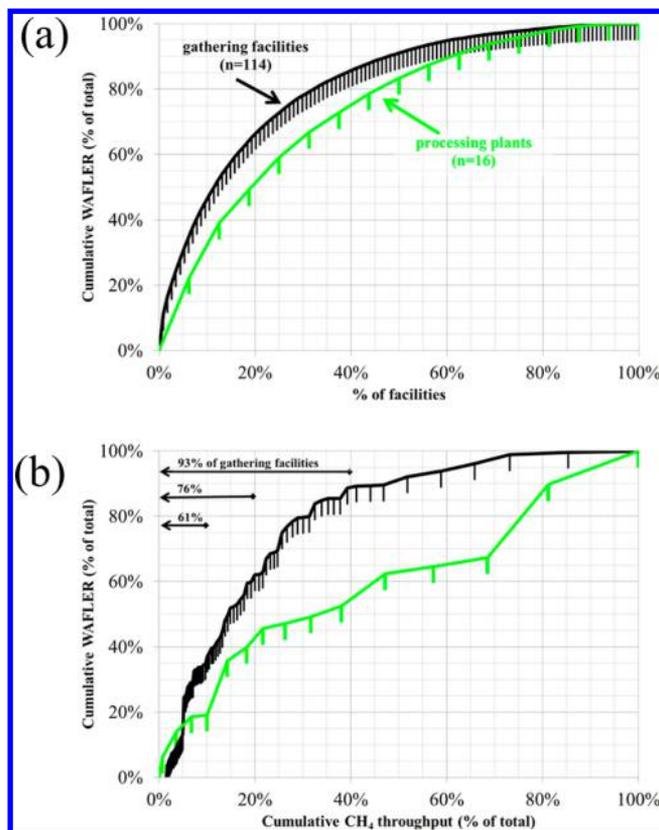

Figure 4. Skew in the methane emissions data illustrated by cumulative distributions of WAFLER (as a % of total methane emissions) of gathering facilities (black) and processing plants (green) sorted in (a) by WAFLER in descending order and (b) by CH_4 throughput (as a % of total) in ascending order. Each tick represents a single facility, and, in (b), the space between ticks represents % of total throughput accounted for by each facility. In (a), more than 80% of emissions come from about 30% of gathering facilities. In (b), the percentage of gathering facilities that contribute 10, 20, and 40% of throughput are indicated by arrows (top left). For example, 76% of the gathering facilities contribute only 20% of the throughput, but account for more than 60% of the emissions. (Included are three C facilities and two C/D facilities that had zero throughput but were still emitting methane.)

The cumulative distributions of WAFLER are skewed, similar to methane emissions data for production wells^{23,24} and transmission and storage facilities.²² In Figure 4(a), the skew is demonstrated by the fact that a minority of facilities contribute to the majority of the emissions. For example, less than 30% of gathering facilities (37 total) are responsible for almost 80% of the total methane emissions. One facility (facility #35) accounts for 10% of total gathering methane emissions. The five zero throughput facilities contributed 1% of the total gathering methane emissions.

Figure 4(b) shows that the emissions are also skewed when viewed from a CH_4 throughput basis. There are many low throughput facilities—61% of the facilities only contributed 10% of the total CH_4 throughput, but almost 40% of the total gathering methane emissions. At the other end of the distribution, nine facilities accounted for more than 60% of the total gathering throughput, but emissions from these nine facilities were only around 10% of the total gathering methane emissions. Without these nine facilities, the cumulative \ln WAFLER of all study gathering facilities would increase

from 0.20% to 0.43%. Cumulative distributions for C and C/D gathering facilities are included in SI N.

Normalized emissions from processing plants were generally lower than gathering facilities (Figure 3(b)) and their cumulative distributions of WAFLER less skewed (Figure 4). One factor may be the LDAR programs employed at processing plants, which are intended to reduce emissions. It is also unlikely that a single, high-magnitude leak would go unnoticed at any processing plant because they are typically staffed by an operator at all times. For example, a 1% leak at the average processing plant (250 tonnes/h) would emit more than 2500 kg/h. A single emission source at even a fraction of this magnitude would likely be visible and/or audible, making detection without infrared camera survey possible. Of the 25 facilities with the lowest tnWAFLER, 19 were staffed by full-time operator(s) (8–24 h/day). All of the processing facilities, but only about 14% of gathering facilities, were staffed. The other facilities were checked by their operator at least a few times a week, most daily.

The skewed distributions shown in Figure 4 are important to consider when making national emissions estimates.²⁵ These data provide insight into the frequency of high emitters (the “fat tail”). However, the sensitivity of the normalized emissions rates presented here to the skewed distributions complicates comparisons to existing GHG inventories. Marchese et al.¹⁰ use these emissions data to estimate the total methane emissions from natural gas gathering and processing in the U.S.

Notes

The authors declare no competing financial interest.

■ ACKNOWLEDGMENTS

We thank the sponsors of this work for financial support, technical advice, and access to sites for sampling. The sponsors were Access Midstream, Anadarko Petroleum Corporation, Environmental Defense Fund (EDF), Hess Corporation, Southwestern Energy, and Williams Corporation. Funding for EDF's methane research series, including this work, is provided by Fiona and Stan Druckenmiller, Heising-Simons Foundation, Bill and Susan Oberndorf, Betsy and Sam Reeves, Robertson Foundation, Alfred P. Sloan Foundation, TomKat Charitable Trust, and the Walton Family Foundation. DCP Midstream, while not a financial sponsor, provided site access for one of their processing plants selected at random. Subsequent to the field sampling campaign of this study, the Williams Companies purchased the controlling interest in Access Midstream Partners L.P. (“Access”) by acquiring 100% of the general partnership interest of Access. A merger between Access and Williams Partners L.P. is planned to occur in the first quarter of 2015. We also thank the project science advisory panel for valuable feedback: David T. Allen, Garvin Heath, Michael Levi, and James McCarthy. The views and opinions expressed are those of the authors and do not necessarily reflect those of the sponsors or the project science advisory panel. Thanks to Alex Davis (Carnegie Mellon University) for consultation on aspects of the data analysis.

S Supporting Information

ABSTRACT: Methane emissions from liquid unloadings were measured at 107 wells in natural gas production regions throughout the United States. Liquid unloadings clear wells of accumulated liquids to increase production, employing a variety of liquid lifting mechanisms. In this work, wells with and without plunger lifts were sampled. Most wells without plunger lifts unload less than 10 times per year with emissions averaging 21 000–35 000 scf methane (0.4–0.7 Mg) per event (95% confidence limits of 10 000–50 000 scf/event). For wells with plunger lifts, emissions averaged 1000–10 000 scf methane (0.02–0.2 Mg) per event (95% confidence limits of 500–12 000 scf/event). Some wells with plunger lifts are automatically triggered and unload thousands of times per year and these wells account for the majority of the emissions from all wells with liquid unloadings. If the data collected in this work are assumed to be representative of national populations, the data suggest that the central estimate of emissions from unloadings (270 Gg/yr, 95% confidence range of 190–400 Gg) are within a few percent of the emissions estimated in the EPA 2012 Greenhouse Gas National Emission Inventory (released in 2014), with emissions dominated by wells with high frequencies of unloadings.

INTRODUCTION

Natural gas production in the United States is increasing, driven by increased use of horizontal drilling and hydraulic fracturing.¹ As natural gas production has increased, interest has increased in the emissions of greenhouse gases along the natural gas supply chain.^{2–10} Methane, the primary component of natural gas, is a potent greenhouse gas, and a variety of sources contribute to methane emissions along the natural gas supply chain. For some of these sources, emission measurements are sparse, including measurements of emissions from pneumatic controllers and liquid unloadings.¹¹ Measurements of emissions from pneumatic controllers have been described in a companion manuscript.¹² This work reports on emissions from gas well liquid unloadings.

A liquid unloading may be necessary when a gas well that also produces oil or water accumulates liquids in the well bore. The liquids accumulation may be due to a variety of causes, including decreases in gas velocity in the well, decreases in reservoir pressure, or changing gas to liquid ratios. As liquids accumulate, well production can decline and an operator may choose to unload the liquids from the well to restore production. Liquids can be unloaded in a variety of ways. For example, the well tubing can be modified to increase gas velocity or a pump may be installed to remove downhole

liquids. Neither of these methods lead to venting emissions. Other unloading methods, such as temporarily diverting the flow from the well to an atmospheric vent, do lead to emissions. This work focuses on unloadings that result in emissions.

In the most recent national inventory of greenhouse gas emissions (for calendar year 2012, released in 2014, referred to here as the EPA 2012 GHG NEI),¹³ the EPA estimates that 60 810 natural gas wells, out of an estimated 470 913 natural gas wells in the United States (not including oil wells with associated gas production), have liquid unloadings that result in methane emissions. This represents 13% of gas wells in the EPA 2012 GHG NEI. Collectively, liquid unloadings from these wells are estimated to emit 273.6 Gg of methane per year (14.2 billion standard cubic feet, bcf), or approximately 14% of the estimated 1992 Gg of methane emissions from the natural gas production portion of the natural gas supply chain.

The estimates of methane emissions from liquid unloadings in EPA 2012 GHG NEI are generally consistent with more recent information collected through the EPA's Greenhouse Gas Reporting Program (for calendar year 2012, released in 2013, referred to here as the EPA 2012 GHGRP).¹⁴ The GHGRP reports approximately 276 Gg of methane emissions from liquid unloadings at facilities that meet threshold reporting requirements. Information for 58 663 wells that have unloading emissions was reported in 2012. In October 2014, GHGRP data were released for reporting year 2013 as well as revised data for reporting year 2012. In the 2014 data release, the number of wells with methane emissions from unloadings was reported as 55 491 for 2013, a 5.4% decrease from the number of wells originally reported for 2012. The number of wells with methane emissions from unloadings in 2012 was revised from 58 663 (released in October 2013) to 59 162 (released in October 2014). In this work, the 2012 data are used in order to allow comparisons with the 2012 GHG NEI. The originally released data are used since changes in reporting for 2012, as reflected in the well count, were relatively minor. Some changes were more significant, however, so a

sensitivity analysis, using revised 2012 and 2013 GHGRP data, is reported in Supporting Information (SI). The liquid unloading emission estimates from the EPA GHGRP are shown, by production region, in SI (Section S1).

Emissions from liquid unloadings of natural gas wells are not uniformly distributed in time or space. Estimated emissions from liquid unloadings are spatially concentrated in Rocky Mountain production regions. Wells in the Rocky Mountain region account for more than half of estimated emissions from liquid unloadings in the 2012 GHGRP. Temporal distributions also vary. Some wells release unloading emissions several times per day while others may release unloading emissions only once per year or once during the well's production life cycle. Wells may only release unloading emissions for a portion of their production lifetime, leading to a dependence of unloading emissions on well age. In addition to spatial and temporal variability in emissions of wells that vent, both estimates and measurements indicate that a small fraction of wells that vent account for a majority of emissions. For example, for one type of well with unloading emissions (wells without plunger lifts, see definition later in text), emission estimates reported by the American Petroleum Institute/America's Natural Gas Alliance (API/ANGA), indicate that three percent of wells accounted for half of emissions from this type of well and half of the wells accounted for more than 90% of emissions.¹⁵ In a limited number of measurements of methane emissions from a single type of well with unloading emissions (wells without plunger lifts—see definition later in text), Allen et al.¹¹ found that 95% of the emissions came from less than half of the wells.

Emission estimates, and a limited number of measurements of methane emissions from liquid unloadings, both suggest that a small fraction of wells, in particular geographical regions, and at particular times in the well's life cycle, account for a large fraction of liquid unloading emissions. These characterizations of unloadings emissions are primarily based on emission estimates, however, and there are few data in the scientific literature to test the reliability of emission estimates. This leads

to potentially large uncertainties in the emissions from this source category. More measurement data are needed, along with a better understanding of the relationships between well characteristics and unloading emissions.

This work reports measurements of methane emissions from 107 natural gas wells with emissions associated with liquid unloading. These data represent the most extensive set of measurements of emissions from liquid unloadings in the scientific literature. The relationships between emissions magnitude, unloading event frequency and other well characteristics are explored.

■ MATERIALS AND METHODS

Emission Measurements. The liquid unloadings reported in this work are grouped as plunger-lift unloadings and unloadings of wells without plunger lifts.

In a manually triggered unloading of a well without a plunger lift, an operator manually diverts the well's flow from a production separator, which typically operates at pressures of multiple atmospheres, to an atmospheric pressure tank. This allows the well to temporarily flow to a lower pressure destination (the atmospheric pressure tank or vent, rather than the pressurized separator). The resulting higher pressure gradient allows more gas to flow, increasing velocity in the production tubing and entraining and lifting liquids out of the well. Gas is discharged through the tank vent to the atmosphere until liquids are cleared. In a small number of wells (~0.1% of wells reported by companies participating in this work), this process is automated, resulting in two subcategories of unloadings for wells without plunger lifts, manual and automatic. All of the measurements reported in this work for wells without plunger lifts are for wells that had unloadings that were manually triggered; no wells without plunger lifts were observed in the sampling that had automated unloadings.

Emissions from unloadings of wells without plunger lifts were measured in this work by directing flow through a temporary stack installed on top of the vent. Figure 1 shows a conceptual diagram of a tank layout on a well site and the positioning of the temporary stack. Grounded metal or metal lined tubing was used to construct the temporary stack, to prevent static discharge. Flow rate through the temporary stack was measured continuously, near the centerline of the temporary stack, using a thermal gas mass flow meter. The thermal meter was extended into the middle of the temporary stack, which was between two and eight inches in diameter, with the diameter depending on the anticipated flow rate. Since the width of the meter's probe was approximately 3.5 cm (1.4 in.), the thermal meter recorded a centerline velocity. Total volumetric flow was calculated by multiplying the product of the measured gas velocity and the cross-sectional area of each stack by a correction factor to convert the centerline velocity in the stack to an estimated average velocity in the stack, accounting for the change in velocity profile from friction near the stack walls and accounting for the cross sectional area of the stack obstructed by the flow meter (see SI Section S2). In some well configurations (31 of the 107 wells on which measurements were made), measurement through a temporary stack on the atmospheric tank was not technically feasible. In these cases, measurements were made by inserting a segment of pipe (with the thermal gas mass flow meter in the pipe) into the process line between the separator and the atmospheric tank in order to measure the flow into the tank.

The methane fraction of the vented gas was assumed to be equal to the methane fraction in the normally produced gas. This was presumed to be a more accurate indicator of total methane emissions than measurements of the gas composition made through the temporary stack. The gas exiting through the temporary stack during the unloading period is a combination of the unloaded gas from the well and the gas initially in the vapor space of the tank (typically much lower in methane than the site's produced gas). At the end of the unloading, the tank will contain more methane, from the unloading, than was in the tank at the start of the unloading. This methane, which is associated with the unloading event, will eventually be released as part of normal tank operations. Multiplying the measured vented gas volume by the methane fraction of the produced gas captures these emissions that occur because of the unloading but that are not released during the period when the tank is actively venting.

Uncertainty in these measurement methods is estimated at 10–20% of the measured emissions and this estimate is dominated by the assumed uncertainty in the flow, which includes both uncertainties in the stack gas volumetric flow measurement, and determining when flows return to zero. Variability in the gas composition from the well is expected to be much less than 10%. As described in the Results section, these measurement uncertainties are small compared to the combined measurement uncertainty and uncertainty introduced by selecting only a subpopulation of wells for measurement (sampling uncertainty), which are 50% or more of measured emissions.

Liquids can also be unloaded from a well using a plunger lift system. This liquid removal operation holds a plunger at the top of the well, and either manually or by automation occasionally closes (shuts-in) the well and releases the plunger, allowing it to fall down the well bore below the accumulated liquids. The well is then reopened, allowing the gas to push the plunger and the liquid back up the well bore as a slug of liquid. If the plunger returns to the top and the liquid and gas flow to the separator, there is no venting and all gas from the separator is routed to sales. In some cases, if the plunger does not return to the surface as expected, the plunger controller may bypass the separator and direct the flow to an atmospheric pressure vent, such as a vented tank. Directing flow to the lower pressure vent causes the plunger to return to the surface but also allows gas to vent. Plunger cycles may be initiated manually, on a timed interval, or based on certain well parameters such as a reduced gas flow. In this work, measurements were made on both wells in which the unloading was automated through use of a controller (automatically triggered), and wells in which the plunger lift cycle was manually initiated by an operator (manually triggered).

In both the manually triggered plunger lift unloadings and the automatically triggered plunger lift unloadings, the volume of vented gas was measured using the same procedures as used for the wells without plunger lifts. For the automatically triggered unloadings, the measurement equipment was typically left in place for one to several days, making measurements continuously. This allowed automated plunger unloading venting events to be measured only when and if they occurred in routine operation, without artificially triggering the events. For all the plunger lift unloading events, the composition of the vented gas was assumed to be the same as the composition of the gas produced by that well. Produced gas composition was provided by site operators.

Table 1. Unloading events measured in this work. Wells with manual unloadings typically had one event per well, while automated Plunger Lift Unloadings Had Multiple Events Per Well; A Mapping of Region Boundaries is Provided in Supporting Information

Sampling Strategies. Emission estimates reported through the EPA 2012 GHGRP¹⁴ indicate that a small fraction of wells, in particular geographical regions, account for a large fraction of emissions from liquid unloadings. The sampling strategy employed in this work was to sample most extensively in regions that were likely to dominate emissions (SI, Section S1). Details of the sampling approach are provided in SI. Briefly, the sampling team would visit a region for one or multiple weeks and sample a randomly selected subset of those wells that were unloading during that period. Consequently, more samples were collected on wells that unloaded more frequently. The features of these sample collection methods (preferential sampling in regions with high estimated emissions from unloadings and sampling of wells that tended to have high unloading frequencies) are important to consider when the data

presented in this work are used to establish national emission estimates.

RESULTS AND DISCUSSION

Methane emissions from liquid unloadings were measured at 107 natural gas wells. A summary of the geographical locations of the wells sampled is provided in Table 1.

For the 32 wells without plunger lifts (manually unloaded) sampled in this work, one event was typically sampled for each well; a few wells had more than one event sampled and for these wells, average values are reported. The unloadings of wells without plunger lifts sampled in this work had durations that lasted between 0.17 and 4.5 h, and vented methane volumes that ranged between 550 and 135 000 standard cubic feet (scf) of methane per event (0.011–2.6 Mg). Representative time series for the methane emissions from wells without

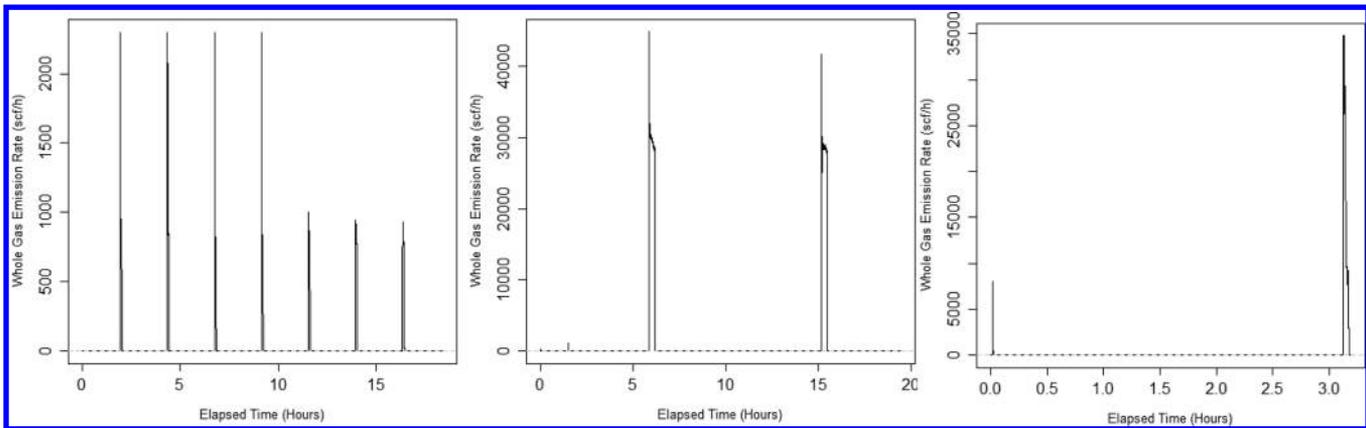

Figure 4. Representative time series of methane flow rates during automatically triggered liquid unloadings from wells with plunger lifts (UBB-42-0401 left; UBB-42-0201 middle; UEF-49-0501 right); Note differences in horizontal and vertical scales.

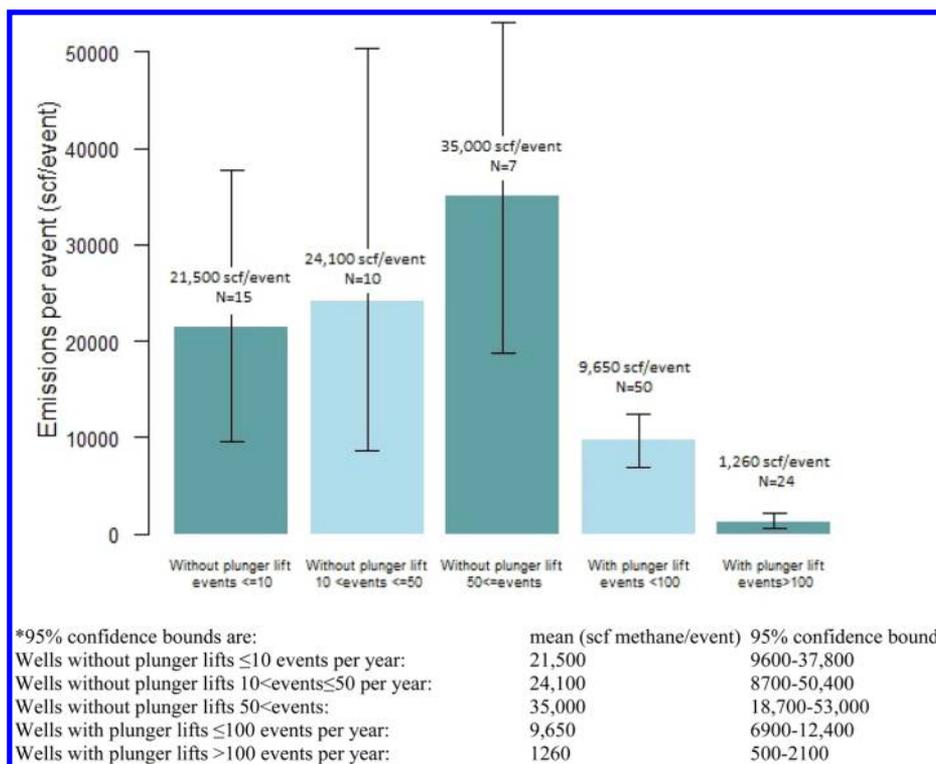

Figure 5. Average emissions per event for wells with and without plunger lifts, sorted by frequency of events (events per year per well).

plunger lifts are shown in Figure 2. These three events shown had durations that ranged from 2.72 to 3.75 h. Vented volumes for these three events shown ranged between 21 000 and 135 000 scf methane (0.40–2.6 Mg). As illustrated by these representative time series, some manual unloadings without plunger lift rapidly rose to a high flow rate, then maintained a steady flow throughout the event; others rose more slowly to a peak flow, then had variable flow during the event; still others rapidly rose to a peak flow, then had declining flows throughout the event. This complex flow behavior makes it difficult to generalize about the flow characteristics for manually triggered unloadings of wells without plunger lifts.

For the 50 plunger lift wells with manually triggered unloadings, one event was typically sampled for each well. The manual unloadings of wells with plunger lifts sampled in this work had durations that lasted between 0.03 h and more than 3 h, and had vented methane volumes that ranged

between approximately 200 and 49 000 scf methane per event (0.004–0.94 Mg). Representative time series for the methane emissions from a manual unloading are shown in Figure 3. These three events shown had durations that ranged from 1.2 to 20 min. Vented volumes ranged between 1220 and 27 000 scf methane for the three events shown (0.02–0.52 Mg). As illustrated by these representative time series, some manually triggered unloadings with plunger lift rapidly rose to a high flow rate, then almost immediately fell rapidly, leading to a relatively short duration event; others rose rapidly to a peak flow that was maintained for 5–10 min or more; still others had complex flow patterns over an event lasting 10 min or more. As was the case for manually triggered unloadings without plunger lifts, this complex flow behavior makes it difficult to generalize about the flow characteristics.

For automated plunger lift wells, the sampling equipment was left in place for one to several days at each well, and

typically more than one event was sampled for each well. The automatically triggered unloadings (with plunger lift) sampled in this work had durations that lasted between <1 min and more than 20 min, and vented methane volumes that ranged from 50 scf methane to more than 8000 scf methane per event) (0.001–0.15 Mg). The numbers of events sampled per well ranged from 2 to more than 70; average values of emissions per event were used when multiple events were recorded. Representative time series for the methane emissions from automated plunger lift unloadings are shown in Figure 4. Individual unloading events for these three wells had durations that ranged from 2 to 20 min. Vented volumes per event ranged between 60 and 8600 scf methane for the three wells shown (0.001–0.15 Mg). As illustrated by these representative time series, some plunger lift wells with automated unloadings had emissions per event that were quite similar, and that occurred with a regular frequency. In contrast, however, some automated plunger lift wells had events that had qualitatively different emissions and/or variable event frequencies.

SI (Section S3) provides details of the unloading emissions and well characteristics for each of the 107 wells sampled in this work. A summary is provided in Figure 5. A relatively small number of wells have high emissions and most wells have much lower emissions. For example, 20% (6 of 32) of the wells account for 83% of the annual emissions for wells without plunger lifts, where annual emissions are estimated by multiplying the emission for an unloading event, measured in this work, by the number of times that well unloaded during calendar year 2012 or 2013 (whichever was the most recent report available), as reported by the well operator. The six wells that account for 83% of the annual emissions of wells without plunger lifts vent 6% of their collective annual production. For manually and automatically triggered plunger lift wells, 20% of the wells account for 65% and 72% of the annual emissions, respectively. These wells vent 2% and 20% of their collective annual production, for manually and automatically triggered wells, respectively.

Because the distributions of event emissions are not normally distributed about a mean, uncertainties in the average values of emissions per event are reported based on the results of a bootstrapping method, rather than as a simple standard deviation of the data set. In the bootstrapping procedure, the original data set of each type of well was recreated by making random event selections, with replacement, from the data set. A total of 1000 of these resampled data sets were created and the mean value of the emissions for each resampled data set was determined. The 95% confidence intervals for the emission estimates represent the 2.5% and 97.5% percentiles of the means in the 1000 resampled data sets. So, for example, for the 25 automatically triggered plunger lift wells, a mean value for emissions per event, for each well, was calculated by selecting 25 emission measurements, at random and with replacement. This mean was tabulated and the process was repeated 1000 times to generate 1000 mean values. The 2.5% and 97.5% percentiles were determined to be 538 and 2085 scf methane per event, and these values are the 95% confidence bounds for the mean value of the measurements (in this case 1260 scf methane/event). The bootstrapping procedure leads to a combined sampling and measurement uncertainty. This uncertainty has a much larger range (typically 50% or more of the mean value, see Figure 5) than would be estimated from the uncertainty associated with the measurement alone (approximately 10–20% of the measured value) and is a

reflection of the heterogeneity of well characteristics in the data sets and the underlying population of wells with unloading emissions.

Statistical analyses were conducted to identify well and unloading event characteristics that could explain the variability in the measured emission data. Variables that were considered included well pressures, well bore volumes, well ages, unloading event durations and unloading frequencies. The variable that explained the largest amount of variability in the observed annual well emissions was unloading frequency, although there was also a positive correlation of event frequencies with well age (older wells had more unloading events per year than younger wells) and a negative correlation of annual emissions with well depth (deeper wells, which were generally newer, had lower annual emissions than shallower, generally older, wells). Correlations with emissions per event were generally weaker than for annual emissions. Additional details are provided in SI (Section S4). As shown in Figure 5, for wells without plunger lifts, average emissions for individual unloading events range between 21 000 and 35 000 scf methane per event, if the events are binned into wells that have less than 10 events per year, between 11 and 50 events per year, and 51 or more events per year. The differences in annual emissions from manually unloaded wells without plunger lifts are largely due to the frequency of events, rather than the volume of gas emitted per event. For wells with plunger lifts, Figure 5 reports average emissions in two frequency bins. Manually triggered plunger lift wells were binned as a single group; all had less than 100 events per year (maximum observed value of 52 events per year). Automatically triggered plunger lift wells were also considered as a single category since all of these wells had more than 180 unloadings per year (average of 1870 unloadings per year in the sampled population). Plunger lift wells that were manually triggered had average emissions per event of 9650 scf methane. Plunger lift wells with automated triggering of the unloading had average emissions of 1260 scf methane per event.

The measured emissions per event were compared to predictions made using emission estimation methods commonly used in EPA GHGRP reporting. For wells with plunger lifts, the emission estimates averaged 4500 scf/event as compared to an average of 8000 scf/event for the study measurements (difference is statistically different, $p = 0.004$). Despite the differences in mean predicted and observed emission rates, the paired measurements and estimates were weakly, but statistically significantly correlated. For wells without plunger lifts, the emission estimates averaged 31 000 scf/event as compared to an average of 27 000 scf/event for the measurements (difference is not statistically significant), however, while the averages are similar, the estimates were not well correlated with the observations. See SI (Section S4) for more details.

Implications for National Emission Estimates. National emissions, based on the measurements made in this work, are estimated by multiplying an emission factor, based on the measurements, by an activity factor. Emission event counts, stratified into categories based on emission events per year per well, were chosen for the activity factor because of the process used for selecting wells to be sampled and because annual emission estimates for wells with unloadings depended most strongly on event frequency.

As documented in SI (Section S1), the measurement team typically visited production Basins for approximately a week, and sampled randomly selected wells that had scheduled (for

manually triggered wells) or anticipated (for automatically triggered wells) unloading events for that week of sampling. This meant that the study team was far more likely to sample wells that unloaded weekly or more frequently, rather than wells that unloaded just a few times per year. This sampling approach resulted in a representative distribution of events, but not a representative distribution of wells. For example, 85% of the wells, without plunger lift, that have unloading emissions and that are operated by the companies that provided sampling sites in this work, had fewer than 10 emission events per year (See SI, Section S5). In the measurements performed for this work, 15 of the 32 wells without plunger lift (47%) had 10 or less events per year. These wells are therefore under-represented in the measurement data, relative to their presence in the participating companies' overall well population. Because of differences in the distributions of event frequency between the sampled wells and the national population of wells, it would not be appropriate to choose an emission factor of emissions per well per year and an activity factor of number of wells, without adjusting for this difference in event frequency distribution.

An additional reason for stratifying wells by frequency of events in the activity factor is the data shown in Figure 5, which indicate a reasonable degree of consistency in per event emissions. Wells without plunger lifts had measured mean values of 21 000–35 000 scf methane/event. Wells with plunger lifts had measured mean values of 1000–10 000 scf methane/event, but much larger ranges of event frequencies. For the calculations reported in this work, national, rather than regional averages of emissions per event will be used, due to the limited number of observations in individual regions.

In this work, national estimates of numbers of unloading events were based on a survey of the participating companies (see SI, Section S5). Data on event counts from the EPA GHGRP were not used since event counts for plunger and nonplunger wells are either partially reported or of uncertain quality. The national event counts were assumed to have the same distributions as reported in the participant survey. Based on this survey, it was estimated that the 32 225 wells with plunger lifts (based on data from the 2012 GHGRP) have a total of 6.8 million events per year. Only 206 500 of these 6.8 million events are associated with wells that vent less than 100 times per year. Total annual emissions from plunger lift wells are estimated at 10 billion cubic feet of methane per year (bcf/yr) (190 Gg/yr), with 80% of those emissions associated with wells that vent more than 100 times per year (additional details in SI, Section S5). For wells that vent more than 100 times per year, the average emissions per well per year are 1 400 000 scf per well per year (27 Mg/yr) with 95% confidence bounds of 600 000–2 500 000 scf (10–50 Mg, based on the confidence bounds in the emissions per event).

For wells without plunger lifts, it was estimated that 26 438 wells (based on data from the 2012 GHGRP) vent a total of 177 000 times per year, with total emissions of 4.4 bcf/yr (84 Gg/yr). Again, the wells that vent with highest frequency have the highest emissions per well. The 1.1% of wells that vent more than 50 times per year have average emissions of 3.2 million scf methane/yr. For wells without plunger lifts, however, these wells account for only 1.1% of the wells with unloading emissions, so the emissions from these wells venting at high frequency account for only 25% of emissions from wells without plunger lifts. Additional details are provided in SI, Section S5).

The overall emission estimate for liquid unloadings (plunger and nonplunger wells), based on the measurements made in this work, is 270 Gg (14 bcf/yr), which is within a few percent of the national emissions estimated in either the 2012 GHG NEI (273 Gg/yr) or the 2012 GHGRP (276 Gg/yr). The 95% confidence range for this estimate is 190–400 Gg/yr, based on the reported confidence ranges in the per event emission factors, but not accounting for uncertainties in event counts. SI (Section S5) reports sensitivity analyses that suggest uncertainties in event count estimates may be large, up to a factor of 2 or more, which could have a significant impact on national emission estimates. Regardless of the exact national total of emissions, however, wells with high frequencies of unloadings have annual emissions that are a factor of 10 or more greater than the annual emissions of wells with low frequencies of unloadings.

S1. Methods for site selection

Goals and overall sampling strategy Sampling of pneumatic controllers was conducted in four major regions (Appalachian, Gulf Coast, Mid-continent, Rocky Mountain); based on current characterizations of pneumatic controller design types (continuous vent or intermittent vent, on/off or throttling), it was anticipated that several types of controller designs would need to be sampled; it was also anticipated that there would be multiple types of controller service (e.g., separator level control service) that would influence actuation frequency and other parameters that affect emissions. To sample regions, controller design types and controller service types, it was anticipated that approximately 350-400 devices would need to be sampled.

Selection of Basins Data from EPA's Greenhouse Gas Reporting Program (GHGRP, Reporting Year 2012) were used to identify the Basins where the ten participant companies had reported pneumatic emissions. Based on this distribution of available Basins in which to sample, the study team selected at least two companies to sample in each region (Appalachian, Gulf Coast, Mid-continent, Rocky Mountain), such that all ten participant companies were sampled. Where possible, the study team selected Basins that produced a mix of device design and service types, rather than visiting sites that reported only one device type. The Study Team was solely responsible for the selection of regions and Basins in which to sample.

Once basins and companies to be sampled in each basin were selected, 2-3 day site visits were planned. In each of these site visits, the focus was on sampling well pads for a single company in a single basin. Thirteen of these 2-3 day visits were conducted.

Selection of well pads Local contacts for participant companies provided descriptions or lists of the well pad sites or central facilities (e.g. sites with separators for multiple wells) in the area to be sampled. The study team selected the sites; all sites identified by the local contacts were available for sampling; depending on the distances between sites, the study team either randomly selected sites or selected sites that were relatively proximate to the starting location, so that a relatively large number of samples could be made without losing efficiency due to long travel times between pad locations. The goal was to sample a cross section of typical facilities. If a company had a mix of old and new facilities, or acquired and company built facilities, the study team selected pad types in proportion to the population in the area.

Sampling of devices on well pads or central facilities Once at a site, the Study Team measured emissions from all pneumatic devices at the site, unless safety or operational issues or lack of access prohibited sampling. This was done to achieve a sample population that would represent controller service and design types currently in use.

S2 Corrections to Instrument Flow Measurements based on Gas Composition

The supply gas flow meter was calibrated by the manufacturer (Fox Thermal Instruments) using pure methane; instrument flow rates were corrected to account for natural gas compositions, which varied from site to site. Because the flow meter measurement is based on thermal conductivity, the composition correction was based on the relative thermal conductivities of the gas used by pneumatic devices at each site and the pure methane used as a calibration gas.

$$scf/h_{corrected} = scf/h_{inst} \left(\frac{k_{CH_4}}{k_{gas}} \right)$$

where scf/h_{inst} is the raw instrument flow rate reading in standard cubic feet per hour, k_{CH_4} is the pure component thermal conductivity (W/m*K) for methane at standard conditions (70°F and 14.7 psia), and k_{gas} is the thermal conductivity of the gas sampled at standard conditions as determined from the company-provided gas analysis for the site. The thermal conductivity of the sampled gas (k_{gas}) was calculated as a molar weighted average:

$$k_{gas} = \sum_{i=1}^6 k_i n_i$$

where n_i is the mole fraction of species i in the gas sample for the site and k_i is the pure component thermal conductivity of the species (<http://webbook.nist.gov/chemistry/fluid/>) under standard conditions. For this work, the pure component species considered were methane, ethane, propane, nitrogen, and carbon dioxide. All higher hydrocarbons with a carbon count of four or greater were lumped with butane for purposes of the gas composition correction. The pure component properties used in the calculations are shown in Table S2-1. For the range of natural gas compositions from sites visited in this project, the composition correction factor ranged between 1.009 (0.9% increase from raw instrument data) and 1.215 (21.5% increase from raw instrument flow data).

| Species | Thermal Conductivity (W/m*K) |
|----------------|------------------------------|
| Methane | 0.033759 |
| Ethane | 0.020491 |
| Propane | 0.017884 |
| Butane + | 0.016181 |
| Nitrogen | 0.025473 |
| Carbon Dioxide | 0.016331 |

Table S2-1. Thermal conductivity (<http://webbook.nist.gov/chemistry/fluid/>) of natural gas components at standard conditions (14.7 psia and 70°F).

S3. Field and laboratory comparisons of supply gas and Hi Flow® measurements

Laboratory measurements

The measurement instruments were laboratory tested using gas flows generated with a mass flow controller. The test flows were designed to mimic the patterns of time varying flow expected from intermittent vent controllers. The flow out of the mass flow controller was routed through the in-line supply gas meter then fed directly into the feed for the Hi Flow® system (the supply gas meter had a sample frequency of 10 Hz, while the Hi Flow® had a sampling frequency of 0.3 – 0.5 Hz). Tests for the High Flow instrument were completed both with the emissions point bagged and with the emissions being directly fed into the Hi Flow® inlet. In selected experiments, the mass flow controller output was compared to the results of a dry test meter.

Multiple tests were conducted. Figure S3-1 shows the results of one test scenario with a pure methane gas stream. The initial flow pattern consisted of three step up-step down flows with a maximum flow of 100 scfh (a simulated controller actuation). The duration of each step was 30 seconds, and the period between simulated actuations was 2.5 minutes. The second part of the test consisted of three step up-step down flows that also had a maximum flow of 100 scfh. Each step had a duration of 3 seconds, and the period between simulated actuations was 2.5 minutes.

The time integrated flow per simulated actuation from the mass flow controller was compared to the time integrated flow for the supply gas meter and the Hi Flow® device. The ratio of the integrated supply gas meter flow to the integrated mass flow controller flow averaged 1.07 for this test; the ratio of the integrated Hi Flow® device flow to the integrated mass flow controller flow averaged 0.983.

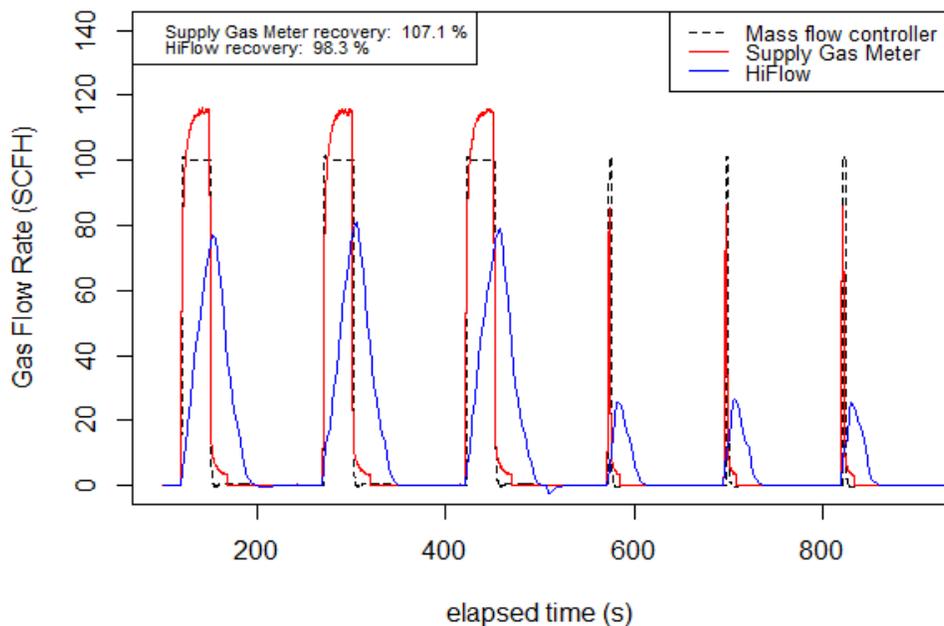

Figure S3-1. Laboratory test comparing supply gas meter to Hi Flow® and mass flow controller. The test consisted of two sets of three 100 scfh simulated actuations; the first set of actuations had a duration of 30 seconds while the second set of actuations had durations of 3 seconds.

For another test (with pure methane test gas), four simulated actuations were performed (30 seconds between actuations), with an increasing maximum flow rate (10, 30, 50, and 100 scfh, respectively); each simulated actuation had a duration of 20 seconds (Figure S3-2). In this test, the ratio of the integrated supply gas meter flow to the integrated mass flow controller flow averaged 1.035; the ratio of the integrated Hi Flow® device flow to the integrated mass flow controller flow averaged 0.952.

Table S3.1 summarizes the laboratory tests that were conducted, showing the relative ratio of integrated flows for each case (with pure methane test gas).

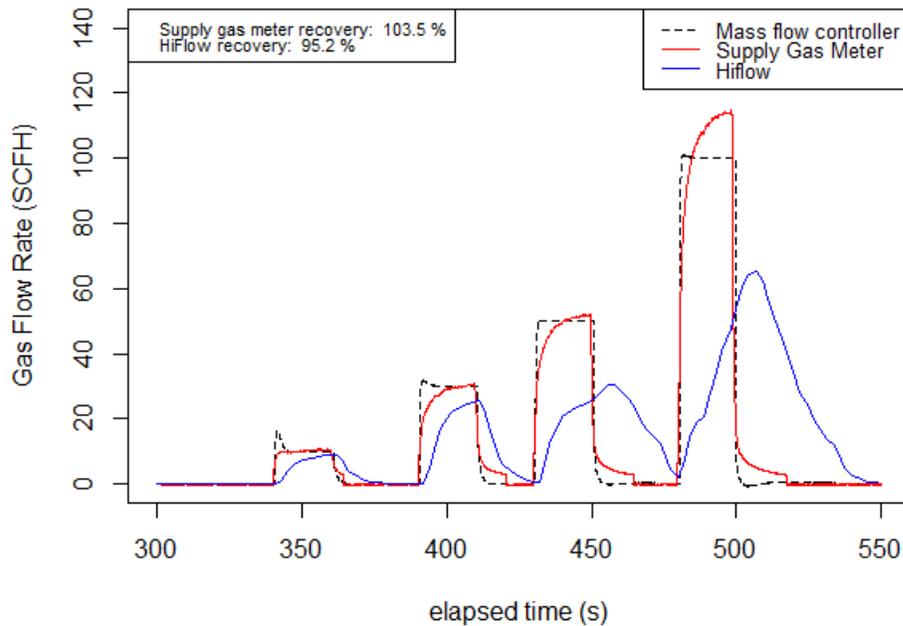

Figure S3-2. Laboratory test comparing Supply Gas Meter to Hi Flow® and Mass Flow Controller. The test consisted of four actuations with maximum flows of 10 scfh, 30 scfh, 50 scfh, and 100 scfh, with a duration of 20 seconds and an interval between actuations of 30 seconds.

| Test Description | Ratio of integrated supply gas meter flow to integrated mass flow controller flow | Ratio of integrated Hi Flow® device flow to integrated mass flow controller flow |
|--|---|--|
| <i>Step up-step down flow. Maximum flow was 100 scfh, duration of each step was 30 seconds and the period between simulated actuations was 2.5 minutes.</i> | 1.07 | 0.983 |
| <i>Set of actuations with maximum flow of 10 scfh, 30 scfh, 50 scfh, and 100 scfh with a duration of 20 seconds per actuation, and an interval of 30 seconds between actuations.</i> | 1.03 | 0.952 |
| <i>Set of actuations with a maximum flow of 100 scfh, 30 scfh and 10 scfh, with a duration of 1 second per actuation and an interval of 1 second between actuations.</i> | 0.856 | 0.959 |
| <i>Set of three actuations with a maximum flow of 100 scfh with a duration of 30 seconds per actuation. Interval of 2.5 minutes between actuations.</i> | 1.10 | 0.922 |
| <i>Set of three actuations with a maximum flow of 100 scfh with a duration of 3 seconds per actuation. Interval of 2.5 minutes between actuations.</i> | 0.829 | 1.58 |

Table S3-1. Laboratory tests simulating controller actuations, using pure methane, comparing the Supply Gas Meter to the Hi Flow® device.

Additional tests with a wet gas surrogate (70.5% methane by volume) were completed in the lab before field sampling (Table S3-2). For the tests listed in Table S3-2, the average ratio of instrument reported mass flow rate to the controller mass flow rate (uncorrected for composition) is 0.878 for the supply gas meter and 0.608 for the Hi Flow®.

| Test Number | Ratio of integrated supply gas meter flow to integrated mass flow controller flow | Ratio of integrated Hi Flow® device flow to integrated mass flow controller flow |
|-------------|---|--|
| 1 | Not Tested | 0.663 |
| 2 | 0.857 | 0.552 |
| 3 | 0.898 | Not Tested |

Table S3-2. Laboratory tests simulating controller actuations, comparing the supply gas meter to the Hi Flow® device with a wet gas surrogate (70.5% methane by volume). Each test consisted of three 30 second bursts at 3 scf/h and at 50 scf/h.

If the supply gas meter is corrected for composition, the average ratio of instrument reported mass flow rate to the controller mass flow rate is 1.034 for the wet gas tests. The Hi Flow® instrument reading is difficult to correct for composition for non-steady flows. At low emission rates, the composition correction would be based on a molar flow rate of carbon, since the sampled gas is catalytically oxidized before it is sent to a thermal conductivity detector. In

contrast, at high flow rates, the sample is sent directly to a thermal conductivity detector and the gas composition adjustment would be based on a molar weighted thermal conductivity (see Section S2). These two adjustments would require precise identification of the transitions between sampling regimes, making the interpretation of field data difficult. Therefore, to adjust Hi Flow® measurements for gas composition in field measurements, the following procedure was used:

1. Determine whether a wet gas or dry gas adjustment will be used; if the percentage methane in the produced gas at a site was greater than 85%, a dry gas correction was used; otherwise a wet gas correction was used
2. For dry gas sites, the Hi Flow® measurement, uncorrected for gas composition, was converted to a supply gas measurement, uncorrected for gas composition. This conversion is based on the laboratory data collected on pure methane reported in Table S3-1 (ratio of Supply gas flow rate to Hi Flow® flow rate of 1.12). The uncorrected supply gas flow rate was then corrected for composition using the method described in Section S2.
3. For wet gas sites, the Hi Flow® measurement, uncorrected for gas composition, was converted to a supply gas measurement, uncorrected for gas composition. This conversion is based on the laboratory data collected on a surrogate wet gas reported in Table S3-2 (ratio of Supply gas flow rate to Hi Flow® flow rate of 0.878/0.608; 1.44). The uncorrected supply gas flow rate was then corrected for composition using the method described in Section S2.

Field Measurements

In field measurements, for 29 controllers, both supply gas and Hi Flow® measurements were made, simultaneously. Four of those measurements will not be analyzed because they occurred at a site (DL02) where the Hi Flow® was capturing a leak signal from equipment located inside the enclosure where the pneumatic devices were installed (not part of the controller). An additional measurement (device XQ01-PC04) will not be analyzed because it was concluded that the controller was not completely bagged.

For the final data set of 24 controllers with coupled measurements, 11 (46%) had emissions of less than 0.005 scf/h of whole gas, as measured by the supply gas meter. The results for the remaining 13 devices are shown in Table S3-2. For devices with an average emission rate greater than 6 scfh (measured by the supply gas meter), the supply gas meter to Hi Flow® measurement ratio is between 0.7 and 1.1. These results suggest that for controllers that account for most of the emissions, the two methods produce similar results. For lower flow rates, the lack of agreement is generally due to higher supply gas measurements, relative to Hi Flow® measurements. This is likely due to leaks in the controller/control valve gas line that were not captured by the Hi Flow® enclosure (e.g., leaks in the downstream valve that the controller was operating). For the samples where the Hi Flow® device was measuring higher emissions than the supply gas meter, the Hi Flow® may have been sampling emissions that were not in the controller/control valve gas line (e.g., a leak in any of the equipment upstream of the meter or near the controller but not in the controller supply line).

Table S3-2. Supply gas meter and Hi Flow® for thirteen controllers where both instruments were used to make measurements.

| Device Name | Supply Gas meter - avg. emission rate Whole Gas (scf/h) | Hi Flow® - avg. emission rate Whole Gas (scf/h) | Supply Gas meter to Hi Flow® measurement ratio |
|-------------|---|---|--|

S4. Pneumatic controller emission data

Tables S4-1 to S4-5 contain the data collected for each of the 377 measured devices. The first letter of the device code indicates the host company that operated the site where the measurement was performed. The second letter of the device code indicates the basin where the measurement was performed. Letters for these codes were randomly selected, but are used consistently (i.e., specific letters always represent the same company or basin). Figure S4-1 shows the boundaries of the geographical regions into which controllers were grouped. Figure S4-2 summarizes the application types, well types, and service types of the sampled population

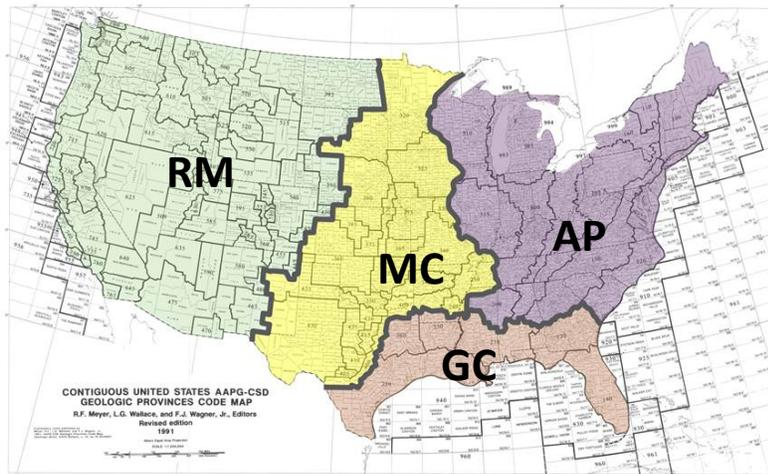

Figure S4-1. Measurements of emissions from pneumatic controllers were categorized into Appalachian (AP), Gulf Coast (GC), Mid-Continent (MC) and Rocky Mountain (RM) regions.

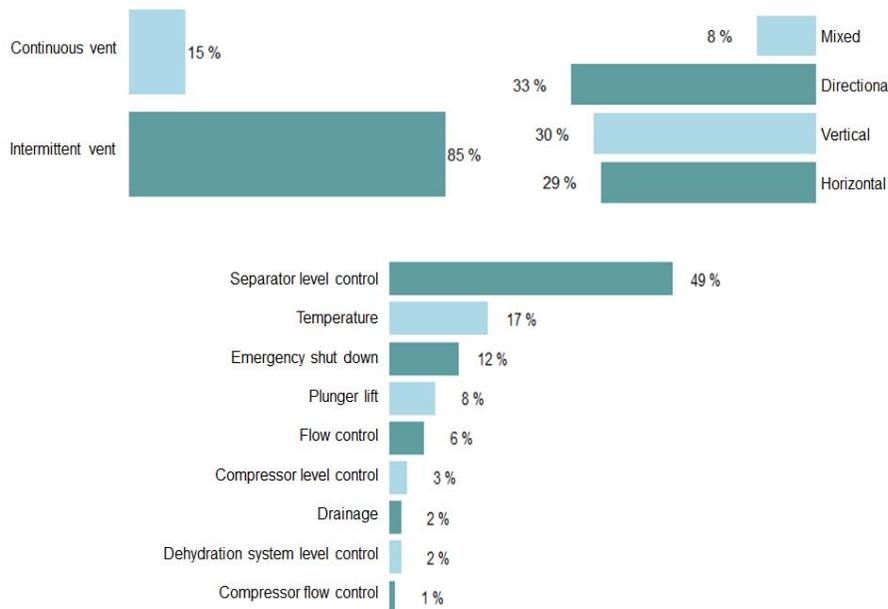

Figure S4-2. Sample population characterized by the service type (upper left, continuous vent or intermittent vent, where intermittent-vent indicates a clear actuation pattern, returning to zero between actuations, and continuous-vent indicates a non-zero pattern with no temporal variability), well type (upper right, horizontal, vertical, directional or mixed type), and type of application in which the controller is used (lower, e.g., separator level control).

Table S4-1 – Descriptive data of measured devices, showing the pneumatic controller application (level, pressure or temperature), process unit they are servicing, and if they are linked to a single well or multiple wells.

| Device Identifier | Region | Controller application | Basic application | Detailed application | Single Well (Y/N) |
|-------------------|--------|------------------------|-------------------|---------------------------|-------------------|
| AA01-PC04 | MC | Level | Separator | Separator - Level Control | Y |
