Uncertainty and Time-Series Consistency

The overall uncertainty associated with both the 2014 CH₄ and N₂O emission estimates from wastewater treatment and discharge was calculated using the 2006 IPCC Guidelines Approach 2 methodology (IPCC 2006). Uncertainty associated with the parameters used to estimate CH₄ emissions include that of numerous input variables used to model emissions from domestic wastewater, and wastewater from pulp and paper manufacture, meat and poultry processing, fruits and vegetable processing, ethanol production, and petroleum refining. Uncertainty associated with the parameters used to estimate N₂O emissions include that of sewage sludge disposal, total U.S. population, average protein consumed per person, fraction of N in protein, non-consumption nitrogen factor, emission factors per capita and per mass of sewage-N, and for the percentage of total population using centralized wastewater treatment plants.

The results of this Approach 2 quantitative uncertainty analysis are summarized in Table 7-16. Methane emissions from wastewater treatment were estimated to be between 9.0 and 15.0 MMT CO₂ Eq. at the 95 percent confidence level (or in 19 out of 20 Monte Carlo Stochastic Simulations). This indicates a range of approximately 39 percent below to 2 percent above the 2014 emissions estimate of 14.7 MMT CO₂ Eq. Nitrous oxide emissions from wastewater treatment were estimated to be between 1.1 and 10.1 MMT CO₂ Eq., which indicates a range of approximately 76 percent below to 108 percent above the 2014 emissions estimate of 4.8 MMT CO₂ Eq.

Table 7-16: Approach 2 Quantitative Uncertainty Estimates for CH₄ Emissions from Wastewater Treatment (MMT CO₂ Eq. and Percent)

| Source | Gas | 2014 Emission Estimate (MMT CO ₂ Eq.) | Uncertainty Range Relative to Emission Estimate ^a | | | |
|-----------------------------|-----------------------|---|--|-------------|-----------------|-----------------|
| | | | Lower Bound | Upper Bound | Lower Bound (%) | Upper Bound (%) |
| Wastewater Treatment | CH₄ | 14.7 | 9.0 | 15.0 | -39% | +2% |
| Domestic | CH ₄ | 9.0 | 5.7 | 9.7 | -37% | +8% |
| Industrial | CH ₄ | 5.7 | 2.4 | 6.8 | -58% | +20% |
| Wastewater Treatment | N₂O | 4.8 | 1.1 | 10.1 | -76% | +108% |

^a Range of emission estimates predicted by Monte Carlo Stochastic Simulation for a 95 percent confidence interval.

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2014. Details on the emission trends through time are described in more detail in the Methodology section, above.

QA/QC and Verification

A QA/QC analysis was performed on activity data, documentation, and emission calculations. This effort included a Tier 1 analysis, including the following checks:

- Checked for transcription errors in data input;
- Ensured references were specified for all activity data used in the calculations;
- Checked a sample of each emission calculation used for the source category;
- Checked that parameter and emission units were correctly recorded and that appropriate conversion factors were used;
- Checked for temporal consistency in time series input data for each portion of the source category;
- Confirmed that estimates were calculated and reported for all portions of the source category and for all years;
- Investigated data gaps that affected emissions estimates trends; and
- Compared estimates to previous estimates to identify significant changes.

All transcription errors identified were corrected. The QA/QC analysis did not reveal any systemic inaccuracies or incorrect input values.

Recalculations Discussion

Production data were updated to reflect revised U.S. Department of Agriculture (USDA) National Agricultural Statistics Service (NASS) datasets. Updates to meat and poultry data based on changes to the 2012 *Census for Agriculture* and 2013 and 2014 annual revisions resulted in animal population changes for beef from 2008 to 2013, veal from 2009 to 2013, and lamb and muttons in 2009 (Bertramsen 2016). In addition, the most recent USDA Economic Research Service (ERS) data were used to update protein data values from 1990 through 2010. The updated ERS data also resulted in changes in forecasted values from 2011 (Cooper 2014).

The estimated number of ethanol plants using dry milling versus wet milling were updated for 1990 to 2014 with data provided by Renewable Fuels Association (RFA) (Cooper 2014). This change resulted in updated values for ethanol produced (both dry and wet) for the entire time series.

Planned Improvements

Due to circumstances, only very limited improvements were made to the wastewater treatment section of this Inventory. As a result, the planned improvements detailed previously will continue to be investigated for possible inclusion in a future Inventory. Below is a brief summary of ongoing investigations.

- EPA is continuing its evaluation of Greenhouse Gas Reporting Program (GHGRP) reports for improvements to activity data and for verifying methodologies currently in use in the Inventory to estimate emissions.
- EPA is working with the National Council of Air and Stream Improvement (NCASI) to determine if there are sufficient data available to update the estimates of organic loading in pulp and paper wastewaters treated on-site.
- EPA is investigating the inclusion of constructed and semi-natural treatment wetlands in Inventory calculations using IPCC's 2013 wetlands supplement (IPCC 2014) using CWNS treatment system data or other data sources.
- EPA is continuing its review of other industrial wastewater treatment sources for those industries believed to discharge significant loads of BOD and COD, including dairy processing wastewater.

Over the longer term, potential sources for updating inventory data continue to be monitored, including:

- Updated sources of activity data for wastewater treatment system type to distinguish between aerobic, anaerobic, and aerobic systems with the potential to generate CH₄;
- Water Environment Federation (WEF) biosolid data as a potential source of digester, sludge, and biogas data from POTWs;
- Reports based on international research and other countries' inventory submissions to inform potential updates to the Inventory's emission factors, methodologies, or included industries;
- Research by groups such as the Water Environment Research Federation (WERF) on emissions from various types of municipal treatment systems, country-specific N₂O emission factors, and flare efficiencies;
- Sources of data for development of a country-specific methodology for N₂O emissions associated with on-site industrial wastewater treatment operations, including the appropriateness of using IPCC's default factor for domestic wastewater (0.005 kg N₂O-N/kg N);
- Data collected by WERF that indicate septic soil systems are a source of N₂O for the potential development of appropriate emission factors for septic system N₂O emissions;
- Additional data sources for improving the uncertainty of the estimate of N entering municipal treatment systems; and
- Data to update the value used for N content of sludge, the amount of sludge produced, and sludge disposal practices, along with increasing the transparency of the fate of sludge produced in wastewater treatment.

See Section 7.2 of the *Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990 through 2013* for full detail of these planned improvements.

7.3 Composting (IPCC Source Category 5B1)

Composting of organic waste, such as food waste, garden (yard) and park waste, and wastewater treatment sludge and/or biosolids, is common in the United States. Advantages of composting include reduced volume of the waste, stabilization of the waste, and destruction of pathogens in the waste. The end products of composting, depending on its quality, can be recycled as a fertilizer and soil amendment, or be disposed of in a landfill.

Composting is an aerobic process and a large fraction of the degradable organic carbon in the waste material is converted into carbon dioxide (CO₂). Methane (CH₄) is formed in anaerobic sections of the compost, which are created when there is excessive moisture or inadequate aeration (or mixing) of the compost pile. This CH₄ is then oxidized to a large extent in the aerobic sections of the compost. The estimated CH₄ released into the atmosphere ranges from less than one percent to a few percent of the initial carbon (C) content in the material (IPCC 2006). Depending on how well the compost pile is managed, nitrous oxide (N₂O) emissions can be produced. The formation of N₂O depends on the initial nitrogen content of the material and is mostly due to nitrogen oxide (NO_x) denitrification during the later composting stages. Emissions vary and range from less than 0.5 percent to 5 percent of the initial nitrogen content of the material (IPCC 2006). Animal manures are typically expected to generate more N₂O than, for example, yard waste; however, data are limited.

From 1990 to 2014, the amount of waste composted in the United States has increased from 3,810 kt to 20,533 kt, an increase of approximately 439 percent. The amount of material composted in the United States in the last decade has increased by approximately 11 percent. Emissions of CH₄ and N₂O from composting have increased by the same percentage. In 2014, CH₄ emissions from composting (see Table 7-17 and Table 7-18) were 2.1 MMT CO₂ Eq. (82 kt), and N₂O emissions from composting were 1.8 MMT CO₂ Eq. (6 kt). The wastes composted primarily include yard trimmings (grass, leaves, and tree and brush trimmings) and food scraps from the residential and commercial sectors (such as grocery stores; restaurants; and school, business, and factory cafeterias). The composted waste quantities reported here do not include backyard composting or agricultural composting.

The growth in composting since the 1990s and specifically over the past decade is attributable to primarily three factors: (1) the enactment of legislation by state and local governments that discouraged the disposal of yard trimmings in landfills, (2) yard trimming collection and yard trimming drop off sites provided by local solid waste management districts/divisions, and (3) an increased awareness of the environmental benefits of composting. Most bans on the disposal of yard trimmings were initiated in the early 1990s by state or local governments (U.S. Composting Council 2010). By 2010, 25 states, representing about 50 percent of the nation's population, had enacted such legislation (BioCycle 2010). An additional 16 states are known to have commercial-scale composting facilities (Shin 2014). Despite these factors, the total amount of waste composted exhibited a downward trend after peaking in 2008 (see Table 7-17 and Figure 7-5), but has been increasing since 2010 and the annual quantity composted is now on par with the 2008 quantity composted. While there is no definitive reason for the decreasing trend in the amount of waste composted, it is most likely a result of the recession and the fact that the quantities composted are estimated using a mass balance approach on the municipal waste stream across the entire United States. As presented in Figure 7-5, the quantity of CH₄ and N₂O emitted from composting operations across the time-series parallels the trends for the quantities composted, although the trend in emissions has a much lower slope compared to the quantities composted.

Table 7-17: CH₄ and N₂O Emissions from Composting (MMT CO₂ Eq.)

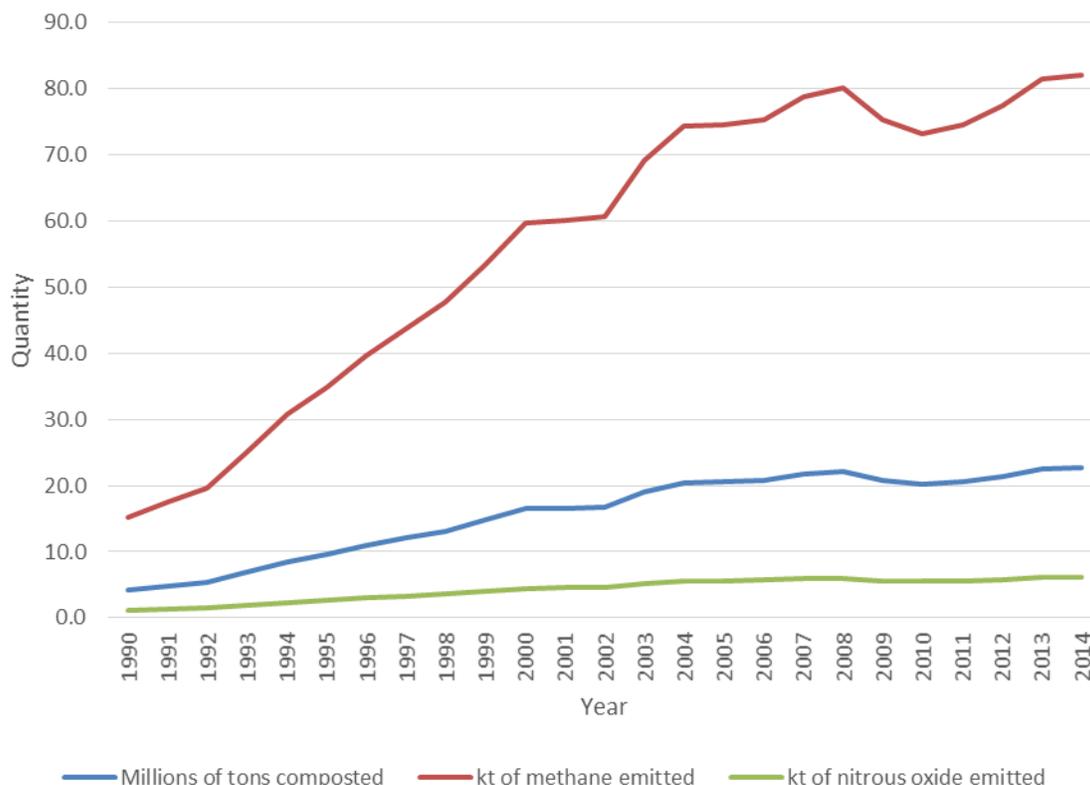

| Activity | 1990 | 2005 | 2010 | 2011 | 2012 | 2013 | 2014 |
|------------------|------------|------------|------------|------------|------------|------------|------------|
| CH ₄ | 0.4 | 1.9 | 1.8 | 1.9 | 1.9 | 2.0 | 2.1 |
| N ₂ O | 0.3 | 1.7 | 1.6 | 1.7 | 1.7 | 1.8 | 1.8 |
| Total | 0.7 | 3.5 | 3.5 | 3.5 | 3.7 | 3.9 | 3.9 |

Note: Totals may not sum due to independent rounding.

Table 7-18: CH₄ and N₂O Emissions from Composting (kt)

| Activity | 1990 | 2005 | 2010 | 2011 | 2012 | 2013 | 2014 |
|------------------|------|------|------|------|------|------|------|
| CH ₄ | 15 | 75 | 73 | 75 | 77 | 81 | 82 |
| N ₂ O | 1 | 6 | 5 | 6 | 6 | 6 | 6 |

Figure 7-5: CH₄ and N₂O Emitted from Composting Operations between 1990 and 2014 (kt or million tons)

Methodology

Methane and N₂O emissions from composting depend on factors such as the type of waste composted, the amount and type of supporting material (such as wood chips and peat) used, temperature, moisture content (e.g., wet and fluid versus dry and crumbly), and aeration during the composting process.

The emissions shown in Table 7-17 and Table 7-18 were estimated using the IPCC default (Tier 1) methodology (IPCC 2006), which is the product of an emission factor and the mass of organic waste composted (note: no CH₄ recovery is expected to occur at composting operations in the emission estimates presented):

$$E_i = M \times EF_i$$

where,

| | | |
|--------|---|---|
| E_i | = | CH ₄ or N ₂ O emissions from composting, kt CH ₄ or N ₂ O |
| M | = | mass of organic waste composted in kt |
| EF_i | = | emission factor for composting, 4 t CH ₄ /kt of waste treated (wet basis) and 0.3 t N ₂ O/kt of waste treated (wet basis) (IPCC 2006) |
| i | = | designates either CH ₄ or N ₂ O |

Estimates of the quantity of waste composted (M) are presented in Table 7-19. Estimates of the quantity composted for 1990, 2005 and 2007 through 2009 were taken from EPA's *Municipal Solid Waste in the United States: 2010 Facts and Figures* (EPA 2011); estimates of the quantity composted for 2006 were taken from EPA's *Municipal Solid Waste In The United States: 2006 Facts and Figures* (EPA 2007); estimates of the quantity composted for 2011 through 2012 were taken from EPA's *Municipal Solid Waste In The United States: 2012 Facts and Figures* (EPA 2014); estimates of the quantity composted for 2013 was taken from EPA's *Advancing Sustainable Materials Management: Facts and Figures 2013* (EPA 2015); and estimates of the quantity composted for 2014 were

extrapolated using the 2013 quantity composted and a ratio of the U.S. population in 2013 and 2014 (U.S. Census Bureau 2015).

Table 7-19: U.S. Waste Composted (kt)

| Activity | 1990 | 2005 | 2010 | 2011 | 2012 | 2013 | 2014 |
|-----------------|-------|--------|--------|--------|--------|--------|--------|
| Waste Composted | 3,810 | 18,643 | 18,298 | 18,661 | 19,351 | 20,358 | 20,533 |

Uncertainty and Time-Series Consistency

The estimated uncertainty from the 2006 IPCC Guidelines is ± 50 percent for the Approach 1 methodology. Emissions from composting in 2014 were estimated to be between 1.9 and 5.8 MMT CO₂ Eq., which indicates a range of 50 percent below to 50 percent above the actual 2014 emission estimate of 3.9 MMT CO₂ Eq. (see Table 7-20).

Table 7-20: Approach 1 Quantitative Uncertainty Estimates for Emissions from Composting (MMT CO₂ Eq. and Percent)

| Source | Gas | 2014 Emission Estimate (MMT CO ₂ Eq.) | Uncertainty Range Relative to Emission Estimate (MMT CO ₂ Eq.) (%) | | | |
|------------|------------------------------------|---|--|-------------|-------------|-------------|
| | | | Lower Bound | Upper Bound | Lower Bound | Upper Bound |
| Composting | CH ₄ , N ₂ O | 3.9 | 1.9 | 5.8 | -50% | +50% |

Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2014. Details on the emission trends through time-series are described in more detail in the Methodology section, above.

QA/QC and Verification

A QA/QC analysis was performed for data gathering and input, documentation, and calculation. A primary focus of the QA/QC checks was to ensure that the amount of waste composted annually was correct according to the latest EPA *Advancing Sustainable Materials Management: Facts and Figures* report.

Recalculations Discussion

The estimated amount of waste composted in 2013 was updated based on new data contained in EPA's *Advancing Sustainable Materials Management: Facts and Figures 2013* report (EPA 2015) relative to the previous report. The amounts of CH₄ and N₂O emission estimates presented in Table 7-17 and Table 7-18 were revised accordingly.

Planned Improvements

For future Inventories, additional efforts will be made to improve the estimates of CH₄ and N₂O emissions from composting. For example, a literature search on emission factors and their drivers (e.g., the type of composting system, material composition, management technique, impact of varying climatic regions) is underway. The purpose of this literature review is to compile all published emission factors to determine whether the emission factors used in the current methodology should be revised, or expanded to account for various composting system, material composition, management techniques, and/or geographical/climatic differences. For example, composting systems that primarily compost food waste may generate CH₄ at different rates than composting yard trimmings because the food waste may have a higher moisture content and more readily degradable material. Further cooperation with estimating emissions in the Land Use, Land-Use Change, and Forestry (LULUCF) Other section will also be investigated.

7.4 Waste Incineration (IPCC Source Category 5C1)

As stated earlier in this chapter, carbon dioxide (CO₂), nitrous oxide (N₂O), and methane (CH₄) emissions from the incineration of waste are accounted for in the Energy sector rather than in the Waste sector because almost all incineration of municipal solid waste (MSW) in the United States occurs at waste-to-energy facilities where useful energy is recovered. Similarly, the Energy sector also includes an estimate of emissions from burning waste tires and hazardous industrial waste, because virtually all of the combustion occurs in industrial and utility boilers that recover energy. The incineration of waste in the United States in 2014 resulted in 9.7 MMT CO₂ Eq. emissions, over half of which (4.9 MMT CO₂ Eq.) is attributable to the combustion of plastics. For more details on emissions from the incineration of waste, see Section 3.3 of the Energy chapter.

Additional sources of emissions from waste incineration include non-hazardous industrial waste incineration and medical waste incineration. As described in Annex 5 of this report, data are not readily available for these sources and emission estimates are not provided. An analysis of the likely level of emissions was conducted based on a 2009 study of hospital/ medical/ infectious waste incinerator (HMIWI) facilities in the United States (RTI 2009). Based on that study's information of waste throughput and an analysis of the fossil-based composition of the waste, it was determined that annual greenhouse gas emissions for medical waste incineration would be below 500 kt CO₂ Eq. per year and considered insignificant for the purposes of Inventory reporting under the UNFCCC. More information on this analysis is provided in Annex 5.

7.5 Waste Sources of Indirect Greenhouse Gases

In addition to the main greenhouse gases addressed above, waste generating and handling processes are also sources of indirect greenhouse gas emissions. Total emissions of nitrogen oxides (NO_x), carbon monoxide (CO), and non-CH₄ volatile organic compounds (NMVOCs) from waste sources for the years 1990 through 2014 are provided in Table 7-21.

Table 7-21: Emissions of NO_x, CO, and NMVOC from Waste (kt)

| Gas/Source | 1990 | 2005 | 2010 | 2011 | 2012 | 2013 | 2014 |
|----------------------------|------------|------------|-----------|-----------|-----------|-----------|-----------|
| NO_x | + | 2 | 1 | 1 | 1 | 1 | 1 |
| Landfills | + | 2 | 1 | 1 | 1 | 1 | 1 |
| Wastewater Treatment | + | 0 | 0 | 0 | 0 | 0 | 0 |
| Miscellaneous ^a | + | 0 | 0 | 0 | 0 | 0 | 0 |
| CO | 1 | 7 | 5 | 5 | 5 | 5 | 5 |
| Landfills | 1 | 6 | 5 | 4 | 4 | 4 | 4 |
| Wastewater Treatment | + | + | + | + | + | + | + |
| Miscellaneous ^a | + | 0 | 0 | 0 | 0 | 0 | 0 |
| NMVOCs | 673 | 114 | 44 | 38 | 38 | 38 | 39 |
| Wastewater Treatment | 57 | 49 | 19 | 17 | 17 | 17 | 17 |
| Miscellaneous ^a | 557 | 43 | 17 | 15 | 15 | 15 | 15 |
| Landfills | 58 | 22 | 8 | 7 | 7 | 7 | 7 |

+ Does not exceed 0.5 kt.

^aMiscellaneous includes TSDFs (Treatment, Storage, and Disposal Facilities under the Resource Conservation and Recovery Act [42 U.S.C. § 6924, SWDA § 3004]) and other waste categories.

Note: Totals may not sum due to independent rounding.

Methodology

Emission estimates for 1990 through 2014 were obtained from data published on the National Emission Inventory (NEI) Air Pollutant Emission Trends web site (EPA 2015), and disaggregated based on EPA (2003). Emission estimates for 2014 for non-electric generating unit (EGU) and non-mobile sources are held constant from 2011 in EPA (2015). Emission estimates of these gases were provided by sector, using a “top down” estimating procedure—emissions were calculated either for individual sources or for many sources combined, using basic activity data (e.g., the amount of raw material processed) as an indicator of emissions. National activity data were collected for individual categories from various agencies. Depending on the category, these basic activity data may include data on production, fuel deliveries, raw material processed, etc.

Uncertainty and Time-Series Consistency

No quantitative estimates of uncertainty were calculated for this source category. Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2014. Details on the emission trends through time are described in more detail in the Methodology section, above.

8. Other

The United States does not report any greenhouse gas emissions under the Intergovernmental Panel on Climate Change (IPCC) “Other” sector.

9. Recalculations and Improvements

Each year, emission and sink estimates are recalculated and revised for all years in the *Inventory of U.S. Greenhouse Gas Emissions and Sinks*, as attempts are made to improve both the analyses themselves, through the use of better methods or data, and the overall usefulness of the report. In this effort, the United States follows the *2006 IPCC Guidelines* (IPCC 2006), which states, “Both methodological changes and refinements over time are an essential part of improving inventory quality. It is *good practice* to change or refine methods when available data have changed; the previously used method is not consistent with the IPCC guidelines for that category; a category has become key; the previously used method is insufficient to reflect mitigation activities in a transparent manner; the capacity for inventory preparation has increased; new inventory methods become available; and for correction of errors.”

The results of all methodological changes and historical data updates made in the current Inventory report are presented in this section; detailed descriptions of each recalculation are contained within each source’s description found in this report, if applicable. Table 9-1 summarizes the quantitative effect of these changes on U.S. greenhouse gas emissions and sinks and Table 9-2 summarizes the quantitative effect on annual net CO₂ fluxes, both relative to the previously published U.S. Inventory (i.e., the 1990 through 2013 report). These tables present the magnitude of these changes in units of million metric tons of carbon dioxide equivalent (MMT CO₂ Eq.).

The Recalculations Discussion section of each source’s description in the respective chapter of this Inventory presents the details of each recalculation. In general, when methodological changes have been implemented, the entire time series (i.e., 1990 through 2013) has been recalculated to reflect the change, per IPCC (2006). Changes in historical data are generally the result of changes in statistical data supplied by other agencies.

The following ten emission sources and sinks underwent some of the most significant methodological and historical data changes. These emission sources consider only methodological and historical data changes. A brief summary of the recalculations and/or improvements undertaken is provided for each of the ten sources.

- *Natural Gas Systems (CH₄)*. EPA received information and data related to the emission estimates through the Inventory preparation process, previous Inventories’ formal public notice periods, GHGRP data, and new studies. EPA carefully evaluated relevant information available, and made several updates, including revisions to production segment activity data, production segment pneumatic controller activity and emissions data, gathering and boosting facility emissions, transmission and storage station activity and emissions data, distribution segment emissions data for pipelines, distribution segment M&R station activity and emissions data, and distribution segment customer meter emissions data. From December 2015 through February 2016, the EPA released four draft memos that discussed the changes under consideration and requested stakeholder feedback on those changes. The impact of all revisions to natural gas systems is an average annual increase in emissions of 12.9 MMT CO₂ Eq. relative to the previous Inventory.
- *Petroleum Systems (CH₄)*. The EPA received information and data related to the emission estimates through the Inventory preparation process, previous Inventories’ formal public notice periods, EPA’s Greenhouse Gas Reporting Program (GHGRP) data, and new studies. The EPA carefully evaluated relevant information available, and made revisions to the production segment methodology for the 2016 Inventory including revised equipment activity data, revised pneumatic controller activity and emissions data, and included a separate estimate for hydraulically fractured oil completions, which were previously not estimated as a distinct subcategory of oil well completions. All these changes resulted in an average annual increase in emissions of 20.7 MMT CO₂ Eq. relative to the previous Inventory.

- *Landfills (CH₄)*. Four major methodological recalculations were performed for the current Inventory. First, a rigorous review of the flare and landfill gas-to-energy (LFGTE) projects across the four recovery databases was conducted. Extensive corrections were made to avoid double counting of projects across the recovery databases. Additionally, several facilities in the LFGTE database were removed because they were not in the published LMOP database for the current or past two years (EPA 2015). Second, the GHGRP CH₄ recovery data were back-calculated for landfills in the GHGRP database for years prior to the first GHGRP reporting year (typically 2010 for most landfills). Third, the flare correction factor was revised. Fourth, the DOC value for landfilled pulp and paper waste was revised from 0.20 to 0.15 based a literature review of pulp and paper waste characterization studies (RTI 2015) and data reported under the GHGRP. The overall impact to the Inventory from these changes resulted in an average increase of nearly 14 percent across the time series. A significant increase in net CH₄ emissions for the years 2010 through 2013 ranging from 20 to 52 percent higher in the current inventory compared to the 1990 to 2013 inventory. These changes resulted in an average annual decrease in emissions of 6.4 MMT CO₂ Eq. relative to the previous Inventory.
- *Agricultural Soil Management (N₂O)*. Methodological recalculations in the current Inventory are associated with the following improvements: (1) driving the DAYCENT simulations with updated input data for land management from the National Resources Inventory extending the time series through 2010; (2) accounting for N inputs from residues associated with additional crops not simulated by DAYCENT including most vegetable crops; (3) modifying the number of experimental study sites used to quantify model uncertainty for direct N₂O emissions; and (4) using DAYCENT for direct N₂O emissions from most flooded rice lands, instead of using the Tier 1 approach for all rice lands. These changes resulted in an increase in emissions of approximately 24 percent on average relative to the previous Inventory and a decrease in the upper bound of the 95 percent confidence interval for direct N₂O emissions from 26 to 24 percent. The differences in emissions and uncertainty are mainly due to increasing the number of study sites used to quantify model uncertainty. These changes resulted in an average annual increase in emissions of 60.1 MMT CO₂ Eq. relative to the previous Inventory.
- *Land Converted to Grassland - Changes in Agricultural Soil Carbon Stocks (CO₂)*. Methodological recalculations in the current Inventory are associated with the following improvements, including: (1) incorporation of updated NRI data for 1990 through 2010; (2) inclusion of federal grasslands in the Tier 2 analysis; (3) improving the simulation of hydric soils in DAYCENT, and (4) incorporating the aboveground biomass C stock losses with Forest Land Converted to Grassland. These changes resulted in an average annual increase in emissions of 49.0 MMT CO₂ Eq. relative to the previous Inventory.
- *Land Converted to Cropland - Changes in Agricultural Carbon Stocks (CO₂)*. Methodological recalculations in the current Inventory are associated with the following improvements: (1) incorporation of updated NRI data for 1990 through 2010; (2) inclusion of federal croplands; (3) improving the simulation of hydric soils in DAYCENT, and (4) incorporating the aboveground biomass C stock losses with Forest Land Converted to Cropland. These changes in SOC stocks resulted in an average annual decrease in emissions of 21.8 MMT CO₂ Eq. relative to the previous Inventory.
- *Cropland Remaining Cropland - Changes in Agricultural Carbon Stocks (CO₂ sink)*. Methodological recalculations in the current Inventory are associated with the following improvements: (1) incorporation of updated NRI data for 1990 through 2010; and (2) inclusion of federal croplands; and (3) improving the simulation of hydric soil. These changes in SOC stocks resulted in an average annual decrease in sequestration of 16.5 MMT CO₂ Eq. relative to the previous Inventory.
- *Forest Land Remaining Forest Land - Changes in Forest Carbon Stock (CO₂ sink)*. Forest ecosystem stock and stock-change estimates differ from the previous Inventory report principally due to the adoption of a new accounting framework (Woodall et al. 2015). The major differences between the framework used this year and past accounting approaches is the sole use of annual FIA data and the back-casting of forest C stocks across the 1990s based on forest C stock density and land use change information obtained from the nationally consistent annual forest inventory coupled with in situ observations of non-tree C pools such as soils, dead wood, and litter. The use of this accounting framework has enabled the creation of the two land use sections for forest C stocks: *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*. In prior submissions (e.g., the 1990 through 2013 Inventory submission), the C stock changes from *Land Converted to Forest Land* were a part of the *Forest Land Remaining Forest Land* section and it was not possible to disaggregate the estimates. A second major change was the adoption of a new approach to estimate forest soil C, the largest C stock in the

United States. For detailed discussion of these new approaches please refer to the Methodology section, Annex 3.13, Domke et al. (in prep), and Woodall et al. (2015). In addition to these major changes, the refined land representation analysis described in Section 6.1 Representation of the U.S. Land Base which identifies some of the forest land in south central and southeastern coastal Alaska as unmanaged; this is in contrast to past assumptions of “managed” land for these forest lands included in the FIA database. Therefore, the C stock and flux estimates for southeast and south central coastal Alaska, as included here, reflect that adjustment, which effectively reduces the managed forest area by approximately 5 percent.

In addition to the creation of explicit estimates of removals and emissions by *Forest Land Remaining Forest Land* versus *Land Converted to Forest Land*, the accounting framework used this year eliminated the use of periodic data (which may be inconsistent with annual inventory data) which contributed to a data artifact in prior estimates of emissions/removals from 1990 to the present. In the previous Inventory report, there was a reduction in net sequestration from 1995 to 2000 followed by an increase in net sequestration from 2000 to 2004. This artifact of comparing inconsistent inventories of the 1980s through 1990s to the nationally consistent inventories of the 2000s has been removed in this Inventory. Overall, there were net C additions to HWP in use and in SWDS combined due, in large part, to updated data on products in use from 2010 to the present. All these changes resulted in an average annual increase in sequestration of 8.9 MMT CO₂ Eq. relative to the previous Inventory.

- *Substitution of Ozone Depleting Substances (HFCs)*. For the current Inventory, reviews of the large retail food and refrigerated transport end-uses resulted in revisions to the Vintaging Model since the previous Inventory report. In addition, a vending machine end-use was added to the Vintaging Model since the previous Inventory. Methodological recalculations were applied to the entire time-series to ensure time-series consistency from 1990 through 2014. For the large retail food end-use, assumptions regarding new installations by system type and refrigerant transitions were revised based on a review of data collected by EPA's GreenChill Partnership and the California Air Resources Board's Refrigerant Management Program. Based on a literature review of technical reports and relevant datasets, the refrigerated transport end-use was updated from an aggregate end-use that covered all the various refrigerated transport modes through average assumptions of charge size, leak rates, stock, and lifetimes to separate end-uses by mode, including road transport, intermodal containers, merchant fishing, reefer ships, and vintage and modern rail. The vending machine end-use was added based on a review of technical reports and sales data. Combined, these assumption changes and additions decreased CO₂-equivalent greenhouse gas emissions on average by 5 percent between 1990 and 2014. Overall, these changes resulted in an average annual decrease in emissions of 6.3 MMT CO₂ Eq. relative to the previous Inventory.
- *Grassland Remaining Grassland - Changes in Agricultural Carbon Stock (CO₂ sink)*. Methodological recalculations in the current Inventory are associated with the following improvements, including (1) incorporation of updated NRI data for 1990 through 2010; (2) inclusion of federal grasslands in the Tier 2 analysis; and (3) improving the simulation of hydric soils in DAYCENT. These changes in soil organic carbon (SOC) stocks resulted in an average annual increase in sequestration of 4.9 MMT CO₂ Eq. relative to the previous Inventory.

Table 9-1: Revisions to U.S. Greenhouse Gas Emissions (MMT CO₂ Eq.)

| Gas/Source | 1990 | 2005 | 2010 | 2011 | 2012 | 2013 | Average Annual Change |

NC - No Change

+ Absolute value does not exceed 0.05 MMT CO₂ Eq. or 0.05 percent.

* Indicates a new source for the current Inventory year

^a Includes the effects of net additions to stocks of carbon stored in forest ecosystem pools and harvested wood products.

^b Estimates include emissions from N fertilizer additions on both *Forest Land Remaining Forest Land* and *Land Converted to Forest Land*, but not from land-use conversion.

^c Estimates include C stock changes in all pools.

^d Estimates include emissions from N fertilizer additions on both *Settlements Remaining Settlements* and *Land Converted to Settlements*.

^e LULUCF emissions include the CO₂, CH₄, and N₂O emissions reported for Non-CO₂ Emissions from Forest Fires, N₂O Fluxes from Forest Soils, CO₂ Emissions from Liming, CO₂ Emissions from Urea Fertilization, Peatlands Remaining Peatlands, and N₂O Fluxes from Settlement Soils.

^f LULUCF Total Net Flux includes any C sequestration gains and losses from all land use and land use conversion categories.

^g The LULUCF Sector Total is the net sum of all emissions (i.e., sources) of greenhouse gases to the atmosphere plus removals of CO₂ (i.e., sinks or negative emissions) from the atmosphere.

Notes: Numbers in parentheses indicate an increase in C sequestration. Totals may not sum due to independent rounding.

California Code of Regulations, Title 17, Division 3, Chapter 1, Subchapter 10 Climate Change, Article 4

PROPOSED REGULATION ORDER

Subarticle 13: Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities

§ 95665. Purpose and Scope.

The purpose of this article is to establish greenhouse gas emission standards for crude oil and natural gas facilities identified in section 95666. This article is designed to serve the purposes of the California Global Warming Solutions Act, AB 32, as codified in sections 38500-38599 of the Health and Safety Code.

NOTE: Authority cited: Sections 38510, 38562, 39600, 39601 and 41511, Health and Safety Code. Reference: Sections 38560, 39600 and 41511, Health and Safety Code.

§ 95666. Applicability.

- (a) This article applies to owners or operators of equipment and components listed in section 95668 located within California, including California waters, that are associated with facilities in the sectors listed below, regardless of emissions level:
- (1) Onshore and offshore crude oil or natural gas production; and,
 - (2) Crude oil, condensate, and produced water separation and storage; and,
 - (3) Natural gas underground storage; and,
 - (4) Natural gas gathering and boosting stations; and,
 - (5) Natural gas processing plants; and,
 - (6) Natural gas transmission compressor stations.
- (b) Owners and operators must ensure that their facilities, equipment, and components comply at all times with all requirements of this subarticle, including all of the standards and requirements identified in section 95668. Owners and operators are jointly and severally liable for compliance with this subarticle.

NOTE: Authority cited: Sections 38510, 38562, 39600, 39601 and 41511, Health and Safety Code. Reference: Sections 38560, 39600 and 41511, Health and Safety Code.

§ 95667. Definitions.

- (a) For the purposes of this article, the following definitions apply:
- (1) "Air district or local air district" means the local Air Quality Management District or the local Air Pollution Control District.

- (2) "Air Resources Board or ARB" means the California Air Resources Board.
- (3) "API gravity" means a scale used to reflect the specific gravity (SG) of a fluid such as crude oil, condensate, produced water, or natural gas. The API gravity is calculated as $[(141.5/SG) - 131.5]$, where SG is the specific gravity of the fluid at 60°F, and where API refers to the American Petroleum Institute.
- (4) "Centrifugal compressor" means equipment that increases the pressure of natural gas by centrifugal action.
- (5) "Centrifugal compressor seal" means a wet or dry seal around the compressor shaft where the shaft exits the compressor case.
- (6) "Circulation tank" means a tank or portable tank used to circulate, store, or hold liquids or solids from a crude oil or natural gas well during or following a well stimulation treatment.
- (7) "Continuous bleed" means the continuous venting of natural gas from a gas powered pneumatic device to the atmosphere. Continuous bleed pneumatic devices must vent continuously in order to operate.
- (8) "Crude oil" means any of the naturally occurring liquids and semi-solids found in rock formations composed of complex mixtures of hydrocarbons ranging from one to hundreds of carbon atoms in straight and branched chain rings.
- (9) "Condensate" means hydrocarbon or other liquid either produced or separated from crude oil or natural gas during production and which condenses due to changes in pressure or temperature.
- (10) "Component" means a valve, fitting, flange, threaded-connection, process drain, stuffing box, pressure-vacuum valve, pipe, seal fluid system, diaphragm, hatch, sight-glass, meter, open-ended line, pneumatic device, pneumatic pump, centrifugal compressor wet seal, or reciprocating compressor rod packing or seal.
- (11) "Critical component" means any component that would require the shutdown of a critical process unit if that component was shutdown or disabled. ..
- (12) "Critical process unit" means a process unit that must remain in service because of its importance to the overall process that requires it to continue to operate, and has no equivalent equipment to replace it or cannot be bypassed, and it is technically infeasible to repair leaks from that process unit without shutting it down and opening the process unit to the atmosphere.

- (13) "Crude oil and produced water separation and storage" means all activities associated with separating, storing or holding of emulsion, crude oil, condensate, or produced water at facilities to which this subarticle applies.
- (14) "Emissions" means the discharge of natural gas into the atmosphere.
- (15) "Emulsion" means any mixture of crude oil, condensate, or produced water with varying quantities of natural gas entrained in the liquids.
- (16) "Equipment" means any stationary or portable machinery, object, or contrivance covered by this subarticle, as set out by sections 95666 and 95668.
- (17) "Facility" means any building, structure, or installation to which this subarticle applies and which has the potential to emit natural gas. Facilities include all buildings, structures, or installations which:
- (1) Are under the same ownership or operation, or which are owned or operated by entities which are under common control;
 - (2) Belong to the same industrial grouping either by virtue of falling within the same two-digit standard industrial classification code or by virtue of being part of a common industrial process, manufacturing process, or connected process involving a common raw material; and,
 - (3) Are located on one or more contiguous or adjacent properties.
- (18) "Flash or flashing" means a process during which gas entrained in crude oil, condensate, or produced water under pressure is released when the liquids are subject to a decrease in pressure or increase in temperature, such as when the liquids are transferred from an underground reservoir to the earth's surface.
- (19) "Flash analysis testing" means the determination of emissions from crude oil, condensate, and produced water by using sampling and laboratory procedures used for measuring the volume and composition of gases released from the liquids, including the molecular weight, the weight percent of individual compounds, and a gas-oil or gas-water ratio.
- (20) "Inaccessible component" means any component located over fifteen feet above ground when access is required from the ground; or any component located over six (6) feet away from a platform when access is required from the platform.
- (21) "Intermittent bleed" means the intermittent venting of natural gas from a gas powered pneumatic device to the atmosphere. Intermittent bleed pneumatic devices may vent all or a portion of their supply gas when control action is necessary but do not vent continuously.

- (22) "Leak or fugitive leak" means the unintentional release of emissions at a rate greater than or equal to the leak thresholds specified in this article.
- (23) "Leak detection and repair or LDAR" means the inspection of components to detect leaks of total hydrocarbons and the repair of components with leaks above specified standards within specified timeframes.
- (24) "Liquids unloading" means an activity conducted with the use of pressurized natural gas to remove liquids that accumulate at the bottom of a natural gas well and obstruct gas flow.
- (25) "Minimize" means tightening, adjusting, or replacing components or equipment for the purpose of stopping or reducing leaks below the lowest leak threshold specified in this subarticle.
- (26) "Natural gas" means a naturally occurring mixture or process derivative of hydrocarbon and non-hydrocarbon gases. Its constituents include the greenhouse gases methane and carbon dioxide, as well as heavier hydrocarbons. Natural gas may be field quality (which varies widely) or pipeline quality.
- (27) "Natural gas gathering and boosting station" means all equipment and components located within a facility fence line associated with moving natural gas to a processing plant or natural gas transmission pipeline.
- (28) "Natural gas processing plant" means a plant used for the separation of natural gas liquids (NGLs) or non-methane gases from produced natural gas, or the separation of NGLs into one or more component mixtures.
- (29) "Natural gas transmission compressor station" means all equipment and components located within a facility fence line associated with moving natural gas from production fields or natural gas processing plants through natural gas transmission pipelines.
- (30) "Natural gas transmission pipeline" means a Federal Energy Regulatory Commission rate-regulated Interstate pipeline, a state rate-regulated Intrastate pipeline, or a pipeline that falls under the "Hinshaw Exemption" as referenced in section 1(c) of the Natural Gas Act, 15 U.S.C. 717-717z (2015).
- (31) "Natural gas underground storage" means all equipment and components associated with the subsurface storage of natural gas in depleted crude oil or natural gas reservoirs or salt dome caverns.
- (32) "Offshore" means all marine waters located within the boundaries of the State of California.

- (33) "Onshore" means all lands located within the boundaries of the State of California.
- (34) "Operator" means any entity, including an owner or contractor, having operational control of components or equipment, including leased, contracted, or rented components and equipment to which this subarticle applies.
- (35) "Owner" means the entity that owns or operates components or equipment to which this subarticle applies.
- (36) "Photo-ionization detector or PID instrument" means a gas detection device that utilizes ultra-violet light to ionize gas molecules and is commonly employed in the detection of non-methane volatile organic compounds.
- (37) "Pneumatic device" means an automation device that uses natural gas, compressed air, or electricity to control a process.
- (38) "Pneumatic pump" means a device that uses natural gas or compressed air to power a piston or diaphragm in order to circulate or pump liquids.
- (39) "Pond" means an excavation or impoundment for the storage and disposal of produced water and is not used for crude oil separation or processing.
- (40) "Portable equipment" means equipment designed for, and capable of, being carried or moved from one location to another and which it resides for less than 365 days. Portability indicators include, but are not limited to, the presence of wheels, skids, carrying handles, dolly, trailer, or platform.
- (41) "Portable pressurized separator" means a pressure vessel that can be moved from one location to another by attachment to a motor vehicle without having to be dismantled and is capable of separating and sampling crude oil, condensate, or produced water at the steady-state temperature and pressure of the separator required for sampling.
- (42) "Portable tank" means a tank that can be moved from one location to another by attachment to a motor vehicle without having to be dismantled.
- (43) "Pressure vessel" means any a hollow container used to hold gas or liquid and rated, as indicated by an ASME pressure rating stamp, and operated to contain normal working pressures of at least 15 psig without vapor loss to the atmosphere and may be used for the separation of crude oil, condensate, produced water, or natural gas.
- (44) "Production" means all activities associated with the production or recovery of emulsion, crude oil, condensate, produced water, or natural gas at facilities to which this subarticle applies.

- (45) "Produced water" means water recovered from an underground reservoir as a result of crude oil, condensate, or natural gas production and which may be recycled, disposed, or re-injected into an underground reservoir.
- (46) "Reciprocating natural gas compressor" means equipment that increases the pressure of natural gas by positive displacement of a piston in a compression cylinder and is powered by an internal combustion engine or electric motor with a horsepower rating supplied by the manufacturer.
- (47) "Reciprocating natural gas compressor rod packing" means a seal comprising of a series of flexible rings in machined metal cups that fit around the reciprocating compressor piston rod to create a seal limiting the amount of compressed natural gas that vents into the atmosphere
- (48) "Reciprocating natural gas compressor seal" means any device or mechanism used to limit the amount of natural gas that vents from a compression cylinder into the atmosphere.
- (49) "Separator" means any tank used for the separation of crude oil, condensate, produced water, or natural gas.
- (50) "Separator and tank system" means a separator and any tank or sump connected directly to the separator. For the purpose of this article, in crude oil production, a pressure vessel used to separate crude oil and produced water is also considered a separator; in dry natural gas production, a pressure vessel used to separate gas from water is also considered a separator. .
- (51) "Successful repair" means tightening or adjusting or replacing equipment or a component for the purpose of stopping or reducing fugitive leaks below the lowest leak threshold specified in this subarticle.
- (52) "Sump" means a lined or unlined surface impoundment or depression in the ground that, during normal operations, is used to separate, store, or hold emulsion, crude oil, condensate, or produced water.
- (53) "Tank" means any container constructed primarily of non-earthen materials used for the purpose of storing, holding, or separating emulsion, crude oil, condensate, or produced water and that is designed to operate below 15 psig normal operating pressure.
- (54) "Underground injection well" means, for the purpose of this subarticle, any well that is used for the subsurface injection of natural gas for disposal.
- (55) "Vapor collection system" means equipment and components installed on pressure vessels, separators, tanks, or sumps including piping, connections,

and flow-inducing devices used to collect and route emissions to a processing, sales gas, or fuel gas system; to an underground injection well; or to a vapor control device.

- (56) "Vapor control device" means destructive or non-destructive equipment used to control emissions.
- (57) "Vapor control efficiency" means the ability of a vapor control device to control emissions, expressed as a percentage, which can be estimated by calculation or by measuring the total hydrocarbon concentration at the inlet and outlet of the vapor control device.
- (58) "Vapor pressure" means the equilibrium partial vapor pressure exerted by an organic liquid measured at maximum tank temperature.
- (59) "Vent or venting" means the intentional or automatic release of natural gas into the atmosphere from components, equipment or activities described in this subarticle.
- (60) "Well" means a boring in the earth that is designed to bring emulsion, crude oil, condensate, produced water, or natural gas to the surface, or to inject natural gas into underground storage.
- (61) "Well stimulation treatment" means the treatment of a well designed to enhance crude oil and natural gas production or recovery by increasing the permeability of the formation and as further defined by the Division of Oil, Gas, and Geothermal Resources SB 4 Well Stimulation Treatment Regulations, Chapter 4, Subchapter 2, Article 2, section 1761(a) (December 30, 2014).

NOTE: Authority cited: Sections 38510, 38562, 39600, 39601 and 41511, Health and Safety Code. Reference: Sections 38560, 39600 and 41511, Health and Safety Code

§ 95668. Standards.

(a) Crude Oil, Condensate, and Produced Water Separation and Storage

- (1) Except as provided in section 95668(a)(2), the requirements in sections 95668(a)(3) through (9) apply to pressure vessels, separators, tanks, and sumps at facilities listed in section 95666:.
- (2) The requirements of this subsection do not apply to the following:
 - (A) Pressure vessels, separators, tanks, and sumps that have not contained crude oil, condensate, or produced water for at least 30 calendar days.
 - (B) Tanks used for temporarily separating, storing, or holding emulsion, crude oil, condensate, or produced water from any newly constructed well for up

to 30 calendar days following initial production from that well but only if the tank is not used to circulate liquids from a well that has been subject to a well stimulation treatment.

- (3) Beginning January 1, 2017, pressure vessels not already subject to a district leak detection and repair program shall comply with the leak detection and repair requirements specified in section 95669.
- (4) Beginning January 1, 2017 and by no later than September 1, 2017, owners or operators of new and existing separator and tank systems which are not controlled for emissions with the use of a vapor collection system shall conduct annual flash analysis testing of the crude oil, condensate, or produced water as described below.
 - (A) Conduct flash analysis testing in accordance with the ARB Test Procedure for Determining Annual Flash Emission Rate of Methane from Crude Oil, Condensate, and Produced Water as described in Appendix C.
 - (B) Sum the annual flash analysis testing results for methane for the crude oil, condensate, and produced water.
 - (C) Maintain a record of flash analysis testing as specified in section 95671 and report the results to ARB as specified in section 95672.
 - (D) Demonstrate that the results of the flash analysis testing are representative of the crude oil, condensate, and produced water processed or stored in the separator and tank system. The ARB Executive Officer may request additional flash analysis testing or information in the event that the test results reported do not reflect representative results of similar systems.
- (5) Beginning January 1, 2018, owners or operators of separator and tank systems with a measured annual flash emission rate greater than 10 metric tons per year of methane shall control the emissions from the separator and tank system with the use of a vapor collection system as specified in section 95668(c).
- (6) Beginning January 1, 2018, separators, tanks, and covered sumps subject to the vapor collection system requirements specified in section 95668(a)(6) shall comply with the leak detection and repair requirements specified in section 95669.
- (7) Owners or operators of separator and tanks systems with a flash emission rate less than or equal to 10 metric tons per year of methane shall conduct flash analysis testing and reporting annually. If the results of flash analysis testing are less than or equal to 10 metric tons per year of methane using three

consecutive years of test results the owner or operator may reduce the frequency of testing and reporting to once every five years.

- (8) Flash analysis testing, record keeping, and reporting shall be conducted within one calendar year of adding a new well to the separator and tank system since the time of previous flash analysis testing.
- (9) Flash emissions shall be recalculated if the annual crude oil, condensate, or produced water throughput increases by more than 10 percent since the time of the previous flash analysis testing provided that the increase in throughput is not a result of adding a new well to the separator and tank system which requires additional flash analysis testing as specified in section 95668(a)(8).
 - (A) The owner or operator shall maintain and make available upon request by the ARB Executive Officer a record of the revised flash emission calculation.

(b) *Circulation Tanks for Well Stimulation Treatments*

- (1) Beginning January 1, 2018, circulation tanks used in conjunction with well stimulation treatments used at facilities listed in section 95666 shall be controlled for emissions of natural gas according to one of the following methods:
 - (A) The circulated liquids shall be controlled for emissions of natural gas prior to entering the circulation tank using a pressure vessel or separator and a vapor collection system as specified in section 95668(c) and the circulation tank shall be covered and comply with the leak detection and repair requirements specified in section 95669; or,
 - (B) Circulation tanks shall be covered and controlled for emissions of natural gas using a vapor collection system as described in section 95668(c) and the tank shall comply with the leak detection and repair requirements specified in section 95669.

(c) *Vapor Collection Systems and Vapor Control Devices*

- (1) Beginning January 1, 2018, the following requirements apply to equipment at facilities listed in section 95666 that are subject to the vapor collection system and control device requirements specified in this subarticle:
- (2) Unless section 95668(c)(3) applies, the vapor collection system shall direct the collected vapors to one of the following:
 - (A) Existing sales gas system; or,
 - (B) Existing fuel gas system; or,

- (C) Existing underground injection well not currently under review by the Division of Oil and Gas and Geothermal Resources.
- (3) If no existing sales gas system, fuel gas system, or underground injection well specified in section 95668(c)(2) is available at the facility, the owner or operator must control the collected vapors as follows:
- (A) For facilities without an existing vapor control device installed at the facility, the owner or operator must install a new vapor control device as specified in section 95668(c)(4); or,
 - (B) For facilities currently operating a vapor control device and which are required to control additional vapors as a result of this subarticle, the owner or operator must replace the existing vapor control device with a new vapor control device as specified in section 95668(c)(4) to control all of the collected vapors.
- (4) Any vapor control device required in section 95668(c)(3) must meet the following requirements:
- (A) If the vapor control device is to be installed in a region classified as in attainment with all state or federal ambient air quality standards, the vapor control device must achieve at least 95% vapor control efficiency of total emissions and must meet all applicable federal, state, and local air district requirements; or,
 - (B) If the vapor control device is to be installed in a region classified as non-attainment with, or which has not been classified as in attainment of, all state and federal ambient air quality standards, the owner or operator must install one of the following devices that meets all applicable federal, state, and local air district requirements:
 - 1. A non-destructive vapor control device that achieves at least 95% vapor control efficiency of total emissions and does not result in emissions of nitrogen oxides (NO_x); or,
 - 2. A vapor control device that achieves at least 95% vapor control efficiency of total emissions and does not generate more than 15 parts per million volume (ppmv) NO_x when measured at 3% oxygen.
- (5) If the collected vapors cannot be controlled as specified in section 95668(c)(2) through (4), the equipment subject to the vapor collection and control requirements specified in this subarticle may not be used or installed and must be removed from service by January 1, 2018.
- (6) Vapor collection systems and control devices are allowed up to 30 calendar days per year for maintenance. A time extension to perform maintenance not

to exceed 14 calendar days may be granted by the ARB Executive Officer. The owner or operator is responsible for maintaining a record of the number of calendar days per calendar year that the vapor collection system or vapor control device is out of service and shall provide a record of such activity at the request of the ARB Executive Officer..

- (A) If an alternate vapor control device compliant with this section is installed prior to conducting maintenance and the vapor collection and control system continues to collect and control vapors during the maintenance operation, the event does not count towards the 30 calendar day limit.
- (B) Vapor collection system and control device shutdowns that result from utility power outages are not subject to enforcement action provided the equipment resumes normal operation as soon as normal utility power is restored. Vapor collection system and control device shutdowns that result from utility power outages do not count towards the 30 calendar day limit for maintenance.

(d) Reciprocating Natural Gas Compressors

- (1) The following requirements apply to reciprocating natural gas compressors at crude oil or natural gas production facilities listed in section 95666 which are not covered under section 95668(d)(2):
 - (A) Beginning January 1, 2017, components on driver engines and compressors shall comply with the leak detection and repair requirements specified in section 95669.
 - (B) Beginning January 1, 2017, for any compressors without a vapor collection system used to control the rod packing or seal vent gas, the rod packing or seal shall comply with the leak detection and repair requirements specified in section 95669; and,
 - (C) The owner or operator shall maintain a record of the rod packing or seal leak concentration measurement as specified in Appendix A, Table 5.
 - (D) A reciprocating natural gas compressor with a rod packing or seal leak concentration measured above the minimum standard specified in section 95669 and which has been approved by the ARB Executive Officer as a critical component as specified in section 95670, shall be successfully repaired by the end of the next process shutdown or within 180 calendar days from the date of the initial leak concentration measurement, whichever is sooner.
- (2) The following requirements apply to reciprocating natural gas compressors at natural gas gathering and boosting stations, processing plants, transmission

compressor stations, and underground natural gas storage facilities listed in section 95666 and which are not covered under section 95668(d)(1):

- (A) Beginning January 1, 2017, components on driver engines and compressors shall comply with the leak detection and repair requirements specified in section 95669.
- (B) Beginning January 1, 2017, any compressor without a vapor collection system used to control the rod packing or seal vent gas shall be equipped with a meter or instrumentation that can measure the rod packing or seal emissions flow rate; or,
- (C) The compressor shall be equipped with a clearly identified access port installed in the rod packing or seal vent stack at a height of no more than six (6) feet above ground level for making individual or combined rod packing or seal emission flow rate measurements; and,
- (D) The rod packing or seal emissions flow rate shall be measured annually by direct measurement (high volume sampling, bagging, calibrated flow measuring instrument) while the compressor is running at normal operating temperature.
- (E) Beginning January 1, 2018, a compressor with a rod packing or seal with a measured emission flow rate greater than two (2) standard cubic feet per minute (scfm), or a combined rod packing or seal emission flow rate greater than the number of compression cylinders multiplied by two (2) scfm, shall be repaired or replaced within 30 calendar days from the date of the initial emission flow rate measurement.
- (F) A reciprocating natural gas compressor with a rod packing or seal emission flow rate measured above the standard specified in section 95688(d)(2)(E) and which has been approved by the ARB Executive Officer as a critical component as specified in section 95670, shall be successfully repaired by the end of the next process shutdown or within 180 days from the date of the initial flow rate measurement, whichever is sooner.

(e) *Centrifugal Natural Gas Compressors with Wet Seals*

- (1) The following requirements apply to centrifugal natural gas compressors with wet seals at facilities listed in section 95666:
- (2) Beginning January 1, 2017, components on driver engines and compressors shall comply with the leak detection and repair requirements specified in section 95669.

- (3) Beginning January 1, 2017, any compressor without a vapor collection system used to control the wet seal vent gas shall be equipped with a meter or instrumentation that can measure the wet seal emissions flow rate; or
- (4) The compressor shall be equipped with a clearly identified access port installed in the wet seal vent stack at a height of no more than six (6) feet above ground level for making wet seal emission flow rate measurements; and,
- (5) The wet seal emissions flow rate shall be measured annually by direct measurement (high volume sampling, bagging, calibrated flow measuring instrument) while the compressor is running at normal operating temperature.
- (6) Beginning January 1, 2018, a compressor with a wet seal emission flow rate greater than three (3) scfm or a combined wet seal emission flow rate greater than the number of wet seals multiplied by three (3) scfm shall control the wet seal emission vent gas with the use of a vapor collection system as specified in section 95668(c); or,
- (7) Minimize the wet seal emission flow rate within 30 calendar days from the date of the initial emission flow rate measurement and replace the wet seal with a dry seal by no later than January 1, 2020.
- (8) A centrifugal natural gas compressor with a wet seal emission flow rate measured above the standard specified in section 95668(e)(6) and which has been approved by the ARB Executive Officer as a critical component as specified in section 95670, shall be successfully repaired by the end of the next process shutdown or within 180 days from the date of the initial flow rate measurement, whichever is sooner.

(f) *Natural Gas Powered Pneumatic Devices and Pumps*

- (1) Except as provided in section 95668(f)(2), the requirements in sections 95668(f)(3) through (6) apply to natural gas powered pneumatic devices and pumps at facilities listed in section 95666:
- (2) A natural gas powered pneumatic device installed prior to January 1, 2015 may be used provided it meets all of the following requirements:
 - (A) The device does not vent natural gas at a rate greater than 6 standard cubic feet per hour (scfh); and,
 - (B) The device is clearly marked with a permanent tag that identifies the vent rate as less than or equal to 6 scfh; and,

- (C) The device is tested during each inspection period as specified in section 95669 by using a direct measurement method (high volume sampling, bagging, calibrated flow measuring instrument); and,
 - (D) A device with a measured emissions flow rate greater than 6 scfh shall be repaired or replaced within 14 calendar days from the date of the initial emission flow rate measurement.
- (3) Beginning January 1, 2018, pneumatic devices shall not vent natural gas to the atmosphere and shall comply with the leak detection and repair requirements specified in section 95669..
 - (4) Beginning January 1, 2018, intermittent bleed pneumatic devices shall not vent natural gas when not actuating determined by testing the device when not actuating in accordance with the leak detection and repair requirements specified in section 95669.
 - (5) Beginning January 1, 2018, pneumatic pumps shall not vent natural gas to the atmosphere and shall comply with the leak detection and repair requirements specified in section 95669.
 - (6) Beginning January 1, 2018, pneumatic devices and pumps shall be retrofitted or replaced to prevent natural gas from venting to the atmosphere or shall be controlled according to one of the following methods:
 - (A) Collect all vented natural gas with the use of a vapor collection system as specified in section 95668(c); or,
 - (B) Use compressed air or electricity to operate.

(g) *Liquids Unloading of Natural Gas Wells*

- (1) Beginning January 1, 2018, owners or operators of natural gas wells at facilities listed in section 95666 that are vented to the atmosphere for the purpose of liquids unloading shall perform one of the following:
 - (A) Collect the vented natural gas with the use of a vapor collection system as specified in section 95668(c); or,
 - (B) Measure the volume of natural gas vented by direct measurement (high volume sampling, bagging, calibrated flow measuring instrument); or,
 - (C) Calculate the volume of natural gas vented using the Liquid Unloading Calculation listed in Appendix B or according to the Air Resources Board Regulation for the Mandatory Reporting of Greenhouse Gas Emissions,

Title 17, Division 3, Chapter 1, Subchapter 10, Article 2, Section 95153(e)
(February, 2015).

- (2) Owners or operators must maintain and report a record of the volume of natural gas vented to perform liquids unloading as well as equipment installed in the natural gas well(s) designed to automatically perform liquids unloading (e.g., foaming agent, velocity tubing, plunger lift, etc.) once per calendar year as specified in sections 95670 and 95671 of this subarticle.

(h) Natural Gas Underground Storage Facility Well Monitoring Requirements

- (1) The following requirements apply to natural gas underground storage facilities listed in section 95666:
- (2) By January 1, 2017, each facility shall develop a plan for surface leak monitoring at the facility on a continuous basis or, if continuous is not feasible, a daily basis. The plan will be evaluated based on sensitivity of instrumentation, coverage of the facility, appropriateness for site, and other relevant criteria. The ARB Executive Officer will approve, [in full or in part, or disapprove, in full or in part](#), the plans with full implementation of monitoring by January 1, 2018.

[Staff is considering a leak emission reduction requirement for large or catastrophic leaks at any oil and gas facility covered by this regulation]

§ 95669. Leak Detection and Repair

- (a) The following requirements apply to components at facilities listed in section 95666 which are not already subject to a local air district leak detection and repair program.
- (b) Beginning January 1, 2017, an owner or operator shall audio-visually (by hearing and by sight) inspect components for leaks at least once every 24 hours for facilities that are visited daily, or at least once per calendar week for unmanned facilities.
- (c) Any audio-visual inspection that indicates a leak which cannot be repaired immediately shall be tested as specified in section 95669(f) within 24 hours after conducting the audio-visual inspection.
- (d) Except as provided in section 95669(e), the requirements in sections 95669(f) through (o) apply to components at facilities listed in section 95666:
- (e) Leak detection and repair requirements do not apply to the following unless required by the local air district:

- (1) Components at a facility upstream of a transfer of custody meter used exclusively for the delivery of commercial quality natural gas to the facility.
 - (2) Components incorporated into produced water lines located downstream of produced water tanks that are controlled with the use of a vapor collection system.
 - (3) Components that are buried below ground. Well casing that extends to the surface is not considered a buried component.
 - (4) One-half inch and smaller stainless steel tube fittings including those used for instrumentation.
 - (5) Components incorporated in lines operating exclusively under negative pressure or below atmospheric pressure.
 - (6) Components and piping located downstream from the point where crude oil, condensate, or natural gas transfer of custody occurs, including components and piping located outside the facility boundaries of natural gas compressor stations and underground storage facilities.
 - (7) Temporary components or equipment used for general maintenance purposes and used less than 300 hours per calendar year if the owner or operator maintains and can provide a record of the date when the components were installed and the number of hours the components have been in operation.
 - (8) Components which are unsafe to monitor when conducting EPA Method 21 measurements and as documented in a safety manual or policy and approved by the ARB Executive Officer.
- (f) Beginning January 1, 2017, components shall be inspected at least once each calendar quarter for leaks of total hydrocarbons in units of parts per million volume (ppmv) calibrated as methane in accordance with EPA Reference Method 21 excluding the use of PID instruments.
- (1) The quarterly inspection frequency may be reduced to annually provided that both of the following conditions are met:
 - (A) All components have been measured below the number of allowable leaks for each leak threshold specified in Table 4 for five (5) consecutive calendar quarters.
 - (B) The change in inspection frequency is substantiated by documentation and approved by the ARB Executive Officer.

- (2) The inspection frequency shall revert to quarterly at any time the number of allowable leaks specified in Table 4 is exceeded during any inspection period.
- (g) Owners or operators shall maintain and report a record of each leak inspection and the component leak concentration(s) and repair date(s) as specified in sections 95671 and 95672.
- (h) Owners or operators shall minimize leaks immediately, but not later than one (1) calendar day after initial leak detection.
- (i) Hatches shall remain closed at all times except during sampling, adding process material, or attended maintenance operations.
- (j) Open-ended lines and valves located at the end of lines shall be sealed with a blind flange, plug, cap or a second closed valve, at all times except during operations requiring liquid or gaseous process fluid flow through the open-ended line.
- (k) Components or component parts which incur five (5) repair actions within a continuous 12-month period shall be replaced or removed from service.
- (l) From January 1, 2017 and through December 31, 2018, any component with a leak concentration measured above the following standards shall be repaired within the time period specified:
 - (1) Leaks with measured total hydrocarbons greater than or equal to 10,000 ppmv but not greater than 49,999 ppmv shall be successfully repaired or removed from service within 14 calendar days of initial leak detection.
 - (2) Leaks with measured total hydrocarbons greater than or equal to 50,000 ppmv shall be successfully repaired or removed from service within five (5) calendar days of initial leak detection.
 - (3) Components measured above the standards specified and which have been approved by the ARB Executive Officer as a critical component as specified in section 95670, shall be repaired to minimize the leak to the maximum extent possible within one (1) calendar day of initial leak detection and the final repair shall be completed by the end of the next process shutdown or within 180 days from the date of initial leak detection, whichever is sooner.

Table 1
Repair Time Periods January 1, 2017 through December 31, 2018

| Leak Threshold | Repair Time Period |
|------------------------|---|
| 10,000-49,999 ppmv | 14 calendar days |
| 50,000 ppmv or greater | 5 calendar days |
| Critical Components | Next shutdown or within 180 calendar days |

- (m) By January 1, 2019, any component with a leak concentration measured above the following standards shall be repaired within the time period specified:
- (1) Leaks with measured total hydrocarbons greater than or equal to 1,000 ppmv but not greater than 9,999 ppmv shall be successfully repaired or removed from service within 14 calendar days of initial leak detection.
 - (2) Leaks with measured total hydrocarbons greater than or equal to 10,000 ppmv but not greater than 49,999 ppmv shall be successfully repaired or removed from service within five (5) calendar days of initial leak detection.
 - (3) Leaks with measured total hydrocarbons greater than or equal to 50,000 ppmv shall be successfully repaired or removed from service within two (2) calendar days of initial leak detection.

Table 2
Repair Time Periods On or After January 1, 2019

| Leak Threshold | Repair Time Period |
|------------------------|---|
| 1,000-9,999 ppmv | 14 calendar days |
| 10,000-49,999 ppmv | 5 calendar days |
| 50,000 ppmv or greater | 2 calendar days |
| Critical Components | Next shutdown or within 180 calendar days |

- (n) Upon detection of a component with a leak concentration measured above the standards specified, the owner or operator shall affix to that component a weatherproof readily visible tag that identifies the date and time of leak detection measurement and the measured leak concentration. The tag shall remain affixed to the component until all of the following conditions are met:
- (1) The leaking component has been repaired or replaced; and,

- (2) The component has been re-inspected and measured below the lowest standard specified for the inspection year when measured in accordance with EPA Reference Method 21, excluding the use of PID instruments.
 - (3) Components measured above the standards specified and which have been approved by the ARB Executive Officer as a critical component as specified in section 95670, shall be repaired to minimize the leak to the maximum extent possible within one (1) calendar day of initial leak detection and the final repair shall be completed by the end of the next process shutdown or within 180 days from the date of initial leak detection, whichever is sooner.
- (o) Compliance with Leak Detection and Repair Requirements:
- (1) The failure of an owner or operator to meet any of the requirements specified shall constitute a violation of this subarticle.
 - (2) Between January 1, 2017 and December 31, 2018, no facility shall exceed the number of allowable leaks specified in Table 3 during any inspection period as determined by the ARB Executive Officer or by the facility owner or operator in accordance with Method 21, excluding the use of PID instruments.
 - (3) By January 1, 2019, no facility shall exceed the number of allowable leaks specified in Table 4 during any inspection period as determined by the ARB Executive Officer or by the facility owner or operator in accordance with Method 21, excluding the use of PID instruments.
 - (4) By January 1, 2019, no component shall exceed a leak of total hydrocarbons greater than or equal to 50,000 ppmv as determined by the ARB Executive Officer or by the facility owner or operator in accordance with Method 21, excluding the use of PID instruments.

**Table 3 - Allowable Leaks Per Number of Components Inspected
January 1, 2017 through December 31, 2018**

| Leak Threshold | 200 or Less Components | More than 200 Components |
|------------------------|-------------------------------|---------------------------------|
| 10,000-49,999 ppmv | 5 | 2% of total inspected |
| 50,000 ppmv or greater | 2 | 1% of total inspected |

**Table 4 - Allowable Leaks Per Number of Components Inspected
On or After January 1, 2019**

| Leak Threshold | 200 or Less Components | More than 200 Components |
|------------------------|-------------------------------|---------------------------------|
| 1,000-9,999 ppmv | 5 | 2% of total inspected |
| 10,000-49,999 ppmv | 2 | 1% of total inspected |
| 50,000 ppmv or greater | 0 | 0 |

§ 95670. Critical Components

- (a) Beginning January 1, 2017, critical components used in conjunction with a critical process unit at facilities listed in section 95666 must be pre-approved by the ARB Executive Officer if owners or operators wish to claim any critical component exemptions available under this subarticle.
- (b) Each critical component shall be identified as shown in Appendix A, Table A3 and submitted to ARB for approval by no later than June 30, 2017 or within 180 days from the installation of a new critical component.
- (c) Owners or operators must provide sufficient documentation showing that a critical component is required as part of a critical process unit and that shutting down the critical component would result in emissions greater than the emissions measured from the component.
- (d) Approval of a critical component may be granted only if owners or operators fully comply with this section. The ARB Executive Officer retains discretion to deny any application for approval.

NOTE: Authority cited: Sections 38510, 38562, 39600, 39601 and 41511, Health and Safety Code. Reference: Sections 38560, 39600 and 41511, Health and Safety Code

§ 95671. Record Keeping Requirements.

- (a) Beginning January 1, 2017, owners or operators of facilities listed in section 95666 subject to requirements specified in sections 95668 and 95669 shall maintain, and make available upon request by ARB a copy of the following records:

Flash Analysis Testing

- (1) Maintain, for at five years from the date of each test, a record of flash analysis testing that shall include the following:

- (A) A sketch or diagram of each separator and tank system tested that identifies the liquid sampling location and all pressure vessels, separators tanks, sumps, and ponds within the system; and,
- (B) A record of the flash analysis testing results, calculations, and a description of the separator and tank system as specified in Appendix A Table A1; and,
- (C) A field testing form for each flash analysis test conducted as specified in Appendix C Form 1; and,
- (D) The laboratory report(s) for each flash analysis test conducted.

Liquids Unloading of Natural Gas Wells

- (2) Maintain, for at least two years following the measurement or calculation, a record of the measured or calculated volume of natural gas vented to perform liquids unloading and equipment installed in the natural gas well(s) designed to automatically perform liquids unloading (e.g., foaming agent, velocity tubing, plunger lift, etc.) as specified in Appendix A Table A2.

Leak Detection and Repair

- (3) Maintain, for at least two years from each inspection, a record of each leak detection and repair inspection as specified in Appendix A Table A4.
- (4) Maintain, for at least two years from each inspection, a component leak concentration and repair form for each inspection as specified in Appendix A Table A5.

NOTE: Authority cited: Sections 38510, 38562, 39600, 39601, 39607, and 41511, Health and Safety Code. Reference: Sections 38560, 39600 and 41511, Health and Safety Code.

§ 95672. Reporting Requirements.

- (a) Beginning January 1, 2018, owners or operators of facilities listed in section 95666 subject to requirements specified in sections 95668 and 95669 shall report the following information to ARB within the timeframes specified:

Flash Analysis Testing(1) Within 90 days of performing flash analysis testing, report the test results, calculations, and a description of the separator and tank system as specified in Appendix A Table A1..

Liquids Unloading of Natural Gas Wells

- (2) Annually, report the measured or calculated volume of natural gas vented to perform liquids unloading and equipment installed in the natural gas well(s) designed to automatically perform liquids unloading as specified in Appendix A Table A3.

Leak Detection and Repair

- (3) Once per calendar year, report the results of each leak detection inspection conducted during the calendar year as specified in Appendix A Table A4.
 - (4) Once per calendar year, report the initial and final component leak concentration(s) for each inspection conducted during the calendar year as specified in Appendix A Table A5.
- (b) Reports may be e-mailed electronically to ARB with the subject line "O&G GHG Regulation Reporting" to oil&gas@arb.ca.gov or mailed to:

California Air Resources Board

§ 95673. Implementation.

(a) Implementation by ARB and by the Local Air Districts

- (1) The requirements of this subarticle are provisions of state law and are enforceable by both ARB and the local air districts where equipment covered by this subarticle is located. Local air districts may incorporate the terms of this subarticle into local air district rules. An owner or operator of equipment subject to this subarticle must pay any fees assessed by a local air district for the purposes of recovering the district's cost of implementing and enforcing the requirements of this subarticle. Any penalties secured by a local air district as the result of an enforcement action that it undertakes to enforce the provisions of this subarticle may be retained by the local air district.
- (2) The ARB Executive Officer, at his or her discretion, may enter into an agreement or agreements with any local air district to further define implementation and enforcement processes, including arrangements further specifying approaches for implementation and enforcement of this subarticle,

and for information sharing between ARB and local air districts relating to this subarticle.

- (3) Implementation and enforcement of the requirements of this subarticle by a local air district may in no instance result in a standard, requirement, or prohibition less stringent than provided for by this subarticle, as determined by the Executive Officer. The terms of any local air district permit or rule relating to this subarticle do not alter the terms of this subarticle, which remain as separate requirements for all sources subject to this subarticle.
- (4) Implementation and enforcement of the requirements of this subarticle by a local air district, including inclusion or exclusion of any of its terms within any local air district permit, or within a local air district rule, or registration of a facility with a local air district or ARB, does not in any way waive or limit ARB's authority to implement and enforce upon the requirements of this subarticle. A facility's permitting or registration status also in no way limits the ability of a local air district to enforce the requirements of this subarticle.

(b) *Requirements for Covered Entities*

- (1) Local Air District Permitting Requirements
 - (A) Owners or operators of facilities or equipment regulated by this subarticle, and who are required by federal, state, or local law to hold local air district permits that cover those facilities or equipment shall ensure that their local air district permits for those facilities or equipment contain terms ensuring compliance with this article. This requirement applies to facilities or equipment upon issuance of any new local air district permit covering these facilities or equipment, or upon the scheduled renewal of an existing permit covering these facilities or equipment.
 - (B) If, after the effective date of this subarticle, any local air district amends or adopts permitting rules that result in additional equipment or facilities regulated by this subarticle becoming subject to local air district permitting requirements, then owners or operators of that equipment or facility must ensure that any applicable local air district permits for that equipment or facility ensures compliance with this subarticle upon issuance of any relevant permit.
- (2) Registration Requirements (A) Owners or operators of facilities or equipment that is regulated by this subarticle shall register the equipment at each facility by reporting the following information to ARB as specified in Appendix A Table A6 no later than January 1, 2019, unless the local air district has established a registration or permitting program that collects at least the following information, and has entered into an MOU with ARB specifying how information is to be shared with ARB.

1. The owner or operator's name and contact information.
 2. The address or location of each facility with equipment regulated by this subarticle.
 3. A description of all equipment covered by this subarticle located at each facility including the following:
 - (a) The number of crude oil or natural gas wells at the facility.
 - (b) A list identifying all pressure vessels, tanks, separators, sumps, and ponds at the facility, including the size of each tank and separator in units of barrels.
 - (c) The annual crude oil, natural gas, and produced water throughput of the facility.
 - (d) A list identifying all reciprocating and centrifugal natural gas compressors at the facility,
 - (e) A count of all pneumatic devices and pumps at the facility.
 4. The permit numbers of all local air district permits issued for the facility or equipment, and an identification of permit terms that ensure compliance with the terms of this subarticle, or an explanation of why such terms are not included.
 5. An attestation that all information provided in the registration is provided by a party authorized by the owner or operator to do so, and that the information is true and correct.
- (B) Updates to these reports, recording any changes in this information, must be filed with ARB, or, as relevant, with the local air district no later than January 1 of the calendar year after the year in which any information required by this subarticle has changed. .
- (3) Owners or operators of equipment subject to this subarticle must comply with all the requirements of sections 95666, 95667, 95668, 95669, 95670, 95671, 95672, and 95673 of this subarticle, regardless of whether or not they have complied with the permitting and registration requirements of this subsection.

NOTE: Authority cited: Sections 38510, 38562, 39600, 39601, 39603, 39607, and 41511, Health and Safety Code. Reference: Sections 38560, 39600, 40701, 40702, 41511, 42300, 42301, and 42311, Health and Safety Code.

§ 95674. Enforcement.

- (a) Failure to comply with the requirements of this subarticle at each individual piece of equipment subject to this subarticle constitutes a single, separate, violation of this subarticle.
- (b) Each day, or portion thereof, that an owner or operator is not in full compliance with the requirements of this subarticle is a single, separate, violation of this subarticle.
- (c) Each metric ton of methane emitted in violation of this subarticle constitutes a single, separate, violation of this subarticle.
- (d) Failure to submit any report required by this subarticle shall constitute a single, separate violation of this subarticle for each day or portion thereof that the report has not been received after the date the report is due.
- (e) Failure to retain and failure to produce any record that this subarticle requires to be retained or produced shall each constitute a single, separate violation of this subarticle for each day or portion thereof that the record has not been retained or produced.
- (f) Falsifying any information or record required to be submitted or retained by this subarticle, or submitting or producing inaccurate information, shall be a violation of this subarticle.

NOTE: Authority cited: Sections 38510, 38562, 38580, 39600, 39601, 39607, and 41511, Health and Safety Code. Reference: Sections 38560, 39600 and 41511, Health and Safety Code.

§ 95675. No Preemption of More Stringent Air District or Federal Requirements

This regulation does not preempt any more stringent requirements imposed by any Air District. Compliance with this subarticle does not excuse noncompliance with any Federal regulation. The ARB Executive Officer retains authority to determine whether an Air District requirement is more stringent than any requirement of this subarticle.

NOTE: Authority cited: Sections 38510, 38562, 39600, 39601 and 41511, Health and Safety Code. Reference: Sections 38560, 39600 and 41511, Health and Safety Code.

§ 95676. Severability

Each part of this subarticle is deemed severable, and in the event that any part of this subarticle is held to be invalid, the remainder of the subarticle shall continue in full force and effect.

DRAFT: February 1, 2016

NOTE: Authority cited: Sections 38510, 38562, 39600, 39601 and 41511, Health and Safety Code. Reference: Sections 38560, 39600 and 41511, Health and Safety Code.

Appendix B

Calculation for Determining Vented Natural Gas Volume from Liquids Unloading of Natural Gas Wells

$$E_{scf} = \left(\frac{V * P_1 * T_2}{P_2 * T_1} \right) + (FR * HR)$$

Where:

E_{scf} is the natural gas emissions per event in scf

$V = \pi * r^2 * D$ (volume of the well)

$r = \frac{CD}{2}$ (radius of the well)

CD is the casing diameter in feet

D is the depth of the well in feet

P_1 is the shut-in pressure of the well in psia

P_2 is 14.7 psia (standard surface pressure)

T_1 is the temperature of the well at shut-in pressure in °F

T_2 is 60 °F (standard surface temperature)

FR is the metered flowrate of the well or the sales flowrate of the well in scf/hour

HR is the hours the well was left open to atmosphere during unloading

$$CH_4 \text{ emissions} = E_{scf} * MF_{CH_4} * MV * MW_{CH_4} * \left(\frac{\text{metric ton}}{2204.6 \text{ lb}} \right)$$

Where:

$CH_4 \text{ emissions}$ is in metric tons per event

$MF_{CH_4} = \frac{\text{lbmole } CH_4}{\text{lbmole gas}}$ (mole fraction of CH₄ in the natural gas)

$MV = \frac{1 \text{ lbmole gas}}{379.3 \text{ scf gas}}$ (molar volume)

$MW_{CH_4} = \frac{16 \text{ lb } CH_4}{\text{lbmole } CH_4}$ (molecular weight of CH₄)

Appendix C

Test Procedure for Determining Annual Flash Emission Rate of Methane from Crude Oil, Condensate, and Produced Water

1. PURPOSE AND APPLICABILITY

In crude oil and natural gas production, flash emissions may occur when gas entrained in crude oil, condensate, or produced water is released from the liquids due to a decrease in pressure or increase in temperature, such as when the liquids are transferred from an underground reservoir to the earth's surface. This procedure is used for determining the annual flash emission rate from tanks used to separate, store, or hold crude oil, condensate or produced water. The laboratory methods required to conduct this procedure are used to measure methane and other gaseous compounds.

2. PRINCIPLE AND SUMMARY OF TEST PROCEDURE

This procedure is conducted by collecting one sample of crude oil or condensate and one sample of produced water upstream of a separator or tank where flashing may occur. Samples shall be collected under pressure and according to the methods specified in this procedure. If a pressure vessel is not available upstream of a separator or tank that can be used for collecting samples under pressure, sampling shall be conducted using a portable pressurized separator.

Two sampling methods are specified for collecting liquid samples while maintaining a positive pressure within a sampling cylinder to prevent flashing within the cylinder. The first method requires a double valve cylinder for collecting crude oil or produced water samples. The second method requires a cylinder equipped with a pressurized piston for collecting condensate or produced water samples. Both methods shall be conducted as specified in this procedure.

The laboratory methods specified for this procedure are based on American Standards and Testing Materials (ASTM), US Environmental Protection Agency (EPA), and Gas Processor Association (GPA) methods. These laboratory methods measure the volume and composition of gases that flash from the liquids, including a Gas-Oil or Gas-Water Ratio, as well as the molecular weight and weight percent of the gaseous compounds. The laboratory results are used with the crude oil or condensate or produced water throughput to calculate the mass of emissions that are flashed from the liquids per year.

3. DEFINITIONS

For the purposes of this procedure, the following definitions apply:

- 3.1** "Air Resources Board or ARB" means the California Air Resources Board.
- 3.2** "API Gravity" means a scale used to reflect the specific gravity (SG) of a fluid such as crude oil, condensate, produced water, or natural gas. The API gravity is calculated as $[(141.5/SG) - 131.5]$, where SG is the specific gravity of the fluid at 60°F, and where API refers to the American Petroleum Institute.
- 3.3** "Condensate" means hydrocarbon and other liquid either produced or separated from crude oil or natural gas during production and which condenses due to changes in pressure or temperature.
- 3.4** "Crude oil" means any of the naturally occurring liquids and semi-solids found in rock formations composed of complex mixtures of hydrocarbons ranging from one to hundreds of carbon atoms in straight and branched chain rings.
- 3.5** "Double valve cylinder" means a metal cylinder equipped with valves on either side for collecting crude oil or produced water samples.
- 3.6** "Emissions" means the discharge of natural gas into the atmosphere.
- 3.7** "Emulsion" means any mixture of crude oil, condensate, or produced water with varying amounts of natural gas contained in the liquid.
- 3.8** "Flash or flashing" means a process during which gas entrained in crude oil, condensate, or produced water under pressure is released when subject to a decrease in pressure or increase in temperature, such as when liquids are transferred from an underground reservoir to a tank on the earth's surface.
- 3.9** "Gas-Oil Ratio (GOR)" means a measurement used to describe the volume of gas that is flashed from a barrel of crude oil or condensate.
- 3.10** "Gas-Water Ratio (GWR)" means a measurement used to describe the volume of gas that is flashed from a barrel of produced water.
- 3.11** "Natural gas" means a naturally occurring mixture or process derivative of hydrocarbon and non-hydrocarbon gases, of which its constituents include methane, carbon dioxide, and heavier hydrocarbons. Natural gas may be field quality (which varies widely) or pipeline quality.
- 3.12** "Operating pressure" means the steady-state pressure of the vessel from which a sample is collected. If no pressure gauge is available or the sampling train pressure gauge reading is greater than +/- 5 psig of the

vessel pressure, the sampling train pressure gauge reading shall be used to record the steady state pressure on Form 1.

- 3.13** "Operating temperature" means the steady-state temperature of the vessel from which a sample is collected. If no temperature gauge is available or the sampling train temperature gauge reading is greater than +/- 4°F of the vessel temperature, the sampling train temperature gauge reading shall be used to record the steady state temperature on Form 1.
- 3.14** "Percent water cut" means the volume percentage of produced water to crude oil or condensate.
- 3.15** "Piston cylinder" means a metal cylinder containing an internal pressurized piston for collecting condensate or produced water samples.
- 3.16** "Portable pressurized separator" means a sealed vessel that can be moved from one location to another by attachment to a motor vehicle without having to be dismantled and is used for separating and sampling crude oil, condensate, or produced water at the steady-state temperature and pressure of the separator and tank system required for sampling.
- 3.17** "Pressure vessel" means any vessel rated, as indicated by an ASME pressure rating stamp, and operated to contain normal working pressures of at least 15 psig without vapor loss to the atmosphere and may be used for the separation of crude oil, condensate, produced water, or natural gas..
- 3.18** "Produced water" means water recovered from an underground reservoir as a result of crude oil, condensate, or natural gas production and which may be recycled, disposed, or re-injected into an underground reservoir.
- 3.19** "Separator" means any tank designed to contain a normal working pressure of less than 15 psig and is used for the separation of crude oil, condensate, produced water, or natural gas.
- 3.20** "Separator and tank system" means any combination of pressure vessels or tanks used to separate, store, or hold emulsion, crude oil, condensate, or produced water with varying quantities of natural gas.
- 3.21** "Tank" means any container constructed primarily of non-earthen materials used for the purpose of storing or holding emulsion, crude oil, condensate, or produced water.
- 3.22** "Throughput" means the average volume of crude oil, condensate, or produced water expressed in units of barrels per day.

4. BIASES AND INTERFERENCES

- 4.1 The sampling method used to collect a liquid sample will have an impact on the final results reported. Liquid samples shall be collected in accordance with the sampling procedures specified in this procedure.
- 4.2 The location from where a sample is collected will have an impact on the final results reported. Liquid samples shall be collected from a pressure vessel or portable pressurized separator as specified in this procedure.
- 4.3 Collecting liquid samples from a pressure vessel or portable pressurized separator that periodically drains liquids will have an impact on the final results reported. Samples shall not be collected from a pressure vessel or portable pressurized separator while it periodically drains liquids.
- 4.4 Collecting liquid samples using an empty double valve cylinder without displacing an immiscible liquid from the cylinder will allow gases to flash from the cylinder and will have an impact on the final results reported. Samples collected using a double valve cylinder shall be collected as specified in this procedure.
- 4.5 Displacing liquids from a double valve cylinder that are reactive and not immiscible with the sample liquid collected will result in gas composition or volume errors and will affect the final results reported. Displacement liquids shall be pre-tested by a laboratory to verify that the liquid is non-reactive and is immiscible with the sample liquid collected.
- 4.6 Non-calibrated equipment including pressure or temperature gauges will have an impact the final results reported. All pressure and temperature measurements shall be conducted with calibrated gauges as specified in this procedure.
- 4.7 Conducting laboratory procedures other than those specified in this procedure will have an impact on the final results reported. All laboratory methods and quality control and quality assurance procedures shall be conducted as specified in this procedure.

5. SAMPLING EQUIPMENT SPECIFICATIONS

- 5.1 A pressure gauge capable of measuring liquid pressures of less than 50 pound per square inch gauge pressure within +/-10% accuracy.
- 5.2 A pressure gauge capable of measuring liquid pressures greater than 50 pounds per square inch gauge pressure within +/- 5% accuracy.
- 5.3 A temperature gauge capable of reading liquid temperature within +/- 2°F and within a range of 32°F to 250°F.

- 5.4 A graduated cylinder capable of measuring liquid in at least five (5) milliliter increments with at least the same capacity as the double valve cylinder used for liquid sampling.
- 5.5 A portable pressurized separator that is sealed from the atmosphere and is used for collecting crude oil, condensate, and produced water samples at the steady state temperature and pressure of the separator and tank system being sampled.

6. SAMPLING EQUIPMENT

- 6.1 A double valve cylinder or a piston cylinder.
- 6.2 A graduated cylinder for use with double valve cylinder.
- 6.3 A waste container suitable for capturing and disposing sample liquid.
- 6.4 High-pressure rated metal components and control valves that can withstand the temperature and pressure of the pressure vessel or portable pressurized separator being sampled.
- 6.5 Pressure gauges with minimum specifications listed in section 5.
- 6.6 A temperature gauge with minimum specifications listed in section 5.
- 6.7 If required, a portable pressurized separator with minimum specifications listed in section 5.

7. DATA REQUIREMENTS

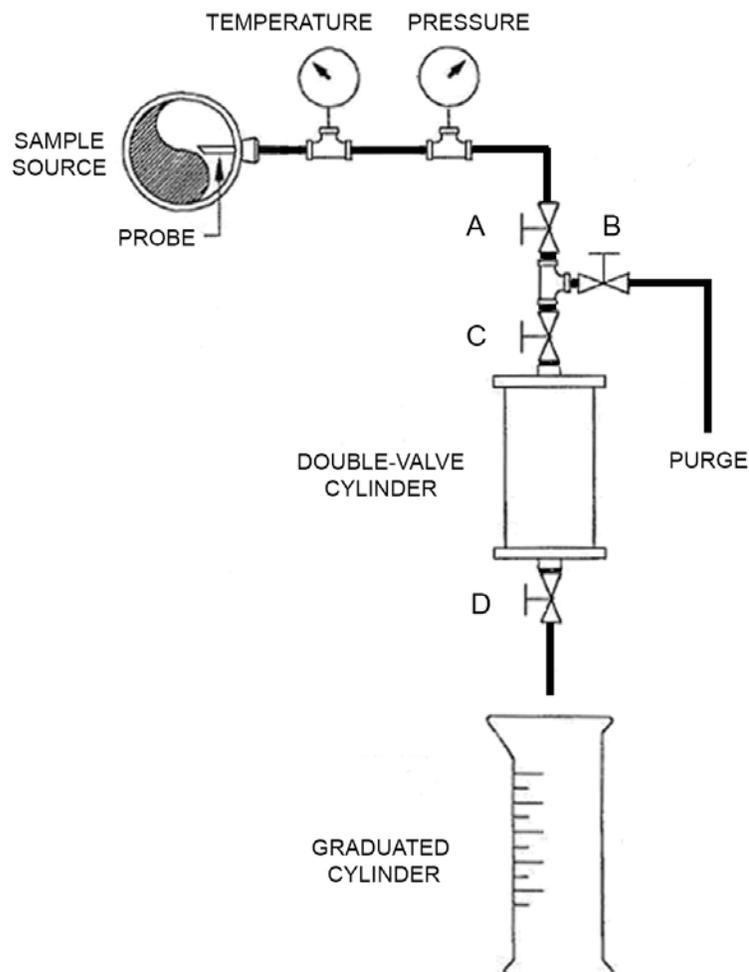

- 7.1 The data requirements required to conduct this procedure shall be provided by the facility owner or operator prior to conducting the sampling methods specified in this procedure. Field sampling shall not be performed until all data requirements are provided as listed in section 7.2 and as specified on Form 1.
- 7.2 For each pressure vessel or portable pressurized separator sampled, the following data shall be recorded on the sample cylinder identification tag and on Form 1 prior to conducting a sample collection method:
 - (a) The separator identification number or description.,
 - (b) The separator temperature and pressure if available.
 - (c) Crude oil or condensate throughput.
 - (d) Produced water throughput.
 - (e) Percent water cut.

- (f) Gas flow rate of three phase separator if available.
- (g) Number of wells in the separator and tank system.
- (h) Days of operation per year.

8. DOUBLE VALVE CYLINDER SAMPLING METHOD

- 8.1** The double valve cylinder sampling method is used for collecting crude oil or produced water samples and is not applicable for collecting samples of condensate. Liquid samples of condensate shall be collected using the piston cylinder sampling method specified in section 9.
- 8.2** Fill the double valve cylinder with non-reactive liquid that is immiscible with the liquid to be collected to prevent flashing within the cylinder and to prevent the displacement liquid from mixing or attaining homogeneity with the sample liquid.
- 8.3** Locate a pressure vessel immediately upstream of the separator or tank required for testing and verify it is pressurized to at least 15 psig. Install a portable pressurized separator if no pressure vessel is available immediately upstream of the separator or tank that can be used to collect crude oil and produced water samples.
- 8.4** Record the sample collection data requirements specified in section 7 on the cylinder identification tag and on Form 1.
- 8.5** Locate the sampling port(s) for collecting liquid samples.
- 8.6** Connect the sampling train as illustrated in Figure 1 to the sampling port on the pressure vessel or portable pressurized separator while minimizing tubing between the purge valve and cylinder as shown. Bushings or reducers may be required.
- 8.7** Purge the sampling train: Place the outlet of valve B into the waste container. With valves B, C and D closed, slowly open valve A completely, and then slowly open valve B to purge the sample train until a steady stream of liquid without gas pockets is observed, and then close valve B.
- 8.8** Prepare for sampling: Orient the double-valve cylinder in the vertical position so that displacement liquid can readily be discharged from the cylinder. Note that the orientation of valves C and D depend on the type of sample being collected and the liquid used for displacement. Based on density differences in liquids, the heaviest liquid must be introduced or expelled from the bottom of cylinder. See Figure 2
- 8.9** Slowly open valve C to the full open position and place the outlet of valve D into the graduated cylinder.

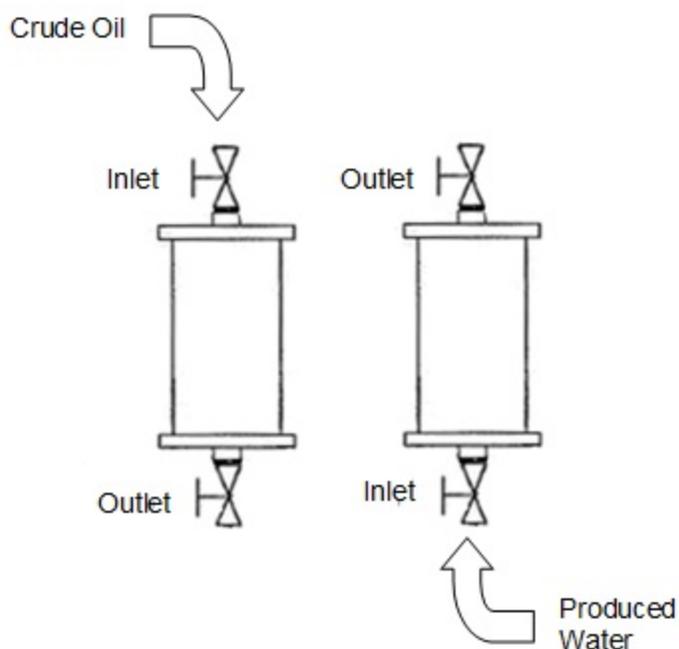

Figure 1: Double Valve Cylinder Sampling Train

8.10 Collect liquid sample: Slowly open valve D to allow a slow displacement of the non-reactive displacement liquid at a rate between 150 and 200 milliliters per minute (3 drips per second) to prevent the sample liquid from flashing inside the cylinder. Continue until 80 to 95 percent of the displacement liquid is measured in the graduated cylinder, then close valves D and C.

8.11 Record the steady state pressure and temperature on Form 1.

Figure 2: Double Valve Cylinder Orientation

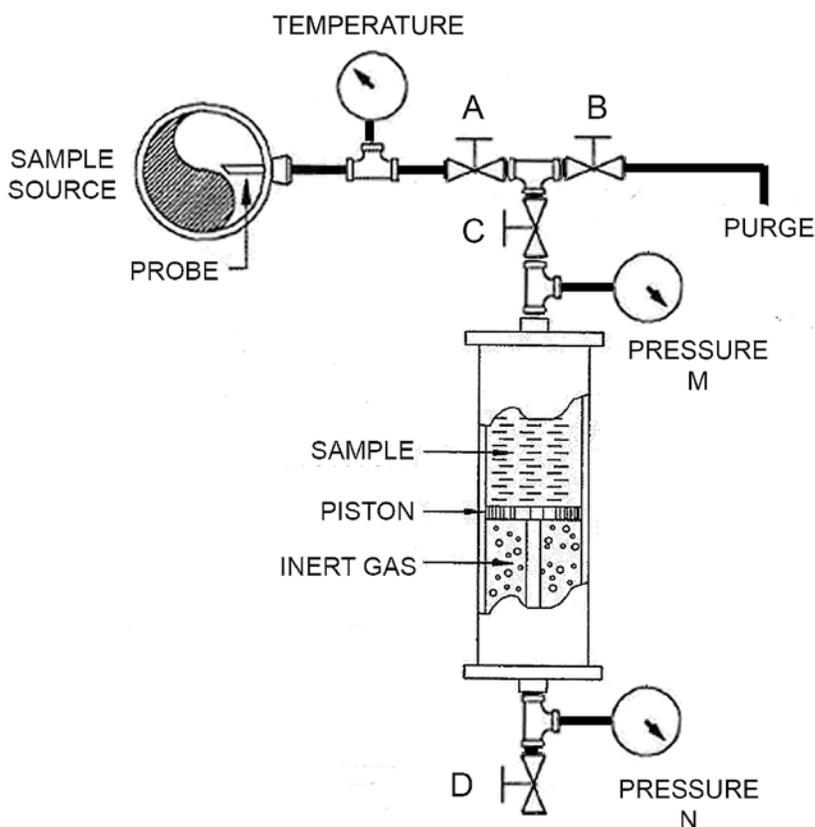

- 8.12 Record the double valve cylinder volume and the volume of liquid sampled on the cylinder identification tag and on Form 1.
- 8.13 Disconnect the sample cylinder from the sampling train and verify that both valves are sealed.
- 8.14 Remove sampling train: With valves D and C closed, purge any remaining liquid in the sampling train through valve B. Then close valves A and B. Disconnect the sampling train from the pressure vessel or portable pressurized separator.
- 8.15 Verify that all of the data requirements are recorded on the cylinder identification tag and on Form 1.
- 8.16 Transport the cylinder to the laboratory for conducting the laboratory methods specified in section 12.

9. PISTON CYLINDER SAMPLING METHOD

- 9.1 Locate a pressure vessel immediately upstream of the separator or tank required for testing and verify it is pressurized to at least 15 psig. Install a portable pressurized separator if no pressure vessel is available immediately upstream of the separator or tank that can be used to collect condensate and produced water samples.

- 9.2 Record the sample collection data requirements specified in section 7 on the cylinder identification tag and on Form 1.
- 9.3 Locate the sampling port(s) for collecting liquid samples.
- 9.4 Connect the sampling train as illustrated in Figure 3 to the pressure vessel or pressurized portable separator while minimizing tubing between the purge valve and cylinder as shown. Bushings or reducers may be required.
- 9.5 Purge the sampling train: Place the outlet of valve B into the waste container. With valves B, C and D closed, slowly open valve A completely, and then slowly open valve B to purge the sample train until a steady stream of liquid without gas pockets is observed, and then close valve B.

Figure 3: Piston Cylinder Sampling Train

- 9.6 Prepare for sampling: With valve B closed and valve A open, slowly open valve C to the full open position, then slowly open valve D until the pressure indicated on Gauge N is equal to Gauge M.

- 9.7 Collect liquid sample: Slowly open Valve D to allow liquid to enter the piston cylinder at a rate of 150 to 200 milliliters per minute until 80 to 95 percent of the cylinder is filled with liquid. Then close valves C and D.
- 9.8 Record the steady state pressure and temperature on Form 1.
- 9.9 Record the cylinder volume and volume of liquid sampled on the cylinder identification tag and on Form 1.
- 9.10 Disconnect the sample cylinder from the sampling train and verify that both valves are sealed.
- 9.11 Remove sampling train: Place the outlet of valve B into the waste container and slowly open valve B to purge all liquid from the sampling train. Then close valves A and B. Disconnect the sampling train from the pressure vessel or portable pressurized separator.
- 9.12 Verify that all of the data requirements are recorded on the cylinder identification tag and on Form 1.
- 9.13 Transport the cylinder to the laboratory for conducting the laboratory methods as specified in section 12.

10. LABORATORY REQUIREMENTS AND METHODS

10.1 Quality Control, Quality Assurance, and Field Records

- (a) Quality control requirements shall be performed in accordance with the laboratory methods specified in this test procedure.
- (b) Each day of sampling, at least one field duplicate sample shall be collected per matrix type (crude oil, condensate, produced water). The field duplicate samples are collected to demonstrate acceptable method precision by the laboratory at the time of analysis. Through this process the laboratory can evaluate the consistency of sample collection and analytical measurements as well as matrix variation. The laboratory should establish control limits based on relative percent difference to evaluate the validity of the measured results.
- (c) Laboratory procedures shall be in place for establishing acceptance criteria for field activities described in sections 7, 8 and 9 of this procedure. All deviations from the acceptance criteria shall be documented. Deviations from the acceptance criteria may or may not affect data quality.

- (d) Laboratory procedures shall be in place to ensure that field staff have been trained on the sampling methods specified in this procedure and retrained on sampling methods if this procedure changes.
- (e) Field records shall provide direct evidence and support necessary for technical interpretations, judgments, and discussions concerning project activities and shall, at a minimum, include a completed copy of Form 1 as provided in this procedure for each sample collected.

10.2 Laboratory Flash Analysis Equipment

- (a) All laboratory equipment used to conduct measurements shall be calibrated in accordance with the manufacturer specifications and in accordance with the laboratory methods specified in this procedure.
- (b) Any chromatograph system that allows for the collection, storage, interpretation, adjustment, or quantification of chromatograph detector output signals representing relative component concentrations may be used to conduct this procedure. All test methods and quality control requirements shall be conducted in accordance with each laboratory method specified.
- (c) The minimum reporting limit of the instruments used for reporting gaseous compounds must be at least 100 parts per million (ppm) for both hydrocarbon and fixed gases.
- (d) The laboratory apparatus used for heating sample cylinders must be capable of heating and maintaining the steady state temperature measured at the time of sampling as reported on Form 1.
- (e) The laboratory apparatus used for collecting gas flashed from liquids must be capable of precisely measuring gas volume, temperature, and pressure.
- (f) The laboratory vessel used for collecting gas flashed from liquids must be capable of collecting or storing gas for chromatography analysis without sample degradation and without compromising the integrity of the sample.
- (g) Additional sample preparation guidance can be found in GPA 2174, GPA 2261 and GPA 2177.

10.3 Laboratory Flash Analysis Procedure

- (a) Heat the sample cylinder to the sample collection temperature as reported on Form 1 and allow the temperature to stabilize for a minimum of 30 minutes.

- (b) After the cylinder temperature has stabilized, open the cylinder and collect all gas flashed from the liquid for a minimum of 30 minutes while monitoring the gas pressure and temperature.
- (c) After all gas has flashed from the cylinder for a minimum of 30 minutes, ensure that the gas pressure has stabilized at ambient pressure with no changes in gas pressure observed. In the event that the gas pressure changes or remains above ambient pressure after 30 minutes, continue to allow the cylinder to flash until the gas pressure stabilizes at ambient pressure. The collected gas sample can now be used for gas chromatography analysis.
- (d) At least 0.20 standard cubic feet of sample gas per barrel of liquid is required to conduct the laboratory procedures specified in this procedure. If insufficient gas volume is collected during the flash analysis procedure, additional laboratory analyses cannot be completed while maintaining the accuracy requirements specified in this procedure.
- (e) After the flash analysis procedure is completed, remove all liquid from the sample cylinder and measure the total liquid volume and volume fractions (for example, 300ml total volume, 285 ml crude oil, 15 ml water) and adjust for any displacement liquid that was not displaced during the sample collection procedure.

10.4 Gas-Oil and Gas-Water Ratio Calculation Methodology

- (a) Convert the volume of gas vapor measured during the laboratory flash analysis procedure to standard atmospheric conditions as derived from the Ideal Gas Law as follows:

$$Vapor_{Std} = \frac{(Volume_{Lab})(459.67 + 60F)(P_{Lab})}{(459.67 + T_{Lab})(14.696)} \quad \text{Equation 4}$$

Where:

Vapor_{Std} = Standard cubic feet of vapor at 60°F and 14.696 psia.

Volume_{Lab} = Volume of vapor measured at laboratory conditions.

T_{Lab} = Temperature of vapor at laboratory conditions, °F.

P_{Lab} = Pressure of vapor at laboratory conditions, psia.

459.67 = Conversion from Fahrenheit to Rankine

60F = Standard temperature of 60°F.

14.696 = Standard atmospheric pressure, psia.

- (b) Convert the volume of crude oil or produced water measured after conducting the laboratory flash analysis procedure to standard conditions as follows:

$$Liquid_{Std} = \left(\frac{Mass_{Liquid}}{Density_{60F}} \right) \left(\frac{1 \text{ gallon}}{3785.412 \text{ ml}} \right) \left(\frac{1 \text{ STB}}{42 \text{ gallons}} \right) \quad \text{Equation 5}$$

Where:

Liquid_{Std} = Standard volume of post-flash liquid at 60°F, barrels.

Mass_{Liquid} = Mass of liquid at laboratory conditions, grams.

Density_{60F} = Density of liquid at 60°F, grams/milliliter.

3785.412 = Conversion from milliliter to US gallons.

STB = Stock Tank Barrel.

42 gallons = Volume of a stock tank barrel at 60°F.

- (d) Calculate the Gas-Oil or Gas-Water Ratio as follows:

$$G = \frac{(Vapor_{Std})}{(Liquid_{Std})} \quad \text{Equation 6}$$

Where:

G = The Gas-Oil or Gas-Water Ratio.

Vapor_{Std} = Standard cubic feet of vapor at 60°F and 14.696 psia.

Liquid_{Std} = Standard volume of post-flash liquid at 60°F, barrels.

Note: For condensate, the volume of liquid used for calculating the Gas-Oil Ratio shall be obtained from the piston cylinder measurement reported on Form 1 at the time of liquid sampling due to the rapid flashing of condensate that occurs during the laboratory flash analysis procedure.

10.5 Analytical Laboratory Methods and Requirements

The following methods are required to evaluate and report flash emission rates from crude oil, condensate, and produced water.

- (a) Oxygen, Nitrogen, Carbon Dioxide, Hydrogen Sulfide (High-Level), Methane, Ethane, Propane, i-Butane, n-Butane, i-Pentane, n-Pentane, Hexanes, Heptanes, Octanes, Nonanes, Decanes+: Evaluate per GPA 2286, ASTM D-1945, ASTM D-3588, and ASTM D-2597 (GC/TCD).
- (b) BTEX: Evaluate per EPA 8021 B (GC/FID) or use ASTM D-3170, GPA 2286, EPA 8260B, EPA TO-14, and EPA TO-15 as alternate methods.
- (c) API Gravity of whole oil at 60°F by ASTM D 287 (Hydrometer Method), ASTM D 4052 (Densitometer), D 5002 (Densitometer), or ASTM D 70 (Pycnometer).

Note: if water is entrained in sample, use ASTM D 287. If needed calculate Specific Gravity 60/60°F = 141.5 / (131.5 + API Gravity at 60°F)

- (d) Specific Gravity of Produced Water at 60°F by ASTM D 287 (Hydrometer Method), ASTM D 4052 (Densitometer), D 5002 (Densitometer), or ASTM D 70 (Pycnometer). If needed calculate API at 60°F = (141.5 / SG at 60°F) - 131.5
- (e) Molecular Weight of gaseous phase by calculation per ASTM D-3588.
- (f) Water and Sediment in Crude Oil by Centrifuge Method per ASTM D-4007.

10.6 Nitrogen and Oxygen Correction

Samples containing oxygen may be an indication that ambient air was introduced during the sample collection or laboratory procedures. For the purpose of this procedure, the detection of oxygen shall be assumed to have been contributed by ambient air that was not contained in the original liquid sample. Any detectable amount of oxygen requires a result for nitrogen to be corrected and the result for oxygen to be reported as zero as follows:

- (a) For the purposes of this procedure, ambient air contains 79% nitrogen and 21% oxygen.
- (b) Correct the amount of nitrogen contained in the sample as follows:

$$Correction_{N_2} = \%N_2 - \left(\frac{79}{21} x \%O_2 \right) \quad \text{Equation 7}$$

Where:

Correction_{N₂} = Corrected value of nitrogen in the sample.

%N₂ = Mole percent of nitrogen in the sample.

%O₂ = Mole percent of oxygen in the sample.

- (c) If the corrected value for nitrogen calculated in section 10.6(b) is less than or equal to zero, report a value of zero for nitrogen and zero for oxygen and normalize all remaining values to 100% after removing the contributions of nitrogen and oxygen from the summed total; or,
- (d) If the corrected value for nitrogen calculated in section 10.6(b) is greater than zero, use the value for nitrogen calculated in section 10.6(b) and zero for oxygen and normalize all remaining values to 100%.

11. CALCULATING RESULTS

The following calculations are performed in conjunction with the data requirements specified in section 7 and the laboratory reports specified in section 12. The same calculations are used for crude oil, condensate, and produced water.

11.1 Calculate the volume of gas flashed from the liquid per year using the Gas Oil or Gas Water Ratio obtained from the laboratory report as follows:

$$Ft^3 / Year = (G) \left(\frac{Barrels}{Day} \right) \left(\frac{Days}{Year} \right) \quad \text{Equation 1}$$

Where:

$Ft^3/Year$ = standard cubic feet of gas produced per year
 G = Gas Oil or Gas Water Ratio (from laboratory report)
 Barrels/Day = barrels per day of liquid (Form 1)
 Days/Year = days of operation per year (Form 1)

11.2 Convert the gas volume to pounds as follows: **Equation 2**

$$Mass_{Gas} / Year = \left(\frac{Ft^3}{Year} \right) \left(\frac{gram}{gram - mole} \right) \left(\frac{gram - mole}{23.690 l} \right) \left(\frac{28.317 l}{Ft^3} \right) \left(\frac{lb}{454 grams} \right)$$

Where:

$Mass_{Gas} / Year$ = pounds of gas per year
 $Ft^3/Year$ = cubic feet of gas produced per year (Equation 1)
 Gram/Gram-Mole = Molecular weight (from laboratory report)
 23.690 l/gr-mole = molar volume of ideal gas at 14.696 psi and 60⁰F

11.3 Calculate the annual mass of methane as follows:

$$Mass_{Methane} / Year = \left(\frac{WT\% \text{ Methane}}{100} \right) \left(\frac{Mass_{Gas}}{Year} \right) \left(\frac{metric ton}{2205 lb} \right) \quad \text{Equation 3}$$

Where:

$Mass_{Methane} / Year$ = metric tons of methane
 $Mass_{Gas} / Year$ = pounds of gas per year (Equation 2)
 WT% Methane = Weight % of methane (from laboratory report)

12. LABORATORY REPORTS

- 12.1** The results of this procedure are used by owners or operators of separator and tank systems to report annual methane flash emissions to ARB. The following information shall be compiled as a report by the laboratory conducting this procedure and provided to the owner or operator each time flash analysis testing is conducted:
- (a) A sketch or diagram of the separator and tank system depicting the sampling location; and,
 - (b) A copy of Form 1 as specified in this procedure for each liquid sample collected; and,
 - (c) The laboratory results for each liquid sample evaluated as specified in section 12.4; and,
 - (d) Other documentation or information necessary to support technical interpretations, judgments, and discussions.
- 12.2** Reports shall be made available to the owner or operator no later than 60 days from the date of liquid sampling.
- 12.3** Reports shall be maintained by the laboratory conducting this procedure for a minimum of five (5) years from the date of liquid sampling and additional copies shall be made available at the request of the owner or operator.
- 12.4** Laboratory reports shall include, at minimum, a listing of results obtained using the laboratory methods specified in this procedure and as specified in Table 1.

13. ALTERNATIVE TEST PROCEDURES, SAMPLING METHODS OR LABORATORY METHODS

Alternative test procedures, sampling methods, or laboratory methods other than those specified in this procedure shall only be used if prior written approval is obtained from ARB. In order to secure ARB approval of an alternative test procedure, sampling method, or laboratory method, the applicant is responsible for demonstrating to the ARB's satisfaction that the alternative test procedure, sampling method, or laboratory method is equivalent to those specified in this test procedure.

- (1) Such approval shall be granted on a case-by-case basis only. Because of the evolving nature of technology and procedures and methods, such approval shall not be granted in subsequent cases without a new request for approval and a new demonstration of equivalency.
- (2) Documentation of any such approvals, demonstrations, and approvals shall be maintained in the ARB files and shall be made available upon request.

Final Report

**For Determining Bleed Rates for Pneumatic Devices in British
Columbia**

December 18, 2013

Executive Summary

Regulations in BC stipulate that all greenhouse gas (GHG) emissions from pneumatic instruments and pumps must be tracked for reporting and compliance purposes. In order to help industry quantify these emissions more efficiently and cost effectively, the BC Climate Action Secretariat (CAS), Ministry of Natural Gas Development and Canadian Association of Petroleum Producers (CAPP) engaged The Prasino Group (Prasino) to determine bleed rates for a suite of common pneumatic controllers and pumps. This survey is the first of its kind and was funded by the Science and Community Knowledge (SCEK) Fund.

Pneumatic controllers and pumps use pressurized fuel gas to perform operations such as pressure control, temperature control, liquid level controller and chemical injection. This fuel gas is subsequently released to the atmosphere after the operation is performed. The bleed rate of a pneumatic device is defined as the amount of fuel gas released to the atmosphere per hour. Figure 1 shows the breakdown of GHG emissions from the oil and gas sector in BC with a detailed breakdown of the sources of vented methane. The high bleed pneumatic controllers and pumps, which are the subject of this study, contribute 436,000 tCO₂e of the 1,723,000 tCO₂e from vented methane. The amount of contribution from pneumatic devices and pumps is expected to change as a result of this study.

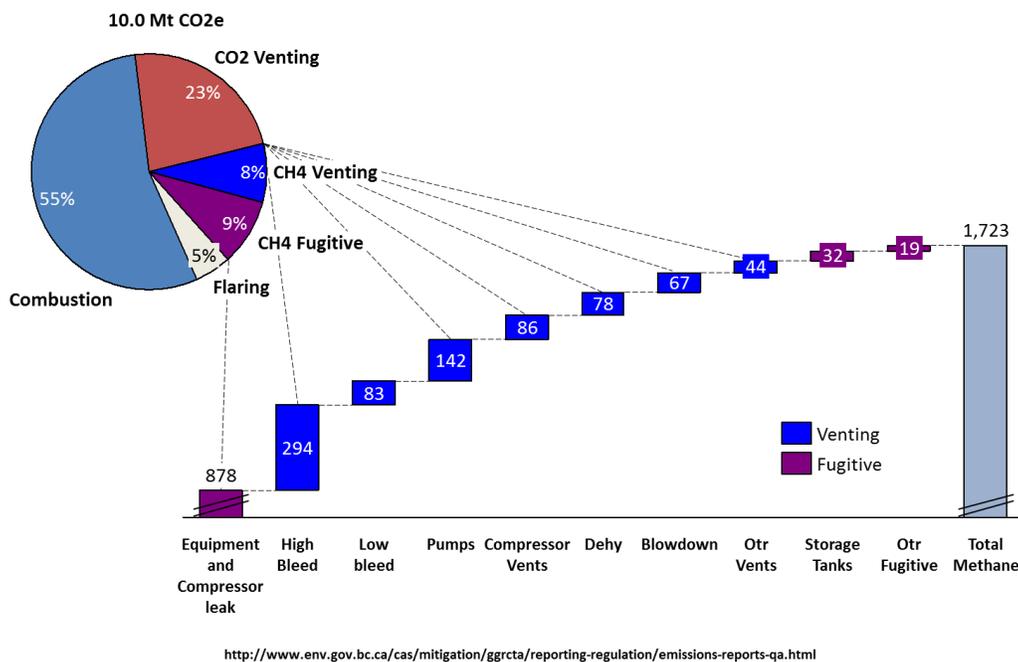

Figure 1: Detailed Breakdown of vented and fugitive methane sources in the BC oil and gas sector (source BC CAS 2013).

The purpose of the survey was to determine the average bleed rate of pneumatic controllers and pumps when operating under field conditions in BC. Bleed rates were sampled from pneumatic devices using a positive displacement bellows meter at upstream oil and gas facilities across a variety of producing fields in the Fort St. John, BC and surrounding, areas. Descriptive statistics, general linear models and regression analysis was performed on the data to investigate the bleed rates and draw robust, relevant conclusions.

All outcomes were achieved. The results of the analysis led to the development of three generic bleed rates and twenty specific bleed rates for common pneumatic controllers and pumps for BC's oil and gas industry. These bleed rates can be used in the development of emission factors for GHG reporting and potentially offset purposes.

Table 1: Summary of Findings

| Pneumatic Device | Average Bleed Rate (m ³ /hr) | Coefficients ¹ (supply pressure, injection pressure, strokes per min) | Equivalent Device |
|--|---|--|------------------------------|
| Generic High Bleed Controller | 0.2605 | 0.0012 | - |
| Generic High Bleed Intermittent Controller | 0.2476 | 0.0012 | - |
| Pressure Controllers | | | |
| Fisher 4150 | 0.4209 | 0.0019 | 4150K, 4150R, 4160, CVS 4150 |
| Fisher C1 | 0.0649 | 0.0003 | - |
| Fisher 4660 | 0.0151 | - | 4660A |
| Level Controllers | | | |
| Fisher 2500 | 0.3967 | 0.0011 | 2500S, 2503, L3 |
| Fisher 2680 | 0.2679 | 0.0014 | 2680A |

1. Introduction

This report outlines the methodology and analytical methods used to develop bleed rates for reporting GHG emissions from pneumatic controllers and pumps (collectively referred to as ‘devices’) in British Columbia (BC). The development of emissions factors may allow for an alternative method of monitoring and reporting GHGs from pneumatic devices, as per an agreement between the Canadian Association of Petroleum Producers (CAPP) and the B.C. Ministry of Environment’s Climate Action Secretariat (CAS). The Prasino Group (Prasino) has been engaged by the Science and Community Environmental Knowledge Fund (SCEK) in order to develop these bleed rates based on quantitative sampling of pneumatic devices in BC. This document is the final project report and builds off the subsequent three reports (Sampling Methodology, First Round Sampling Report and Final Sampling Report) that were submitted to SCEK. This document is meant to be a standalone report and describes:

- The sampling methodology used to obtain the field bleed rate samples;
- The characteristics of the samples;
- The statistical analysis performed on the field bleed rate samples as well as a discussion of the results; and
- The recommended bleed rates for each pneumatic device included in the survey.

2. Sampling Methodology

Pneumatic devices used in B.C.’s oil and gas sector fall into two categories:

1. Pneumatic chemical injection pumps (typically injecting methanol into a pipeline); and,
2. Pneumatic controllers, which regulate pressure, temperature, fluid level, or some other process variable.

There are dozens of manufacturers of the types of pneumatic devices listed above. Even though the device types perform similar functions, they have inherently different bleed rates. Due to constraints, it was necessary to narrow sampling to the most common or representative devices. A “Device Selection Approach” was used to narrow the sample and determine the most common devices in the field.

Figure 2 below outlines the steps that were followed to develop the initial list of devices for sampling. Further detail will be provided in the next section. The following section describes the process that was used for selecting which devices to include in the sampling regime.

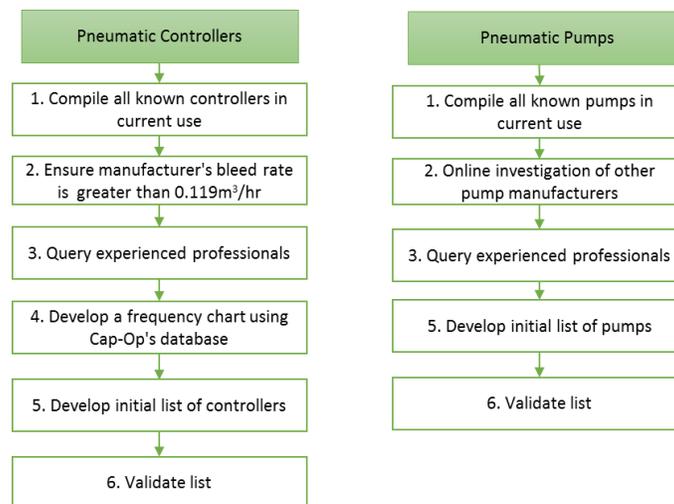

Figure 2: Device Selection Approach²

2.1 Pneumatic Controllers

In order to determine which pneumatic controllers to include in our sample, multiple steps were undertaken as illustrated in

Figure 2. Through this process, 15 controllers were identified as common. For the rare devices that are not within the scope of this project, a generic high-bleed rate has been developed for all high-bleed controllers. This ensures that any pneumatic controller can apply a bleed rate that is representative of field conditions.

Step 1: Compile All Known Controllers

Prasino initially developed a complete list of all known pneumatic low and high-bleed controllers that were anticipated to be used in the upstream oil and gas industry in BC. Using one or more of the sources listed below, the make, model, and manufacturers' stated bleed rate of each controller was determined:

- *Canadian Environmental Technology Advancement Corporation-West (CETAC): Efficient Use of Fuel Gas in Chemical Injection Pumps. Fuel Gas Best Management Practices.* The BMP lists manufacturer bleed rates of controllers in m³/hr of natural gas.
- *Pacific Carbon Trust (PCT): High-Bleed to Low-Bleed Conversion for Pneumatic Controllers. Meta-Protocol for Oil and Gas Emission Reductions Projects.* In the protocol, the bleed rates were stated in standard cubic feet per hour (scfh) of air, based on manufacturer stated specifications. The volume of air bled was converted to natural gas by multiplying by 1.3³. When a range of bleed rates was listed, the highest value was taken to be conservative.
- *Environmental Protection Agency: Gas STAR – Options for Reducing Methane Emissions from Pneumatic Devices in the Natural Gas Industry.* This document stated the bleed rates of high- and low-bleed controllers in scfh of air. These values were converted to m³/hr of natural gas.
- *Western Climate Initiative (WCI): Final Essential Requirements of Mandatory Reporting.* This report references the BMP, PCT Protocol and EPA Gas STAR for the pneumatic controller list and bleed rates. The manufacturer bleed rates in this document are in m³/hr.
- *Manufacturer websites* were referenced to determine the steady state air consumption for pneumatic controllers. The highest steady state air consumption was recorded. The bleed rates were stated in m³/hr and scfh.
- *Cap-Op Energy samples from the DEEPP database* were used to look at controllers and pumps that are already in the field and have been sampled previously by GreenPath Energy Ltd⁴.

Step 2: Equivalent Devices

Controllers may have different makes and models but serve the same function. Controllers are considered equivalent devices if they have interchangeable parts. A list of equivalent devices was compiled using information from device vendors and subject matter experts, and is presented in Appendix A (J. Anhalt, personal communication, July 2013; B. Van Vliet, personal communication, July 2013).

² "Cap-Op's Database" refers to Cap-Op Energy's Distributed Energy Efficiency Project Platform (DEEPP), which was queried for historical pneumatic controller information. Cap-Op Energy is a sub-contractor to Prasino.

³ The value 1.3 is based on the density and molar mass of air and natural gas in ideal gas conditions. This manner of conversion is an industry standard.

⁴ GreenPath Energy Ltd. is the contractor who was responsible for completing the field sampling protocol.

Step 3: Ensure Manufacturer Bleed Rates are Greater than 0.119 m³/hr

Manufacturer bleed rates were used to determine which controllers are considered high bleed and therefore relevant for sampling. However, these manufacturer bleed rates are based on manufacturer lab testing and may not reflect actual field conditions. The steady state bleed rates reported are static bleed rates of controllers that are not actuating and thus dynamic bleeding is not captured. Therefore, the manufacturer bleed rates may not accurately express the actual vented natural gas through these controllers because the steady state does not include dynamic bleeding. The relationship between the bleed rates of controllers that are running on dirty/wet natural gas compared to air is unknown. It is likely that controllers operating in the field bleed more than controllers tested in a laboratory using air.

The current definition whether a controller is a high or low bleed controller is based on the WCI Reporting Regulation definition: “high-bleed devices are defined as all natural gas powered devices which continuously bleed at a rate greater than 0.17 m³/hr.”

Many controllers have manufacturer bleed rates just below 0.17 m³/hr, and thus appear to be a low-bleed controller. Since manufacturers do not consider the dynamic bleed rate in their stated bleed rate, many low-bleed controllers in fact bleed more than 0.17 m³/hr on a regular basis. To ensure all relevant controllers that bleed more than 0.17 m³/hr (including static and dynamic bleeding) are included within the sample, the manufacturer bleed rates were compared to a limit of 0.119 m³/hr (CAS, 2013). In many cases, the manufacturer states a range of bleed rates that are dependent on other operating parameters of the controller (i.e. 1.4 scfh at 20 psi vs. 3 scfh at 30 psi). In this case, the highest bleed rate was recorded to ensure that all controllers with the potential to bleed higher than 0.17 m³/hr were included. Refer to Appendix A for highest manufacturer bleed rates. Controllers that have been excluded from sampling as a result of this step are represented at the bottom of the table in Appendix A.

Step 4: Query Subject Matter Experts

Subject matter experts were queried as per the request of CAS to determine if the list of pneumatic devices was inclusive and representative. Several low-bleed controllers below the limit of 0.119 m³/hr have been included based on these discussions to investigate if controllers that are labelled according to manufacturer specification actually perform as a low bleed device in the field. Four low-bleed controllers were included in the survey: Fisher C1, Fisher 4660, SOR 1530 and Kimray HT-12. The results of the query are represented in Appendix A.

Step 5: Determine the Frequency of Occurrence of Controllers

Using Cap-Op’s DEEPP database, the eligible list of all pneumatic controllers was filtered down to focus sampling on devices that are considered common. Cap-Op Energy has an extensive +2000 sample database from previous work on pneumatic devices from the upstream oil and gas industry in Alberta and BC. This database was used as a proxy for determining which controllers are common among producers in the Canadian oil and gas industry. The samples could not however be included in the survey because they were taken using the Bacharach High-Flow Sampler and this survey is using the Calscan vent gas bellows meter for reasons presented in Section 2.4.3. These eligible controllers were compared with the extensive field samples database from Cap-Op Energy’s DEEPP to examine the frequency of eligible controllers previously surveyed in the field. The results are depicted in Figure 3 below.

Step 6: Develop Initial List

The common list of pneumatic controllers used to guide first round sampling can be found in Appendix B. The results include:

- The top 10 controllers represent 89% of the surveyed controllers in the Cap-Op database.
- The top 15 controllers represent 97% of the surveyed controllers in the Cap-Op database.
- Rare devices are those that comprise the remaining 3% of the surveyed controllers in the Cap-Op database.

This initial list was used to guide first round of sampling because the selected devices were anticipated to be frequent enough to produce statistically valid emissions factors.

Step 7: Validate list

Upon completion of the first round of sampling the original list was compared with what was observed in the field to determine if the anticipated list of 15 devices was the most common. Based on survey data collected in the field, two devices were found to be common and added to the sample: Fairchild TXI7800; and Murphy L1200. Two devices were found to be rarer than initially thought and thus have been removed from the sample population: Fisher 2660 (no devices found in the field); and Dyna-Flo 4000 (two devices found in the field).

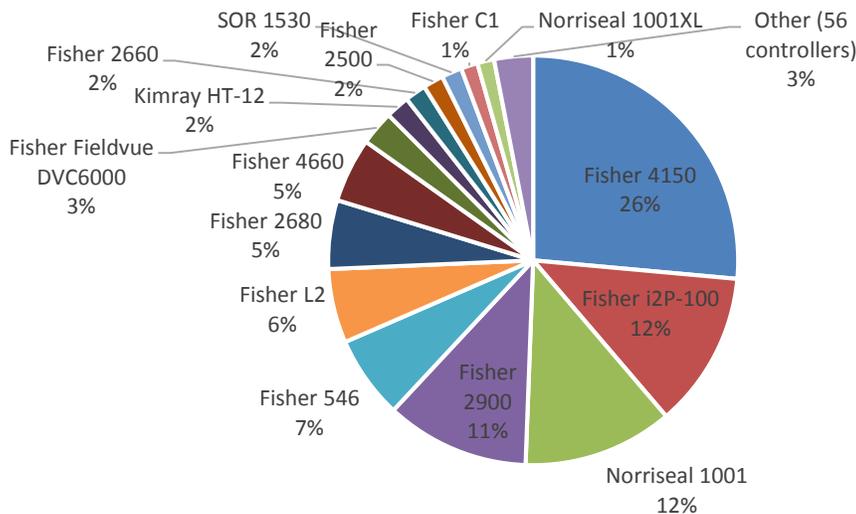

Figure 3: Frequency of pneumatic controllers found in the Cap-Op database

2.2 Pneumatic Pumps

The methodology used for determining the list of pneumatic pumps does not mirror the methodology used for pneumatic controllers because the Cap-Op database does not contain sufficient pump field samples to draw similar conclusions. The list of pneumatic pumps was compiled from the CAPP (2008), PCT (2011) and the Cap-Op DEEPP database. These sources were cross-referenced with manufacturer websites and subject matter experts to make a comprehensive initial list, presented in Appendix B. This initial list was used to guide first round of sampling; however, all pumps were sampled in the first round to determine which types were common among the producers sampled. Five common pumps were identified after the first round of sampling and were targeted during the second round of sampling: Texsteam 5100; Morgan HD 312; Williams P125; Williams P250; Williams P500.

2.3 Sampling Approach

The following section provides detail on how the field samples were collected as well as justification for which companies and geographic areas were selected for sampling.

The analysis and discussions in this report distinguish the ‘sample set’ or ‘sample’ from the ‘population’. In general, this analysis operates under the assumptions that the true number and state of the population (i.e. all pneumatic devices in BC) is unknown. Determining whether the sample is representative of the population, and to what extent is a major

component of this report and helps to characterize the validity of the results. Statistical analyses and conclusions are contingent on the assumption of an unknown population.

2.3.1 Bleed Rate Metering

The metering requirements for this project are unique and as such there are few options for determining gas vent rates from devices in a cost effective manner.

The desired meter must have the following characteristics:

- Mobility – the meter will have to be mobile such that the sampling teams can apply the meter to pneumatic devices in-service at various facilities throughout BC. This requires a relatively simple installation and removal procedure, with a low weight and portability such that it can be moved by one or two people to within a few feet of an existing pneumatic device as it is installed on-site. Breaking, cutting or disassembling process pipes, flanges or joints is not acceptable, however vent tubing may be intercepted for measurement.
- Range – the meter must be designed to accommodate the measurement of flow rates between zero and approximately 1m³/h of gas at pressures ranging from atmospheric to a few feet of water column with minimal back pressure.
- Explosive Environment – All electronic devices intended for use within CSA classified zones require intrinsically safe electronic enclosures such that potentially arcing /sparking ignition sources are completely isolated from potentially explosive atmospheres that occur in oil and gas facilities. This is a minimum safety requirement for all sampling team and on-site personnel.

The desired meter should have the following characteristics:

- Time series data to distinguish static and dynamic operation on pneumatic devices.
- Minimal to no back pressure
- High precision, 2% or less uncertainty on reported values
- High accuracy, with correction for variable parameters such as gas composition, temperature, barometric pressure, humidity, etc.

Based on an extensive review of meters available in the industry, two options which were found to be best candidates included the Bacharach High Flow Sampler and the Calscan Hawk 9000 Vent Gas Meter. The Bacharach High Flow Sampler is designed to measure the rate of gas leakage around various processes in natural gas transmission, storage and compressor facilities. This is accomplished by sampling at a very large flow rate (8 to 10 scfh) to completely capture any gas leaking from the component. By accurately measuring the flow rate of the sampling stream and the natural gas concentration, it is possible to calculate the rate of gas leak.

Prasino elected to use the Hawk 9000 vent gas meter (supplied by Calscan Energy) to measure and digitally log flow vent gas over time (which will vary based on the device sampled). This allowed for both the static and dynamic bleed rates for pneumatic controllers, as well as the dump cycles for pneumatic pumps and level controllers, to be captured. A drawback of the Bacharach High Flow Sampler is that it captures a snapshot in time; rather than a time series measurement. The Bacharach High Flow Sampler can fail to capture the dynamic bleeding events. The Hawk 9000 meter uses a positive displacement diaphragm meter that detects flow rates down to zero, and can also effectively measure any type of vent gas (methane, air, or propane). In addition, the Hawk uses a precision pressure sensor, an external temperature probe and industry standard gas flow measurement algorithms to accurately measure the gas rates and correct for pressure and temperature differences. As a result, flow measurement accuracies within $\pm 2\%$ ⁵. A picture of the Calscan Hawk 9000 is presented in Figure 3 and an example output chart is provided in Figure 5 below.

Figure 4: Calscan Hawk 9000 Meter

⁵ The meter is calibrated from -40°C to +60°C and uses “Gas Rate Algorithm AGA7” and “Equation of State AGA8”.

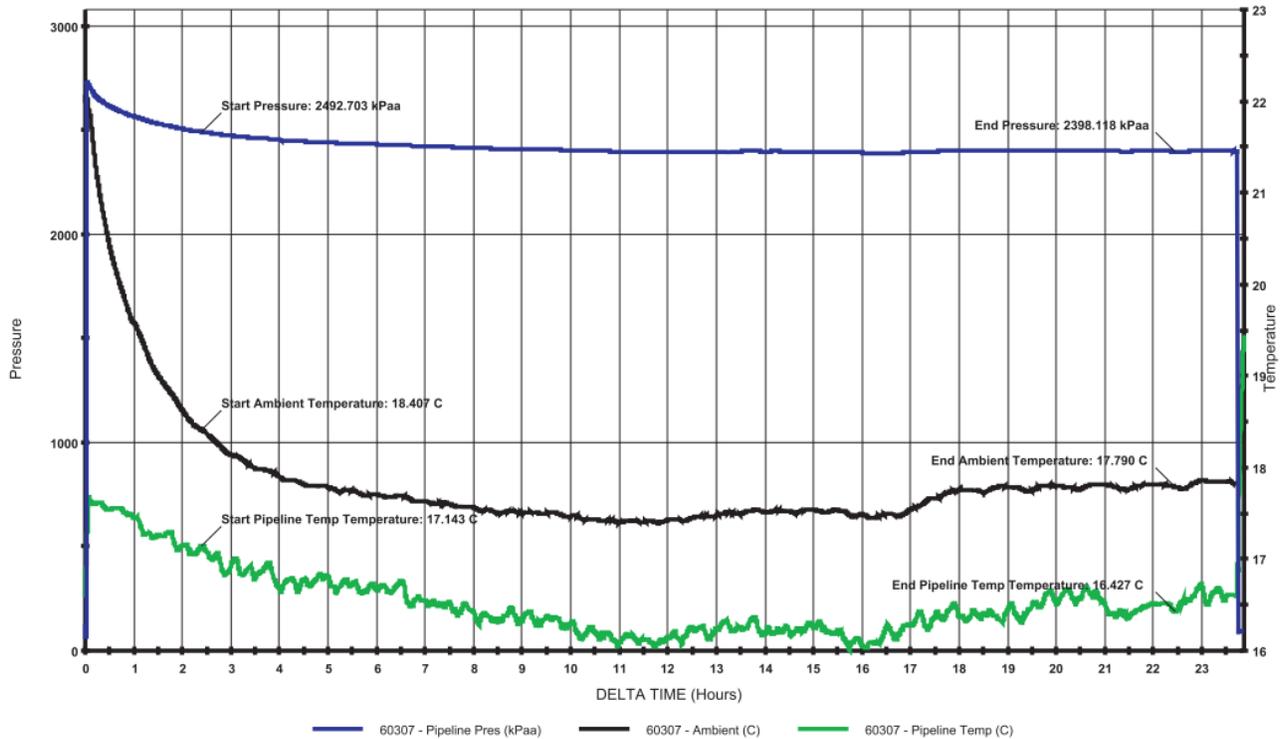

Figure 5: Example of Calscan Output Graph

2.3.2 Sample Size

The sampling program aimed to collect thirty samples of each device type identified as common according to Section 2.0 Sampling Methodology. Thirty was chosen as a minimum sample size in order to allow for statistical inferences to be drawn. When the sample size is sufficiently large (conventionally, 30 or larger), the standard error can be used to calculate a one-tail 95% confidence interval. As the sample population increases, the confidence interval should get smaller due to a decreased standard error (McClave and Sincich, 2003). In general, when calculating confidence interval, larger sample sizes and narrow confidence intervals must be balanced against the cost of additional sampling and the diminishing returns of incrementally smaller improvements to confidence intervals with each additional sample. Thirty samples for each common device type allows for the quantification of bleed rates with confidence intervals within a realistic budget and time frame.

2.3.3 Data Collection and Transfer

To manage the large amount of data that was collected during this sampling program, Cap-Op designed a software application (app) to be used in the field in order to increase data quality and tracking, and eliminate manual data recording. A field sampling guide was followed by the Greenpath sampling team and is provided in Appendix C.

All parameters were inputted into the app at the sampling location. Where appropriate, the app has dropdown menus to increase efficiency in compiling data. Numeric input fields have expected ranges of values and options for the units, so that if a value is entered outside of the range a message appears for the user to ensure the input is correct.

When the user has access to internet, the app will sync with Cap-Op Energy's DEEPP. The DEEPP will provide various functionalities for managing the data collected in the field including data storage and organizing the data into the desired output format of a download-able Excel files.

2.3.4 Errors, Uncertainty and Biases

Errors, uncertainty and biases are part of every analysis and are discussed here for transparency and clarity. Overall, through critical review of the potential errors, uncertainties and biases inherent to this study, robust and reliable results can be attained.

An error is an unsupported result or conclusion that arose through improper application of methods, calculations, or data management. Every effort has been made to eliminate errors from the analysis and a system of checks has been employed to eliminate error from the analysis. Error can be eliminated from analysis, while bias and uncertainty cannot be.

Uncertainty, as it pertains to measurement of physical states or processes, describes the precision (or lack thereof) at which a characteristic or parameter can be defined. The precision associated with the measurement of bleed rates from a pneumatic device can be characterized through review of the techniques used to measure the parameters in question.

The meter chosen for this project (see Section 2.3.1) uses self-actuating, reciprocating bellows to discretely count fixed volumes of gas being vented from the device in five second intervals. The limitations associated with this type of measurement, and the uncertainties imposed, include:

- Volumes of gas vented lower than the fixed volume of one inflated bellow in a five second interval cannot be resolved. The uncertainty of any values of bleed rate reported by the meter under this value is large. This effect is typically characterized as the ‘turn-down ratio’ of a meter and every meter will have limits, turn-down or some range beyond which its reported values are unreliable. The Hawk 9000 meter has the range of flows that is appropriate for the intent of this study and thus mitigates this form of uncertainty to the extent possible.
- Pressures of vented gas lower than the back pressure imposed by the meter will significantly alter the value of gas being vented by the device. Back-pressure is a significant concern when measuring pneumatic control devices since the performance and bleed rate of the device may be inherently dependent on the back pressure of vented gas. This uncertainty impacts all ranges of gas flow, but in general will impose large uncertainty on high flows of gas since back pressure increases with flow. Devices which reported a zero bleed rate may actually have simply been ‘plugged’ by the internal actuating mechanisms of the meter. In general, it is impossible to measure the state of a system without disturbing the system, and this effect is unavoidable regardless of the type or extent of metering equipment chosen. It is anticipated that while the metering system chosen does impose a back pressure which may be more significant than other metering systems, the benefits of this metering system (time series bleed rate values and temperature pressure compensation) outweigh the detrimental effects of back pressure on the validity of results.
- Gas compositions vary from location to location and from moment to moment and the estimation of gas composition at each measurement point is a source of uncertainty. It is prohibitively expensive to have real-time gas composition parameters available to the measurement devices such that the uncertainty associated with gas composition could be further reduced. The estimations and assumptions made on gas composition for temperature and pressure correction of measured volumes is considered appropriate for the scope of this project.
- Digitization of data imposes uncertainty to values recorded during measurement through the limitation of significant digits (decimal places). The uncertainty imposed through the significant digits carried by data management systems in this project is considered to have contributed a negligible degree of uncertainty to the overall result.

In general, a statistic is biased if it is determined by an approach or method which systematically gives rise to differences between sample data and population data. Every effort was made in this sampling approach to avoid or minimize the effects of biases, nevertheless biases exist and are discussed below:

- Opportunistic Sampling Approach - The sampling approach used is a non-probability technique called opportunistic sampling, where sampling locations were chosen purposefully. The locations were chosen based on the following criteria:
 - The proximity to Fort St. John. Fort St. John is arguably a hub of oil and gas production within BC, with a majority of activity found within 500 km. In order to determine device bleed rates in an efficient and cost-effective manner, sampling was focused in this area. Sampling did not occur in the Fort Nelson region because many sites in Northern BC are winter access only or only accessible by helicopter.
 - The accessibility due to seasonality. Field locations with winter access only were excluded from the survey due to logistics and cost.
 - Producer identified device “hot spots”. Areas with a high concentration of devices were identified by cross-referencing producer’s inventories with the list of common devices.

- Sweet natural gas well-sites were preferred, followed by compressor stations and batteries, then sour gas well sites. Sweet sites were preferred over sour sites because they are typically run off compressed natural gas, whereas sour sites are typically run off propane or air. Well-sites were preferred over larger facilities because they typically house the common pneumatic controllers and pumps.

Opportunistic sampling has known limitations, including the sampling error⁶ which cannot be estimated, and that exclusion bias may arise from the non-random choice of sampling locations. However, random sampling was logistically impractical in this scenario and all efforts to minimize exclusion bias were made, by choosing sampling locations that were representative of a multitude of producers operating in BC, and production fields and sub-districts.

The effect of this exclusion bias is that the statistics describing the sample, may not accurately reflect the population statistics, and the extent to which this occurs cannot be determined. The likelihood and impact of this bias has been minimized by ensuring a sufficiently large sample size (the greater the sample size, the less selection biases will impact a result).

- Producer Influence – The sampling approach described above inherently allows for a set of biases which are the possibility for intentional and unintentional skewed sampling. Since permission was required from producers to access sites, and moreover, recommendations on which sites to visit were solicited from producers, it must be acknowledged that the producers may have unintentionally directed sampling to areas with more or less bleeding devices.
- Location – Pneumatic devices in the province of BC are limited to operation in the northern boreal shield or boreal plains climates at altitudes approximately centered around 690m above sea level. Oil and gas reserves are limited to those found in the western Canadian sedimentary basin and are not representative of global conditions. Biases arise from these geographic limitations and apply should the results of this study be implicated in jurisdictions outside of BC, however are irrelevant within the context of BC pneumatic device emissions.

⁶ *Sampling error* is an estimation of the difference between the true population mean and the sample mean, usually expressed in terms of standard error. Standard error cannot be reliably calculated using non-probability sampling techniques, although a mean, standard deviation, and confidence interval can be calculated with large (>30) sample numbers.

3. Sample Characteristics

In order to calculate a statistically significant bleed rate, with 95% confidence, a minimum of 30 samples was required per device. A total of 765 samples were taken across 28 producing fields in BC and 2 producing fields in Alberta.

Table 2. Number of Samples by Device Type

| Device Type | | Number of Samples |
|------------------------------|------------------------|-------------------|

| Total | 149 | 35 | 184 |

3.3 Producers

To reduce sampling bias, a cross-section of oil and gas producing companies were included in the survey to ensure sampling was representative and spread across producers as well as producing fields. Figure 3 (below) shows the breakdown of sampling across the eight producers.

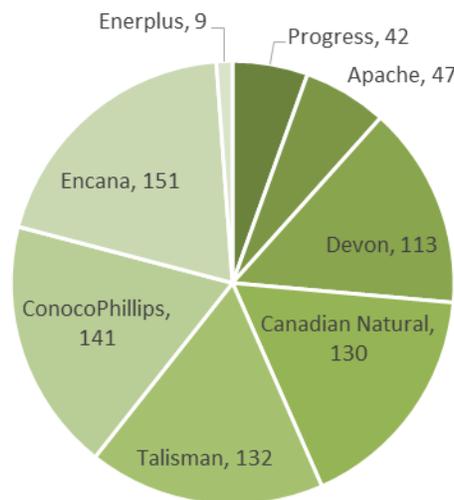

Figure 7: Breakdown of Samples by Producer

3.4 District and Sub-District

Table 5 outlines the number of samples per district as well as a breakdown of samples by producing field. Samples were collected from areas in northeastern BC; in the Fort St John, Brooks, Dawson Creek, Grand Prairie and Hanna districts (Figure 8). In total samples were taken from 30 different producing fields, with 756 samples coming from BC and 9 from Alberta.

Figure 8: Sampling Location

4. Analysis

The analytical approach began by determining the mean sample bleed rate for each pneumatic controller and pump included in the survey. Table 6 below show the mean bleed rates, the 95% confidence interval (CI) and the standard deviation for the 20 common devices included in the survey. These bleeds rates are corrected for temperature, pressure and gas type.

Table 6: Results of Analysis by Device Model

4.1 Analysis for Determining a Generic Bleed Rate

The next step of the analysis was to determine if a generic bleed rate could be generated for high-bleed controllers and pumps. Devices that were determined to be high bleeding (i.e. bleed rate > 0.17 m³/hr) were grouped together in the analysis. If the calculated mean bleed rate was larger than the threshold, the device was included in the analysis, and if the calculated mean bleed rate was smaller than the threshold, the device was excluded from the analysis for determining a generic bleed rate. Certain controllers that are considered low-bleeding according to WCI or manufacturer specifications actually bled above the low bleed threshold and were therefore included in the analysis. Using Minitab, a statistical analysis software, a general linear model (GLM) was performed on the data to determine if there was a significant difference between the mean bleed rates of controllers and pumps. The results are presented in Table 7.

Table 7: Results of the Overview Analysis

| Pneumatic Device | Number of Samples | Average Bleed Rate (m ³ /hr) | 95% Confidence Interval (m ³ /hr) | Standard Deviation (m ³ /hr) | P-Value |
|-------------------------|-------------------|---|--|---|---------|
| High Bleed Controllers | 406 | 0.2605 | 0.2880 | 0.3371 | 0.129 |
| High Bleed Intermittent | 195 | 0.2476 | .2893 | 0.3537 | 0.738 |
| Piston Pumps | 96 | 0.5917 | 0.6926 | 0.6007 | 0.060 |
| Diaphragm Pumps | 85 | 1.0542 | 1.1948 | 0.7878 | 0.362 |

For high bleed controllers, a p-value > 0.05 was calculated, meaning that there was no significant differences between the mean bleed rates. The mean bleed rate is representative of the population and can therefore be applied to any high bleed controller model. For intermittent high bleed controller, a p-value > 0.05 was calculated, meaning that there was no significant differences between the mean bleed rates. The mean bleed rate is representative of the population and can therefore be applied to any intermittent high bleed controller model. For all pumps, a p-value < 0.05 was calculated, meaning that there is a significant difference between all pump models and a generic bleed rate may not be representative of the entire population. Due to the large variance in bleed rates across all pumps, the pumps were grouped into two categories: diaphragm pumps and piston pumps. A p-value > 0.05 was calculated for both types of pumps, meaning that the mean bleed rate is representative of the entire population.

Box plot distributions of all field samples are presented in Appendix D.

4.2 Bleed Rate Equations

The most accurate bleed rate would take into account quantitative variables. A regression analysis was performed to investigate which quantitative variables affected the bleed rate. A regression analysis showed that there was a positive correlation between certain pneumatic controller bleed rates and supply pressure. A regression analysis showed that there was a positive correlation between pneumatic pump bleed rates, supply pressure, injection pressure and strokes per minute.

Controller Bleed Rate Equation $Bleed Rate_j = m * SP_j$

Where:

m = the supply pressure coefficient (see Appendix E)

SP_j = the supply pressure of controller j

Pump Bleed Rate Equation⁸ $Bleed Rate_j = (g * SP_j) + (n * DP_j) + (p * SPM_j)$

Where:

g = the supply pressure coefficient (see Appendix E)

SP_j = the supply pressure of pump j, (kPa)

n = the discharge pressure coefficient, (see Appendix E)

DP_j = the discharge pressure of pump j, (kPa)

p = the strokes per minute coefficient (see Appendix E)

SPM_j = the strokes per minute of pump j

For producers who know the operating conditions of their devices, they should use the following bleed rate equations. It should be noted that this method will only provide a more accurate bleed rate compared to the average bleed rate shown in Table 7 and Table 8 if the producer is certain of the operating conditions. Adding complexity may increase the overall error in bleed rates if operating conditions are estimated. Figure 9 provides an overview of the approach used to analyze the data.

⁸ It should be noted that if the pump is operating at less than five strokes per minute, the emissions equation is not applicable and the mean bleed rate should be used.

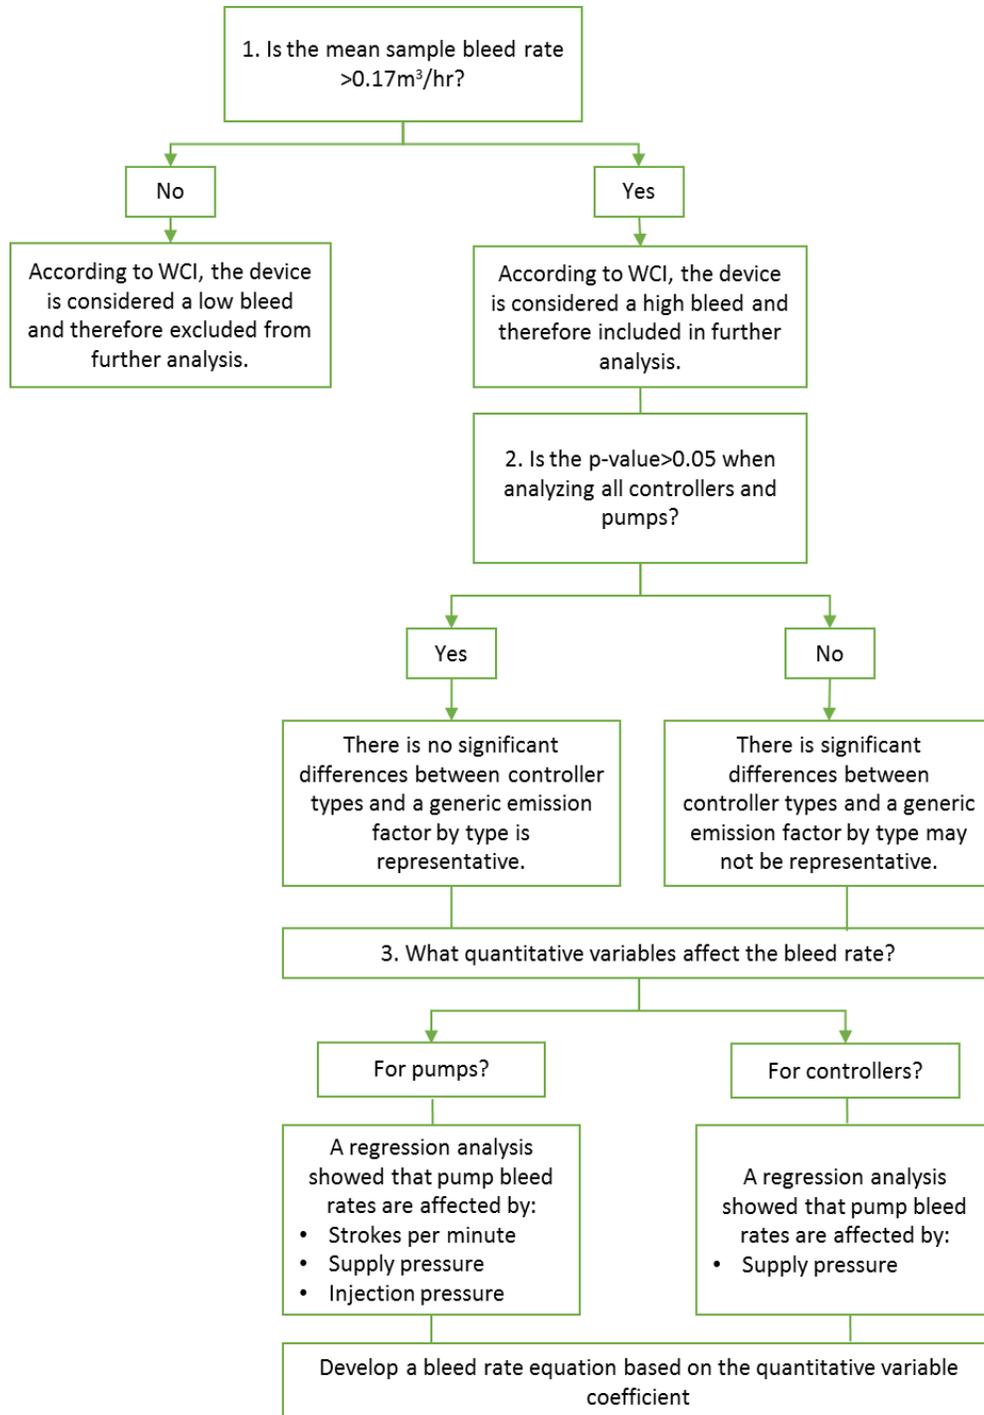

Figure 9: Diagram Illustrating the Quantitative Analysis

5. Comparison of Bleed Rates

Table 8 and Table 9 compare the average bleed rate to the manufacturer’s specification as well as previously published bleed rates. A discussion on variability between the mean bleed rate and the manufacturer specification is provided in Section 6 below. A discussion on variability between the mean bleed rate and the EPA default is provided below. Overall, the average bleed rate for high bleed and intermittent controllers were lower than the EPA default; however, the average bleed rate for low bleed controllers and pumps were both higher than the EPA default. These findings align with a similar study that was performed in the United States by the University of Texas (Allen *et al.* 2013).

Table 8: Comparison of Pneumatic Controller Bleed Rates

6. Discussion

6.1 Outliers

Outliers were not excluded from the sample population because the purpose of the survey was to capture real field conditions and generate a bleed rate that is representative of all field conditions. Certain controllers can have abnormally high bleed rates due to operations and maintenance; however, these bleed rates are representative of real world conditions and therefore were included in the analysis.

6.2 Throttling vs. Snap-Acting Controllers

Two types of controllers were sampled in the field, throttling and snap-acting controllers. Throttling controllers bleed continuously as they constantly throttle between static and dynamic states. Actuating or intermittent bleed devices perform snap-acting control and release gas only when they stroke a valve open or closed. The static bleed rate is steady-state gas consumption. When a controller performs an action, the pressurized gas is subsequently vented through the controller to the atmosphere, also known as the dynamic bleed rate.

The dynamic bleed rate can be much greater than the static bleed rate based on the operating conditions of the controller. The total bleed rate (static + dynamic) depends on the frequency the controller is performing an action. Snap-acting controllers typically have greater variability in dynamic and static action due to the intermittency of the actions. Snap-acting controllers are predominantly in their static, inactive state until an action is required, which results in a short burst of dynamic bleeding.

Figure 10 shows an example of how the bleed rate varies over time for a snap-acting controller. The difference between the static rate and the amplitude of the dynamic event is the dynamic bleed rate. The most important variable that dictates the bleed rate however is the frequency of the dynamic events, which is dependent on a number of variables (dry/wet gas, tank size, etc.) Level controllers are a prime example of a snap-acting controller because they only dynamically bleed when they are prompted by an event, typically to empty a liquids tank.

¹¹ The stated manufacturer max air consumption value assumes a supply pressure of 690 kPa (100 psi), which is a max supply pressure.

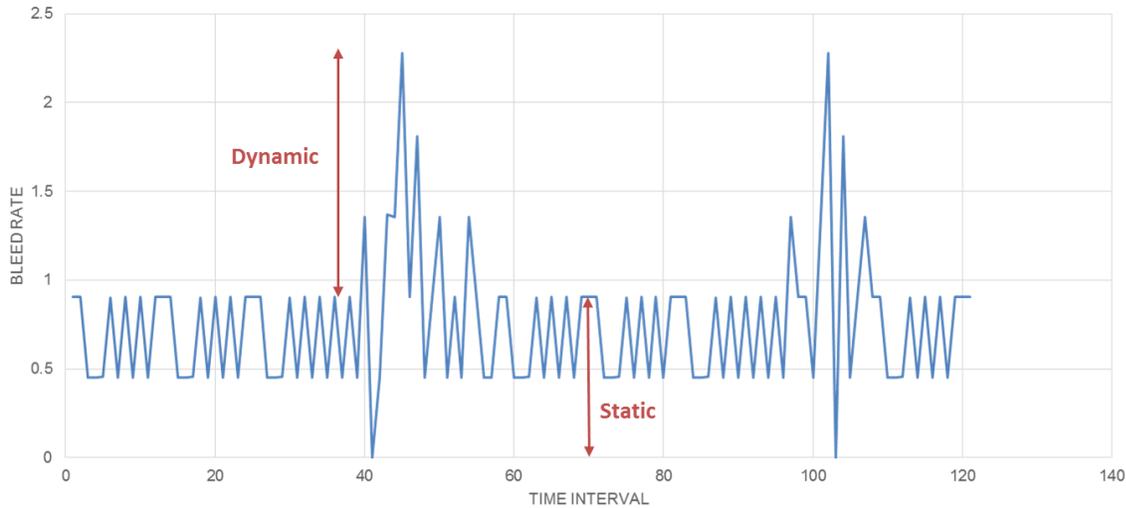

Figure 10: Graph Showing the Dynamic and Static Action

Since the sampling methodology limited the sample time to 30 minutes, there was variability in the amount of static and dynamic action that was captured from a given controller. This variability was due to the frequency of dynamic events. Depending on operating conditions, certain controllers did not perform an action within the 30 minute timeframe, so only the static bleed rate was captured. For example, if a level controller dumps on average every four hours, the sampling team may or may not have caught the dynamic bleed rate of the controller. This created variability in the amount of dynamic versus static bleeds that were captured by an individual sample; however, due to our large sample sets, this variability is representative of how controllers are performing under real operating condition.

This variance was mostly seen in level controllers because they are snap-acting and operate in an on or off type condition. The level controller samples showed a range of values depending on how many dynamic events occurred over a sampling period. This was an expected outcome because level controllers have primarily static bleed rates with variable dynamic events. Our analysis captured both static and dynamic events over the sampling time frame and are both accounted for when using the average as a representative bleed rate for the samples with skewed and bimodal distribution.

6.3 Manufacturer Specification

Differences are observed between the average bleed rate and the manufacturer specification. It should be noted that this variability was expected. The manufacturer specification measures the steady-state air consumption in a lab setting. The purpose of the survey is to determine the average bleed rate of pneumatic controllers and pumps when operating under real field conditions. The field bleed rates differed from manufacturer rates because they are operating under real world conditions with variability in dynamic and static action. For pumps, the field bleed rates are different than manufacturer rates because they are provided with a maximum air consumption using a maximum supply pressure.

6.4 Gas vs. Air vs. Propane

The majority of the field samples were taken at sweet well sites; however, as devices became harder to find, the sampling team targeted compressor stations and batteries as well as sour sites in order to reach the 30 sample threshold. A handful of air samples were obtained from larger facilities because typically, bigger facilities run compressed air instead of pressurized natural gas. A handful of propane samples were obtained from sour well sites because an alternative to process natural gas is required at sour sites, so pressurized propane is typically used. Air and propane samples were corrected using a density ratio in order to compare equivalent volumes of natural gas bled.

6.5 Calscan Vent Gas Meter

When determining which metering device to use during sampling, the Calscan bellows meter was chosen over the Bacharach High-Flow Sampler because it has greater accuracy and has the ability to capture the static and dynamic bleed rates (see Section 2.3.1 for a complete discussion on the differences). A drawback exists; however, that should be discussed and may explain some of the variability in the data. It is well-known that metering a device can affect the operation of the device when hooked up due to back pressure. It is possible that certain controllers didn't produce enough pressure when hooked up to overcome the back pressure, resulting in a zero reading.

6.6 Producer and Sub-District

A multitude of producers and sub districts within British Columbia were sampled; however, the purpose was not to determine differences between producers and sub-districts but determine generic BC wide bleed rates that reflect values from a variety of locations and producers. Since we have taken our samples from a variety of fields, the average bleed rate captures the variability between producers and sub-districts. The intent of the survey was not to determine whether producers and sub-districts were influencing variables; however, the methodology was designed to ensure that these variables were accounted.

6.7 Adding a Device Model to the Survey

If a producer wishes to develop an average bleed rate for a controller or pump that was outside the scope of this survey, they can follow the sampling methodology outlined in Section 2. A minimum of 30 bleed rates per device model must be achieved using a mass flow meter from a variety of producing fields and producers. Please reference the Project Methodology (July 29th 2013) report for the full protocol.

6.8 Mean vs. Median

Many of the snap acting level controllers had skewed or bi-modal distribution. Typically the median is used to represent the value for central tendency in non-normal distributions; however, the goal for this project was to develop an average where all the samples are weighted equally. The mean is recommended because it weights all samples equally; whereas the median would neglect samples on the tail of the distribution. The median would not accurately reflect the combined static and dynamic bleed rate; whereas the mean places equal weight on each sample. Using the median as a measure of central tendency would ignore the data that represents the dynamic action over the course of sampling. Thus, when calculating the most accurate bleed rate, the mean is more representative than the median because of static and dynamic actions.

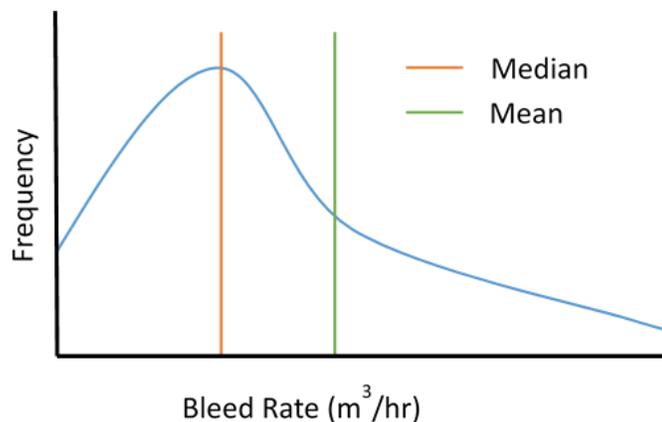

Figure 11: Non-Normal Distribution

6.9 General Linear Model

A general linear model is a statistical test that analyzes variance between sample populations. It was chosen to compare the samples because some populations showed a non-normal distribution and because the samples sizes differed. This statistical test incorporates different ANOVA tests and non-parametric tests to produce an accurate p-value. A general linear model is more robust when dealing with different normalities and variance in sample populations compared to a standard ANOVA and was therefore selected (Bolker *et al.* 2009).

6.10 Summer vs. Winter Sampling

The sampling was performed over the summer months of August and early September. The Calscan Hawk 9000 meter normalized all the samples for temperature and pressure differences in order to eliminate the different operating variables. A known constraint of our sampling methodology was that not all chemical injection pumps operate in the summer months. To eliminate this issue, the sampling team would turn the pump on and perform samples at three normal operating speeds (high, medium and low strokes per minute).

7. Applications of the Analysis

The mean bleed rates calculated in this survey are applicable for GHG reporting. A decision tree is provided in **Figure 12** and Figure 13 below to aid producers in determining which bleed rate to apply.

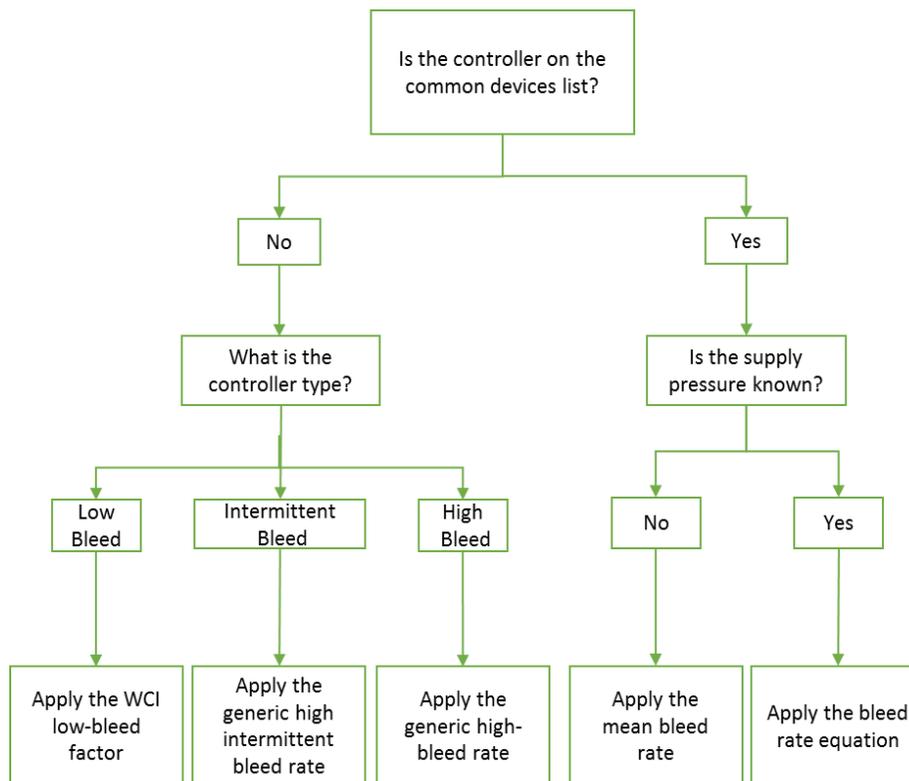

Figure 12: Controller Decision Tree

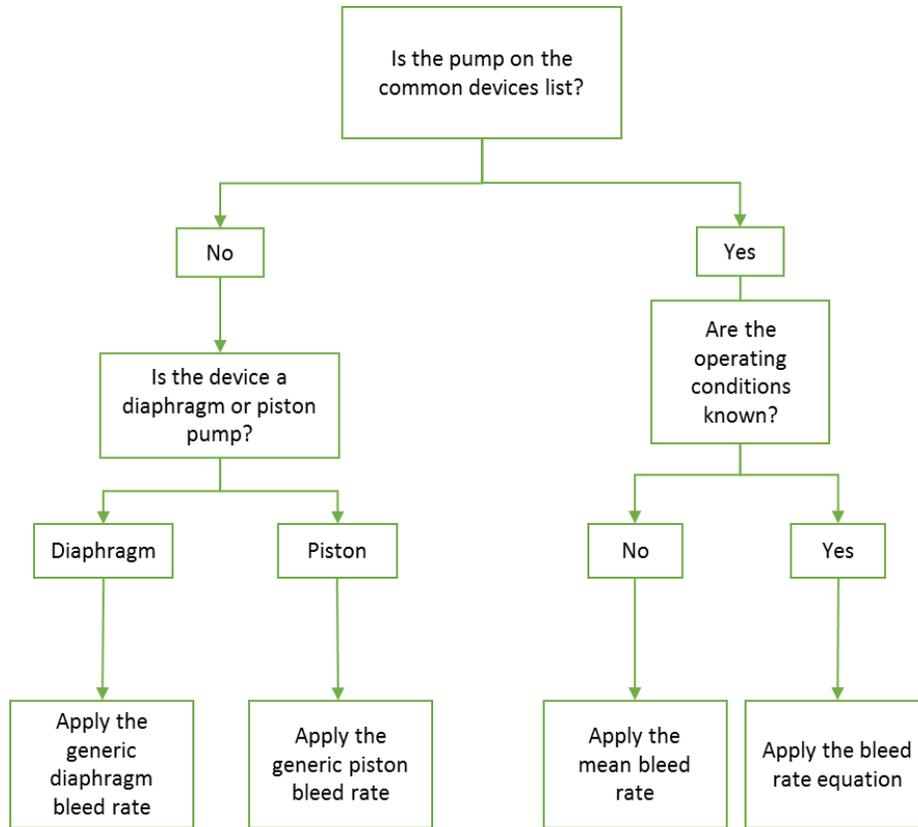

Figure 13: Pump Decision Tree

8. Observations

This study involved comprehensive analysis of pneumatic devices and a significant fieldwork program. This, combined with the fact that this study was one of the first of its kind, resulted in the research team observing several instances where the general body of scientific knowledge in this area could be advanced. These are outlined below:

1. Dynamic vs. static bleed rates: By nature, controller devices have a baseline bleed rate with dynamic events where more gas may be vented. In this study, the maximum sampling time was set at 30 minutes for each device, which added variability to the amount static and dynamic action captured in the sampling of snap-acting controllers (see section 6.2 for further discussion). The time interval between dynamic events may be longer than a 30 minute cycle. Future surveys investigating intermittent bleeding controllers, if undertaken, may consider capturing two complete dynamic cycles if reasonably practicable.
2. Categorisation of ‘high’, ‘intermittent’, and ‘low bleed’: The survey was focused around high-bleed pneumatic controllers. It was observed that for some high bleed devices the calculated mean bleed rate fell below the 0.17m³/hr WCI high bleed threshold and some tested low bleed controllers were higher. As an analysis of the observed differences were not within the scope of the project no further work to assess possible cause was undertaken, at this time. It is observed that future studies may consider all types of pneumatic controllers so that categorisation can be more fully tested and to ensure that field tested emission factors are available for all emitting pneumatic devices.

9. Conclusion

The purpose of the survey was to determine a representative average bleed rate for high bleed pneumatic controllers and pneumatic pumps when operating under field conditions. All outcomes were achieved. The results of the analysis led to the development of three generic bleed rates and twenty specific bleed rates for common pneumatic controllers and pumps for BC's oil and gas industry. These bleed rates can be used in the development of emission factors for GHG reporting and potentially offset purposes.

| Williams | P500 |

Appendix C: Field Sampling Guide

The subsequent guidelines were taken from the full Sampling Methodology report and were followed by the GreenPath field sample team:

What to Sample On-Site

- Sample all pneumatic controllers (including their equivalents) from the list provided (found in Appendix B).
- Sample all pumps. If pumps are turned off and you have permission from the operator to turn it on, take separate samples of the pump at different operating speeds (high, medium and low strokes per minute). Limit different operating speeds to speeds that the pump would function under normal operating conditions.

Duration of Sampling

All samples need to:

- be taken for at least 30 min, or
- until 2 ft³ of gas has been collected

Sampling Device

- Attach the Calscan Hawk 9000 positive displacement bellows meter to the pneumatic device according to manufacturer specification.

Appendix D: Box Plot Distributions

A box plot distribution graph is a way to show the distribution of categorical samples. The black line represents the median value for a sample population. The grey box represents the first and third quartile or 50% of the data. The black lines show the range of observations. The median is represented by the horizontal line and the mean is the circle in the grey box.

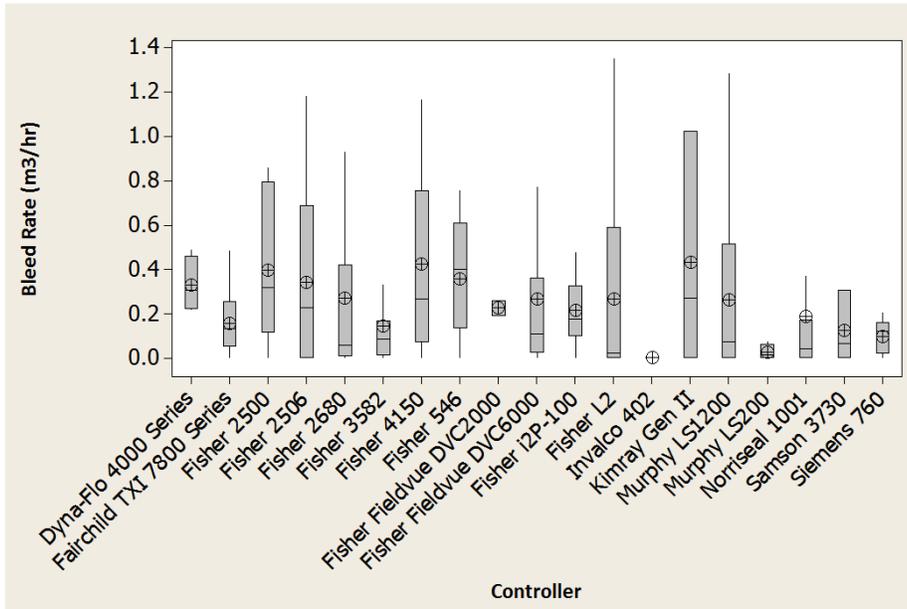

Figure 14: Box Plot Distribution for High-Bleed Controllers

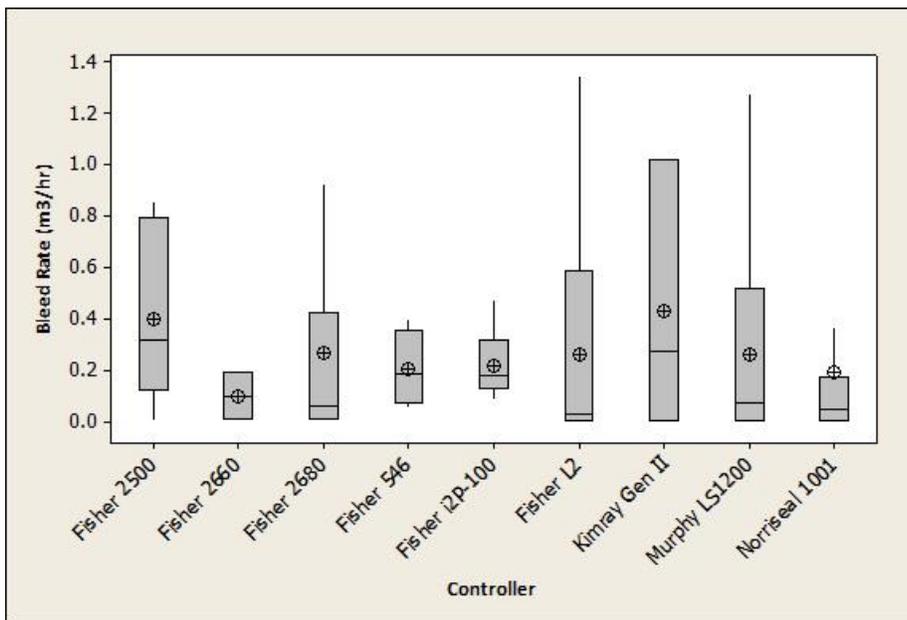

Figure 15: Box Plot Distribution for High Bleed Intermittent Controllers

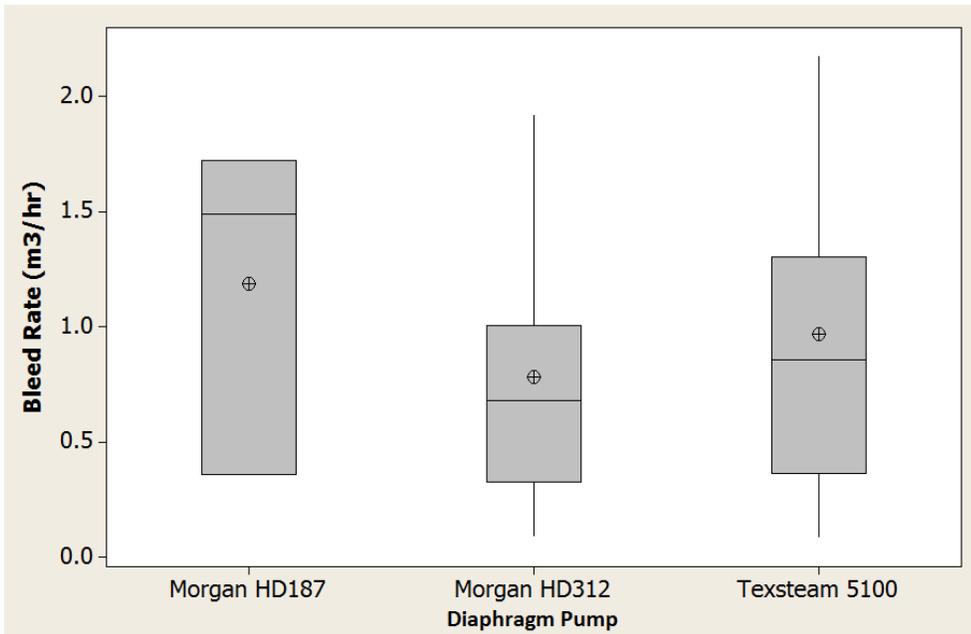

Figure 16: Box Plot Distribution for Diaphragm Pumps

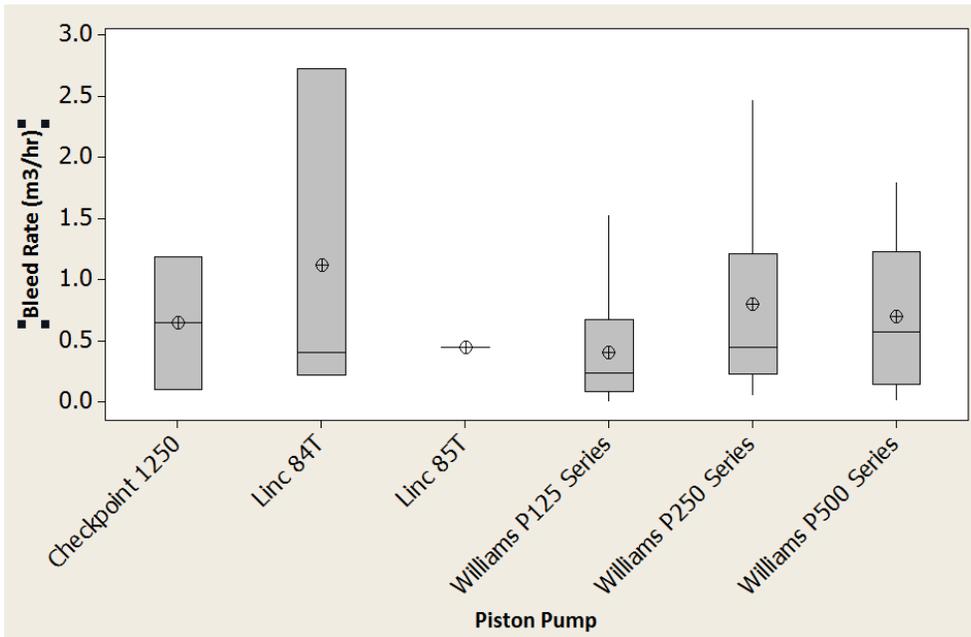

Figure 17: Box Plot Distribution for Piston Pumps

Appendix E: Bleed Rate Equation Coefficients

Pneumatic Controllers

A regression analysis showed that there was a positive correlation between certain pneumatic controller bleed rates and supply pressure.

Table 10: Controller Bleed Rate Equation Coefficients

| Controller | Mean Bleed Rate (m ³ /hr) | Coefficient ¹⁵ | R ² | Correlation ¹⁶ |
|-------------------------------------|--------------------------------------|---------------------------|----------------|---------------------------|
| High Bleed Pneumatic Controllers | 0.2605 | 0.0012 | 0.41 | Positive |
| High Bleed Intermittent Controllers | 0.2476 | 0.0012 | 0.35 | Positive |
| Pressure Controller | | | | |
| Fisher 4150 | 0.4209 | 0.0019 | 0.46 | Positive |
| Fisher C1 | 0.0649 | 0.0003 | 0.25 | Positive |
| Fisher 4660 | 0.0151 | - | 0.05 | Weak |
| Level Controller | | | | |
| Fisher 2500 | 0.3967 | 0.0011 | 0.73 | Strong |
| Fisher 2680 | 0.2679 | 0.0014 | 0.39 | Positive |
| Fisher 2900 | 0.1447 | - | 0.13 | Weak |
| Fisher L2 | 0.2641 | 0.0012 | 0.33 | Positive |
| Murphy L1200 | 0.2619 | 0.0012 | 0.38 | Positive |
| Norriseal 1001 | 0.1868 | - | 0.23 | Weak |
| SOR 1530 | 0.0531 | - | 0.21 | Weak |
| Positioners | | | | |
| Fisher DVC 6000 | 0.2649 | 0.0011 | 0.75 | Strong |
| Temperature Controller | | | | |
| Kimray HT-12 | 0.0351 | - | 0.06 | Weak |
| Transducer | | | | |
| Fairchild TXI7800 | 0.1543 | 0.0009 | 0.60 | Positive |
| Fisher 546 | 0.3547 | 0.0017 | 0.77 | Strong |
| Fisher i2P-100 | 0.2157 | 0.0009 | 0.65 | Strong |

¹⁵ Controllers showing a weak correlation to supply pressure do not have a representative bleed rate equation and should therefore use the mean bleed rate instead of the emission equation.

¹⁶ Strong correlation indicates $R^2 > 0.64$
 Positive correlation indicates $0.25 < R^2 < 0.64$
 Weak correlation indicates $R^2 < 0.25$

Pneumatic Pumps

A regression analysis showed that there was a positive correlation between pneumatic pump bleed rates, supply pressure, injection pressure and strokes per minute. The most accurate bleed rate would take into account these 3 operating variables when calculating the bleed rate for a pneumatic pump.

Table 11: Pump Bleed Rate Equation Coefficients

| Pneumatic Pump | Mean Bleed Rate (m ³ /hr) | Supply Pressure Coefficient (g) ¹⁷ | Injection Pressure Coefficient (n) ¹⁷ | Strokes Per Minute Coefficient (p) ¹⁷ | R ² | Correlation ¹⁸ |
|----------------|--------------------------------------|---|--|--|----------------|---------------------------|
| Diaphragm | 1.0542 | 0.00202 | 0.000059 | 0.0167 | 0.68 | Strong |
| Piston | 0.5917 | 0.00050 | 0.000027 | 0.0091 | 0.49 | Positive |
| Morgan HD312 | 1.1292 | 0.00418 | 0.000034 | 0.0073 | 0.66 | Strong |
| Texsteam 5100 | 0.9670 | 0.00030 | 0.000034 | 0.0207 | 0.74 | Strong |
| Williams P125 | 0.4098 | 0.00019 | 0.000024 | 0.0076 | 0.53 | Positive |
| Williams P250 | 0.8022 | 0.00096 | 0.000042 | 0.0079 | 0.53 | Positive |
| Williams P500 | 0.6969 | 0.00224 | -0.000031 | 0.0046 | 0.74 | Strong |

¹⁷ The coefficients are to be used in the pump bleed rate equation:
 Bleed Rate = m * (Supply Pressure in kPa) + n * (Injection Pressure in kPa) + p * (Strokes per Min)

¹⁸ Strong correlation indicates R²>0.64
 Positive correlation indicates 0.25<R²<0.64
 Weak correlation indicates R²<0.25

made recommendations, including more checks and balances, many of which the IPCC adopted. However, adding complexity adds to the workloads of already overstretched scientists and will never eliminate errors completely. I believe that the process is already rigorous enough and that adding further complexity should be resisted.

Compensate lead authors for their time.

Although practices vary between countries and institutions, there is no system of compensation for IPCC lead authors, other than for travel expenses. The authors devote significant amounts of time, often with no reduction in workload from their main employers. This limits the time that they can spend on the reports.

Lead authors should not profit from being involved in the IPCC, because this could be perceived as a conflict of interest. But governments should offer to cover the costs to their host institutions of teaching relief, or of employing a research assistant to ease their workload, allowing them to maintain scientific output. Although this would increase the cost of producing the reports, the extra expense would be trivial compared with the benefit of having the best possible assessment of climate change.

So why should scientists take part in IPCC assessment reports? Because the future of the world will be severely affected by climate change and we have a responsibility to make the risks known. The IPCC remains the most effective way to do that. ■

Floods brought parts of Britain to a standstill earlier this year.

Improve economic models of climate change

Costs of carbon emissions are being underestimated, but current estimates are still valuable for setting mitigation policy, say **Richard L. Revesz** and colleagues.

On 31 March, the Intergovernmental Panel on Climate Change (IPCC) released its latest report on the impacts of climate change on humans and ecosystems (see go.nature.com/ad5v1b). These are real risks that need to be accounted for in planning for adaptation and mitigation. Pricing the risks with integrated models of physics and economics lets their costs be compared to those of limiting climate change or investing in greater resilience.

Last year, an interagency working group for the US government used three leading economic models to estimate that a tonne of carbon dioxide emitted now will cause future harms worth US\$37 in today's dollars¹. This 'social cost of carbon' represents the money saved from avoided damage, owing to policies that reduce emissions of carbon dioxide.

Governments, agencies and companies use such estimates to guide decisions about how much to invest in reducing ►

▶ emissions. In the United States, a previous estimate² made in 2010 informed the stricter fuel-economy requirements for new cars. The latest value is motivating President Barack Obama's plan to impose greenhouse-gas limits on coal-fired power plants by next year. Canada, Mexico, the United Kingdom, France, Germany and Norway have used similar numbers to guide regulatory decisions, as has the International Monetary Fund to analyse fossil-fuel subsidies.

Yet the social-cost benchmark is under fire. Industry groups, politicians — including leaders of the energy and commerce committee of the US House of Representatives — and some academics say that uncertainties render the estimate useless.

As legal, climate-science and economics experts, we believe that the current estimate for the social cost of carbon is useful for policy-making, notwithstanding the significant uncertainties. The leading economic models all point in the same direction: that climate change causes substantial economic harm, justifying immediate action to reduce emissions. In fact, because the models omit some major risks associated with climate change, such as social unrest and disruptions to economic growth, they are probably understating future harms. The alternative — assigning no value to reductions in carbon dioxide emissions — would lead to regulation of greenhouse gases that is even more lax.

Instead, climate-economic models need to be extended to include a wider range of social and economic impacts. Gaps need to be filled, such as the economic responses of developing countries and estimates of damages at extreme temperatures. Today, only a

handful of researchers in the United States and Europe specialize in such modelling. A broader programme involving more people exploring more phenomena is needed to better estimate the social cost of carbon and to guide policy-makers. Otherwise policies will become untethered from economic realities.

SOCIAL COST

The models in question aim to integrate estimates of the costs of greenhouse-gas emissions and of steps to reduce them. First, they translate scenarios of economic and population growth, and resulting emissions, into changes in atmospheric composition and global mean temperature. Then the models apply 'damage functions' that approximate the global relationships between temperature changes and the economic costs from impacts such as changes in sea level, cyclone frequency, agricultural productivity and ecosystem function. Finally, the models translate future damages into present monetary value.

Sources of uncertainty are numerous³. They include: how the climate responds to carbon dioxide concentrations; positive and negative feedback loops in the climate system; emissions growth rates for various socio-economic scenarios; the completeness and accuracy of damage functions (especially with regard to catastrophic harms, migration and conflict, weather variability and feedbacks on economic growth); the ability of future generations to adapt to climate change; and

"The models omit social unrest and disruptions to economic growth."

the economic 'discount rate' used to translate future costs to current dollars.

The 2013 US analysis¹ used the then-most recent vintages of three long-standing models: FUND 3.8, DICE 2010, and PAGE09. Each model applies different climatic and economic functions to simplify the complex picture. Despite the range of approaches and uncertainties, each one predicted sizeable economic damage from greenhouse-gas emissions for warming beyond 2°C above pre-industrial levels. Two models, ENVISAGE and CRED, published since the US analysis was structured in 2010, have broadly similar projections to these three (see 'Carbon's costly legacy'). The analysis suggested that — depending on assumptions about how future damages are valued in today's money — the expected global cost of one tonne of carbon dioxide emitted in 2020 is between \$12 and \$64 (with \$43 as the central value).

GREATER HARM

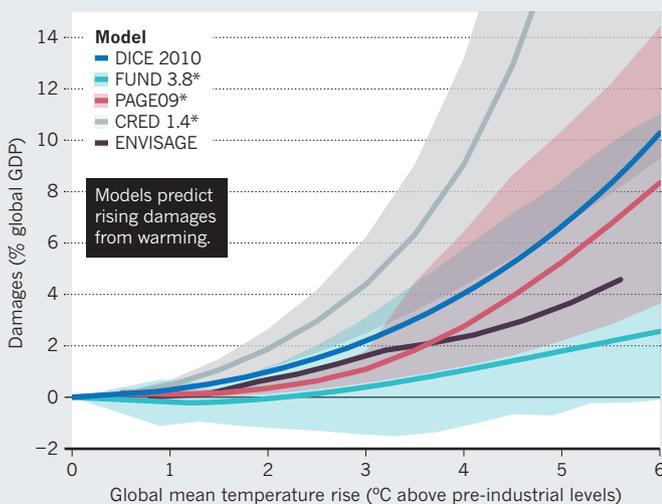

The future costs of climate change could be even higher, for four reasons. First, the impacts of historic temperature changes suggest that societies and economies may be more vulnerable than current models predict and that weather variability is more important than average weather in determining impacts, particularly for crop growth and food security. For example, the yields of some crops may decline rapidly above certain temperatures⁴.

Second, the models omit damages to labour productivity, to productivity growth, and to the value of the capital stock, including buildings and infrastructure. By lowering the annual growth rate, these damages

CARBON'S COSTLY LEGACY

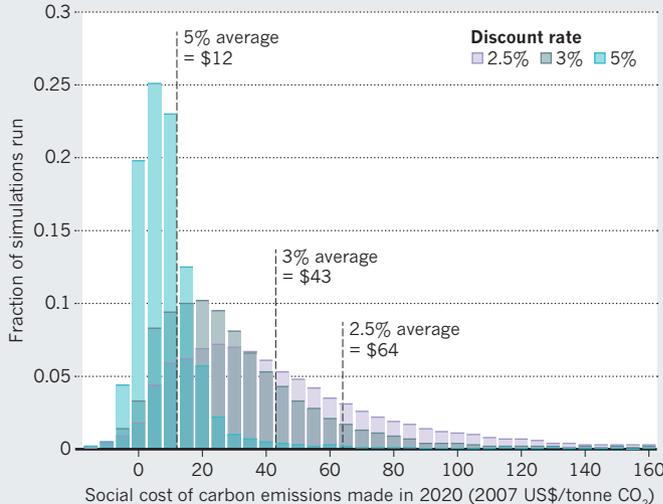

Economic models of climate change project that resulting damage worldwide (A) will increase with future emissions and may cost several per cent of global gross domestic product (GDP) with the warming expected by 2100. Uncertainties in future socio-economics, emission rates and climate impacts result in a range of estimates of the social cost of carbon, which is also affected by the choice of 'discount rate' used to convert future harms into today's money (B).

A PROJECTED DAMAGES

*Shaded regions indicate 5% and 95% confidence intervals for FUND 3.8 and PAGE09, and a high-low range for CRED 1.4.

B SOCIAL COSTS FROM US GOVERNMENT ANALYSIS

SOURCE: A, REF.1 (DICE, FUND, PAGE); ROSON, R. & MENSBRUGHE, D. V. D. (INT. J. SUST. ECON. 4, 270-285 (2012)) (ENVISAGE)/ACKERMAN, F., STANTON, E. A. & BUENO, R. (ECON. 85, 166-176 (2013)) (CRED); B, REF.1

Storms caused chaos on roads in northwestern Italy in 2011.

be beyond human experience. If warming continues unchecked into the twenty-second century, it could render parts of the planet effectively uninhabitable during the hottest days of the summer, with consequences that would be challenging to monetize¹⁰.

The models should be revised more frequently to accommodate scientific developments. Researchers commonly test model sensitivity to new parameters. But the structure and in some cases the calibration of the damage models is stuck in the 1990s, when the original versions were created, owing to a lack of funding.

IPCC reports help to set the research agenda on climate. The release of the Fifth Assessment Report reminds us of the progress so far. It is important to ensure that the sixth assessment takes a substantive step forward. By facilitating efforts to refine estimates of the social cost of carbon, the IPCC will be performing its most important function: informing the global political conversation about how best to address the looming threat of climate change. ■

could have deeper and longer-lasting effects on the global economy than the static losses of annual economic output currently represented in the three main models^{5,6}. A significant decline in human welfare is possible in the medium and long run owing to the compounding effects of lost growth. Also not taken into account are the risks of climate-induced wars, coups or societal collapses and the resulting economic crises⁷.

Third, the models assume that the value that people attach to ecosystems will remain constant⁸. Yet as a commodity becomes more scarce, its value increases. In the desert, water is extremely valuable. During a flood, dry land is highly prized. Because the services provided by ecosystems are likely to decline as warming degrades them, the costs of future ecosystem damage from climate change will rise faster than the models predict.

Fourth, the US analysis assumes a constant discount rate to translate future harms into today's money. However, for impacts that are both highly uncertain and occurring in the distant future, economists have shown⁹ that a discount rate that declines over time should be used, with discount rates for the far future significantly below those that were used in the 2013 analysis. This approach would

yield a higher present value to the long-term impacts of climate change and thus a higher value for the social cost of carbon.

It is true that future technological developments might better equip society to cope with climate change. And of course overall bias cannot be determined simply by adding biases in each direction. But the bulk of the literature and arguments indicates that social-cost models are underestimating climate-change harms.

BETTER MODELS

What now? Modellers, scientists and environmental economists must continue to step outside their silos and work together to identify research gaps and modelling limitations.

Climate hot spots in the developing world are one such gap, because economic responses in these regions cannot be extrapolated simply from estimates made for developed countries. The impacts of extreme temperatures are also uncertain. Current damage estimates are generally calibrated for warming of less than 3 °C (ref. 6). Yet without mitigation, the IPCC projects that we could see warming in excess of 4 °C by the end of the century. Such conditions would

Glossary

| Term | Definition |
|-------------------------------------|--|
| AB 32 | Assembly Bill 32, The California Global Warming Solutions Act of 2006 (Stats. 2006, ch. 488) |
| Active Wells | Wells that are producing crude oil or natural gas throughout the year |
| AGR Unit | Acid Gas Removal Unit. These units remove sulfur or CO ₂ from natural gas streams. |
| Air District | An air pollution control district (APCD) or air quality management district (AQMD) |
| API Gravity | A scale used to reflect the specific gravity (SG) of a fluid such as crude oil, water, or natural gas. The API gravity is calculated as $[(141.5/SG) - 131.5]$, where SG is the specific gravity of the fluid at 60°F |
| ARB | California Air Resources Board |
| Automated Control Device | A device that uses compressed gas or air to affect mechanical motion. Commonly referred to as pneumatic devices. |
| Automated Control Device Actuator | A device that accurately locates the valve plug in a position dictated by the control signal. |
| Automated Control Device Controller | Positions its movable part (a plug, ball or vane) relative to the stationary seat of the valve. |
| Board | California Air Resources Board |
| BTU | British Thermal Unit |
| CEC | California Energy Commission |
| CEIDARS | ARB's California Emission Inventory Development and Reporting System Database |
| Centrifugal Compressor | Centrifugal compressors increase the pressure of natural gas by centrifugal action, employing rotating movement of the drive shaft. |

| Term | Definition |
|-------------------------|--|
| CH ₄ | Methane |
| CHP | Combined Heat and Power |
| CIPA | California Independent Petroleum Association |
| CNG | Compressed natural gas |
| CO ₂ | Carbon dioxide |
| CO ₂ e | Carbon dioxide equivalents |
| Cogeneration | An integrated system that produces electric energy and useful thermal energy. Synonymous with combined heat and power. |
| Combined Cycle Turbine | A turbine that generates electricity and the waste heat of which is used to make steam. The steam is then used to generate electricity through a steam turbine or injected into a geological formation to increase production. |
| Combined Heat and Power | An integrated system that produces electric energy and useful thermal energy. Synonymous with cogeneration. |
| Combustion Emission | Greenhouse gas emission occurring during the exothermic reaction of a fuel with oxygen |
| Compressor | Any machine for raising the pressure of a natural gas stream by drawing in low pressure natural gas and discharging significantly higher pressure natural gas |
| Dehydrator | Equipment that removes water from a natural gas stream by passing it over glycol or a desiccant. |
| DOGGR | Department of Conservation's Division of Oil, Gas, and Geothermal Resources |
| Dry Gas | Natural gas produced from a gas well without associated crude oil |
| EIA | The US Department of Energy's Energy Information Administration |
| EOR | Enhanced oil recovery |

| Term | Definition |
|----------------------------|--|
| External Combustion Engine | An engine where an internal fluid is heated by an external heat source |
| FAR | IPCC Fourth Assessment Report |
| Four-Stroke Engine | An engine in which the piston completes four separate strokes, intake, compression, power, and exhaust, during two separate revolutions of the engine's crankshaft. |
| Fractionation | The process of separating natural gas liquids into their constituent liquid products. |
| Fugitive Emission | Unintentional release of greenhouse gas vapors to the atmosphere |
| Gas Injection EOR | The method of injecting a gas such as natural gas, nitrogen, or carbon dioxide into a geological formation to increase crude oil production |
| GHG | Greenhouse Gas |
| GWP | Global warming potential. Unitless measure of the radiative forcing of a particular compound relative to CO ₂ |
| H ₂ S | Hydrogen Sulfide |
| Heater/Treater | Oil/water separators that use heat to expedite the separation process |
| Heavy Crude | Crude oil with an API gravity of 10 to 20 |
| HHV | Higher Heating Value |
| Hydraulic Fracturing | Well stimulation technique using high pressure pumps to increase fluid pressure at the bottom of a well. This fluid pressure cracks the formation and proppants such as sand or walnut hulls are injected into the newly formed crevices to keep them open when the fluid pressure is removed. |
| I&M Program | Inspection and Maintenance Program |
| Internal Combustion Engine | An engine where fuel is burned inside a combustion chamber. The expansion of the gas applies direct force to a component of |

| Term | Definition |
|---------------------------------|--|
| | the engine such as a piston or turbine blade. |
| IOPA | Independent Oil Producers' Agency |
| IPCC | United Nation's Intergovernmental Panel on Climate Change |
| Lean Burn Engine | Engines that may operate up to the lean flame extinction limit, with exhaust oxygen levels of 12 percent or greater. The air to fuel ratios of lean-burn engines range from 20:1 to 50:1 and are typically higher than 24:1. The exhaust excess oxygen levels of lean-burn engines are typically around 8 percent, ranging from 4 to 17 percent. |
| Light Crude | Crude oil with an API gravity of 20 to 30 |
| N ₂ O | Nitrous oxide |
| Natural Gas Gathering Pipelines | Small natural gas pipelines located on a production facility that route natural gas |
| PD | Protected data. In this survey report, data values that do not represent at least three companies. |
| PERP | Portable Equipment Registration Program |
| Pipeline Pig | A device sent down a pipeline to clean or inspect the pipeline. |
| Pits | Open pits that are used for oil/water separation or for emergency containment. |
| Production Facility | Facility that extracts crude oil and/or natural gas |
| Reboiler | Units that heat glycol to remove water, or heat amine to remove acid gas. |
| Reciprocating Compressor | Reciprocating compressors increase the pressure of natural gas by positive displacement, employing linear movement of a shaft driving a piston in a cylinder. |
| Rich Burn Engine | Engines that operate near the stoichiometric air-to-fuel ratio (16:1) with exhaust excess oxygen levels less than 4 percent (typically closer to 1 percent) |
| ROG | Reactive Organic Gas |

| Term | Definition |
|----------------------|---|
| Rotary Compressor | Rotary compressors have blades or a cylinder that rotate off center to compress the natural gas. Synonymous with screw compressors. |
| SAR | IPCC Second Assessment Report |
| Screw Compressor | Screw compressors have blades or a cylinder that rotate off center to compress the natural gas. Synonymous with rotary compressors. |
| Separator | Separators split the fluids that come out of a well by gravity, heat, or both. |
| Simple Cycle Turbine | A turbine that generates electricity and does not utilize the waste heat. |
| Specific Gravity | The ratio of the density of a substance to the density of a reference substance. The reference substance is generally water. |
| Steam Generator | Equipment that produces steam using an external heat source |
| Sump | Open pit that is used for oil/water separation or for emergency containment. |
| TAR | IPCC Third Assessment Report |
| Thermal EOR | The method of injecting steam into a geological formation to increase crude oil production |
| TOG | Total Organic Gas |
| Turbine | An internal combustion engine where the force from the combustion chamber moves a blade rather than a piston. |
| Two-Stroke Engine | In a 2-stroke engine, the air-to-fuel charge is injected with the piston near the bottom of the power stroke. The intake ports are then covered or closed, and the piston moves to the top of the cylinder, compressing the charge. Following ignition and combustion, the power stroke starts with the downward movement of the piston. As the piston reaches the bottom of the power stroke, exhaust ports or valves are opened to exhaust, or scavenge, the combustion products, and a new air-to-fuel |

| Term | Definition |
|-------------------|--|
| | charge is injected. |
| Ultra-Heavy Crude | Crude oil with an API gravity of less than 10 |
| Ultra-Light Crude | Crude oil with an API gravity of greater than 30 |
| US EPA | United States Environmental Protection Agency |
| Vapor Recovery | Equipment located at the source of potential gas emissions to the atmosphere that is used for collecting and routing the gas back into the process as a product and/or fuel or for destruction. |
| Vented Emission | Intentional release of greenhouse gas vapors to the atmosphere |
| Waterflood EOR | The method of injecting water into a geological formation to increase crude oil production. |
| Well Cellars | Lined or unlined pits around one or more wells that: (a) allow access to the wellhead components for servicing, or (b) contain intermittent flows of crude oil or water during an emergency or from drilling and petroleum production processes. |
| Well Cleanups | Well maintenance activities that include fracturing or removing fluids to increase production. |
| Well Completions | The final step to bringing a newly drilled well into production. |
| Well Workovers | The process of performing major maintenance or remedial treatments on an oil or gas well. |
| WSPA | Western States Petroleum Association |

Executive Summary

On September 27, 2006, Governor Schwarzenegger signed Assembly Bill 32 (AB 32), the California Global Warming Solutions Act of 2006 (Núñez, Statutes of 2006, chapter 488). AB 32 establishes a comprehensive program of regulatory and market mechanisms to achieve real, cost-effective, quantifiable reductions of greenhouse gases (GHG). AB 32 charges the Air Resources Board (ARB) as the agency responsible for monitoring and regulating many GHG emission sources to reduce California's GHG emissions to 1990 levels by 2020.

Among the measures that the ARB staff is considering to help reach this AB 32 goal is a measure to reduce GHG emissions from upstream crude oil and natural gas production, processing, and storage operations. In order for staff to determine the potential GHG emission reductions, the technical feasibility, and the cost-effectiveness of any potential control measure, the ARB staff conducted a survey of the crude oil and natural gas industry to improve estimates of GHG emissions in California from these operations.

In February 2009, the 2007 Oil and Gas Industry Survey was mailed out to crude oil and natural gas production, processing, and storage facilities in California. The survey was completed by 325 companies representing over 1,600 facilities and approximately 97 percent of the 2007 crude oil and natural gas production in California.

Emissions were calculated using equipment information from the survey and commonly used emission equations and emission factors listed in Appendix B of this report. Total emissions for equipment covered under this survey are estimated to be 17.7 million metric tons of CO₂e. Combustion sources (equipment burning fuel for energy) account for 93 percent of the total CO₂e emissions. The remaining 7 percent of the CO₂e emissions, or about 1.3 million metric tons of CO₂e, come from vented and fugitive sources, which are intentional and unintentional releases of gases to the atmosphere, respectively.

In August 2011, staff released a draft of this report for public comment. Staff finalized this report in December 2011 based on the comments received, which resulted in the addition of a Glossary, minor text changes to improve clarity, and the inclusion of the survey cover letter and survey instructions in Appendix A.

While examining the data in detail at the equipment level as part of potential regulatory development, staff discovered several instances of equipment with unusually large emissions. Upon further review, staff determined these emissions were due to reporting errors, in some cases caused by instructions that were not applicable in specific instances. Staff worked with the survey respondents to correct these reporting errors. Staff recalculated the emissions which, in most cases, were lower. The affected equipment types were dehydrators, acid gas removal units, and other gas processing equipment.

This Revised Final Report contains these corrected emissions, as reflected in revised Chapters 3, 11, 12, 13, 14, 20, and 21. In addition, production and emissions data broken down by air district have been added to Chapters 2 and 3. Other minor text corrections discovered since December 2011 have also been made to this Revised Final Report.

Chapter 1 – Survey Development

Background

On September 27, 2006, Governor Schwarzenegger signed Assembly Bill 32 (AB 32), the California Global Warming Solutions Act of 2006 (Núñez, Statutes of 2006, chapter 488). This law required the reduction of greenhouse gas (GHG) emissions to 1990 levels by 2020.

AB 32 designated the California Air Resources Board (ARB or Board) as the lead agency for implementing AB 32 and mapped out major milestones for achieving this goal. ARB met the first milestones in 2007 by developing a list of discrete early action measures, assembling an inventory of historic emissions, establishing GHG reporting requirements, and setting the 2020 emissions limit.

In November 2007, ARB published the 1990 – 2004 California GHG inventory. The oil and gas production sector, as well as the natural gas transmission and distribution pipeline system, were identified as large sources of GHG emissions. In late 2007, a team of staff was assembled to evaluate potential reductions from these sectors.

Among the measures that the ARB staff is developing to help reach the AB 32 goal of reducing GHG emissions to 1990 levels by 2020 is one potential measure to reduce emissions from the crude oil and natural gas production, processing, and storage sector. This report provides the results of the 2007 survey of emissions from the crude oil and natural gas production, processing, and storage sector (2007 Oil and Gas Industry Survey).

Development of the 2007 Oil and Gas Industry Survey

In April 2008, ARB staff held a public workshop to discuss preliminary concepts for reducing greenhouse gases from the oil and gas production, transmission and distribution, and refinery sectors. Attendees were encouraged to sign up to be part of industry workgroups. After that workshop, the sector was split into three discrete sections: an oil and gas production section, a natural gas transmission and distribution section, and a refinery section.

Ultimately, the oil and gas production sector contained the following types of facilities:

- Crude oil extraction;
- Natural gas extraction;
- Natural gas storage;
- Crude oil processing not including refineries;
- Natural gas processing including gas plants;
- Crude oil pipelines; and
- Crude oil tank farms not including tank farms at refineries.

The natural gas transmission and distribution sector contained:

- Natural gas transmission pipelines;
- Natural gas distribution pipelines;
- Natural gas compressor stations; and
- Natural gas metering stations.

The refinery sector included only crude oil refineries.

In the months preceding the April 2008 public workshop, staff gathered available data from ARB's California Emission Inventory Development and Reporting System (CEIDARS) database, local air district permit data, and a small amount of individual company data. It was concluded that the quality and uniformity of the data were not robust enough to support regulation development. Staff then proposed surveying the sector to create a current baseline inventory.

To create a comprehensive survey that could be used to create a robust GHG emissions inventory for the oil and gas production sector, staff determined that research, industry and air district meetings, and site visits were necessary. To that end, staff spent the next 10 months educating themselves and developing a survey in cooperation with the industry, industry trade groups, and local air districts (Table 1-1).

Appendix A is a copy of the survey, and Appendix B lists the calculation methods and emission factors used to estimate emissions. Appendix C contains a more detailed version of Table 1-1.

Table 1-1: Site Visits and Meetings

| Date | Action |
|--------------------------|--|
| April 2008 | <ul style="list-style-type: none"> • Staff held public workshop. • Industry and district working groups created. |
| May 2008 to January 2009 | <ul style="list-style-type: none"> • Staff met with the Western States Petroleum Association (WSPA), California Independent Petroleum Association (CIPA), Independent Oil Producers' Agency (IOPA), and air district staff. • Staff toured over twenty oil and gas facilities. • Staff developed a draft survey and worked with the industry and district working groups to revise. • Staff developed general instructions for completing the survey and electronic templates. |
| February 19, 2009 | <ul style="list-style-type: none"> • ARB staff mailed out the Oil and Gas Industry Survey. |
| March 26, 2009 | <ul style="list-style-type: none"> • Staff traveled to Bakersfield to conduct a training seminar for filling out the survey. |
| February to August 2009 | <ul style="list-style-type: none"> • Survey responses were due on April 30, 2009. • Survey database was developed and surveys uploaded as |

The 2007 Oil and Gas Industry Survey

This report presents the results from the 2007 Oil and Gas Industry Survey conducted by ARB to estimate greenhouse gas emissions in California. This survey was a one-time collection of data intended to accurately quantify operations and processes needed to estimate greenhouse gas emissions. The survey pertained to all upstream crude oil and natural gas facilities regardless of the size of operation.

For the purpose of this survey, upstream crude oil and natural gas facilities include:

Oil or Natural Gas Extraction Facilities: any facility that extracts crude oil, natural gas, or both crude oil and natural gas.

Processing Facilities: any facility that processes crude oil or natural gas for use or distribution. This survey does not include refineries.

Crude Oil Transmission Facilities: crude oil pipelines or crude oil bulk loading operations. This includes ship, truck, or rail car loading facilities.

Storage Facilities: any facility that stores crude oil or natural gas, including underground natural gas storage facilities. This survey excludes crude oil tank farms located on refinery premises.

Additional facilities or operations covered under this survey include:

Drilling or Workover Companies: any owner of drilling or workover rigs that performed well services on crude oil or natural gas facilities.

Cogeneration Plants/Combined Heat and Power: any facility that produced electricity and thermal energy for use at a crude oil extraction or storage facility.

Produced Water Disposal: any facility that stored produced water from crude oil or natural gas extraction or storage facilities.

Some companies considered the data provided in the survey to be trade secret and confidential. To address this concern, but still allow the publishing of survey results, ARB implemented the historical practice of concealing all data values that did not represent at least three companies, otherwise known as the “Three Company Rule.” In addition, this report contains summarized survey data, rather than lists of individual survey responses to further protect confidentiality. Every effort was made to reveal as much of the survey data as possible without compromising the “Three Company Rule.” However, instances did arise where it was necessary to conceal certain portions of the survey results. Throughout this report the term “Protected Data” (or PD) is used to reflect that compliance with the “Three Company Rule” could not be satisfied and the data were concealed to protect company confidentiality.

Chapter 2 – General Information

Survey Response

The 2007 Oil and Gas Industry Survey was sent out to 1,429 companies. ARB received over 750 surveys, representing 389 companies from our original mailing list. Of the remaining 1,040 companies, 960 names were removed due to the following reasons:

- The company was out of business,
- The company had merged or been bought by another, or
- The company was not in the crude oil or natural gas business.

The remaining 80 companies did not respond. Thus, there was an 83 percent response rate for relevant companies. The response rate is probably even greater assuming many of the 80 nonresponsive companies fall into one of the three removal categories above.

This report details the results of this equipment and process survey. The total number of companies that completed the survey was 325. This number is smaller than the 389 companies listed on our mailing list due to several companies being listed with multiple addresses.

In the tables that follow, it should be noted that the percentages reported may not add to 100 percent due to rounding and that percentages that round to less than one percent are shown as zero percent.

The unique nature of crude oil and natural gas extraction added complexity to assigning emissions to a company. Many companies have multiple fields, with multiple facilities. To accommodate this, ARB allowed the company to list a company name, a facility location, and a facility identification number (ID). The facility location was generally the field or lease name and the facility ID was generally an air district identification number. In both cases, the facility location and facility ID were defined by contiguous property boundaries. As a result, 325 companies representing 1,379 facility locations, and 1,632 facility IDs in 17 air districts across California completed the survey. For the remainder of this report, the term “facility” will be used for facility ID.

Table 1 of the 2007 Oil and Gas Industry Survey required companies to fill out general information about each facility and facility location. This included business type. Table 2-1 lists the number of facilities by business type. Because facilities were allowed to list multiple business types for one facility, the total number of facilities by business type is larger than the total number of facilities that completed the survey.

The business type “other” includes the following self-reported facility types:

- CNG compression and marketing
- Cogeneration

- Combined heat and power
- Electricity generation
- Portable heating
- Water disposal
- Vapor recovery services.

Table 2-1: Number of Facilities by Business Type

| Type | Number |
|-----------------------------------|--------------|
| Onshore Crude | 668 |
| Offshore Crude | 17 |
| Onshore Natural Gas | 786 |
| Offshore Natural Gas | 8 |
| Natural Gas Storage | 11 |
| Natural Gas Processing | 282 |
| Crude Pipeline | 111 |
| Crude Storage | 258 |
| Crude Processing | 92 |
| PERP ¹ Equipment Owner | 60 |
| Other | 54 |
| Totals: | 2,347 |

1. PERP = Portable Equipment Registration Program

Throughout the remainder of this report, the term “primary business” will be used. This term is used to assign emissions for a particular facility to its primary business. Primary business type was assigned to each facility using the following list in this order:

- Onshore crude oil production
- Offshore crude oil production
- Onshore natural gas production
- Offshore natural gas production
- Natural gas storage facility
- Natural gas processing
- Crude oil pipeline
- Crude oil storage
- Crude oil processing
- PERP equipment owner
- Other

The above list shows the order in which a primary business was assigned to each facility. Thus, a facility listing the business types “onshore crude”, “natural gas processing”, and “crude storage” would have “onshore crude” designated as its primary business.

Table 2-2 shows the number of facilities by primary business type. Crude storage and crude processing were combined to protect confidential data.

Table 2-2: Number of Facilities by Primary Business Type

| Type | Number |
|---------------------------------|--------------|
| Onshore Crude Production | 668 |
| Offshore Crude Production | 16 |
| Onshore Natural Gas Production | 703 |
| Offshore Natural Gas Production | 0 |
| Natural Gas Storage | 10 |
| Natural Gas Processing | 17 |
| Crude Pipeline | 65 |
| Crude Processing and Storage | 42 |
| PERP Equipment Owner | 58 |
| Other | 53 |
| Totals: | 1,632 |

California Production

Table 2 of the 2007 Oil and Gas Industry Survey required companies to fill out their production for each facility location. This table asked for the number of

- active wells,
- well cellars,
- new wells drilled,
- workovers that required tubing removal,
- well cleanups (also known as liquid unloading), and
- well completions.

The production type was also required. California crude oil production was reported by the American Petroleum Institute (API) gravity range. API gravity measures how heavy or light a petroleum product is compared to water. The lower the API gravity number, the heavier the petroleum product is compared to water. Thus, companies filled out the above list by type of production:

- dry gas production (referred to as Produced Natural Gas in the survey),
- natural gas storage,
- ultra-heavy (API < 10) crude oil production,
- heavy (API 10 - 20) crude oil production ,
- light (API 20 - 30) crude oil production, and
- ultra-light (API > 30) crude oil production.

Table 2 of the 2007 Oil and Gas Industry Survey also gathered production volume, the composition of the natural gas produced, the volume of crude oil transported, and the miles of crude oil pipeline.

Crude oil and natural gas extraction is a large industry in California. In 2007, California produced 243 million barrels of crude oil, making it the fourth largest producer of domestic crude oil (DOGGR, 2008; EIA, 2009b). This production accounts for 38 percent of the total crude oil delivered to California refineries. The other sources of

crude oil delivered to California refineries are 45 percent foreign, 16 percent Alaskan, and one percent from gulf coast states (CEC, 2010).

The 2007 Annual Report of the State Oil and Gas Supervisor stated that 58 percent of California's 2007 crude oil production was extracted through enhanced oil recovery (EOR) techniques (DOGGR, 2008). EOR techniques include thermal, waterflood, and gas injection. Thermal EOR injects steam into the formation, waterflood EOR injects water into the formation, and gas injection EOR injects natural gas, nitrogen, or carbon dioxide into the formation. Of the production that was recovered through EOR techniques, 68 percent used thermal, 27 percent used waterflood, and 5 percent used gas injection techniques (DOGGR, 2008).

The crude oil production reported under ARB's 2007 Oil and Gas Industry Survey represents 96 percent of California's total production. Table 2-3 lists the California crude oil production reported in the 2007 Oil and Gas Industry Survey by API range. Table 2-4 lists the California crude oil production by air district.

There were 882,953,716 barrels of crude oil transported through 6,799 miles of pipeline. This total includes California production and imported crude oil. The amount of crude oil transported through crude oil pipelines is greater than the 639,189,000 barrels delivered to refineries (CEC, 2010) because many crude oil extraction facilities listed crude oil transport from their facility to one of the major pipeline companies. Thus, some crude oil transport was counted twice.

Table 2-3: Crude Oil Totals

| Type | Barrels Crude Oil Produced | Percent of Total Production Reported |
|---------------------------|----------------------------|--------------------------------------|
| Ultra-Heavy Oil (API <10) | 614,683 | 0% |
| Heavy Oil (API 10 - 20) | 156,304,520 | 67% |
| Light Oil (API 20 - 30) | 61,524,698 | 26% |
| Ultra-Light Oil (API >30) | 15,649,398 | 7% |
| Totals: | 234,093,299 | |

Table 2-4: Crude Oil Totals by Air District

| Air District | Ultra-Heavy Oil (API <10) (bbl) | Heavy Oil (API 10 - 20) (bbl) | Light Oil (API 20 - 30) (bbl) | Ultra-Light Oil (API >30) (bbl) |
|-----------------------------|---------------------------------|-------------------------------|-------------------------------|---------------------------------|
| Bay Area AQMD | 0 | 0 | PD | 0 |
| Monterey Bay Unified APCD | 0 | 3,561,595 | PD | PD |
| Santa Barbara County APCD | PD | 13,500,536 | 4,565,827 | 574,103 |
| South Coast AQMD | 0 | 19,027,656 | 10,143,280 | 977,986 |
| San Joaquin Valley APCD | PD | 117,483,089 | 44,194,051 | 13,516,247 |
| San Luis Obispo County APCD | 0 | PD | 0 | PD |
| Ventura County APCD | 0 | 2,190,819 | 2,603,320 | 576,597 |
| Yolo/Solano AQMD | 0 | PD | 0 | 0 |
| Totals: | 614,683 | 156,304,520 | 61,524,698 | 15,649,398 |

Natural gas production and natural gas storage have very similar processes. Natural gas production extracts virgin natural gas that is then processed and sold. Natural gas storage takes clean, processed gas from pipelines or large producers and injects it into a geological formation for storage. The gas is then removed at a later date when needed.

There are discrepancies between the amounts of natural gas produced that was reported to the Energy Information Administration (EIA), the Department of Conservation Division of Oil, Gas, and Geothermal (DOGGR), and the 2007 Oil and Gas Industry survey. According to the EIA Natural Gas 2007 Annual Report (EIA, 2009a), these discrepancies may be due to the way operators fill out their reports. The amount of natural gas extracted that was reported to EIA was 339 billion cubic feet (EIA, 2009a). This amount is larger than the 312 billion cubic feet reported to DOGGR (DOGGR, 2008). The amount reported in the 2007 Oil and Gas Industry survey is shown in Table 2-5 and is larger than both the EIA and DOGGR numbers. However, if the amount combusted onsite is subtracted from the amount produced, the amount available becomes similar to the EIA number. Table 2-6 shows the amount of natural gas reported by air district.

Table 2-5: Natural Gas Totals

| Type | MSCF ¹ Natural Gas Produced | MSCF Natural Gas Combusted | MSCF Natural Gas Available to Consumers |
|----------------|--|----------------------------|---|
| Associated Gas | 291,115,743 | 54,444,514 | 236,671,230 |
| Dry Gas | 99,211,175 | 4,597,875 | 94,613,300 |
| Totals: | 390,326,918 | 59,042,389 | 331,284,529 |

1. MSCF is 1000 standard cubic feet

| Tehama County APCD | 0 | 7,818,949 | 179,094 | 7,639,855 |
| Ventura County APCD | 4,980,163 | PD | 1,168,313 | PD |
| Yolo/Solano AQMD | PD | 17,254,359 | 1,031,913 | 16,751,007 |
| Totals: | 291,115,743 | 99,211,175 | 59,042,389 | 331,284,529 |

In 2007, 2,326 billion cubic feet of natural gas were delivered to California consumers (EIA, 2009a). This includes gas used in residential, commercial, and industrial

applications; vehicular fuel; and electric power generation. According to the 2007 Oil and Gas Industry survey, California produced 14 percent of the total natural gas used in state. The remaining 86 percent came in through interstate transmission pipelines crossing the border at Arizona, Nevada, and Oregon (EIA, 2009a).

California withdrew 211 billion cubic feet of gas from natural gas storage facilities in 2007. The storage numbers include in-state production and imported natural gas.

Global Warming Potentials

The 2007 Oil and Gas Industry Survey collected comprehensive equipment and process data for the California crude oil and natural gas industry. The data from the survey are used to calculate greenhouse gas (GHG) emissions. The major GHG compounds emitted from this sector are carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O). Carbon dioxide equivalents (CO₂e) are calculated by multiplying the mass of the GHG compound by its global warming potential (GWP). GWP numbers are the amount of radiative forcing a particular compound has compared to CO₂. GWP numbers are published by the Intergovernmental Panel on Climate Change (IPCC) in their Assessment Reports. Table 2-5 lists the GWP for CO₂, CH₄, and N₂O from the Second, Third, and Fourth IPCC Assessment Reports (IPCC 2007, 2001, and 1995).

Table 2-7: Global Warming Potentials

| | CO ₂ | CH ₄ | N ₂ O |
|--------------------------------|-----------------|-----------------|------------------|
| Second Assessment Report (SAR) | 1 | 21 | 310 |
| Third Assessment Report (TAR) | 1 | 23 | 296 |
| Fourth Assessment Report (FAR) | 1 | 25 | 298 |

ARB's and US EPA's Mandatory GHG Reporting rules both use the SAR to calculate emissions. To remain consistent with both of these programs, all the CO₂e calculations in this report use the SAR GWP numbers.

Chapter 3 of this report gives an overview of the total emissions calculated from the 2007 Oil and Gas Industry Survey. Chapters 4 through 19 go through the emissions calculated from each table of the survey. The remaining chapters of the report total the emissions for oil production and natural gas production separately.

Chapter 3 – Overview of Total California Emissions

Total Emissions

This chapter combines the emissions from all equipment surveyed in the 2007 Oil and Gas Industry Survey. These emissions do not include extrapolated emissions for equipment not covered by the survey. The emissions were calculated using equipment information from the survey and the emission equations and emissions factors listed in Appendix B. Table 3-1 shows the total California statewide emissions for the crude oil and natural gas sector for the equipment covered by the survey in 2007. Combustion sources are equipment burning fuel for energy. Vented emissions are intentional releases of vapors to the atmosphere. Fugitive emissions are unintentional releases of vapors to the atmosphere. The majority of the total CO₂e emissions in California are from combustion sources. Only 7 percent of the CO₂e emissions come from vented or fugitive sources.

Table 3-1: Total California 2007 Emissions (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-------------------|-----------------|------------------|-------------------|------------------------------------|
| Combustion | 16,073,395 | 10,836 | 314 | 16,398,268 | 93% |
| Vented | 56,021 | 16,026 | 0 | 392,563 | 2% |
| Fugitive | 107,322 | 37,533 | 0 | 895,513 | 5% |
| Totals: | 16,236,738 | 64,394 | 314 | 17,686,345 | |

Table 3-2 lists total CO₂e emissions by primary business type. Primary business type is defined in Chapter 2. The business type “other” includes the following self-reported facility types:

- CNG compression and marketing
- Cogeneration
- Combined heat and power
- Electricity generation
- Portable heating
- Water disposal
- Vapor recovery services

The facility types “crude processing” and “crude storage” were combined to protect confidential company data. The facility types “onshore crude production” and “other” account for 42 percent of the total number of facilities for this sector. However, they emit 84 percent of the total CO₂e for the state. The remaining 58 percent of the facilities account for only 16 percent of the emissions.

**Table 3-2: Total California Emissions by Primary Business Type
(Metric Tons/Year)**

| Type | Number of Facilities | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|--------------------------------|----------------------|-------------------|-----------------|------------------|-------------------|------------------------------------|
| Onshore Crude Production | 668 | 9,645,891 | 30,568 | 178 | 10,343,089 | 58% |
| Other | 53 | 4,579,097 | 567 | 108 | 4,624,612 | 26% |
| Natural Gas Processing | 17 | 913,595 | 6,090 | 6 | 1,043,400 | 6% |
| Onshore Natural Gas Production | 703 | 205,336 | 16,247 | 4 | 547,624 | 3% |
| Crude Processing and Storage | 42 | 370,666 | 1,719 | 2 | 407,239 | 2% |
| Natural Gas Storage | 10 | 200,638 | 6,263 | 9 | 334,864 | 2% |
| PERP Equipment Owner | 58 | 148,082 | 339 | 1 | 155,577 | 1% |
| Offshore Crude Production | 16 | 101,807 | 1,772 | 4 | 140,118 | 1% |
| Crude Pipeline | 65 | 71,625 | 829 | 3 | 89,821 | 1% |
| Totals: | 1,632 | 16,236,738 | 64,394 | 314 | 17,686,345 | |

Table 3-3 lists the combustion, vented, fugitive, and total CO₂e emissions by primary business type. The facility types “crude processing” and “crude storage” were combined to protect confidential company data.

**Table 3-3: Total California Combustion, Vented, and Fugitive Emissions
by Primary Business Type (Metric Tons/Year)**

| Type | Number of Facilities | Combustion (CO ₂ e) | Vented (CO ₂ e) | Fugitive (CO ₂ e) | Total CO ₂ e | Percent of Total CO ₂ e |
|--------------------------------|----------------------|--------------------------------|----------------------------|------------------------------|-------------------------|------------------------------------|
| Onshore Crude Production | 668 | 9,784,578 | 125,428 | 433,082 | 10,343,089 | 58% |
| Other | 53 | 4,616,047 | 53 | 8,512 | 4,624,612 | 26% |
| Natural Gas Processing | 17 | 879,601 | 24,102 | 139,698 | 1,043,400 | 6% |
| Onshore Natural Gas Production | 703 | 218,910 | 117,835 | 210,879 | 547,624 | 3% |
| Crude Processing and Storage | 42 | 346,952 | 15,940 | 44,347 | 407,239 | 2% |
| Natural Gas Storage | 10 | 226,569 | 90,537 | 17,758 | 334,864 | 2% |
| PERP Equipment Owner | 58 | 148,825 | 1,960 | 4,793 | 155,577 | 1% |
| Offshore Crude Production | 16 | 104,272 | 16,708 | 19,138 | 140,118 | 1% |
| Crude Pipeline | 65 | 72,515 | 0 | 17,306 | 89,821 | 1% |
| Totals: | 1,632 | 16,398,268 | 392,563 | 895,513 | 17,686,345 | |

Total Emissions by Air District

Crude oil and natural gas operations are found in 17 air pollution control districts (APCD) and air quality management districts (AQMD) in California. Total CO₂e emissions for each air district are shown in Table 3-4. Several companies had a facility that was located in more than one air district. In those cases, the CO₂e emissions for that facility were split equally between each air district. This resulted in the total number of facilities being larger than the 1,632 facilities that reported in the survey. Nearly 80 percent of the statewide total CO₂e emissions for these operations occur in the San Joaquin Valley APCD.

Table 3-4: Total California Emissions by Air District (Metric Tons/Year)

| Air District | Number of Facilities | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|-----------------------------|----------------------|-------------------|-----------------|------------------|-------------------|------------------------------------|
| San Joaquin Valley APCD | 456 | 13,289,187 | 30,588 | 240 | 14,005,872 | 79% |
| South Coast AQMD | 265 | 1,045,442 | 6,773 | 57 | 1,205,313 | 7% |
| Santa Barbara County APCD | 63 | 890,593 | 7,458 | 5 | 1,048,824 | 6% |
| Monterey Bay Unified APCD | 19 | 494,994 | 130 | 2 | 498,249 | 3% |
| Ventura County APCD | 83 | 226,188 | 1,760 | 5 | 264,804 | 1% |
| Sacramento Metro AQMD | 155 | 71,031 | 2,933 | 1 | 133,043 | 1% |
| Yolo/Solano AQMD | 200 | 57,023 | 2,339 | 1 | 106,509 | 1% |
| Glenn County APCD | 79 | 16,989 | 3,549 | 0 | 91,584 | 1% |

Total Emissions by CO₂e Range

Total CO₂e emissions were calculated for each facility. All facilities were then categorized into ranges of CO₂e emissions. Table 3-15 lists the number of facilities in each range and the total CO₂e emissions for all the facilities in that range. Ninety-four percent of the facilities in this sector account for only 6 percent of the total emissions while 2 percent of the facilities account for over 80 percent of the emissions.

Table 3-15: Total California Emissions by CO₂e Range (Metric Tons/Year)

| Range (CO ₂ e per Facility) | Number of Facilities | CO ₂ e | Percent of Total CO ₂ e |
|--|----------------------|-------------------|------------------------------------|
| < 10,000 | 1,537 | 983,552 | 6% |
| 10,000 to 25,000 | 28 | 451,872 | 3% |
| 25,000 to 50,000 | 19 | 679,163 | 4% |
| 50,000 to 100,000 | 12 | 815,119 | 5% |
| 100,000 to 500,000 | 27 | 5,122,394 | 29% |

Chapter 4 – Wells

Wells are essential to extracting crude oil and natural gas from geological formations. These wells have emissions from the site of the well as well as from maintenance activities. Table 2 of the 2007 Oil and Gas Industry Survey required companies to fill out the number of

- active wells,
- well cellars,
- new wells drilled,
- workovers that required tubing removal,
- well cleanups (also known as liquid unloading), and
- well completions.

Active wells are wells that are producing crude oil or natural gas throughout the year. Well cellars are lined or unlined pits around one or more wells that: (a) allow access to the wellhead components for servicing, or (b) contain intermittent flows of crude oil or water during an emergency or from drilling and petroleum production processes.

Well completions are the final step to bringing a newly drilled well on to production. In some cases, a new well will be completed in a different reporting period than when the well was drilled. Thus, the number of well completions for crude oil in 2007 is larger than the number of wells drilled in that same year.

Well workovers are the process of performing major maintenance or remedial treatments on an oil or gas well. This can be done with the production tubing remaining in place or being removed. The number of well workovers listed in Tables 4-3 and 4-4 only include workovers that required tubing removal.

Well cleanups are well maintenance activities that included hydraulic fracturing or removing fluids to increase production. Hydraulic fracturing uses high pressure pumps to increase fluid pressure at the bottom of the well. This fluid pressure cracks the formation and proppants such as sand or walnut hulls are injected into the newly formed crevices to keep them open when the fluid pressure is removed. This increases the flow of the crude oil or natural gas. Fluid removal is a natural gas well maintenance activity that removes built up fluids from the well to increase natural gas production.

Table 4-1 lists the number of crude oil active wells and well cellars by API range. Table 4-2 lists the number of active wells and well cellars for natural gas.

Table 4-1: Number of Crude Oil Active Wells and Well Cellars by API Range

| Type | Number of Active Wells | Number of Well Cellars |
|---------------------------|------------------------|------------------------|
| Ultra-Heavy Oil (API <10) | 47 | 22 |
| Heavy Oil (API 10 - 20) | 36,619 | 7,461 |
| Light Oil (API 20 - 30) | 14,261 | 4,998 |
| Ultra-Light Oil (API >30) | 1,323 | 2,168 |
| Totals: | 52,250 | 14,649 |

Table 4-2: Number of Natural Gas Active Wells and Well Cellars

| Type | Number of Active Wells | Number of Well Cellars |

| Natural Gas Storage | PD | PD | PD | PD |
| Totals: | PD | PD | PD | PD |

Emissions

Emissions for wells and their maintenance activities are detailed in this section. Emissions from active wells and well cellars are categorized as fugitive emissions. Fugitive emissions are unintentional emission leaks. Emissions from well workovers and well cleanups are vented emissions. Vented emissions are intentional emission leaks. All CO₂ and CH₄ values are multiplied by their corresponding GWP (1 for CO₂ and 21 for CH₄) to get the CO₂e number.

Active Wells

The emissions of CO₂ and CH₄ are calculated using emission factors multiplied by the number of active wells. The calculations and emission factors are detailed in Appendix B.

Table 4-5 lists the number of wells and the calculated emissions by API range. Table 4-6 lists the number of wells and calculated emissions for natural gas. In 2007, there were 59,856 wells producing crude oil and 1,540 active dry gas wells (DOGGR, 2008). Thus, 87 percent of the actively producing crude oil wells and 91 percent of the actively producing dry gas wells in California were reported in the survey.

Table 4-5: Emissions of Crude Oil Wells by API Range (Metric Tons/Year)

| Type | Number of Active Wells | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|---------------------------|------------------------|-----------------|-----------------|-------------------|------------------------------------|
| Ultra-Heavy Oil (API <10) | 47 | 0 | 0 | 4 | 0% |
| Heavy Oil (API 10 - 20) | 36,619 | 66 | 155 | 3,327 | 9% |
| Light Oil (API 20 - 30) | 14,261 | 459 | 1,415 | 30,163 | 83% |
| Ultra-Light Oil (API >30) | 1,323 | 19 | 139 | 2,932 | 8% |
| Totals: | 52,250 | 543 | 1,709 | 36,427 | |

Table 4-6: Emissions of Natural Gas Wells (Metric Tons/Year)

| Type | Number of Active Wells | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|---------------------|------------------------|-----------------|-----------------|-------------------|------------------------------------|
| Dry Gas | 1,397 | 14 | 253 | 5,321 | 78% |
| Natural Gas Storage | 372 | 1 | 70 | 1,479 | 22% |
| Totals: | 1,769 | 16 | 323 | 6,801 | |

Well Cellars

The emissions of CO₂ and CH₄ are calculated using emission factors multiplied by the number of well cellars. The calculations and emission factors are detailed in Appendix B.

Table 4-7 lists the number of well cellars and their emissions by crude oil API. Emission factors for natural gas well cellars do not exist at this time.

Table 4-7: Emissions of Crude Oil Well Cellars by API Range (Metric Tons/Year)

| Type | Number of Well Cellars | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|---------------------------|------------------------|-----------------|-------------------|------------------------------------|
| Ultra-Heavy Oil (API <10) | 22 | 3 | 58 | 0% |
| Heavy Oil (API 10 - 20) | 7,461 | 933 | 19,585 | 43% |
| Light Oil (API 20 - 30) | 4,998 | 850 | 17,843 | 39% |
| Ultra-Light Oil (API >30) | 2,168 | 369 | 7,740 | 17% |
| Totals: | 14,649 | 2,154 | 45,225 | |

Drilling and Maintenance

GHG emissions can be calculated from well drilling and maintenance activities. At this time, there are emission calculations for CO₂ and CH₄ emissions from well workovers and cleanups but not for new wells drilled and well completions. The emissions are calculated using the number of workovers or cleanups, the percent CO₂ and CH₄ in the associated or dry gas, and emission factors. These calculations are detailed in Appendix B.

Tables 4-8 through 4-11 list the calculated emissions for well workovers and well cleanups. As these tables show, well workovers account for the majority of the CO₂e emissions from well maintenance activities.

**Table 4-8: Emissions of Crude Oil Well Workovers by API Range
(Metric Tons/Year)**

| Type | Number of Well Workovers | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|---------------------------|--------------------------|-----------------|-----------------|-------------------|------------------------------------|
| Ultra-Heavy Oil (API <10) | 0 | 0 | 0 | 0 | 0% |

Chapter 5 – Electricity Generation and Use

Many crude oil and natural gas facilities often produce their own electricity. This is done using generators, cogeneration units, or combined heat and power units. Many of the cogeneration units and combined heat and power units are used to generate steam as well as electricity.

Table 3 of the 2007 Oil and Gas Industry Survey required facilities to report the amount of electricity generated onsite, exported, and purchased. Table 5-1 lists the total electricity by primary business type. Twenty-four terra-watt hours (Twh) of electricity was generated by facilities through generators, cogeneration units, or combined heat and power units. Sixty percent of the generated electricity was used on site, with the remainder exported to either the grid or other facilities. Crude oil and natural gas facilities purchased 17 Twh of electricity in 2007. This is nine percent of the 200 Twh of electricity that was purchased by non-residential customers (CEC, 2007).

Table 5-1: Electricity by Primary Business (Metric Tons/Year)

| Type | Generated (MWh) | Used (MWh) | Exported (MWh) | Purchased (MWh) |
|--------------------------------|-------------------|-------------------|------------------|-------------------|
| Onshore Crude Production | 15,564,710 | 14,259,805 | 1,304,905 | 17,183,986 |
| Offshore Crude Production | 81,739 | 81,739 | 0 | 69,056 |
| Onshore Natural Gas Production | PD | PD | PD | PD |
| Natural Gas Storage | 7,729 | 7,729 | 0 | 27,976 |
| Natural Gas Processing | 49,037 | 18,078 | 30,959 | 60,393 |
| Crude Pipeline | 19,202 | 5,195 | 14,007 | 194,877 |
| Crude Processing | PD | PD | PD | PD |
| Crude Storage | 0 | 0 | 0 | 67,270 |
| PERP Equipment Owner | PD | PD | PD | PD |
| Other | 8,472,167 | 152,854 | 8,319,313 | 7,888 |
| Totals: | 24,582,599 | 14,910,228 | 9,672,371 | 17,676,795 |

The business type “other” includes the following self-reported facility types:

- CNG compression and marketing
- Cogeneration
- Combined heat and power
- Electricity generation
- Portable heating
- Water disposal
- Vapor recovery services.

Chapter 6 – Vapor Recovery

Vapor recovery is the process of collecting vapors so their emissions to the atmosphere are substantially reduced. Vapor recovery equipment collects or converts these vapors. Table 4 of the 2007 Oil and Gas Industry Survey collected information about four types of vapor recovery units. These include flares, incinerators, thermal oxidizers, and carbon adsorbers. Flares, incinerators, and thermal oxidizers convert vapors while carbon adsorbers collect them. In the oil and gas production sector, these units are also used to convert or collect natural gas that is not of good enough quality to enter a natural gas transmission pipeline or that is stranded, and which would otherwise be emitted to the atmosphere.

Table 4 of the Oil and Gas Industry Survey collected the following information about each facility's vapor recovery units.

- Type
 - Flare, incinerator, thermal oxidizer, or carbon adsorber
- Use
 - Vapor recovery or emergency were choices on the survey
 - Some facilities added other uses such as gas disposal and planned flaring
- For flares, incinerators, and thermal oxidizers
 - Size in btu/hr
 - Throughput in scf
 - Combustion efficiency
 - CH₄ and CO₂ content of the gas stream
 - Carbon mole ratio
- For carbon adsorbers
 - Size in cubic feet
 - Throughput in scf
 - Capture efficiency
 - CH₄ content of the gas stream

Table 6-1 lists the number of vapor recovery units by type. Flares represented the most common type. They account for 77 percent of the total number of vapor recovery units.

Table 6-1: Number of Vapor Recovery Units by Type

| Type | Number of Units |
|------------------|-----------------|
| Flare | 196 |
| Thermal Oxidizer | 19 |
| Incinerator | 23 |
| Carbon Adsorbers | 17 |
| Totals: | 255 |

Emissions

Emissions from flares, incinerators, thermal oxidizers, and carbon adsorbers are detailed in this section. Emissions from flares, incinerators, and thermal oxidizers are categorized as combustion emissions from burning fuel. Emissions from carbon adsorbers are considered vented emissions. The emissions are calculated using fuel data supplied in the survey and are detailed in Appendix B. The CO₂, CH₄, and N₂O emissions are multiplied by their corresponding GWP (1 for CO₂, 21 for CH₄, and 310 for N₂O) to get the CO₂e value.

Table 6-2 lists the combustion emissions from flares, incinerators, and thermal oxidizers. Some equipment types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. For example, incinerators, burners, and afterburners were combined into the category “incinerator.” This table shows that flares and thermal oxidizers have similar CO₂e emissions even though there are 10 times as many flares as thermal oxidizers. This is because both flares and thermal oxidizers combusted similar volumes of gas.

Table 6-2: Vapor Recovery Combustion Emissions by Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|------------------|-----------------|-----------------|-----------------|------------------|-------------------|------------------------------------|
| Flare | 196 | 242,454 | 812 | 0.4 | 259,623 | 50% |
| Thermal Oxidizer | 19 | 216,378 | 80 | 0.3 | 218,155 | 42% |
| Incinerator | 23 | 44,846 | 49 | 0.1 | 45,896 | 9% |
| Totals: | 238 | 503,678 | 941 | 0.7 | 523,675 | |

Table 6-3 lists the vented emissions from carbon adsorbers. The CO₂e emissions from carbon adsorbers are a very small fraction of the total emissions from vapor recovery units.

Table 6-3: Carbon Adsorber Vented Emissions (Metric Tons/Year)

| Type | Number of Units | CH ₄ | CO ₂ e |
|------------------|-----------------|-----------------|-------------------|
| Carbon Adsorbers | 17 | 54 | 1,131 |
| Totals: | 17 | 54 | 1,131 |

Table 6-4 lists the uses of flares, incinerators, and thermal oxidizers. All carbon adsorbers were used for vapor recovery. Some vapor recovery uses were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar equipment uses. Below is a list of use categories and the types they represent.

- Unknown – unknown, not in use, and dormant
- Emergency – emergency, emergency and vapor recovery, planned and unplanned flaring, and standby

- o Gas Disposal – gas disposal, maintenance, tank degassing, fuel limited, and vapor recovery/gas disposal

As this table shows, vapor recovery is the dominant use. It accounts for 73 percent of the total CO₂e emissions.

Table 6-4: Vapor Recovery Combustion Emissions by Use (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-----------------|------------------|-------------------|------------------------------------|
| Vapor Recovery | 123 | 373,813 | 475 | 0.5 | 383,949 | 73% |
| Emergency | 92 | 90,949 | 364 | 0.1 | 98,629 | 19% |
| Unknown | 11 | 29,236 | 75 | 0.1 | 30,835 | 6% |
| Gas Disposal | 12 | 9,680 | 28 | 0.0 | 10,262 | 2% |
| Totals: | 238 | 503,678 | 941 | 0.7 | 523,675 | |

Table 6-5 lists the combustion vapor recovery units by their rated size. It includes all flares, incinerators, and thermal oxidizers reported in the 2007 Oil and Gas Industry Survey.

Table 6-5: Number of Combustion Vapor Recovery Units by Size

| Range (MMBtu/Hr) | Number of Units | Percent of Total |
|------------------|-----------------|------------------|
| Unknown | 26 | 11% |
| <5 | 84 | 35% |
| 5 to 25 | 55 | 23% |
| 25 to 100 | 17 | 7% |
| 100 to 500 | 32 | 13% |
| 500 to 1000 | 9 | 4% |
| >1000 | 15 | 6% |
| Totals: | 238 | |

Chapter 7 – Combustion Equipment

Combustion equipment encompasses many different types of equipment that all burn a fuel for energy. The 2007 Oil and Gas Industry Survey collected information about two main categories of combustion equipment: external combustion units and internal combustion units.

Table 5 of the Oil and Gas Industry Survey collected the following information about each facility's combustion equipment.

- Type
 - External
 - Boiler, steam generator, heater/treater, oil heater, glycol reboiler, or amine reboiler
 - Facilities could also specify a type not listed above
 - Internal combustion
 - Reciprocating two-stroke or four-stroke and either lean or rich burn, combined heat and power, simple or combined cycle turbine, microturbine, drill rig, or workover rig,
 - Facilities could also specify a type not listed above
- Use for internal combustion equipment
 - Compressor, vapor recovery, crude oil pump, well pump, or water injection pump
 - Facilities could also specify a use not listed above
- Fuel type
 - Including volume, higher heating value (hhv), carbon weight percent, liquid fuel density, and gaseous fuel molecular weight as appropriate
- Manufacturer
- Model year
- Average load in HP, BTU, or MW
- Inspection frequency
- Permitting and PERP registration

Emissions

Emission calculations for combustion equipment are dependent on the information reported in the survey. Three methods are available to calculate CO₂, CH₄, and N₂O. The first method uses a mass balance approach, the second uses equipment-specific emission factors, and the third method uses fuel-specific emission factors. The mass balance approach is used first if fuel composition was reported. If fuel composition was not reported, the equipment-specific emission factors are used. For combustion equipment emission calculations that could not utilize either the first or second method, fuel-specific emission factors were used. These equations and emission factors are detailed in Appendix B. The CO₂, CH₄, and N₂O emissions are multiplied by their corresponding GWP numbers (1 for CO₂, 21 for CH₄, and 310 for N₂O) to get the CO₂e values.

External Combustion

An external combustion engine is an engine where an internal fluid is heated by an external heat source. The most common types of external combustion units are steam generators and boilers. Some equipment types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. Below is a list of equipment categories and the types they represent:

- Boilers – boilers and locomotive boilers;
- Heaters – heaters, central process heaters, tank heaters, forced air furnaces, water heaters, hot water circulating heaters, line heaters, oil heaters, and process heaters; and
- Vapor Recovery – flares, incinerators, and thermal oxidizers that were reported on Table 5 rather than Table 4 of the Oil and Gas Industry Survey.

Steam generators create steam that is injected into the geological formation to increase crude oil production. Cogeneration units produce steam for injection and electricity generation. Heater/Treaters are oil/water separators that use heat to expedite the separation process. Reboilers include glycol and amine reboilers. These units heat glycol or amine to remove water in dehydrators and the acid gas in amine units.

Table 7-1 lists the CO₂, CH₄, and N₂O emissions from external combustion equipment. This table shows that the majority of the emissions are from steam generators.

Table 7-1: External Combustion Emissions by Equipment Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|-----------------|-----------------|------------------|-----------------|------------------|-------------------|------------------------------------|
| Steam Generator | 587 | 6,658,156 | 2,973 | 115 | 6,756,167 | 83% |
| Cogeneration | 34 | 930,377 | 15 | 2 | 931,185 | 12% |
| Boiler | 132 | 140,240 | 245 | 0 | 145,454 | 2% |
| Heater | 294 | 116,301 | 34 | 2 | 117,584 | 1% |
| Heater/Treater | 371 | 115,607 | 47 | 2 | 117,226 | 1% |
| Reboiler | 201 | 17,466 | 15 | 0 | 17,782 | 0% |
| Vapor Recovery | 11 | 10,681 | 0 | 0 | 10,690 | 0% |
| Totals: | 1,630 | 7,988,827 | 3,328 | 121 | 8,096,089 | |

Table 7-2 lists the age of the external combustion equipment. The age of each unit was determined from the model year. As this table shows, 80 percent of the units did not have a reported model year. Of the remaining units, most are 5 to 10 years old.

Table 7-2: Age of External Combustion Units

| Type | < 5 Years | 5 – 10 Years | 10 – 20 Years | 20 – 30 Years | >30 Years | Unknown | Total |
|-----------------|-----------|--------------|---------------|---------------|-----------|--------------|--------------|
| Boiler | 3 | 28 | 4 | 15 | 1 | 81 | 132 |
| Cogeneration | 0 | 0 | 0 | 0 | 0 | 34 | 34 |
| Heater | 1 | 30 | 3 | 4 | 6 | 250 | 294 |
| Heater/Treater | 11 | 61 | 5 | 21 | 5 | 268 | 371 |
| Reboiler | 5 | 50 | 5 | 7 | 5 | 129 | 201 |
| Steam Generator | 10 | 11 | 1 | 25 | 0 | 540 | 587 |
| Vapor Recovery | 0 | 4 | 1 | 0 | 0 | 6 | 11 |
| Totals: | 30 | 184 | 19 | 72 | 17 | 1,308 | 1,630 |

Internal Combustion

An internal combustion engine is an engine where fuel is burned inside a combustion chamber. The expansion of the gas applies direct force to a component of the engine such as a piston or turbine blade. Some equipment types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. Below is a list of equipment categories and the types they represent:

- Other – generators, pumps, accumulators, and welders; and
- Turbines – turbines, turbines – combined cycle, turbines – simple cycle, and turbines – combined heat and power.

Table 7-3 lists the combustion emissions for internal combustion engines. The type “internal combustion engines” encompasses all the general use reciprocating engines. The type “combined heat and power” and turbines together account for 82 percent of the emissions. The term “combined heat and power” is interchangeable with the term “cogeneration” listed above in “external combustion”. Such units produce electricity and useful heat. The heat is either used to create steam for injection into the geological formation or used to create more electricity. Combined heat and power units could be turbines or reciprocating engines. Facilities reported cogeneration and combined heat and power differently. Thus, they appear as both internal and external combustion.

Table 7-3: Internal Combustion Emissions by Equipment Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------------------|-----------------|------------------|-----------------|------------------|-------------------|------------------------------------|
| Combined Heat and Power | 23 | 3,568,017 | 612 | 7 | 3,583,006 | 46% |
| Turbine | 64 | 2,731,036 | 835 | 153 | 2,796,035 | 36% |
| Internal Combustion Engine | 2,698 | 1,004,624 | 4,537 | 16 | 1,104,754 | 14% |
| Microturbine | 29 | 232,240 | 581 | 17 | 249,584 | 3% |
| Drill Rig | 174 | 31,600 | 1 | 0 | 31,708 | 0% |
| Workover Rig | 225 | 13,300 | 1 | 0 | 13,345 | 0% |
| Other | 77 | 72 | 0 | 0 | 73 | 0% |
| Totals: | 3,290 | 7,580,889 | 6,567 | 193 | 7,778,505 | |

Table 7-4 lists the age of internal combustion units by type. Almost half of the units did not have a reported model year in their survey; thus, their ages are unknown.

Table 7-4: Age of Internal Combustion Units

| Type | < 5 Years | 5 – 10 Years | 10 – 20 Years | 20 – 30 Years | >30 Years | Unknown | Total |
|----------------------------|------------|--------------|---------------|---------------|------------|--------------|--------------|
| Combined Heat and Power | 0 | 4 | 13 | 1 | 5 | 0 | 23 |
| Drill Rig | 123 | 11 | 10 | 17 | 12 | 1 | 174 |

| Totals: | 519 | 446 | 156 | 278 | 300 | 1,591 | 3,290 |

Internal Combustion Engines

The type category “internal combustion engines” was reported on Table 5 of the 2007 Oil and Gas Industry Survey as reciprocating engines. Many internal combustion engine uses were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar equipment uses. Appendix D lists the use categories and the types they represent.

Table 7-5 lists the combustion emissions by use. The use “unknown” accounts for equipment where a use was not specified on the survey. The use “pump” is separate from “crude oil pump” and “water pump” as it was not indicated on the survey which kind of pump it is. Cogeneration is listed here as a use for a reciprocating engine. As stated above, cogeneration units can be either reciprocating engines or turbines.

Table 7-5: Combustion Emissions of Internal Combustion Engines by Use (Metric Tons/Year)

| Use | Number of Units | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|--------------------|-----------------|------------------|-----------------|------------------|-------------------|------------------------------------|

| Totals: | 2,698 | 1,004,624 | 4,537 | 16 | 1,104,754 | |

Compressors account for the majority of the emissions for internal combustion engines. They emit 73 percent of the internal combustion engine CO₂e emissions. Crude oil

pumps account for the next highest percentage. The remaining 17 percent of the emissions are distributed among the remaining ten use categories.

Table 7-6 lists combustion emissions by rich burn, lean burn, two-stroke, or four-stroke. Survey respondents did not report the type for about half of the units. Of the remaining units for which a type was not specified, 66 percent are rich burn, four-stroke engines. Rich burn two-stroke engines are the least common.

Table 7-6: Combustion Emissions of Internal Combustion Engines by Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|-----------------------|-----------------|------------------|-----------------|------------------|-------------------|------------------------------------|
| Rich Burn Four-Stroke | 914 | 378,030 | 828 | 3 | 396,392 | 36% |
| Rich Burn Two-Stroke | 78 | 17,134 | 13 | 0 | 17,431 | 2% |
| Lean Burn Four-Stroke | 284 | 395,947 | 3,279 | 10 | 467,823 | 42% |
| Lean Burn Two-Stroke | 115 | 43,195 | 356 | 2 | 51,262 | 5% |
| Unknown | 1,307 | 170,318 | 62 | 1 | 171,846 | 16% |
| Totals: | 2,698 | 1,004,624 | 4,537 | 16 | 1,104,754 | |

Turbines

Turbines are a type of internal combustion engine where the force from the combustion chamber moves a blade rather than a piston. Some turbine uses were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar equipment uses. Below is a list of use categories and the types they represent:

- Cogeneration – cogeneration, electrical and steam generation, electrical and process heat generation;
- Electricity – electrical generation and power generation; and
- Other – compressors and pumps.

Table 7-7 lists the combustion emissions for turbines by use. Cogeneration accounts for 81 percent of the total emissions.

Table 7-7: Turbine Combustion Emissions by Use (Metric Tons/Year)

| Use | Number of Units | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|------------------|-----------------|------------------|-------------------|------------------------------------|
| Cogeneration | 46 | 2,207,183 | 791 | 125 | 2,262,524 | 81% |
| Electricity | 6 | 308,823 | 22 | 21 | 315,810 | 11% |
| Other | 12 | 215,029 | 22 | 7 | 217,701 | 8% |
| Totals: | 64 | 2,731,036 | 835 | 153 | 2,796,035 | |

Table 7-8 lists the combustion emissions from turbines by the type of cycles they use. Combined cycle turbines have a gas turbine that generates electricity, and the waste heat is used to make steam. The steam is then used to generate electricity through a

steam turbine or injected into the geological formation to increase production. Simple cycle turbines generate electricity in the same manner as combined cycle turbines. The difference is that the waste heat is not used to create steam for more electricity or useful steam.

Some turbine cycle types were combined from what was listed on individual surveys to protect confidential company data:

- Turbine Combined Cycle – turbine combine cycle and turbines-combined heat and power.

Table 7-8 shows that the majority of the emissions are from combined cycle turbines.

Table 7-8: Turbine Combustion Emissions by Cycle Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|------------------------|-----------------|------------------|-----------------|------------------|-------------------|------------------------------------|
| Turbine Combined Cycle | 23 | 1,648,609 | 167 | 124 | 1,690,680 | 60% |
| Turbine | 26 | 682,553 | 640 | 1 | 696,374 | 25% |
| Turbine Simple Cycle | 15 | 399,873 | 28 | 27 | 408,981 | 15% |
| Totals: | 64 | 2,731,036 | 835 | 153 | 2,796,035 | |

Cogeneration

Cogeneration and combined heat and power are interchangeable terms. Both refer to engines that produce electricity and waste heat. In these categories, the waste heat is used to create steam. This steam is then injected into geological formations to increase crude oil production or used to create more electricity.

Cogeneration and combined heat and power units were reported in the 2007 Oil and Gas Industry Survey in many different ways. Table 7-9 lists these units together in the manner they were reported. Two turbine types were combined from what was listed on individual surveys to protect confidential company data. The type “turbines combined cycle” and “turbines-combined heat and power” were combined under the type “turbine combined cycle.”

Table 7-9: Cogeneration Combustion Emissions by Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------------------|-----------------|------------------|-----------------|------------------|-------------------|------------------------------------|
| Combined Heat and Power | 23 | 3,568,017 | 612 | 7 | 3,583,006 | 50% |
| Turbine Combined Cycle | 19 | 1,642,198 | 153 | 124 | 1,683,882 | 24% |
| Cogeneration | 34 | 930,377 | 15 | 2 | 931,185 | 13% |
| Turbine | 23 | 563,939 | 638 | 1 | 577,654 | 8% |
| Turbine Simple Cycle | 10 | 309,869 | 21 | 21 | 316,799 | 4% |
| Internal Combustion Engine | 54 | 36,143 | 19 | 0 | 36,633 | 1% |
| Totals: | 163 | 7,050,543 | 1,457 | 155 | 7,129,158 | |

Total Combustion Emissions

Table 7-10 lists the combustion emissions from equipment listed on both Tables 4 and 5 of the Oil and Gas Industry Survey. It shows that the majority of the emissions are from external and internal combustion engines. Vapor recovery units, which include flares, thermal oxidizers, and incinerators, only account for 3 percent of the total combustion emissions from this sector.

Table 7-10: Combustion Emissions by Combustion Type (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-------------------|-----------------|------------------|-------------------|------------------------------------|
| External | 7,988,827 | 3,328 | 121 | 8,096,089 | 49% |
| Internal | 7,580,889 | 6,567 | 193 | 7,778,505 | 47% |
| Vapor Recovery | 503,678 | 941 | 1 | 523,675 | 3% |
| Totals: | 16,073,395 | 10,836 | 314 | 16,398,268 | |

Table 7-11 lists the total combustion emissions by primary business type. This table shows that 88 percent of the emissions are from onshore crude production and the business type “other.”

The business type “other” includes the following self-reported facility types:

- CNG compression and marketing,
- Cogeneration,
- Combined heat and power,
- Electricity generation,
- Portable heating, and
- Water disposal.

Table 7-11: Combustion Emissions by Primary Business (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|--------------------------------|-------------------|-----------------|------------------|-------------------|------------------------------------|
| Onshore Crude Production | 9,601,843 | 6,069 | 178 | 9,784,578 | 60% |
| Other | 4,579,058 | 161 | 108 | 4,616,047 | 28% |
| Natural Gas Processing | 832,060 | 2,173 | 6 | 879,601 | 5% |
| Crude Processing and Storage | 334,290 | 580 | 2 | 346,952 | 2% |
| Natural Gas Storage | 200,225 | 1,126 | 9 | 226,569 | 1% |
| Onshore Natural Gas Production | 204,801 | 620 | 4 | 218,910 | 1% |
| PERP Equipment Owner | 148,048 | 19 | 1 | 148,825 | 1% |
| Offshore Crude | 101,521 | 78 | 4 | 104,272 | 1% |
| Crude Pipeline | 71,548 | 9 | 3 | 72,515 | 0% |
| Totals: | 16,073,395 | 10,836 | 314 | 16,398,268 | |

Table 7-12 lists the total combustion emissions by fuel types. Natural gas accounts for 99 percent of the total combustion emissions. Pipeline natural gas and associated gas are the top two of all the natural gas fuels.

Table 7-12: Combustion Emissions by Fuel Type (Metric Tons/Year)

| Type | Volume Combusted (mscf or gal) | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------------|--------------------------------|-------------------|-----------------|------------------|-------------------|------------------------------------|
| Pipeline Quality Gas | 202,096,976 | 11,313,493 | 3,718 | 231 | 11,463,292 | 70% |
| Associated Gas | 54,465,754 | 3,424,822 | 5,740 | 71 | 3,567,473 | 22% |
| Waste Gas | 17,656,611 | 886,192 | 619 | 5 | 900,899 | 5% |
| Dry Gas | 4,623,503 | 252,638 | 749 | 4 | 269,709 | 2% |
| Diesel | 18,195,581 | 180,052 | 8 | 2 | 180,688 | 1% |
| Landfill Gas | 332,047 | 14,007 | 0 | 0 | 14,014 | 0% |
| Propane | 419,638 | 1,748 | 0 | 0 | 1,750 | 0% |

| Totals: | | 16,073,395 | 10,836 | 314 | 16,398,268 | |

Chapter 8 – Components

In the 2007 Oil and Gas Industry Survey, Table 6 asked for counts of components by service type. Service type was natural gas, light crude oil (API >20), and heavy crude oil (API <20). Facilities were asked to report counts of the following component types:

- Components 1 inch and above
 - Manual valves, flanges, connectors, open-ended lines, and threaded components; and
- Other components
 - Pump seals, pressure relief valves, bursting discs, diaphragms, hatches, meters, polished rod stuffing boxes, sight glasses, loading arms, and dump lever arms.

Table 8-1 lists the number of components by service type that was reported. The service type “natural gas” includes dry gas, associated gas, and gas storage. This table shows that the total number of all components is fairly equally distributed throughout the three service types.

Table 8-1: Number of Components by Service Type

| Type | Natural Gas | Light Crude (API >20) | Heavy Crude (API <20) | Total |
|-----------------------------|------------------|-----------------------|-----------------------|------------------|
| Connectors | 1,006,166 | 963,565 | 1,401,237 | 3,370,968 |
| Threaded Components | 992,715 | 633,749 | 531,380 | 2,157,844 |
| Manual Valves | 471,916 | 244,296 | 321,321 | 1,037,533 |
| Flanges | 348,579 | 260,939 | 370,274 | 979,792 |
| Polished Rod Stuffing Boxes | 1,925 | 8,441 | 35,174 | 45,540 |
| Pressure Relief Valves | 16,754 | 7,293 | 3,614 | 27,661 |
| Meters | 8,997 | 3,687 | 5,670 | 18,354 |
| Open-ended Lines | 5,639 | 1,543 | 9,608 | 16,790 |
| Pump Seals | 8,049 | 3,327 | 3,942 | 15,318 |
| Hatches | 5,043 | 2,410 | 4,820 | 12,273 |
| Sight Glasses | 2,983 | 1,825 | 2,740 | 7,548 |
| Diaphragms | 5,142 | 995 | 1,114 | 7,251 |
| Dump Lever Arm | 2,963 | 515 | 1,337 | 4,815 |
| Bursting Discs | 1,354 | 195 | 175 | 1,724 |
| Loading Arms | 547 | 137 | 334 | 1,018 |
| Totals: | 2,878,772 | 2,132,917 | 2,692,740 | 7,704,429 |

Emissions

Components are connections from which vapors could leak. Emissions from components are considered fugitive emissions because these connections are not designed to intentionally leak. CO₂ and CH₄ emissions are calculated using emission factors and total component counts and are detailed in Appendix B. The CO₂ and CH₄ emissions are multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 8-2 lists the fugitive emissions by primary business type. The business type “other” includes the following self-reported facility types:

- CNG compression and marketing,
- Cogeneration,
- Combined heat and power,
- Electricity generation,
- Portable heating,
- Water disposal, and
- Vapor recovery services.

This table shows that the majority of the number of components and the total CO₂e are from onshore crude production. This business type includes both oil and associated natural gas components. It accounts for 76 percent of the emissions and 82 percent of the number of components.

**Table 8-2: Fugitive Emissions of Components by Primary Business Type
(Metric Tons/Year)**

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|------------------------|------------------|-----------------|-----------------|-------------------|------------------------------------|
| Onshore Crude | 6,339,732 | 232 | 617 | 13,198 | 76% |
| Natural Gas Processing | 738,279 | 8 | 69 | 1,457 | 8% |
| Onshore Natural Gas | 195,062 | 1 | 34 | 712 | 4% |
| Crude Processing | PD | PD | PD | PD | PD |
| Offshore Crude | 231,733 | 7 | 28 | 604 | 3% |
| Natural Gas Storage | 47,486 | 0 | 12 | 245 | 1% |
| Crude Pipeline | 69,612 | 1 | 10 | 216 | 1% |
| Crude Storage | 25,586 | 1 | 6 | 130 | 1% |
| Other | PD | PD | PD | PD | PD |
| Totals: | 7,704,429 | 256 | 811 | 17,283 | |

Table 8-3 lists the fugitive emissions by service type. Natural gas components account for 40 percent of the CO₂e emissions. The emissions are relatively evenly distributed among natural gas, heavy crude, and light crude service.

**Table 8-3: Fugitive Emissions of Components by Service Type
(Metric Tons/Year)**

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|------------------|-----------------|-----------------|-------------------|------------------------------------|
| Natural Gas | 2,878,772 | 68 | 324 | 6,866 | 40% |
| Heavy Crude | 2,692,740 | 160 | 263 | 5,680 | 33% |
| Light Crude | 2,132,917 | 29 | 224 | 4,737 | 27% |
| Totals: | 7,704,429 | 256 | 811 | 17,283 | |

Table 8-4 lists the fugitive emissions by type of component. Connectors, manual valves, flanges, and threaded components account for 83 percent of the emissions. They also account for 98 percent of the total number of components.

Table 8-4: Fugitive Emissions of Components by Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|-----------------------------|------------------|-----------------|-----------------|-------------------|------------------------------------|
| Connectors | 3,370,968 | 44 | 239 | 5,063 | 29% |
| Manual Valves | 1,037,533 | 44 | 152 | 3,234 | 19% |
| Flanges | 979,792 | 99 | 141 | 3,057 | 18% |

1. Heavy Crude is crude oil with an API gravity less than 20.

Chapter 9 – Automated Control Devices

Table 7 of the 2007 Oil and Gas Industry Survey asked facilities to report the number of automated control devices. Automated control devices are also commonly referred to as pneumatic devices. Facilities were asked to report the following information about their automated control devices:

- Controllers
 - Gas, electric, or air actuated
 - Continuous bleed, intermittent bleed, low bleed, or no bleed
 - Number on gas recovery, and
- Actuators
 - Gas, electric, or air actuated
 - Piston valve, hydraulic valve, or turbine valve operator
 - Number on gas recovery.

Emissions

Emissions from automated control devices are considered vented emissions as these devices are designed to leak. CO₂ and CH₄ emissions from automated control devices are calculated by multiplying the number of devices by an emission factor; those calculations are detailed in Appendix B. The number of each type of device used to calculate emissions is the total number of devices minus the number on gas recovery. Devices on gas recovery capture the gas used to actuate. The CO₂ and CH₄ emissions are multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 9-1 lists the vented emissions by primary business type. The business type “other” includes the following self-reported facility types:

- Cogeneration,
- Combined heat and power,
- Electricity generation,
- Portable heating,
- Water disposal, and
- Vapor recovery services.

This table shows that the majority of the vented emissions are from automated control devices found in onshore natural gas production facilities. However, these facilities account for only 3 percent of the total number of devices in California. Onshore crude oil production facilities have 79 percent of the number of automated control devices but account for only 4 percent of the emissions.

Table 9-1: Vented Emissions of Automated Control Devices by Primary Business Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|------------------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Onshore Natural Gas | 2,526 | 88 | 5,056 | 106,267 | 88% |
| Natural Gas Storage | 2,585 | 2 | 380 | 7,984 | 7% |
| Onshore Crude | 57,549 | 69 | 253 | 5,378 | 4% |
| Natural Gas Processing | 832 | 1 | 36 | 764 | 1% |
| Offshore Crude | 6,197 | 0 | 2 | 35 | 0% |
| Crude Storage | PD | PD | PD | PD | PD |
| Crude Pipeline | 2,517 | 0 | 0 | 0 | 0% |
| Crude Processing | PD | PD | PD | PD | PD |
| Other | 109 | 0 | 0 | 0 | 0% |
| Totals: | 72,861 | 161 | 5,727 | 120,434 | |

Table 9-2 lists the vented emissions by type of automated control device. This table also lists the total number of devices and the number on gas recovery. Several facilities listed electric and air controllers and actuators on gas recovery. We are assuming that controllers and actuators that are either air or electrically actuated do not have any emissions associated with them. Continuous bleed and intermittent bleed controllers account for 99 percent of the vented emissions from this category. However, they only account for 2 percent of the total number of devices.

Table 9-2: Vented Emissions of Automated Control Devices by Type (Metric Tons/Year)

| Type | Number of Units | Number on Gas Recovery | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|--------------------------|-----------------|------------------------|-----------------|-----------------|-------------------|------------------------------------|
| Controllers | | | | | | |
| Continuous Bleed | 1,151 | 2 | 89 | 4,915 | 103,298 | 86% |
| Intermittent Bleed | 405 | 24 | 69 | 760 | 16,019 | 13% |
| Low Bleed | 50 | 0 | 2 | 46 | 969 | 1% |
| No Bleed | 1,054 | 0 | 0 | 0 | 0 | 0% |
| Electric Controller | 6,391 | 384 | 0 | 0 | 0 | 0% |
| Air Controller | 7,995 | 599 | 0 | 0 | 0 | 0% |
| Actuators | | | | | | |
| Piston Valve Operator | 1,030 | 111 | 0 | 1 | 15 | 0% |

| Turbine Valve Operator | 3 | 0 | 0 | 0 | 1 | 0% |
| Electric Actuator | 6,205 | 18 | 0 | 0 | 0 | 0% |
| Air Actuator | 48,441 | 643 | 0 | 0 | 0 | 0% |
| Totals: | 72,861 | 1,781 | 161 | 5,727 | 120,434 | |

Chapter 10 – Inspection and Maintenance

Many air districts in California require crude oil and natural gas facilities to routinely inspect their fugitive components. Table 8 of the 2007 Oil and Gas Industry Survey collected information about each facility's inspection and maintenance program (I&M). The following information were requested:

- Whether or not the facility follows an I&M program;
- District rule number governing the I&M program; and
- Leak Threshold.

An I&M program is a routine that a facility follows to inspect components for vapor leaks. Many air districts require facilities to inspect their components a specific number of times per year. They will also designate a leak threshold to test against. A component leaking above the threshold or below the threshold will determine how long the facility has to repair the leak. Components with a higher leak rate generally must be repaired sooner than ones with a lower leak rate.

Of the 1,632 facilities that completed the survey, 602 have an I&M program, 566 do not have an I&M program, and 470 did not complete Table 9 of the survey. Table 10-1 lists the number of facilities utilizing each leak threshold. Many facilities have more than one leak threshold they test against depending on the type of component. Thus, the total number of facilities listed in Table 10-1 will add up to more than the total 602 facilities with an I&M program.

Table 10-1: Number of Facilities Utilizing Each Leak Threshold

| Leak Threshold | Number of Facilities |
|---------------------|----------------------|
| 0 – 500 ppm | 247 |
| 500 – 1,000 ppm | 217 |
| 1,000 – 2,000 ppm | 146 |
| 2,000 – 10,000 ppm | 166 |
| 10,000 – 50,000 ppm | 145 |
| > 50,000 ppm | 60 |

Chapter 11 – Natural Gas Dehydrators

Natural gas dehydrators remove water from gas streams by passing natural gas through glycol or over a desiccant material. Table 9 of the 2007 Oil and Gas Industry Survey (Appendix A) collected process information about natural gas dehydrators. Facilities were asked to report the following information:

- Type
 - Glycol or desiccant
 - Facilities could also specify a type not listed above;
- Average natural gas composition
 - Percent CH₄, H₂S, CO₂ for input and output streams
 - Higher heating value (HHV) in btu for input and output streams;
- Input and output volume in standard cubic feet;
- Quantity of liquids removed in tons/year;
- For glycol units
 - Circulation rate (gal/hr)
 - Average flash tank pressure (psia)
 - Average contactor pressure (psia)
 - Whether a gas assisted pump, electric pump, stripping gas, or a flash separator was used;
- For desiccant units
 - Volume of dehydrator (ft³)
 - Pressure (psig)
 - Percent of packed vessel volume that is natural gas
 - Frequency of desiccant replacement (days); and
- For all units' vapor recovery system
 - Type
 - Flare, incinerator, collection system
 - Facilities could also specify a type not listed above
 - Control efficiency.

Emissions

Dehydrators have combustion, vented, and fugitive emissions. Combustion emissions were calculated from Table 5 of the 2007 Oil and Gas Industry Survey and are listed under “reboiler” emissions in Chapter 7 of this report. Vented and fugitive emissions are summarized here.

There are two methods for calculating vented emissions from dehydrators and one method for calculating fugitive. The first venting method is for glycol units. It uses process information to calculate venting losses. The second venting method is for desiccant units. It calculates vented emissions based on replacement of the desiccant material. The third method calculates the fugitive emissions using a mass balance approach. Appendix B details the calculations for all three methods. The CO₂ and CH₄

emissions are adjusted by the vapor recovery efficiency and then multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 11-1 lists the vented emissions by type of dehydrator. Some equipment types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. Below is a list of equipment categories and the types they represent:

- Desiccant – desiccant and scrubber dehydrators; and
- Chiller – gas chiller, methanol chiller, low temperature separation, and refrigeration dehydrators.

Glycol dehydrators make up 85 percent of the dehydrators in California and are responsible for almost all the CO₂e emissions.

**Table 11-1: Vented Emissions of Natural Gas Dehydrators by Type
(Metric Tons/Year)**

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Glycol | 261 | 308 | 1,974 | 41,772 | 100% |
| Desiccant | 41 | 0.01 | 0.09 | 1.94 | 0% |
| Chiller | 6 | 0 | 0 | 0 | 0% |
| Totals: | 308 | 308 | 1,975 | 41,774 | |

Table 11-2 lists the fugitive emissions by type of dehydrator. Again, glycol dehydrators emit the vast majority of the CO₂e emissions reported in this survey.

**Table 11-2: Fugitive Emissions of Natural Gas Dehydrators by Type
(Metric Tons/Year)**

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Glycol | 261 | 16,567 | 718 | 31,643 | 74% |
| Chiller | 6 | 0 | 534 | 11,224 | 26% |
| Desiccant | 41 | 0 | 0 | 0 | 0% |
| Totals: | 308 | 16,567 | 1,252 | 42,866 | |

Table 11-3 lists the total input volume for each dehydrator type. This volume includes natural gas, water, and other impurities. As indicated, nearly the entire input volume is moved through glycol dehydrators.

Table 11-3: Volume of Natural Gas Dehydrators by Type

| Type | Volume (MSCF) | Percent of Total |
|----------------|--------------------|------------------|
| Glycol | 701,123,262 | 100% |
| Desiccant | 1,338,428 | 0% |
| Chiller | 1,119,742 | 0% |
| Totals: | 703,581,432 | |

Table 11-4 lists the combustion, vented, and fugitive emissions from all natural gas dehydrators. The combustion emissions are from Table 5 of the 2007 Oil and Gas Industry Survey and were calculated using the methods detailed in Chapter 7 of this report. This table shows that vented and fugitive CO₂e emissions make up the majority of the emissions from this category.

Table 11-4: Total Emissions of Natural Gas Dehydrators (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|------------------|-------------------|------------------------------------|
| Combustion | 14,093 | 14 | 0 | 14,406 | 15% |
| Vented | 308 | 1,975 | 0 | 41,774 | 42% |
| Fugitive | 16,567 | 1,252 | 0 | 42,866 | 43% |
| Totals: | 30,968 | 3,241 | 0 | 99,046 | |

Table 11-5 lists the number of dehydrators that have vapor recovery units. Less than 50 percent of the glycol dehydrators have vapor recovery units. Overall, only 44 percent of all the dehydrators reported in this survey have vapor recovery units.

Table 11-5: Natural Gas Dehydrators Percent with Vapor Recovery

| Type | Number of Units | Number on Vapor Recovery | Type-Specific Percent on Vapor Recovery |
|----------------|-----------------|--------------------------|---|
| Glycol | 261 | 125 | 48% |
| Chiller | 6 | 5 | 83% |
| Desiccant | 41 | 5 | 12% |
| Totals: | 308 | 135 | 44% |

Table 11-6 lists the types of vapor recovery units used on dehydrators. Some vapor recovery types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. Below is a list of equipment categories and the types they represent:

- Flare – flares and emergency flares;
- Combustion Unit – burn lines, burners, reboilers, and turbines; and
- Collection System – compressors, collection systems, and carbon adsorbers.

Table 11-6: Natural Gas Dehydrators Types of Vapor Recovery

| Type | Number of Units | Percent of Total |
|-------------------|-----------------|------------------|
| None | 173 | 56% |
| Collection System | 77 | 25% |
| Combustion Unit | 25 | 8% |
| Incinerator | 17 | 6% |
| Flare | 11 | 4% |
| Thermal Oxidizer | 5 | 2% |
| Totals: | 308 | |

Chapter 12 – Natural Gas Sweetening and Acid Gas Removal

Natural gas sweetening and acid gas removal units (AGR) remove sulfur and CO₂ from the gas streams. Table 10 of the Oil and Gas Industry Survey collected process information about AGR units. Facilities were asked to report the following information:

- Type
 - Solid and non-solid material (Specific types listed in Appendix A)
 - Facilities could also specify a type not listed;
- Average natural gas composition
 - Percent CH₄, H₂S, CO₂ for input and output streams
 - Higher heating value (HHV) in btu for input and output streams;
- Input and output volume in standard cubic feet;
- Quantity of liquids removed in tons/year;
- CO₂ removal
 - Total CO₂ removed (tons/year)
 - Amount vented (tons/year)
 - Amount incinerated (tons/year)
 - Amount captured (tons/year);
- For solid material units
 - Volume of unit (ft³)
 - Pressure (psig)
 - Percent of packed vessel volume that is natural gas
 - Frequency of material replacement (days); and
- For all units' vapor recovery system
 - Type
 - Flare, incinerator, collection system
 - Facilities could also specify a type not listed above
 - Control efficiency.

Emissions

Natural gas sweetening and AGR units have combustion, vented, and fugitive emissions. Combustion emissions were calculated from Table 5 of the Oil and Gas Industry Survey and are listed under “reboiler” emissions in Chapter 7 of this report. Vented and fugitive emissions are summarized here.

Vented emissions are only calculated for replacing the solid material in solid material AGR units. Fugitive emissions are calculated using a mass balance approach for both solid and non-solid material units. See Appendix B for detailed calculations. The CO₂ and CH₄ emissions are adjusted by the vapor recovery efficiency and then multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 12-1 lists the vented emissions by type of AGR unit. These emissions contain the calculated vented emissions from solid material replacement as well as the reported

vented CO₂ values. Some equipment types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. Below is a list of equipment categories and the types they represent:

- Sulfa – sulfa scrubs, sulfa treats, sulfurchecks, soluroxes, and sulfide scavengers; and
- Other – triazine, claus process, grace membrane, contactor, liquid redox, lo-cat, molecular gate.

This table shows that 63 percent of the vented CO₂e emissions are from amine AGR units.

**Table 12-1: Vented Emissions of Natural Gas AGR Units by Type
(Metric Tons/Year)**

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Amine | 19 | 32,727 | 0 | 32,727 | 63% |
| Other | 8 | 19,002 | 16 | 19,349 | 37% |
| Sulfa | 38 | 19 | 3 | 72 | 0% |
| Totals: | 65 | 51,749 | 19 | 52,148 | |

Table 12-2 lists the fugitive emissions by type of AGR unit. As listed above for Table 12-1, the same categories were combined to protect confidential company data and to aggregate similar pieces of equipment. This table shows that fugitive emissions are more spread out among the three categories. Here, 50 percent of the fugitive CO₂e emissions are from the “other” category. The remaining 50 percent is split between amine units and sulfa units.

**Table 12-2: Fugitive Emissions of Natural Gas AGR Units by Type
(Metric Tons/Year)**

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Other | 8 | 27,651 | 425 | 36,578 | 50% |
| Sulfa | 38 | 22,755 | 0 | 22,756 | 31% |
| Amine | 19 | 11,199 | 151 | 14,360 | 19% |
| Totals: | 65 | 61,605 | 576 | 73,694 | |

Table 12-3 lists the combustion, vented, and fugitive emissions from all natural gas AGR units. The combustion emissions are from Table 5 of the 2007 Oil and Gas Industry Survey and were calculated using the methods detailed in Chapter 7 of this report. This table shows that vented and fugitive CO₂e emissions make up the majority of the emissions from this category.

Table 12-3: Total Emissions of Natural Gas AGR Units (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|------------------|-------------------|------------------------------------|
| Combustion | 3,373 | 0 | 0 | 3,377 | 3% |
| Vented | 51,749 | 19 | 0 | 52,148 | 40% |
| Fugitive | 61,605 | 576 | 0 | 73,694 | 57% |
| Totals: | 116,727 | 595 | 0 | 129,219 | |

Table 12-4 lists the number of AGR units that have vapor recovery units. Overall, 75 percent of all the AGR units in California have vapor recovery units.

Table 12-4: Natural Gas AGR Units Percent on Vapor Recovery

| Type | Number of Units | Number on Vapor Recovery | Type-Specific Percent on Vapor Recovery |
|----------------|-----------------|--------------------------|---|
| Amine | 19 | 11 | 58% |
| Other | 8 | 5 | 63% |
| Sulfa | 38 | 33 | 87% |
| Totals: | 65 | 49 | 75% |

Table 12-5 lists the types of vapor recovery units used on AGR units. Some vapor recovery types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. Below is a list of equipment categories and the types they represent:

- Combustion Unit – boilers, heater/treaters, steam generators, and combustion equipment;
- Collection System – compressors and collection systems.

Table 12-5: Natural Gas AGR Units Types of Vapor Recovery

| Type | Number of Units | Percent of Total |
|-------------------|-----------------|------------------|
| Collection System | 30 | 46% |
| None | 16 | 25% |
| Combustion Unit | 10 | 15% |
| Flare | PD | PD |
| Incinerator | PD | PD |
| Thermal Oxidizer | PD | PD |
| Totals: | 65 | |

Chapter 13 – Other Natural Gas Processing

Other natural gas processing includes all other units that process natural gas but are not dehydrators (Chapter 10) or AGR units (Chapter 11). Table 11 of the Oil and Gas Industry Survey collected information about these units. The following information was requested from each facility:

- Type
 - Fractionation, nitrogen removal, mercury removal
 - Facilities could list a type not listed above;
- Average natural gas composition
 - Percent CH₄, H₂S, CO₂ for input and output streams
 - Higher heating value (HHV) in btu for input and output streams;
- Input and output volume in standard cubic feet;
- Quantity of liquids removed in tons/year; and
- For all units' vapor recovery system
 - Type
 - Flare, incinerator, collection system
 - Facilities could also specify a type not listed above
 - Control efficiency.

Emissions

Emissions of CO₂ and CH₄ from natural gas processing units are calculated using a mass balance approach. This calculation is detailed in Appendix B. Because a mass balance approach calculates the total vapor loss, determining whether they are vented emissions or fugitive emissions or both is not possible. Thus, emissions from these units are categorized as fugitive. The CO₂ and CH₄ emissions are adjusted by the vapor recovery efficiency and then multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 13-1 lists the emissions of the natural gas processing units by type. This table shows that almost all the emissions from this category come from fractionation units.

Table 13-1: Emissions of Other Natural Gas Processing Units by Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|------------------------------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Fractionation | 5 | 24,888 | 225 | 29,620 | 100% |
| Liquefied Petroleum Gas Extraction | PD | PD | PD | PD | PD |
| Denitrification | PD | PD | PD | PD | PD |
| Scrubber | PD | PD | PD | PD | PD |
| Totals: | 14 | 24,888 | 228 | 29,676 | |

Table 13-2 lists the number of natural gas processing units with vapor recovery by type of unit. This table shows that nearly all fractionation units have vapor recovery and that,

overall, 93 percent of the natural gas processing units have vapor recovery. Collection systems and flares are used as vapor recovery for these natural gas processing units.

Table 13-2: Other Natural Gas Processing Units Percent on Vapor Recovery

| Type | Number of Units | Number on Vapor Recovery | Type-Specific Percent on Vapor Recovery |
|-----------------|------------------------|---------------------------------|--|
| Fractionation | 5 | 5 | 100% |
| LPG Extraction | PD | PD | PD |
| Scrubber | PD | PD | PD |
| Denitrification | PD | PD | PD |
| Totals: | 14 | 13 | 93% |

Chapter 14 – Total Natural Gas Processing Emissions

This chapter combines the emissions from the various natural gas processing equipment discussed in previous chapters. This includes dehydrators (Chapter 11), natural gas sweetening and acid gas removal units (Chapter 12), and other natural gas processing (Chapter 13).

Table 14-1 lists the total California emissions from natural gas processing. As shown, fugitive emissions account for 57 percent of the total emissions from this category while vented emissions account for 36 percent.

Table 14-1: Total California Emissions (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|------------------|-------------------|------------------------------------|
| Combustion | 17,466 | 15 | 0 | 17,782 | 7% |
| Vented | 52,056 | 1,994 | 0 | 93,922 | 36% |
| Fugitive | 103,061 | 2,056 | 0 | 146,237 | 57% |
| Totals: | 172,584 | 4,064 | 0 | 257,941 | |

Table 14-2 lists the total natural gas processing emissions by type. This table shows that 50 percent of the emissions from natural gas sweetening and acid gas removal units.

Table 14-2: Natural Gas Processing Emissions by Type (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|-----------------------------|-----------------|-----------------|------------------|-------------------|------------------------------------|
| Sweetening/Acid Gas Removal | 116,727 | 595 | 0 | 129,219 | 50% |
| Dehydration | 30,968 | 3,241 | 0 | 99,046 | 38% |
| Other Processing | 24,888 | 228 | 0 | 29,676 | 12% |
| Totals: | 172,584 | 4,064 | 0 | 257,941 | |

Chapter 15 – Natural Gas Compressors

Natural gas compressors compress natural gas to higher pressures and lower volumes. Table 12 of the 2007 Oil and Gas Industry Survey required facilities to provide the following information about their compressors:

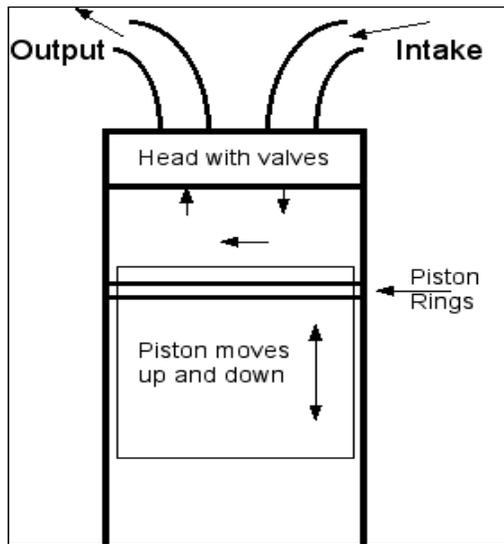

- Type
 - Centrifugal, reciprocating, rotary
 - Facilities could specify a type not listed above;
- For centrifugal
 - Number of wet seals and dry seals;
- For reciprocating
 - Number of cylinders;
- Primary driver type
 - Electric, turbine, piston engine, or integral;
- Starter type
 - Natural gas expansion, instrument air expansion, electric, or hydraulic
 - Facilities could specify a type not listed above;
- Manufacturer;
- Model year;
- Annual usage (hours);
- Inspection frequency;
- Maintenance frequency;
- Discharge pressure (psia);
- Discharge temperature (°F);
- Idle pressure (psia);
- For blowdowns
 - Number
 - Volume of natural gas vented, flared, or recovered; and
- For startups
 - Number
 - Volume of natural gas vented, flared, or recovered.

Table 15-1 lists the number of compressors by type. Some compressor types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. The compressor type “rotary” contain the types rotary, rotary vane, screw, and vane.

Table 15-1: Number of Compressors by Type

| Type | Number of Compressors |
|----------------|-----------------------|
| Centrifugal | 47 |
| Reciprocating | 911 |
| Rotary | 97 |
| Unknown | 16 |
| Totals: | 1,071 |

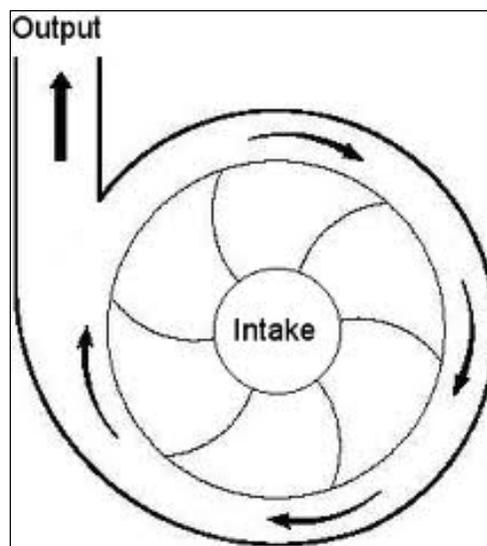

Figure 15-1: Reciprocating Compressor

Figures 15-1 through 15-3 shows the compression chambers for each type of compressor.

Reciprocating compressors increase the pressure of natural gas by positive displacement, employing linear movement of a shaft driving a piston in a cylinder.

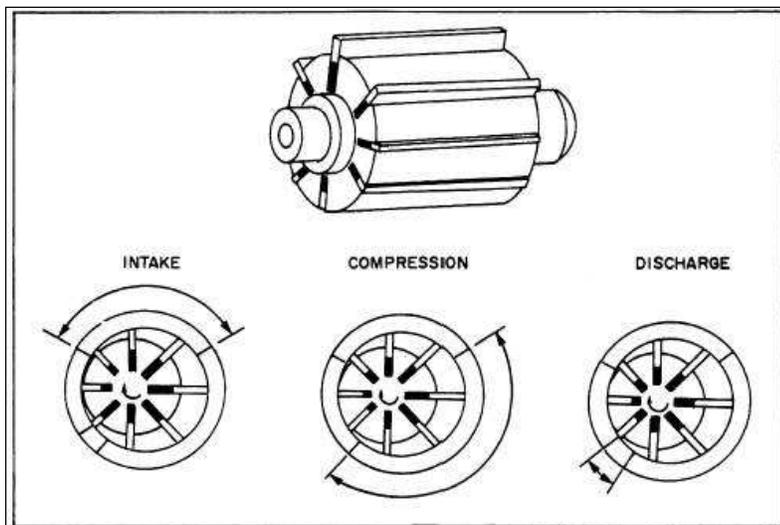

Figure 15-2: Centrifugal Compressor

Centrifugal compressors increase the pressure of natural gas by centrifugal action, employing rotating movement of the drive shaft.

Rotary and screw compressors have blades or a cylinder that rotate off center to compress the natural gas.

Figure 15-3: Rotary Compressor

Each compressor type can have a different driver, which is the engine that drives the compressor. The driver could be electric, turbine, piston engine, or integral. Integral compressors are unique in that the compressor is integrated into the engine design. Essentially the two cannot be separated. Table 15-2 lists the number of compressors by type of compressor and primary driver.

Table 15-2: Number of Primary Drivers by Type

| Type | Electric | Integral | Piston Engine | Turbine | Total |
|----------------|------------|-----------|---------------|-----------|--------------|
| Centrifugal | 18 | PD | 24 | PD | 47 |
| Reciprocating | 313 | PD | 516 | PD | 911 |
| Rotary | 83 | PD | 14 | PD | 97 |
| Unknown | 16 | PD | 0 | PD | 16 |
| Totals: | 430 | PD | 554 | PD | 1,071 |

Compressor starters also vary across the different types of compressors. Some natural gas compressor starters use natural gas expansion. These starters use high-pressure natural gas expanded across the starter to initiate the startup of the engine. The gas is then either vented to the atmosphere or recovered back into the sales line or routed to a flare. Table 15-3 lists the number of compressors by type of compressor and starters.

Table 15-3: Number of Starters by Type

| Type | Electric | Gas Expansion - Instrument Air | Gas Expansion - Natural Gas | Total |
|----------------|------------|--------------------------------|-----------------------------|--------------|
| Centrifugal | 20 | 0 | 27 | 47 |
| Reciprocating | 367 | 52 | 492 | 911 |
| Rotary | 86 | PD | PD | 97 |
| Unknown | 16 | PD | PD | 16 |
| Totals: | 489 | 54 | 528 | 1,071 |

Compressor blowdowns are the depressurization of the compressor. The natural gas in the compressor chamber is either vented to atmosphere, flared, or recovered and piped back into the system. Table 15-4 lists the volumes of natural gas that are flared, recovered, or vented for both compressor blowdowns and natural gas expansion startups.

Table 15-4: Startup and Blowdown Volumes

| Type | Flared (mcsf) | Recovered (mcsf) | Vented (mcsf) |
|----------------|---------------|------------------|----------------|
| Startup | 821 | 42 | 4,196 |
| Blowdown | 9,835 | 26,246 | 189,062 |
| Totals: | 10,657 | 26,288 | 193,259 |

Emissions

Natural gas compressors have combustion, vented, and fugitive emissions. Combustion emissions were calculated from Table 5 of the 2007 Oil and Gas Industry Survey. They are included with the types of internal combustion engines listed in Chapter 7 of this report. Vented and fugitive emissions are calculated here.

Vented emissions are calculated from the volumes of gas released from startups and blowdowns. Fugitive emissions are calculated from the number and type of compressor seals, the hours of operation and seal-specific emission factors. These calculations are detailed in Appendix B. The CO₂ and CH₄ emissions are multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 15-5 lists the vented emissions from natural gas compressor startups, and Table 15-6 lists the vented emissions from blowdowns. The majority of the emissions come from reciprocating compressors. The compressor type “unknown” encompasses survey responses where “other” was checked but the type was not specified.

Table 15-5: Natural Gas Compressor Startup Vented Emissions (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-------------------|------------------------------------|
| Reciprocating | 4 | 68 | 1,438 | 98% |
| Rotary | 0.08 | 0.87 | 18 | 1% |
| Centrifugal | 0.01 | 0.26 | 6 | 0% |
| Unknown | 0 | 0 | 0 | 0% |
| Totals: | 4 | 69 | 1,462 | |

Table 15-6: Natural Gas Compressor Blowdown Vented Emissions (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-------------------|------------------------------------|
| Reciprocating | 170 | 3,210 | 67,578 | 99% |

| Totals: | 2,025 | 17,679 | 373,274 | |

Table 15-8 lists the combustion, vented, and fugitive emissions from all natural gas compressor units. The combustion emissions are from Table 5 of the Oil and Gas Industry Survey (Appendix A) and are categorized under internal combustion engines and turbines in Chapter 7 of this report. This table shows that combustion CO₂e emissions make up the majority of the emissions from this category while fugitive CO₂e account for the majority of the remaining 34 percent.

Table 15-8: Total Emissions of Natural Gas Compressors (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|------------------|-------------------|------------------------------------|
| Combustion | 782,515 | 4,210 | 19 | 876,891 | 66% |
| Vented | 176 | 3,307 | 0 | 69,627 | 5% |

| Totals: | 784,716 | 25,196 | 19 | 1,319,792 | |

Table 15-9 shows the total compressor emissions by primary business type. These numbers include combustion, vented, and fugitive emissions. The business type “other” includes the following self-reported facility types:

- CNG compression and marketing,
- Cogeneration,
- Combined heat and power,
- Electricity generation,
- Portable heating ,
- Water disposal, and
- Vapor recovery services.

Table 15-9: Compressor Emissions by Primary Business (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|------------------------|-----------------|-----------------|------------------|-------------------|------------------------------------|

Chapter 16 –Pipeline Pigging and Natural Gas Gathering Pipelines

Pipelines are used to transport crude oil and natural gas around the facility and throughout the state. This chapter only includes information about natural gas gathering system pipelines and pipeline pigging operations for both crude oil and natural gas. It does not include natural gas transmission or distribution pipelines. Table 13 of the 2007 Oil and Gas Industry Survey required facilities to provide the following information about their pipelines:

- Length of natural gas gathering system pipelines;
- Maintenance activities for natural gas gathering system pipelines;
 - Type and volume of natural gas vented, flared, or recovered; and
- Pigging operations
 - Number of crude oil and natural gas launchers and receivers
 - Number of types each launcher and receiver was opened
 - If launcher or receiver was purged with inert gas prior to being opened.

Pipelines in a natural gas gathering system are pipes of various sizes that move natural gas around the facility. They move the natural gas to combustion units, gas processing units, or to compressors to be put into transmission lines. Table 16-1 lists the number of miles of natural gas gathering system pipelines by primary business type. The business type “other” includes the following self-reported facility types:

- CNG compression and marketing,
- Cogeneration,
- Combined heat and power,
- Electricity generation,
- Portable heating ,
- Water disposal, and
- Vapor recovery services.

Table 16-1: Miles of Natural Gas Gathering System Pipelines by Primary Business Type

| Primary Business | Miles of Natural Gas Gathering System Pipeline |
|-------------------------|---|
| Natural Gas Processing | 1,124 |
| Onshore Natural Gas | 626 |
| Onshore Crude | 321 |
| Natural Gas Storage | 169 |
| Offshore Crude | 54 |
| Crude Processing | PD |
| Other | PD |
| Totals: | 2,295 |

Maintenance activities of these natural gas gathering systems encompass repairs or improvements that are done to the pipelines. These activities often result in natural gas being vented to the atmosphere. Table 16-2 lists the volumes of natural gas that were vented, recovered, or flared due to pipeline maintenance activities.

Table 16-2: Natural Gas Gathering System Pipeline Maintenance Activity Volumes

| Type | Flared (mscf) | Recovered (mscf) | Vented (mscf) |
|----------------|----------------|------------------|----------------|
| Pipeline Gas | 2,002 | 628,149 | 3,962 |
| Associated Gas | 349,193 | 1,379,138 | 180,340 |
| Dry Gas | 1,902 | 2,367,936 | 75 |
| Totals: | 353,097 | 4,375,223 | 184,377 |

Pigging refers to sending a device (a “pig”) through a pipeline to clean it. Pigging is used in both crude oil and natural gas pipelines. The natural gas pig launchers and receivers are pressurized with natural gas. This gas is either purged with an inert gas prior to opening, or the gas is vented to atmosphere. Table 16-3 lists the number of pig launchers/receivers and the number of openings.

Table 16-3: Pigging Operations

| Type | Number of Launchers/Receivers | Number of Openings |
|----------------|-------------------------------|--------------------|
| Crude Oil | 786 | 989 |
| Natural Gas | 146 | 1,417 |
| Totals: | 932 | 2,406 |

Emissions

Vented emissions are calculated from the amount of gas vented from natural gas gathering system maintenance activities, and the number of natural gas pigging operations. These are multiplied with an emission factor to yield emission estimates. No emission factor is available for crude oil pigging. Fugitive emissions are calculated from the miles of natural gas pipeline and an emission factor. These calculations are detailed in Appendix B. The CO₂ and CH₄ emissions are multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 16-4 lists the vented emissions from the natural gas gathering system maintenance activities and natural gas pigging operations. As shown, pipeline maintenance activities account for almost all of the vented emissions from pipelines.

Table 16-4: Natural Gas Vented Emissions from Gathering Pipeline Maintenance and Pigging Operations (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|-----------------------|-----------------|-----------------|-------------------|------------------------------------|
| Natural Gas Pipelines | 2,659 | 2,490 | 54,940 | 100% |
| Natural Gas Pigging | 104 | 5 | 211 | 0% |
| Totals: | 2,763 | 2,495 | 55,151 | |

Table 16-5 lists the fugitive emissions from natural gas pipelines.

**Table 16-5: Natural Gas Fugitive Emissions from Gathering Pipelines
(Metric Tons/Year)**

| Type | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|-----------------------|-----------------|-----------------|-------------------|------------------------------------|
| Natural Gas Pipelines | 327 | 867 | 18,541 | 100% |
| Totals: | 327 | 867 | 18,541 | |

Chapter 17 – Separators

Separators are used to split the fluids that come out of a well. In crude oil fields, this fluid can be made of crude oil, natural gas, water, and other contaminants. In natural gas fields, this fluid can contain natural gas, water, and other contaminants. Table 14 of the 2007 Oil and Gas Industry Survey gathered information about separators. Facilities were required to submit the following information about their separators:

- Type
 - Free water knockout, heater/treater, horizontal separator, vertical separator, flow splitter, wemco, emulsion treater, or condensate tank
 - Facilities could also specify a type not listed above;
- Subtype
 - Bolted or welded;
- Size;
- Number of degassing events;
- Throughput in barrels crude oil per year or scf of natural gas per year;
- Crude oil API;
- Reactive organic gas (ROG) and total organic gas (TOG) emissions in tons/year
 - For working, breathing, and flashing losses
 - Average concentration of CH₄ and CO₂ in the vapor losses;
- Whether the separator had an access hatch or pressure relief valve
 - Were they counted in the components from Table 6 of the 2007 Oil and Gas Industry Survey;
- Vapor recovery system type
 - Flare, incinerator, collection system, or none
 - Facilities could also specify a type not listed above; and
- Vapor recovery system control efficiency.

Table 17-1 lists the number of separators by primary business type. The business type “crude processing” and “crude pipeline” were combined to protect confidential company data.

Table 17-1: Number of Separators by Primary Business Type

| Primary Business | Number of Separators |
|-------------------------------|----------------------|
| Onshore Crude | 3,228 |
| Onshore Natural Gas | 891 |
| Natural Gas Processing | 379 |
| Natural Gas Storage | 75 |
| Offshore Crude | 40 |
| Crude Processing and Pipeline | 5 |
| Totals: | 4,618 |

Emissions

Vented emissions are calculated from separator degassing events. This is where the separator is completely emptied of fluids and opened to atmosphere for cleaning or repair. Fugitive emissions are calculated from the total organic gas emissions from working, breathing, and flashing losses and the head space vapor concentrations. These equations are detailed in Appendix B. The CO₂ and CH₄ emissions are adjusted by the vapor recovery efficiency and then multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 17-2 lists the total vented and fugitive emissions from separators as reported in the survey. As shown, almost all of the emissions are fugitive.

Table 17-2: Total Emissions of Separators (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-------------------|------------------------------------|
| Vented | 0 | 1 | 24 | 1% |
| Fugitive | 11 | 170 | 3,578 | 99% |
| Totals: | 11 | 171 | 3,602 | |

Table 17-3 lists the fugitive emissions by type of separator. For approximately 90 percent of the separators reported, a value for ROG or TOG was not reported. Thus, emissions from separators are most likely underestimated. Some separator types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar equipment uses. Appendix E lists the categories and the types they represent.

Table 17-3: Fugitive Emissions of Separators by Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Separator | 715 | 0 | 68 | 1,435 | 40% |
| Shipping Tank | 88 | 5 | 54 | 1,139 | 32% |
| Wash Tank | 188 | 1 | 15 | 319 | 9% |
| Vertical Separator | 604 | 1 | 14 | 288 | 8% |
| Produced Water Tank | 130 | 1 | 8 | 160 | 4% |
| Crude Oil Separator | 37 | 1 | 7 | 140 | 4% |
| Wemco | 65 | 0 | 3 | 61 | 2% |
| Free Water Knockout | 297 | 0 | 1 | 19 | 1% |
| Settling tanks | 10 | 0 | 0 | 7 | 0% |
| Heater/Treater | 309 | 0 | 0 | 5 | 0% |
| Stage Separator | 88 | 0 | 0 | 2 | 0% |
| Horizontal Separator | 1,046 | 0 | 0 | 1 | 0% |
| Condensate tank | 81 | 0 | 0 | 0 | 0% |
| Gas Separator | 102 | 0 | 0 | 0 | 0% |
| Surge Tank | 9 | 0 | 0 | 0 | 0% |
| Scrubber | 257 | 0 | 0 | 0 | 0% |
| Trap Separator | 90 | 0 | 0 | 0 | 0% |
| Well Tester | 502 | 0 | 0 | 0 | 0% |
| Totals: | 4,618 | 11 | 170 | 3,578 | |

Seventy-two percent of the emissions come from the categories “separator” and “shipping tank”. The majority of separators in the category “separator” were not reported by a specific type. Shipping tanks are tanks that should have been listed on Table 16 of the 2007 Oil and Gas Industry Survey but were instead listed on Table 15.

Table 17-4 lists the fugitive emissions by subtype of separator. Bolted separators account for 57 percent of the emissions but only 12 percent of the total number. The subtype “unknown” is the next largest contributor to the total fugitive emissions.

Table 17-4: Fugitive Emissions of Separators by Subtype (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Bolted | 537 | 9 | 97 | 2,044 | 57% |
| Unknown | 2,062 | 1 | 68 | 1,423 | 40% |
| Welded | 1,999 | 0 | 5 | 111 | 3% |

| None | PD | PD | PD | PD | PD |
| Poly | PD | PD | PD | PD | PD |
| Riveted | PD | PD | PD | PD | PD |
| Totals: | 4,618 | 11 | 170 | 3,578 | |

Table 17-5 lists the number of separator units with vapor recovery by type of separator. This table shows that, overall, 70 percent of separators have vapor recovery.

Table 17-5: Separator Units by Type Percent on Vapor Recovery

| Type | Number of Units | Number on Vapor Recovery | Percent on Vapor Recovery |
|----------------------|-----------------|--------------------------|---------------------------|
| Scrubber | 257 | 257 | 100% |
| Settling tanks | 10 | 10 | 100% |
| Well Tester | 502 | 500 | 100% |
| Surge Tank | 9 | 8 | 89% |
| Stage Separator | 88 | 78 | 89% |
| Gas Separator | 102 | 90 | 88% |
| Wemco | 65 | 56 | 86% |
| Trap Separator | 90 | 74 | 82% |
| Horizontal Separator | 1,046 | 819 | 78% |
| Free Water Knockout | 297 | 209 | 70% |
| Condensate tank | 81 | 52 | 64% |
| Heater/Treater | 309 | 196 | 63% |
| Crude Oil Separator | 37 | 23 | 62% |
| Vertical Separator | 604 | 325 | 54% |
| Produced Water Tank | 130 | 68 | 52% |
| Shipping Tank | 88 | 43 | 49% |
| Separator | 715 | 349 | 49% |
| Wash Tank | 188 | 66 | 35% |
| Totals: | 4,618 | 3,223 | 70% |

Table 17-6 lists the number of separator units with vapor recovery by subtype of separator. For both the welded and bolted subtype, about 50 percent have vapor

recovery. The subtype “unknown” has 96 percent with vapor recovery. The percentages for the remaining subtypes are not shown due to protected data.

Table 17-6: Separator Units by Subtype Percent with Vapor Recovery

| Type | Number of Units | Number with Vapor Recovery | Percent with Vapor Recovery |
|----------------|-----------------|----------------------------|-----------------------------|
| Unknown | 2,062 | 1,975 | 96% |
| Bolted | 537 | 275 | 51% |
| Welded | 1,999 | 966 | 48% |
| Both | PD | PD | PD |
| Riveted | PD | PD | PD |
| None | PD | PD | PD |
| Poly | PD | PD | PD |
| Totals: | 4,618 | 3,223 | 70% |

Table 17-7 lists the types of vapor recovery units used on separators. Some vapor recovery types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. Below is a list of equipment categories and the types they represent:

- Flare – flares, flares/collection systems, flares/collection systems/combustion equipment;
- Combustion Unit – steam generators, pump engines, oil heaters, gas plants, and boilers; and
- Collection System – compressors, collection systems, disposal wells, pressure vessels, fuel gas systems, and carbon adsorbers.

This table shows that 65 percent of the total number of separators uses a collection system for vapor recovery. Four percent send the vapors directly to a flare, incinerator, or combustion unit. The remaining 30 percent have no vapor recovery unit.

Table 17-7: Separator Units by Types of Vapor Recovery

| Type | Number of Units | Percent of Total |
|-------------------|-----------------|------------------|
| Collection System | 3,019 | 65% |
| None | 1,405 | 30% |
| Flare | 105 | 2% |
| Incinerator | 55 | 1% |
| Combustion Unit | 34 | 1% |
| Totals: | 4,618 | |

Chapter 18 – Crude Oil Sumps and Pits

Crude oil sumps and pits are open pits that are used for oil/water separation or for emergency containment. Table 15 of the 2007 Oil and Gas Industry Survey gathered information about sumps and pits. Facilities were required to submit the following information about their sump/pits:

- Level
 - Primary, secondary, tertiary;
- Crude oil API;
- Number of days in use;
- Dimensions
 - Area and depth;
- Vapor recovery system type
 - Flare, incinerator, collection system, cover, or none
 - Facilities could also specify a type not listed above; and
- Vapor recovery system control efficiency.

Primary sumps/pits contain crude oil emulsions straight from the well. The liquids have not gone through any separation. Secondary sumps/pits contain emulsions that have gone through separation and thus contain mostly water and very little crude oil. Tertiary sumps/pits are primarily water.

Emissions

Fugitive emissions from sumps/pits are calculated using emission factors based on the type, area, and the days of use of the sump. These equations are detailed in Appendix B. The CO₂ and CH₄ emissions are adjusted by the vapor recovery efficiency and then multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 18-1 lists the fugitive emissions by type of sump/pit. About half the emissions are from primary sumps/pits. The remaining half is split between secondary and tertiary sumps/pits.

Table 18-1: Fugitive Emissions of Sumps/Pits by Type (Metric Tons/Year)

| Type | Number of Sumps | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-------------------|------------------------------------|
| Primary | 62 | 128 | 2,678 | 48% |
| Secondary | 94 | 80 | 1,674 | 30% |
| Tertiary | 94 | 57 | 1,200 | 22% |
| Totals: | 250 | 264 | 5,552 | |

Table 18-2 lists the fugitive emissions by type of sump/pit for each air district. Only seven air districts contain sump/pits. Most of the CO₂e emissions from sumps/pits are in the San Joaquin Valley and Santa Barbara County air districts.

Table 18-2: Fugitive Emissions of Sumps/Pits by Air District (Metric Tons/Year)

| Air District | Type | Number of Sumps | CH ₄ | CO ₂ e |
|-----------------------------|-----------|-----------------|-----------------|-------------------|
| Bay Area AQMD | Secondary | PD | PD | PD |
| Monterey Bay Unified APCD | Secondary | PD | PD | PD |
| Santa Barbara County APCD | Primary | 36 | 76 | 1,587 |
| | Secondary | 29 | 39 | 826 |
| | Tertiary | 15 | 2 | 40 |
| South Coast AQMD | Primary | PD | PD | PD |
| | Secondary | 27 | 1 | 18 |
| | Tertiary | 34 | 0 | 5 |
| San Joaquin Valley APCD | Primary | 14 | 46 | 971 |
| | Secondary | 18 | 18 | 372 |
| | Tertiary | 30 | 55 | 1,151 |
| San Luis Obispo County APCD | Tertiary | PD | PD | PD |
| Ventura County APCD | Primary | PD | PD | PD |
| | Secondary | 17 | 5 | 100 |
| | Tertiary | 14 | 0 | 4 |
| Totals: | | 250 | 264 | 5,552 |

Table 18-3 lists the number of sumps/pits with vapor recovery. Less than 20 percent of the primary sumps/pits have vapor recovery. Overall, only 50 percent of all sumps/pits have vapor recovery.

Table 18-3: Sumps/Pits by Percent on Vapor Recovery

| Type | Number of Units | Number on Vapor Recovery | Percent on Vapor Recovery |
|----------------|-----------------|--------------------------|---------------------------|
| Primary | 62 | 12 | 19% |
| Secondary | 88 | 75 | 80% |
| Tertiary | 94 | 38 | 40% |
| Totals: | 250 | 125 | 50% |

Table 18-4 lists the types of vapor recovery used on sumps/pits. Some vapor recovery types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. Below is a list of equipment categories and the types they represent:

- Collection System – compressors, collection systems, tanks, and carbon adsorbers; and
- Cover – covers, covers and pressure relief devices, and covers and activated carbon.

This table shows most of the sumps/pits that have vapor recovery use either a cover or a collection system. The remaining sumps/pits have no vapor recovery.

Table 18-4: Sumps/Pits by Types of Vapor Recovery

| Type | Number of Units | Percent of Total |
|-------------------|------------------------|-------------------------|
| None | 125 | 50% |
| Cover | 73 | 29% |
| Collection System | 48 | 19% |
| Flare | PD | PD |
| Incinerator | PD | PD |
| Totals: | 250 | |

Chapter 19 – Crude Oil Storage Tanks

Crude oil storage tanks store crude oil before it's transported to a refinery for processing. They can be located on crude oil extraction sites, at tank farms, along pipelines, or at the refinery. Table 16 of the 2007 Oil and Gas Industry Survey collected information about crude oil storage tanks. Storage tanks at refineries were not included. Facilities were required to submit the following information about their tanks:

- Type
 - Fixed roof, internal floating roof, external floating roof, or open top roof;
- Subtype
 - Bolted or welded;
- Size in barrels;
- Number of degassing events;
- Average crude oil API gravity;
- Reactive organic gas (ROG) and total organic gas (TOG) emissions in tons/year
 - For working, breathing, and flashing losses
 - Average concentration of CH₄ and CO₂ in the vapor losses;
- Whether the storage tank had an access hatch or pressure relief valve
 - Were they counted in the components from Table 6 of the 2007 Oil and Gas Industry Survey;
- For floating roof tanks only
 - Deck leg height in feet
 - Tank diameter in feet
 - Primary seal type
 - Secondary seal type;
- Vapor recovery system type
 - Flare, incinerator, collection system, or none
 - Facilities could also specify a type not listed above; and
- Vapor recovery system control efficiency.

Emissions

Vented emissions are calculated from storage tank degassing events. This is where the storage tank is completely emptied of fluids and opened to atmosphere for cleaning or repair. Fugitive emissions are calculated from the total organic gas emissions from working, breathing, and flashing losses and the head space vapor concentrations. These equations are detailed in Appendix B. The CO₂ and CH₄ emissions are adjusted by the vapor recovery efficiency and then multiplied by their corresponding GWP numbers (1 for CO₂ and 21 for CH₄) to get the CO₂e values.

Table 19-1 lists the total vented and fugitive emissions from storage tanks. As shown, nearly all of the emissions are fugitive.

Table 19-1: Total Emissions of Storage Tanks (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-------------------|------------------------------------|
| Vented | 0 | 5 | 109 | 0% |
| Fugitive | 1,084 | 11,501 | 242,594 | 100% |
| Totals: | 1,084 | 11,506 | 242,703 | |

Table 19-2 lists the fugitive emissions by tank type. Most of the emissions are from fixed roof storage tanks. Fixed roof tanks also account for 94 percent of the total number of storage tanks in California. Approximately 65 percent of the storage tanks reported did not have a value reported for ROG or TOG. Thus, emissions for storage tanks are most likely underestimated.

Table 19-2: Fugitive Emissions of Storage Tanks by Type (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|------------------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Fixed Roof | 3,417 | 993 | 9,795 | 206,683 | 85% |
| Internal Floating Roof | 34 | 71 | 1,492 | 31,396 | 13% |
| External Floating Roof | 138 | 18 | 193 | 4,063 | 2% |
| Open Top Roof | 37 | 2 | 16 | 348 | 0% |
| Unknown | 13 | 0 | 5 | 105 | 0% |
| Totals: | 3,639 | 1,084 | 11,501 | 242,594 | |

Table 19-3 lists the fugitive emissions by subtype. Bolted tanks account for 80 percent of the total fugitive emissions and 61 percent of the total number of storage tanks.

Table 19-3: Fugitive Emissions of Storage Tanks by Subtype (Metric Tons/Year)

| Type | Number of Units | CO ₂ | CH ₄ | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-----------------|-----------------|-----------------|-------------------|------------------------------------|
| Bolted | 2,220 | 937 | 9,239 | 194,960 | 80% |
| Welded | 694 | 141 | 1,463 | 30,874 | 13% |
| Unknown | 653 | 5 | 785 | 16,480 | 7% |
| Riveted | PD | PD | PD | PD | PD |
| Steel | PD | PD | PD | PD | PD |
| Poly | PD | PD | PD | PD | PD |
| Open Top | PD | PD | PD | PD | PD |
| Totals: | 3,639 | 1,084 | 11,501 | 242,594 | |

Table 19-4 lists the number of storage tanks that have vapor recovery by the type of tank. As shown, less than half of the fixed roof tanks have vapor recovery. Floating roof tanks, both internal and external, are considered a type of vapor recovery system for a storage tank. They typically will not have an additional vapor recovery system. Overall, only 45 percent of all the storage tanks have vapor recovery units.

Table 19-4: Storage Tanks by Type Percent with Vapor Recovery

| Type | Number of Units | Number with Vapor Recovery | Percent with Vapor Recovery |
|------------------------|-----------------|----------------------------|-----------------------------|
| Unknown | 13 | 10 | 77% |
| Fixed Roof | 3,417 | 1,579 | 46% |
| Internal Floating Roof | 34 | 10 | 29% |
| External Floating Roof | 138 | 40 | 29% |
| Open Top Roof | 37 | 9 | 24% |
| Totals: | 3,639 | 1,648 | 45% |

Table 19-5 lists the number of storage tanks that have vapor recovery by subtype. Sixty percent of the welded tanks and 44 percent of the bolted tanks have vapor recovery units.

Table 19-5: Storage Tanks by Subtype Percent with Vapor Recovery

| Type | Number of Units | Number with Vapor Recovery | Percent with Vapor Recovery |
|----------------|-----------------|----------------------------|-----------------------------|
| Welded | 694 | 415 | 60% |
| Bolted | 2,220 | 970 | 44% |
| Unknown | 653 | 208 | 32% |
| Steel | PD | PD | PD |
| Poly | PD | PD | PD |
| Riveted | PD | PD | PD |

| Totals: | 3,639 | 1,648 | 45% |

Table 19-6 lists the type of vapor recovery systems used on storage tanks. Some vapor recovery types were combined from what was listed on individual surveys to protect confidential company data and to aggregate similar pieces of equipment. Below is a list of equipment categories and the types they represent:

- Flare – flares, flares/collection systems, flares/collection systems/combustion equipment;
- Combustion Unit – boilers, gas plants, heaters, heater/treaters, and steam generators; and
- Collection System – collection system, carbon adsorber, compressor, and disposal well.

As shown, most of the storage tanks with vapor recovery utilize collection systems.

Table 19-6: Storage Tanks by Types of Vapor Recovery

| Type | Number of Units | Percent of Total |
|-------------------|-----------------|------------------|
| None | 2,019 | 55% |
| Collection System | 1,313 | 36% |
| Flare | 131 | 4% |
| Combustion Unit | 61 | 2% |
| Incinerator | 61 | 2% |
| Unknown | 54 | 1% |
| Totals: | 3,639 | |

Chapter 20 – Overview of California Emissions from Crude Oil Production, Processing, and Storage

Total Crude Oil Emissions

This chapter gives an overview of emissions from crude oil production, processing, and storage. This encompasses the primary business types: onshore crude production, offshore crude production, crude processing, crude storage, and crude pipelines. These categories account for 62 percent of California's statewide GHG emissions from the oil and gas sector. As can be seen in Table 20-1, most of the emissions come from combustion sources.

Table 20-1: Crude Oil Emissions (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|-------------------|-----------------|------------------|-------------------|------------------------------------|
| Combustion | 10,109,202 | 6,737 | 186 | 10,308,317 | 94% |
| Vented | 34,848 | 5,868 | 0 | 158,077 | 1% |
| Fugitive | 45,939 | 22,283 | 0 | 513,874 | 5% |
| Totals: | 10,189,989 | 34,888 | 186 | 10,980,268 | |

The emissions in Table 20-1 do not include 13 cogeneration units that supply steam to oil fields but do not have any production associated with them. They were listed under the primary business type "other" and their emissions are included in Chapter 8 of this report.

Table 20-2 lists the combustion, vented, and fugitive emissions for crude oil facilities by primary business type. The primary business types crude oil processing and crude oil storage were combined to protect confidential data. Most of the emissions are from onshore crude oil production facilities. The remaining 6 percent of the emissions are from offshore production, processing, storage, and pipelines.

Table 20-2: Crude Oil Emissions by Primary Business Type (Metric Tons/Year)

| Type | Number of Facilities | Combustion (CO ₂ e) | Vented (CO ₂ e) | Fugitive (CO ₂ e) | Total CO ₂ e | Percent of Total CO ₂ e |
|------------------------------|----------------------|--------------------------------|----------------------------|------------------------------|-------------------------|------------------------------------|
| Onshore Crude Production | 668 | 9,784,578 | 125,428 | 433,082 | 10,343,089 | 94% |
| Crude Processing and Storage | 42 | 346,952 | 15,940 | 44,347 | 407,239 | 4% |
| Offshore Crude Production | 16 | 104,272 | 16,708 | 19,138 | 140,118 | 1% |
| Crude Pipeline | 65 | 72,515 | 0 | 17,306 | 89,821 | 1% |
| Totals: | 791 | 10,308,317 | 158,077 | 513,874 | 10,980,268 | |

Total CO₂e emissions were calculated for each facility. The facilities were then categorized into ranges of CO₂e emissions. Table 20-3 lists the number of facilities in each range and the total CO₂e emissions for the facilities in that range. As this table shows, 83 percent of the emissions come from two percent of the facilities.

Table 20-3: Crude Oil Total Emissions by CO₂e Range (Metric Tons/Year)

| Range (CO ₂ e per Facility) | Number of Facilities | CO ₂ e | Percent of Total CO ₂ e |
|--|----------------------|-------------------|------------------------------------|
| < 10,000 | 732 | 438,940 | 4% |
| 10,000 to 25,000 | 20 | 314,565 | 3% |
| 25,000 to 50,000 | 13 | 476,097 | 4% |
| 50,000 to 100,000 | 9 | 653,132 | 6% |
| 100,000 to 500,000 | 11 | 2,475,235 | 23% |
| > 500,000 | 6 | 6,622,297 | 60% |
| Totals: | 791 | 10,980,268 | |

Tables 20-4, 20-5, and 20-6 list the number of facilities and total CO₂e emissions for combustion, vented, and fugitive sources. These tables are similar to Table 20-3 in that the majority of the emissions come from a small fraction of the facilities.

Table 20-4: Crude Oil Combustion Emissions by CO₂e Range (Metric Tons/Year)

| Range (CO ₂ e per Facility) | Number of Facilities | CO ₂ e | Percent of Total CO ₂ e |
|--|----------------------|-------------------|------------------------------------|
| < 10,000 | 742 | 337,672 | 3% |
| 10,000 to 25,000 | 15 | 231,994 | 2% |
| 25,000 to 50,000 | 12 | 454,116 | 4% |
| 50,000 to 100,000 | 6 | 449,261 | 4% |
| 100,000 to 500,000 | 10 | 2,254,854 | 22% |
| > 500,000 | 6 | 6,580,418 | 64% |
| Totals: | 791 | 10,308,317 | |

Tables 20-5 and 20-6 list the number of facilities and total CO₂e emissions for vented and fugitive emissions separately. With the combustion emissions removed, the range of CO₂e values is much smaller. The majority of the facilities fall in the “less than 1,000 metric ton CO₂e per year” range, while a small fraction of the facilities account for a majority of the GHG emissions.

Table 20-5: Crude Oil Vented Emissions by CO₂e Range (Metric Tons/Year)

| Range (CO ₂ e per Facility) | Number of Facilities | CO ₂ e | Percent of Total CO ₂ e |
|--|----------------------|-------------------|------------------------------------|
| <1,000 | 776 | 17,152 | 11% |
| 1,000 to 5,000 | 9 | 20,571 | 13% |
| 5,000 to 10,000 | PD | PD | PD |
| 10,000 to 25,000 | PD | PD | PD |
| > 25,000 | PD | PD | PD |
| Totals: | 791 | 158,077 | |

Table 20-6: Crude Oil Fugitive Emissions by CO₂e Range (Metric Tons/Year)

| Range (CO ₂ e per Facility) | Number of Facilities | CO ₂ e | Percent of Total CO ₂ e |
|--|----------------------|-------------------|------------------------------------|
| < 1,000 | 734 | 76,445 | 15% |
| 1,000 to 5,000 | 40 | 74,675 | 15% |
| 5,000 to 10,000 | 8 | 60,736 | 12% |
| 10,000 to 25,000 | PD | PD | PD |
| > 25,000 | PD | PD | PD |
| Totals: | 791 | 513,874 | |

Average Emissions per Barrel Produced

This section includes emissions from onshore and offshore crude production. A way to classify facilities is to determine their average total CO₂e emissions per barrel of crude oil produced. This can be calculated in two ways, as a facility average and as a production-weighted average.

Facility Average

The average CO₂e emissions per barrel of crude oil produced was calculated for each facility by dividing the facility's total CO₂e emissions by its total production. Those values were then averaged for each range of production, as a facility average and as a production-weighted average.

$$\text{Avg. CO}_2\text{e}/\text{bbl}_{\text{range}} = \sum[(\text{CO}_2\text{e}/\text{bbl}_{\text{facility}})]_{\text{range}}/\text{number facilities}_{\text{range}}$$

Production-Weighted Average

The average CO₂e emissions per barrel of crude production was calculated by summing the total CO₂e emissions for each range of production and dividing it by the total barrels produced in that range.

$$\text{Avg. CO}_2\text{e}/\text{bbl}_{\text{range}} = (\text{total CO}_2\text{e}_{\text{range}})/(\text{total bbl}_{\text{range}})$$

The above calculations were done for total emissions and combustion, vented, and fugitive emissions separately. Table 20-7 shows the average CO₂e emissions per barrel for total emissions. The range "not reported" includes facilities that listed themselves as crude production but did not fill out their crude oil production for 2007. Most of the CO₂e emissions per barrel numbers are very close with the exception of the range 10,000 to 25,000. This range is skewed upwards due to facilities generating electricity as well as producing crude oil.

**Table 20-7: Average Total CO₂e Emissions per Barrel Crude Oil Produced
(Metric Tons/Year)**

| Range (Barrels Crude Oil produced per Year) | Number of Facilities | Total Barrels of Crude Oil Produced | Total CO ₂ e | Facility Average CO ₂ e per Barrel | Production Weighted Average CO ₂ e per Barrel |
|---|-------------------------|---|-------------------------|---|---|
| Not Reported | 87 | Not Reported | 208,300 | N/A | N/A |
| < 1,000 | 87 | 42,720 | 3,444 | 0.12 | 0.08 |
| 1,000 to 10,000 | 238 | 961,326 | 36,480 | 0.04 | 0.04 |
| 10,000 to 25,000 | 84 | 1,267,662 | 273,644 | 0.31 | 0.22 |
| 25,000 to 50,000 | 57 | 2,093,042 | 72,740 | 0.04 | 0.03 |
| 50,000 to 75,000 | 21 | 1,344,532 | 101,704 | 0.07 | 0.08 |
| 75,000 to 100,000 | 11 | 896,802 | 16,528 | 0.02 | 0.02 |
| > 100,000 | 99 | 227,371,062 | 9,770,367 | 0.05 | 0.04 |
| Totals: | 684 | 233,977,146 | 10,483,207 | 0.08 | 0.04 |

Table 20-8 shows the average CO₂e emissions per barrel for combustion emissions only. Most of the ranges are relatively similar except for the 10,000 to 25,000 range. Again, this is due to facilities generating electricity as well as producing crude oil.

**Table 20-8: Average Combustion CO₂e Emissions per Barrel Crude Oil Produced
(Metric Tons/Year)**

| Range (Barrels Crude Oil produced per Year) | Number of Facilities | Total Barrels of Crude Oil Produced | Total CO ₂ e | Facility Average CO ₂ e per Barrel | Production Weighted Average CO ₂ e per Barrel |
|---|-------------------------|---|-------------------------|---|---|
| Not Reported | 87 | Not Reported | 176,148 | N/A | N/A |
| < 1,000 | 87 | 42,720 | 1,267 | 0.03 | 0.03 |
| 1,000 to 10,000 | 238 | 961,326 | 25,122 | 0.03 | 0.03 |
| 10,000 to 25,000 | 84 | 1,267,662 | 258,871 | 0.30 | 0.20 |
| 25,000 to 50,000 | 57 | 2,093,042 | 39,504 | 0.02 | 0.02 |
| 50,000 to 75,000 | 21 | 1,344,532 | 92,469 | 0.07 | 0.07 |
| 75,000 to 100,000 | 11 | 896,802 | 4,782 | 0.01 | 0.01 |
| > 100,000 | 99 | 227,371,062 | 9,290,688 | 0.03 | 0.04 |
| Totals: | 684 | 233,977,146 | 9,888,850 | 0.06 | 0.04 |

Table 20-9 shows that vented CO₂e emissions per barrel produced are relatively consistent for all ranges of production.

**Table 20-9: Average Vented CO₂e Emissions per Barrel Crude Oil Produced
(Metric Tons/Year)**

| Range (Barrels Crude Oil produced per Year) | Number of Facilities | Total Barrels of Crude Oil Produced | Total CO ₂ e | Facility Average CO ₂ e per Barrel | Production Weighted Average CO ₂ e per Barrel |
|---|----------------------------|---|----------------------------|---|---|
| Not Reported | 87 | Not Reported | 15,848 | N/A | N/A |
| < 1,000 | 87 | 42,720 | 113 | 0.0025 | 0.0027 |
| 1,000 to 10,000 | 238 | 961,326 | 1,846 | 0.0019 | 0.0019 |
| 10,000 to 25,000 | 84 | 1,267,662 | 1,312 | 0.0010 | 0.0010 |
| 25,000 to 50,000 | 57 | 2,093,042 | 2,213 | 0.0011 | 0.0011 |
| 50,000 to 75,000 | 21 | 1,344,532 | 1,616 | 0.0012 | 0.0012 |
| 75,000 to 100,000 | 11 | 896,802 | 381 | 0.0004 | 0.0004 |
| > 100,000 | 99 | 227,371,062 | 118,807 | 0.0049 | 0.0005 |
| Totals: | 684 | 233,977,146 | 142,137 | 0.0019 | 0.0006 |

Table 20-10 shows the CO₂e emissions per barrel for fugitive emissions only. The high average CO₂e emission per barrel for the < 1,000 range is due to a number of facilities that produce less than 1 barrel of crude oil per day.

**Table 20-10: Average Fugitive CO₂e Emissions per Barrel Crude Oil Produced
(Metric Tons/Year)**

| Range (Barrels Crude Oil produced per Year) | Number of Facilities | Total Barrels of Crude Oil Produced | Total CO ₂ e | Facility Average CO ₂ e per Barrel | Production Weighted Average CO ₂ e per Barrel |

Chapter 21 – Overview of California Emissions from Dry Natural Gas Production, Processing, and Storage

Total Natural Gas Emissions

This chapter gives an overview of natural gas production, processing, and storage. This encompasses the primary business types: onshore natural gas production, natural gas processing, and natural gas storage. These categories account for 11 percent of California's statewide GHG emissions from the oil and gas sector. As can be seen in Table 21-1, about 70 percent of the emissions come from combustion sources and about a third come from vented and fugitive sources.

Table 21-1: Natural Gas Emissions (Metric Tons/Year)

| Type | CO ₂ | CH ₄ | N ₂ O | CO ₂ e | Percent of Total CO ₂ e |
|----------------|------------------|-----------------|------------------|-------------------|------------------------------------|
| Combustion | 1,237,087 | 3,918 | 18 | 1,325,080 | 69% |
| Vented | 21,160 | 10,063 | 0 | 232,473 | 12% |
| Fugitive | 61,322 | 14,620 | 0 | 368,335 | 19% |
| Totals: | 1,319,569 | 28,601 | 18 | 1,925,888 | |

Table 21-2 lists the combustion, vented, and fugitive emissions for natural gas facilities. About half of the emissions come from natural gas processing. The remaining emissions are split between onshore gas production and natural gas storage.

Table 21-2: Natural Gas Emissions by Primary Business Type (Metric Tons/Year)

| Type | Number of Facilities | Combustion (CO ₂ e) | Vented (CO ₂ e) | Fugitive (CO ₂ e) | Total CO ₂ e | Percent of Total CO ₂ e |
|------------------------|----------------------|--------------------------------|----------------------------|------------------------------|-------------------------|------------------------------------|
| Natural Gas Processing | 17 | 879,601 | 24,102 | 139,698 | 1,043,400 | 54% |
| Onshore Natural Gas | 703 | 218,910 | 117,835 | 210,879 | 547,624 | 28% |
| Natural Gas Storage | 10 | 226,569 | 90,537 | 17,758 | 334,864 | 17% |
| Totals: | 730 | 1,325,080 | 232,473 | 368,335 | 1,925,888 | |

“Natural gas processing” covers facilities that only process gas but do not extract gas. They are generally referred to as gas plants. Many extraction facilities have gas processing equipment onsite while others send their gas to gas plants.

The CO₂e emissions were calculated for each facility. The facilities were then categorized into ranges of CO₂e emissions. Table 21-3 lists the number of facilities in each range and the CO₂e emissions for the facilities in that range. As this table shows, about 75 percent of the emissions come from about 2 percent of the facilities.

Table 21-3: Total Natural Gas Emissions by CO₂e Range (Metric Tons/Year)

| Range (CO ₂ e per Facility) | Number of Facilities | CO ₂ e | Percent of Total CO ₂ e |
|--|----------------------|-------------------|------------------------------------|
| < 1,000 | 580 | 154,516 | 8% |
| 1,000 to 5,000 | 118 | 231,265 | 12% |
| 5,000 to 10,000 | 15 | 106,265 | 6% |
| 10,000 to 25,000 | 6 | 87,945 | 5% |
| > 25,000 | 11 | 1,345,898 | 70% |
| Totals: | 730 | 1,925,888 | |

Table 21-4 lists the number of facilities in each range and the total combustion CO₂e emissions for all the facilities in that range. Again, most of the emissions come from a small fraction of the facilities. Most of the facilities fall into the < 1,000 CO₂e range.

Table 21-4: Natural Gas Combustion Emissions by CO₂e Range (Metric Tons/Year)

| Range (CO ₂ e per Facility) | Number of Facilities | CO ₂ e | Percent of Total CO ₂ e |
|--|----------------------|-------------------|------------------------------------|
| < 1,000 | 679 | 70,852 | 5% |
| 1,000 to 5,000 | 31 | 67,690 | 5% |
| 5,000 to 10,000 | 5 | 31,319 | 2% |
| 10,000 to 25,000 | 8 | 117,233 | 9% |
| > 25,000 | 7 | 1,037,986 | 78% |
| Totals: | 730 | 1,325,080 | |

Tables 21-5 and 21-6 show the number of facilities and the total CO₂e emissions for vented and fugitive sources separately. Information for three ranges is listed as "PD" to protect confidential data.

Table 21-5: Natural Gas Vented Emissions by CO₂e Range (Metric Tons/Year)

| Range (CO ₂ e per Facility) | Number of Facilities | CO ₂ e | Percent of Total CO ₂ e |
|--|----------------------|-------------------|------------------------------------|
| <1,000 | 700 | 82,528 | 35% |
| 1,000 to 5,000 | 25 | 48,270 | 21% |

| 5,000 to 10,000 | PD | PD | PD |
| 10,000 to 25,000 | PD | PD | PD |
| > 25,000 | PD | PD | PD |
| Totals: | 730 | 368,335 | |

Average Emissions per MSCF Produced

This section includes emissions from onshore and offshore natural gas production. A way to classify facilities is to determine their average total CO₂e emissions per thousand cubic feet (mscf) of natural gas produced. This can be calculated in two ways.

Facility Average

The average CO₂e emissions per mscf natural gas produced was calculated for each facility by dividing the facility's total CO₂e emissions by its total production. Those values were then averaged for each range of production.

$$\text{Avg. CO}_2\text{e/mscf}_{\text{range}} = \sum[(\text{CO}_2\text{e/mscf}_{\text{facility}})]_{\text{range}} / \text{number facilities}_{\text{range}}$$

Production – Weighted Average

The average CO₂e emissions per mscf natural gas production was calculated by summing the total CO₂e emissions for each range of production and dividing it by the total mscf produced in that range.

$$\text{Avg. CO}_2\text{e/mscf}_{\text{range}} = (\text{total CO}_2\text{e}_{\text{range}}) / (\text{total mscf}_{\text{range}})$$

The above calculations were done for total emissions and combustion, vented, and fugitive emissions separately. Table 21-7 shows the average CO₂e emissions per mscf for total emissions. The range “not reported” includes facilities that listed themselves as natural gas production but did not fill out their natural gas production for 2007.

Table 21-7 shows that most of the ranges have similar average CO₂e emissions per mscf of natural gas produced except for the two lowest ranges. The “< 1,000 mscf” range has several facilities that produce less than one mscf of natural gas. This artificially increases the CO₂e emissions per mscf. The “1,000 to 50,000 mscf” range is larger than the remaining ranges due to several facilities with compressors onsite.

Table 21-7: Average Total CO₂e Emissions per MSCF Natural Gas Produced (Metric Tons/Year)

| Range (MSCF Natural Gas Produced per Year) | Number of Facilities | Total MSCF of Natural Gas Produced | Total CO ₂ e | Facility Weighted Average CO ₂ e per MSCF | Production Weighted Average CO ₂ e per MSCF |
|--|----------------------|------------------------------------|-------------------------|--|--|
| Not Reported | 31 | Not Reported | 50,656 | N/A | N/A |
| < 1,000 | 57 | 5,196 | 1,023 | 25.438 | 0.197 |
| 1,000 to 50,000 | 329 | 9,181,032 | 202,829 | 0.052 | 0.022 |
| 50,000 to 250,000 | 242 | 34,859,306 | 252,624 | 0.007 | 0.007 |
| 250,000 to 500,000 | 35 | 10,830,889 | 27,687 | 0.003 | 0.003 |
| > 500,000 | 9 | 13,178,870 | 12,805 | 0.001 | 0.001 |
| Totals: | 703 | 68,055,293 | 547,624 | 2.090 | 0.008 |

Table 21-8 lists the average CO₂e emissions per mscf natural gas produced for combustion emissions by range of production. Here, the bottom two ranges have higher CO₂e per mscf values due to the reasons stated above for Table 21-7.

Table 21-8: Average Combustion CO₂e Emissions per MSCF Natural Gas Produced (Metric Tons/Year)

| Range (MSCF Natural Gas Produced per Year) | Number of Facilities | Total MSCF of Natural Gas Produced | Total CO ₂ e | Facility Weighted Average CO ₂ e per MSCF | Production Weighted Average CO ₂ e per MSCF |
|--|----------------------|------------------------------------|-------------------------|--|--|
| Not Reported | 31 | Not Reported | 36,316 | N/A | N/A |
| < 1,000 | 57 | 5,196 | 178 | 0.0056 | 0.0343 |
| 1,000 to 50,000 | 329 | 9,181,032 | 108,511 | 0.0227 | 0.0118 |

Appendix A: 2007 Oil and Gas Industry Survey

**California Air Resources Board
Oil and Gas Industry Survey**

Air Resources Board

Mary D. Nichols, Chairman

1001 I Street • P.O. Box 2815
Sacramento, California 95812 • www.arb.ca.gov

Arnold Schwarzenegger
Governor

Linda S. Adams
Secretary for
Environmental Protection

February 17, 2009

Dear Sir or Madam:

The Air Resources Board (ARB) is requesting your participation in a survey of the oil and natural gas sector. This sector includes oil and gas extraction, processing, storage, and crude oil pipelines. The purpose of this survey is to improve our current estimate of greenhouse gas emissions in California. Gathering this information is part of our responsibilities under AB 32, the California Global Warming Solutions Act of 2006 (California Health and Safety Code section 38500 to 38599). Due to the wide range of operations in this sector, your participation is important to help us make accurate estimates.

We have designed the enclosed survey in a table format. We will also accept electronic data transfers and have included both Microsoft Excel and Access templates on the enclosed compact disc for your convenience. Please see the enclosed instructions for assistance and to locate staff who can answer specific questions.

Pursuant to California state law, **completion and submittal of this survey is a mandatory requirement.** The information being requested is for use by the ARB to develop a baseline greenhouse gas emissions inventory. This request for information is made pursuant to sections 39607, 39701, and 41511 of the California Health and Safety Code, and Title 17, California Code of Regulations, section 91100. These sections authorize the ARB to require the submission of information needed to estimate atmospheric emissions and to carry out its other statutory responsibilities.

All data will be protected as confidential in accordance with Title 17, California Code of Regulations, section 91000 to 91022 and the California Public Records Act (Government Code section 6250 et seq.).

We appreciate your participation and are available to provide assistance. Please submit the completed survey or electronic data transfers by **April 30, 2009**.

The energy challenge facing California is real. Every Californian needs to take immediate action to reduce energy consumption. For a list of simple ways you can reduce demand and cut your energy costs, see our website: <http://www.arb.ca.gov>.

Oil & Natural Gas Industry Survey

General Instructions

Mailing Address:

California Air Resources Board
P.O. Box 2815
Sacramento, California 95812
Attention: SSD / Oil & Gas Survey

February 2009

Overview

The Oil & Natural Gas Industry Survey has been designed to improve our estimates of greenhouse gas emissions in California. We are collecting data for the 2007 calendar year in order to accurately quantify equipment and operation processes. This survey is intended to be a one-time collection of information needed to develop a statewide inventory baseline. This survey is not being used as a compliance tool nor is it part of other mandatory reporting programs. This survey pertains to all upstream oil and natural gas facilities regardless of the size of the operation.

The following instructions have been provided to answer general questions pertaining to the individual survey tables. Since this survey covers a wide range of processes and operations, some companies may not need to complete every table.

Who should fill out this survey? Any owner or operator of the following facilities:

Oil or Natural Gas Extraction Facilities: includes any facility that extracts crude oil, natural gas, or both crude oil and natural gas.

Processing Facilities: includes any facility that processes crude oil or natural gas for use or distribution. This survey does not include refineries.

Crude Oil Transmission Facilities: includes crude oil pipelines or crude oil bulk loading operations. This includes ship, truck, or rail car loading facilities.

Storage Facilities: includes any facility that stores crude oil or natural gas, including underground natural gas storage facilities. This survey excludes crude oil tank farms that are located on refinery premises.

Submission Format. Paper forms, Microsoft Excel/Access files, or a combination of both paper and electronic files are acceptable. It is preferable to have all data submitted electronically. We have staff available to provide assistance or answer questions via e-mail or telephone.

Permitted and Non-Permitted Equipment. This survey covers both air district permitted and non-permitted equipment and includes equipment that is registered under the Portable Equipment Registration Program (PERP). Therefore, this survey includes equipment that is moved more than once annually and includes non-air district permitted equipment that is below 50-horsepower in rating.

Questions? Please contact any of the following ARB staff for questions or assistance:

|----------------|----------------|--|
| Stephanie Lee | (916) 324-8024 | sjlee@arb.ca.gov |
| Joseph Fischer | (916) 445-0071 | joseph.fischer@arb.ca.gov |
| Luis Leyva | (916) 323-1079 | lleyva@arb.ca.gov |

General Instructions

Table 1: Facility Description

This survey and the Facility Description Table are to be completed one time per geographically distinct facility (i.e., property boundary) by the entity that has operational control of the equipment. Even though a single operator may oversee operations at multiple facilities, please complete one survey per geographically distinct facility in order for us to determine the locations of equipment and processes.

PERP Equipment Owners: In the case where a company owns and operates equipment that is portable (e.g., PERP registered equipment such as drill rigs, portable gas compressors) please use the company headquarters contact information as the facility description.

Inside a facility there may be different Facility ID numbers provided by the local air district (e.g., multiple gas plants). Please provide the facility ID number where indicated. In some cases, a Facility ID number may not be available and a generic number must be created. One way to create a unique ID number is by using the first two letters of the local air district where the facility is located and a number. For example, a facility located in San Joaquin Valley APCD could use "SJ1, SJ2, etc."

Table 2: Facility Production

The Facility Production Table is designed to list active wells, production, and workover information for the 2007 calendar year. Enter information in the corresponding categories. Indicate the number of new wells drilled, completions, and workovers for the facility. For well workovers, enter the number that required tubing removal only. The number that did not require tubing removal is not required. Well cleanups (also referred to as well unloading) include fluids removal or well fracturing, where in either case fluids are removed from the well.

There is a separate column listed for underground natural gas storage facilities. Some of these facilities may intermittently produce crude oil with the natural gas. For simplification, please enter the volume of oil intermittently produced from the gas wells in Box 1 under the Natural Gas Storage Column, and enter the total volume of natural gas extracted in Box 2. For all companies, please enter the average natural gas composition and volume in Box 2.

For crude oil transmission facilities, a section has been included for length of pipeline and barrels of crude oil transported. These facilities are located after a production facility's LACT unit. A production facility does not enter information in Box 3.

Table 3: Facility Electrification

The Facility Electrification Table is designed to determine the level of electrification at crude oil and natural gas facilities. This information is important to understand the level of electrification within the sector. In some instances, a facility may generate or export its own electricity using Generators, Microturbines, Turbines, or Combined Heat and Power units. This includes electricity generated from standby or backup, on-site generators used in the event of power outages. Please indicate the amount of electricity generated, exported, and purchased. Estimated values are acceptable.

Table 4: Vapor Recovery and Flaring

Vapor recovery units consist of flares, thermal oxidizers, incinerators, and carbon adsorption units. These units control the release of hydrocarbons and may be designed for continuous or emergency operation. Table 4 is to be completed one time for each piece of equipment. In most cases, it may be easier to use one of the electronic templates.

Enter the throughput volume and rated size of the unit. For flares, enter the size in terms of btu/hour. For carbon adsorption units, enter the size in terms of the volume of the unit (height x diameter, etc.). In some cases the units are source tested for combustion or capture efficiency. If test data are available, please enter the efficiency where indicated.

For flares, thermal oxidizers, or incinerators, the average composition of the raw natural gas stream is required to enter the average gas composition and calculate the Carbon Mole Ratio. In many cases, a Gas Chromatograph (GC) analysis will have all of the values but the Carbon Mole Ratio must be calculated. If you are unsure on how to calculate these parameters, please call or submit a copy of a GC analysis and we will provide assistance. For convenience, the formula and a simplified example are shown below.

$$\text{Carbon Mole Ratio} = \sum \left[\frac{\text{mole \% hydrocarbon}}{100} \right] * \text{Number carbons in hydrocarbon}$$

The carbon mole ratio is calculated by adding up each of the mole percentages multiplied by the number of carbons in each species. The following is a simplified example:

| Species | Mole % |
|--|--------|
| Methane (CH ₄) | 80 |
| Ethane (C ₂ H ₂) | 15 |
| Propane (C ₃ H ₈) | 5 |

In this example, the carbon mole ratio would be calculated as follows:

$$\text{Carbon Mole Ratio} = (80/100)*(1) + (15/100)*(2) + (5/100)*(3) = \underline{1.25}$$

Table 5: Combustion Equipment

Table 5 is to be completed one time for each piece of combustion equipment. In most cases, it may be easier to use one of the electronic templates. This table is designed to accommodate a wide variety of external and internal combustion equipment. List both air district and nonair district permitted equipment. The table also includes a box to indicate if the equipment is included in the Portable Equipment Registration Program (PERP).

The purpose of this survey is to perform an accurate statewide inventory baseline. Therefore, this survey includes equipment that is moved more than once annually and includes non-air district permitted equipment that is below 50-horsepower in rating.

We have provided examples from which to choose and the option to specify equipment not included as an example. For engines powering compressors, enter a unique ID number that will be used with the natural gas compressor table (Table 12). This number will link the primary driver engine with the natural gas compressor.

Enter the manufacturer name where indicated. For some external combustion units (e.g., steam generators) it is acceptable to enter the name of the burner manufacturer if no other information is available. Enter the inspection frequency and indicate the frequency that involves testing with instruments, visual inspections, and the use of a third-party tester. Estimated inspection frequencies are acceptable.

Fuel Type and Fuel Properties

Under fuel type, list the primary and, if necessary, the secondary fuel type and volume as metered or calculated. The average Higher Heating Value and Liquid Fuel Density may be entered as standard values. If available, it is preferred to have actual values. A Gas Chromatograph (GC) analysis will provide the values for you.

In many cases, a GC analysis will list values or allow figures to be computed. If you are unsure on how to calculate these parameters, please call or submit a copy of a GC analysis and we will provide assistance. For convenience, the formula for Gaseous Fuel Molecular Weight is provided below.

$$\text{Gaseous Fuel MW} = \frac{1}{100} * \sum [(Mole \%_{\text{compound}}) * (MW_{\text{compound}})]$$

Where:

$Mole \%_{\text{compound}} = \text{indicated on GC analysis}$

$$MW_{\text{compound}} = \sum Weight_{\text{element}} * Coefficient_{\text{element}}$$

An example calculation for MW_{compound} : $CH_4 = (12*1) + (1*4) = \underline{16}$

Table 6: Component Counts

Table 6 provides a means of organizing components by natural gas, heavy crude, and light crude oil. If the actual number of components is unknown for a facility, it is acceptable to estimate the number using an average number of components per unit and then multiply by the total number of similar units. Table 6 has been designed similarly to local air district inspection and maintenance (I&M) programs and should be completed in conjunction with Table 8.

Table 7: Automated Control Devices

Automated Control Devices (i.e., pneumatic devices) control the flow of fluids or gases. The devices may be connected to a central vapor recovery system or plumbed back into a natural gas system (gas recovery). Table 7 has been designed similarly to local air district inspection and maintenance (I&M) programs and should be completed in conjunction with Table 8.

Typically, a single unit consists of one or more components. For example, a controller is used to control an actuator and the actuator is used to operate a block or turbine valve. Intermittent bleed devices are the actuators that only emit when actuated. Low bleed devices are the controllers that continuously emit less than 6 scfh. Figure 1 shows the common components. For additional information, please refer to the manufacturer catalogue or look at the EPA Natural Gas Star web site for topics on pneumatic devices, such as http://www.epa.gov/gasstar/documents/II_pneumatics.pdf

Due to design characteristics of the various units, indicate how many controllers and actuators are located at the facility and whether the devices are instrument air, gas, or electronically actuated. If the actual number of components is unknown for a facility, an estimated number of components are acceptable.

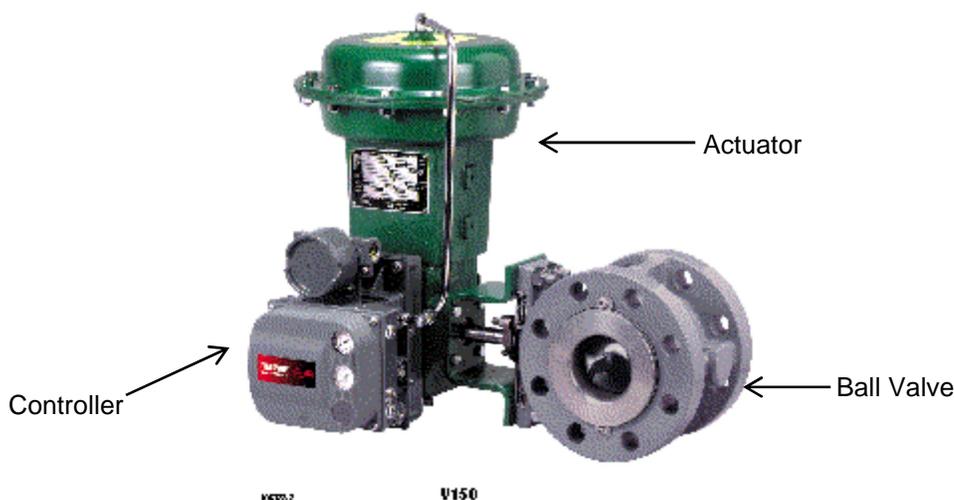

Figure 1. Typical Vee-Ball® Valves with Type 1052 Actuators and DVC6020 Digital Valve Controllers.

Table 8: Inspection and Maintenance Program

An inspection and maintenance (I&M) program requires a facility operator to routinely screen for and repair leaks from equipment at their facility. Many facilities are required to comply with local air district I&M programs. Table 8 is designed to list how companies comply with the various requirements. Check the box or boxes that indicate the stratum range that the facility tests to. Indicate a different leak threshold should the facility test to a different level within the indicated stratum range.

In many cases oil and gas facilities store I&M data electronically. This data may be provided by a third-party tester, etc. If you have I&M data available in electronic format, submittal of the information would help prevent overestimating emissions or relying on national averages. Please submit electronic I&M program data in any Microsoft Excel or Access format. Submittal of hard copy data is not required.

Table 9: Natural Gas Dehydration

Natural Gas Dehydration units are used to remove moisture from a natural gas stream. The most common types are glycol and desiccant units. Please complete one table for each unit. In some cases, it may be simpler to use one of the electronic templates.

Enter the average input and output gas composition and enter the estimated volume of liquids removed for the 2007 calendar year. Indicate if the unit is connected to a vapor recovery system and if available, enter the control efficiency of the vapor recovery system.

For glycol units, there are fields provided for average circulation rate, pump type, and stripping gas. Check each box and fill in the appropriate fields that apply. Similarly, a separate box is included for desiccant units. For desiccant units, indicate the volume of the unit (height x diameter, etc.) and indicate the average remaining volume that exists after the unit is packed with desiccant (a typical value is 45 percent). If you can estimate a more precise percent packed volume value, please provide where indicated.

Table 10: Natural Gas Sweetening or Acid Gas Removal

Natural gas sweetening and acid gas removal units are used to condition gas for combustion or resale. Table 10 is designed to accommodate a large variety of units. In some cases all fields may not need to be completed. Please complete one table for each particular unit. It may be convenient to use one of the electronic templates.

Enter the average input and output gas composition. Enter the Higher Heating Value of the input and output gas streams (average values are acceptable).

In some units CO₂ is mixed with waste gas and sent to an incinerator or vented. Indicate the method of CO₂ disposal. For units that require regular solid material replacement, indicate the average remaining volume that exists after the unit is packed with material

(a typical value is 45 percent). If you can estimate a more precise percent packed volume value, please enter the value where indicated.

Table 11: Other Natural Gas Processing

Table 11 is for listing other processing units used for removing natural gas liquids other than CO₂, H₂S, and water. Please complete one table for each particular unit. It may be convenient to use one of the electronic templates.

Enter the average input and output gas composition and average volume of liquids removed. Indicate if the unit is connected to a vapor recovery system and list the estimated control efficiency of the vapor recovery system where indicated. In some cases it may be necessary to estimate total throughput.

Table 12: Natural Gas Compressors

Table 12 is designed to cover a variety of natural gas compressors. Please complete one table for each individual unit. This table should be completed using the unique compressor ID number from Table 5. This will link the compressor with the primary driver engine.

The primary types of compressors are reciprocating, centrifugal, rotary, and integral. In an integral unit, the primary driver engine and compressor are combined into a single unit. In other cases, the primary driver engine (internal combustion or turbine engine) are separated by a drive shaft.

For centrifugal units, indicate the type and number of wet or dry seals under the corresponding seal type. Wet seals, also known as lubricated seals, use oil as a means to retain internal compressor pressure. Wet seal units may be identified as having a separate "seal oil" pump used to maintain seal pressure. Dry seal compressors may be identified as having a separate "seal gas" outlet for gas to escape the compressor. Both wet and dry seal compressors will have a lube oil pump.

Indicate the primary driver and starter type. Enter the average discharge and idle pressure in units of pounds per square inch and the discharge temperature in degrees F. The discharge pressure is the average pressure inside the unit during operation. The idle pressure is the average pressure when the unit is idle.

Indicate the hours of usage, number of start-ups and blowdowns, and the inspection frequency. The maintenance frequency is the number of times the unit had to be disassembled to replace valves, seals, or packing. If actual numbers are not available, estimated values are acceptable.

Table 13: Pipelines

Table 13 pertains to natural gas gathering systems found within an extraction or underground natural gas storage facility (prior to a gas meter). Enter, or estimate, the length of the natural gas pipeline gathering system where indicated. Enter estimated volumes depicting how gas is handled for system maintenance or modification activities.

Table 13 also pertains to crude oil transmission and natural gas pipeline pigging operations conducted at the facility. Enter, or estimate how many times a pig was sent or received for the 2007 calendar year. Please indicate whether the operations were for crude oil or natural gas pipeline.

Table 14: Crude Oil or Natural Gas Separation Units

Table 14 is designed to accommodate a variety of crude oil and natural gas separation units. There are a variety of units in this category. We have included a list of some examples and an option to specify units at the facility that may go by a different name. Please complete one table per individual unit. In some cases, it may be more convenient to use one of the electronic templates provided.

Enter the Working, Breathing, and Flashing Losses as calculated with *TANKS* (US Environmental Protection Agency) or similar software or calculation, or enter the values as listed on the district permit. If the calculations have not been performed and are not required by the local air district, please leave these fields blank.

In order to prevent double counting of components, indicate if the separation unit components were included in Table 6 and indicate if the unit is controlled by a vapor recovery system.

Table 15: Crude Oil Separation Units Sumps or Pits

Crude oil separation sumps or pits are used to separate water from crude oil and may be used for permanent or emergency purposes. Indicate whether the sump is primary, secondary, or tertiary and list the average crude oil API number and number of days the sump or pit was in use. In some cases, a sump may be used in conjunction with a cover or a vapor collection system. Please indicate if either type of system is used.

Table 16: Crude Oil Storage Tanks

Table 16 is designed to accommodate fixed roof and floating roof crude oil storage tanks. Please complete one table per storage tank. In some cases, it may be convenient to use one of the electronic templates.

Enter the tank type, size, and average crude oil API number. Enter the number of degassing events that required the tank to be completely emptied of liquid and vapor.

For fixed roof and floating roof tanks, enter the Working, Breathing, and Flashing Losses as reported to the local air district. If available, enter the average methane and carbon dioxide values as depicted in a Gas Chromatograph analysis. If information is not available for methane or carbon dioxide concentration, please leave those fields blank.

Appendix B: Emission Calculation Methodologies and Corresponding Emission Factors

**California Air Resources Board
Oil and Gas Industry Survey**

**Emission Calculation Methodologies
and
Corresponding Emission Factors**

Appendix B details the individual equations and emission factors used to calculate greenhouse gas emissions. Default mole percent of CH₄ and CO₂ are 78.8 percent and 3 percent, respectively (API, 2004). For equipment that has vapor recovery, CO₂ and CH₄ emissions are reduced by the vapor recovery efficiency before conversion to CO₂e. All CO₂, CH₄, and N₂O values are multiplied by their corresponding GWP (1 for CO₂, 21 for CH₄, and 310 for N₂O) to get the CO₂e number.

Method 1 – Active Wells

The 2007 Industry survey separates crude oil into four categories: ultra-heavy, heavy, light, and ultra-light. It also separates gas wells by dry gas fields and gas storage fields. When calculating GHG emissions from active wells, the categories ultra-heavy and heavy crude use the emission factor “heavy crude”, light and ultra-light crude use the emission factor “light crude”, and dry gas and gas storage use the emission factor “natural gas”.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{CO}_2 \text{ EF}) * (\text{Number}) * (\text{CO}_2 \text{ Mole Fraction} \backslash 0.03)$$

Where

CO₂ EF = See Table 1

Number = Number of active wells

CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)

Data Requirements

1. Number of active wells
2. Mole % CO₂

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ EF}) * (\text{Number}) * (\text{CH}_4 \text{ Mole Fraction} \backslash 0.788)$$

Where

CH₄ EF = See Table 1

Number = Number of active wells

CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)

Data Requirements

1. Number of active wells
2. Mole % CH₄

Table 1: Wellheads

| Type | CH ₄ (tonnes/well-year) | % Methane Assumption | CO ₂ (tonnes/well-year) | % CO ₂ Assumption |
|-------------|---------------------------------------|-------------------------|---------------------------------------|---------------------------------|
| Natural Gas | 0.157 ¹ | 78.8 | 1.644E-02 ¹ | 3 |
| Light Crude | 0.108 ¹ | 78.8 | 1.128E-02 ¹ | 3 |
| Heavy Crude | 4.568E-03 ¹ | 78.8 | 4.782E-04 | 3 |

1. API (2004)

Method 2 – Well Cellars

The 2007 Industry survey separates crude oil into four categories: ultra-heavy, heavy, light, and ultra-light. When calculating GHG emissions from well cellars, an average dimension of 6 feet by 6 feet is used (Kern County APCD,1990). Additionally, the categories ultra-heavy and heavy crude use the emission factor “heavy crude”, light and ultra-light crude use the emission factor “light crude”.

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ EF}) * (\text{Number})$$

Where

CH₄ EF = See Table 2

Number = number of well cellars

Data Requirements

1. Number of well cellars

Table 2: Well Cellars

| Type | CH ₄ (tonnes/well cellar-year) |
|-------------|--|
| Light Crude | 0.170 ¹ |
| Heavy Crude | 0.125 ¹ |

1. Kern County APCD (1990)

Method 3 – New Wells Drilled

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ EF}) * (\text{Number})$$

Where

CH₄ EF = See Table 3

Number = Number of wells drilled

Data Requirements

1. Number of wells drilled

Table 3: New Wells Drilled

| Type | CH ₄ (tonnes/well-year) |
|-------------|---------------------------------------|
| Natural Gas | |
| Light Crude | |
| Heavy Crude | |

Method 4 – Well Workovers and Cleanups

The calculations for well workovers and cleanups assume an average well depth, casing diameter, and tubing diameter and that only one well volume is released. For crude oil wells, the volume of gas released is assumed to be the space between the casing and tubing. For natural gas wells, the volume of gas released is assumed to be the entire volume of the casing.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{EF}) * (\text{CO}_2 \text{ Mole Fraction}) * (\text{D}) * (\text{Events})$$

Where

EF = See Table 4

CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)

D = (molar volume)*(Molecular Weight CO₂)*(tonne/2204.6lb)

Molar Volume = (1 lbmole gas)/(379.3 scf gas)

Molecular Weight CO₂ = (44 lb CO₂)/(lbmole CO₂)

Events = Number of well workovers and cleanups

Data Requirement

1. Number of well workovers and cleanups
2. Mole % CO₂

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{EF}) * (\text{CH}_4 \text{ Mole Fraction}) * (\text{D}) * (\text{Events})$$

Where

EF = See Table 4

CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)

D = (molar volume)*(Molecular Weight CH₄)*(tonne/2204.6lb)

Molar Volume = (1 lbmole gas)/(379.3 scf gas)

Molecular Weight CH₄ = (16 lb CH₄)/(lbmole CH₄)

Events = Number of well workovers and cleanups

Data Requirement

1. Number of well workovers and cleanups
2. Mole % CH₄

Emission Factor Calculation (Listed in Table 4)

$$\text{Equation} = [(V) * (P_1) * (T_2)] / [(P_2) * (T_1)]$$

Where

V = volume of well

P₁ = shut-in pressure (psia) of well

P₂ = 14.7 psia (standard surface pressure)

T₁ = temperature in well at shut-in pressure

T₂ = 60°F (standard surface temperature)

Assumptions

Depth = 5000 ft

Casing Diameter = 7 in

Tubing Diameter = 2.875 in

P₁ = 100 psia

T₁ = 60°F

Table 4: Well Workovers and Cleanups

| Type | CH ₄ /CO ₂ (scf/event) |
|-------------|---|
| Natural Gas | 9090.256 |
| Light Crude | 7556.855 |
| Heavy Crude | 7556.855 |

Method 5 – Well Completions

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ EF}) * (\text{Number})$$

Where

CH₄ EF = See Table 5

Number = Number of wells completed

Data Requirements

1. Number of wells completed

Table 5: Well Completions

| Type | CH ₄ (tonnes/well) |
|-------------|----------------------------------|
| Natural Gas | |
| Light Crude | |
| Heavy Crude | |

Method 6 – Flares, Incinerators, Thermal Oxidizers

CO₂ and CH₄ emission calculations based on the following mass balance equations (API, 2004).

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{Combustion Emissions}) + (\text{Vented Emissions})$$

$$\text{Combustion emissions (tonnes/year)} = (\text{Throughput}) * (\text{Carbon Mole Ratio}) * (\text{Combustion Efficiency}) * (D)$$

Where

Throughput = volume of gas flared (scf gas/year)

Carbon Mole Ratio = $\sum[(\text{mole \% hydrocarbon}/100) * (\# \text{ carbons in hydrocarbon})]$

D = (molar volume) * (Molecular Weight CO₂) * (tonne/2204.6lb)

Molar Volume = (1 lbmole gas)/(379.3 scf gas)

Molecular Weight CO₂ = (44 lb CO₂)/(lb mole CO₂)

Data Requirements

1. Throughput (scf gas/year)
2. Combustion Efficiency (98% will be assumed if no combustion efficiency is supplied)
3. Carbon Mole Ratio of gas

$$\text{Vented emissions (tonnes/year)} = (\text{Throughput}) * (\text{CO}_2 \text{ Mole Fraction}) * (D)$$

Where

Throughput = volume of gas flared (scf/year)

CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)

D = (molar volume) * (Molecular Weight CO₂) * (tonne/2204.6lb)

Molar Volume = (1 lbmole gas)/(379.3 scf gas)

Molecular Weight CO₂ = (44 lb CO₂)/(lb mole CO₂)

Data Requirements

1. Throughput (scf/year)
2. Mole % CO₂

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{Throughput}) * (\text{CH}_4 \text{ Mole Fraction}) * (\% \text{ Residual CH}_4) * (D)$$

Where

$$\begin{aligned} \text{Throughput} &= \text{volume of gas flared (scf gas/year)} \\ \text{CH}_4 \text{ Mole Fraction} &= (\text{lbmole CH}_4) / (\text{lbmole gas}) \\ \% \text{ Residual CH}_4 &= 100 - (\text{Combustion Efficiency}) \\ D &= (\text{molar volume}) * (\text{Molecular Weight CH}_4) * (\text{tonne}/2204.6\text{lb}) \\ \text{Molar Volume} &= (1 \text{ lbmole gas}) / (379.3 \text{ scf gas}) \\ \text{Molecular Weight CH}_4 &= (16 \text{ lb CH}_4) / (\text{lb mole CH}_4) \end{aligned}$$

Data Requirements

1. Throughput (scf gas/year)
2. Combustion Efficiency (98% will be assumed if no combustion efficiency is supplied)
3. Mole % CH₄

$$\text{N}_2\text{O emissions (tonnes/year)} = (\text{Throughput}) * (\text{N}_2\text{O Emission Factor})$$

Where

$$\begin{aligned} \text{Throughput} &= \text{volume of gas flared (scf gas/year)} \\ \text{N}_2\text{O Emission Factor} &= 1\text{E-}10 \text{ tonnes/scf gas (INGAA, 2005)} \end{aligned}$$

Data Requirements

1. Throughput (scf/year)

Method 7 – Carbon Adsorbers

The vented emission calculation for carbon adsorbers assumes that 100% of the methane in the gas stream passes through the adsorber.

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{Throughput}) * (\text{CH}_4 \text{ Mole Fraction}) * (D)$$

Where

$$\begin{aligned} \text{Throughput} &= \text{volume of gas (scf gas/year)} \\ \text{CH}_4 \text{ Mole Fraction} &= (\text{lbmole CH}_4) / (\text{lbmole gas}) \\ D &= (\text{molar volume}) * (\text{Molecular Weight CH}_4) * (\text{tonne}/2204.6\text{lb}) \\ \text{Molar Volume} &= (1 \text{ lbmole gas}) / (379.3 \text{ scf gas}) \\ \text{Molecular Weight CH}_4 &= (16 \text{ lb CH}_4) / (\text{lbmole CH}_4) \end{aligned}$$

Data Requirements

1. Throughput (scf gas/year)
2. Mole % CH₄

Method 8 – Mass Balance Fuel Consumption

CO₂ and CH₄ combustion calculations for all combustion equipment (except flares, incinerators, and thermal oxidizers) are based on the following mass balance equations (INGAA, 2005).

Gaseous Fuels

CO₂ emissions (tonnes/year) = (Combustion Emissions) + (Vented Emissions)

Combustion Emissions (tonnes/year) = (Fuel Use)*(MW_{fuel})*(Carbon Weight %)*(COX)*(D)

Where

Fuel Use = fuel use (scf/year)

MW_{fuel} = molecular weight of fuel (lb fuel/lbmole fuel)

Carbon Weight % = (lb C/lb fuel)

COX = fraction of fuel oxidized (assumed to be 99%)

D = (molar volume)*(1/MW_C)*(lbmole CO₂/lbmole C)*(MW_{CO₂})*(tonne/2204.6 lb)

Molar Volume = (1 lbmole gas)/(379.3 scf gas)

MW_C = (12 lb C)/(lb mole C)

MW_{CO₂} = (44 lb CO₂)/(lb mole CO₂)

Data Requirements

1. Fuel Use (scf gas/year)
2. Molecular Weight of fuel
3. Carbon Weight % of fuel
4. COX (if different from assumed value of 99%)

Vented Emissions (tonnes/year) = (Fuel Use)*(1-COX)*(CO₂ Mole Fraction)*(D)

Where

Fuel Use = fuel use (scf/year)

COX = fraction of fuel oxidized (assumed to be 99%)

D = (molar volume)*(MW_{CO₂})*(tonne/2204.6 lb)

Molar Volume = (1 lbmole gas)/(379.3 scf gas)

MW_{CO₂} = (44 lb CO₂)/(lb mole CO₂)

Data Requirements

1. Fuel Use (scf gas/year)
2. COX (if different from assumed value of 99%)
3. Mole % CO₂

CH₄ emissions (tonnes/year) = (Fuel Use)*(CH₄ Mole Fraction)*(1-COX)*(D)

Where

Fuel Use = fuel use (scf/year)

COX = fraction of fuel oxidized (assumed to be 99%)

D = (molar volume)*(MW_{CH₄})*(tonne/2204.6 lb)

Molar Volume = (1 lbmole gas)/(379.3 scf gas)

MW_{CH₄} = (16 lb CH₄)/(lb mole CH₄)

Data Requirements

1. Fuel Use (scf gas/year)
2. COX (if different from assumed value of 99%)
3. Mole % CH₄

Liquid Fuels

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{Fuel Use}) * (\text{Fuel Density}) * (\text{Carbon Weight \%}) * (\text{COX}) * (\text{D})$$

Where

Fuel Use = fuel use (gal/year)

Fuel Density = density of fuel (lb fuel/gal fuel)

Carbon Weight % = (lb C/lb fuel)

COX = fraction of fuel oxidized (assumed to be 99%)

$D = (1/MW_C) * (\text{lbmole CO}_2/\text{lbmole C}) * (MW_{\text{CO}_2}) * (\text{tonne}/2204.6 \text{ lb})$

$MW_C = (12 \text{ lb C})/(\text{lb mole C})$

$MW_{\text{CO}_2} = (44 \text{ lb CO}_2)/(\text{lb mole CO}_2)$

Data Requirements

1. Fuel Use (gal fuel/year)
2. Fuel Density
3. Carbon Weight % of fuel
4. COX (if different from assumed value of 99%)

Method 9 - Equipment Specific

Combustion calculations for equipment with equipment specific emission factors. This method is used only for those equipment that have emission factors listed in Table 6.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{Fuel Use}) * (\text{HHV}) * (\text{CO}_2 \text{ Emission Factor}) * (10^{-6})$$

Where

Fuel Use = volume of fuel used (scf/year or gal/year)

HHV = Higher Heating Value of fuel (Btu/scf or Btu/gal)

CO₂ Emission Factor = See Table 6

Data Requirement

1. Type of equipment
2. Fuel Use (scf/year or gal/year)
3. HHV of fuel (Btu/scf or Btu/gal)

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{Fuel Use}) * (\text{HHV}) * (\text{CH}_4 \text{ Emission Factor}) * (10^{-6})$$

Where

Fuel Use = volume of fuel used (scf/year or gal/year)

HHV = Higher Heating Value of fuel (Btu/scf or Btu/gal)

CH₄ Emission Factor = See Table 6

Data Requirement

1. Type of equipment
2. Fuel Use (scf/year or gal/year)
3. HHV of fuel (Btu/scf or Btu/gal)

$$\text{N}_2\text{O emissions (tonnes/year)} = (\text{Fuel Use}) * (\text{HHV}) * (\text{N}_2\text{O Emission Factor}) * (10^{-6})$$

Where

Fuel Use = volume of fuel used (scf/year or gal/year)

HHV = Higher Heating Value of fuel (Btu/scf or Btu/gal)

N₂O Emission Factor = See Table 6

Data Requirement

1. Type of equipment
2. Fuel Use (scf/year or gal/year)
3. HHV of fuel (Btu/scf or Btu/gal)

Table 6: Combustion Equipment

| Equipment Type | CO ₂ (tonnes/MMBtu) | CH ₄ (tonnes/MMBtu) | N ₂ O (tonnes/MMBtu) |
|---------------------------|-----------------------------------|-----------------------------------|------------------------------------|
| Natural Gas Fired | | | |
| Boilers | 0.0534 ² | 1.023E-06 ⁴ | 9.8E-07 ⁵ |
| Steam Generators | 0.0534 ² | 1.023E-06 ⁴ | 9.8E-07 ⁵ |

Method 10 – Fuel Based

Combustion calculations for equipment using fuel based emission factors listed in Table 7.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{Fuel Use}) * (\text{HHV}) * (\text{CO}_2 \text{ Emission Factor}) * (10^{-6})$$

Where

Fuel Use = volume of fuel used (scf/year or gal/year)
 HHV = Higher Heating Value of fuel (Btu/scf or Btu/gal)
 CO₂ Emission Factor = See Table 7

Data Requirement

1. Fuel Use (scf/year or gal/year)
2. HHV of fuel (Btu/scf or Btu/gal)

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{Fuel Use}) * (\text{HHV}) * (\text{CH}_4 \text{ Emission Factor}) * (10^{-6})$$

Where

Fuel Use = volume of fuel used (scf/year or gal/year)
 HHV = Higher Heating Value of fuel (Btu/scf or Btu/gal)
 CH₄ Emission Factor = See Table 7

Data Requirement

1. Fuel Use (scf/year or gal/year)
2. HHV of fuel (Btu/scf or Btu/gal)

$$\text{N}_2\text{O emissions (tonnes/year)} = (\text{Fuel Use}) * (\text{HHV}) * (\text{N}_2\text{O Emission Factor}) * (10^{-6})$$

Where

Fuel Use = volume of fuel used (scf/year or gal/year)
 HHV = Higher Heating Value of fuel (Btu/scf or Btu/gal)
 N₂O Emission Factor = See Table 7

Data Requirement

1. Fuel Use (scf/year or gal/year)
2. HHV of fuel (Btu/scf or Btu/gal)

Table 7: Fuels

| Fuel Type | CO ₂ (tonnes/MMBtu) | CH ₄ (tonnes/MMBtu) | N ₂ O (tonnes/MMBtu) |
|---------------------------|-----------------------------------|-----------------------------------|------------------------------------|

2. ARB Mandatory Reporting (2008) Distillate Fuel Oil #1, #2, #4

Method 11 – Components

Components for other equipment (e.g. storage tanks) will be backed out of this calculation.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{CO}_2 \text{ EF}) * (\text{Number}) * (\text{CO}_2 \text{ Mole Fraction}/0.03)$$

Where

CO₂ EF = See Table 8

Number = Number of components

CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)

Data Requirements

1. Mole % CO₂
2. Number of components

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ EF}) * (\text{Number}) * (\text{CH}_4 \text{ Mole Fraction}/0.788)$$

Where

CH₄ EF = See Table 8

Number = Number of components

CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)

Data Requirements

1. Mole % CH₄
2. Number of components

Table 8: Components

| Component Type | Natural Gas ¹ | Light Crude ² (tonnes/component-year) | Heavy Crude ³ |

Method 12 – Automated Control Devices

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{CO}_2 \text{ Emission Factor}) * (\text{CO}_2 \text{ Mole Fraction}/0.03) * (\# \text{ Devices})$$

Where

CO₂ Emission Factor = See Table 9

CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)

Devices = Number of automated control devices

Data Requirements

1. Mole % CO₂
2. Number of automated control devices

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ Emission Factor}) * (\text{CH}_4 \text{ Mole Fraction}/0.788) * (\# \text{ Devices})$$

Where

CH₄ Emission Factor = See Table 9

CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)

Devices = Number of automated control devices

Data Requirements

1. Mole % CH₄
2. Number of automated control devices

Table 9: Automated Control Devices

| Device Type | CH ₄ (tonnes/device-year) | % Methane Assumption | CO ₂ (tonnes/device-year) | % CO ₂ Assumption |

1. API (2004); 2. EPA (2003a); 3. EPA (1996a)

Method 13 – Natural Gas Dehydration (Glycol Units)

Vented emissions from glycol dehydrators (CEC 2006).

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{Throughput}) * (\text{EF} \setminus 0.90) * (\text{CO}_2 \text{ Mole Fraction}) * D$$

Where

$$\text{EF} = [(0.0066) * (\text{GCR}) * (\text{P}) * (\text{GAP})] + (\text{SG})$$

$$\text{EF units} = (\text{Mcf CH}_4/\text{year per MMcf gas throughput/day})$$

$$\text{EF conversion} = [(1 \text{ year}) / (365 \text{ days})] * [(1 \text{ MMcf gas}) / (10^6 \text{ scf gas})] * [(1000 \text{ scf CH}_4) / (1 \text{ Mcf CH}_4)]$$

$$0.90 = \% \text{ methane used to create EF (lbmole CH}_4) / (\text{lbmole gas})$$

$$\text{GCR} = \text{glycol circulation rate (gph)}$$

$$\text{P} = \text{flash tank or contactor pressure (psia)}$$

$$\text{GAP} = 2.5 \text{ if a gas assist pump is installed or } 1.0 \text{ if there is no gas assist pump}$$

$$\text{SG} = 0.245 \text{ if stripping gas is used or } 0 \text{ if no stripping gas is used}$$

$$\text{CO}_2 \text{ Mole Fraction} = (\text{lbmole CO}_2) / (\text{lbmole gas})$$

$$D = (\text{CH}_4 \text{ Density}) * (\text{lb}/453.5 \text{ grams}) * (1/\text{MW}_{\text{CH}_4}) * (\text{MW}_{\text{CO}_2}) * (\text{tonne}/2204.6\text{lb}) * (\text{EF conversion})$$

$$\text{CH}_4 \text{ Density} = (19.2 \text{ grams}) / (\text{scf CH}_4)$$

$$\text{MW}_{\text{CH}_4} = (16 \text{ lb CH}_4) / (\text{lbmole CH}_4)$$

$$\text{MW}_{\text{CO}_2} = (44 \text{ lb CO}_2) / (\text{lbmole CO}_2)$$

Data Requirements

1. Throughput (scf/year)
2. Input Mole % CO₂
3. Glycol circulation rate (gallons/hour)
4. Flash tank pressure (psia)
5. Contactor pressure (psia)
6. Gas assist pump installation
7. Stripping gas use

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{Throughput}) * (\text{EF} \setminus 0.90) * (\text{CH}_4 \text{ Mole Fraction}) * D$$

Where

$$\text{EF} = [(0.0066) * (\text{GCR}) * (\text{P}) * (\text{GAP})] + (\text{SG})$$

$$\text{EF units} = (\text{Mcf CH}_4/\text{year per MMcf gas throughput/day})$$

$$\text{EF conversion} = [(1 \text{ year}) / (365 \text{ days})] * [(1 \text{ MMcf gas}) / (10^6 \text{ scf gas})] * [(1000 \text{ scf CH}_4) / (1 \text{ Mcf CH}_4)]$$

$$0.90 = \% \text{ methane used to create EF (lbmole CH}_4) / (\text{lbmole gas})$$

$$\text{GCR} = \text{glycol circulation rate (gph)}$$

$$\text{P} = \text{flash tank or contactor pressure (psia)}$$

$$\text{GAP} = 2.5 \text{ if a gas assist pump is installed or } 1.0 \text{ if there is no gas assist pump}$$

$$\text{SG} = 0.245 \text{ if stripping gas is used or } 0 \text{ if no stripping gas is used}$$

$$\text{CH}_4 \text{ Mole Fraction} = (\text{lbmole CH}_4) / (\text{lbmole gas})$$

$$D = (\text{CH}_4 \text{ Density}) * (\text{lb}/453.5 \text{ grams}) * (\text{tonne}/2204.6\text{lb}) * (\text{EF conversion})$$

$$\text{CH}_4 \text{ Density} = (19.2 \text{ grams}) / (\text{scf CH}_4)$$

Data Requirements

1. Throughput (scf/year)
2. Input Mole % CH₄
3. Glycol circulation rate (gallons/hour)
4. Flash tank pressure (psia)
5. Contactor pressure (psia)
6. Gas assist pump installation
7. Stripping gas use

Method 14 – Natural Gas Dehydration (Desiccant Units)

Vented emissions from refilling desiccant (EPA 2003b).

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{EF}) * (\text{CO}_2 \text{ Mole Fraction}) * \text{D}$$

Where

$$\text{EF} = [(P_2) * (G) * (365 \text{ days/yr}) * (V)] / [(P_1) * (T)]$$

$$P_1 = 14.7 \text{ psia (atmospheric pressure)}$$

$$P_2 = (\text{Pressure of Gas (psig)}) + 14.7$$

$$G = \% \text{ of Packed Vessel Volume that is Natural Gas}$$

$$V = \text{Volume of Dehydrator (ft}^3\text{)}$$

$$T = \text{Frequency of Desiccant Replacement (days)}$$

$$\text{CO}_2 \text{ Mole Fraction} = (\text{lbmole CO}_2) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CO}_2) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CO}_2 = (44 \text{ lb CO}_2) / (\text{lbmole CO}_2)$$

Data Requirements

1. Mole % CO₂
2. Volume of Dehydrator
3. Pressure of Natural Gas
4. Frequency of Desiccant Replacement
5. % of Packed Vessel Volume that is Natural Gas (45% will be assumed if no value is provided)

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{EF}) * (\text{CH}_4 \text{ Mole Fraction}) * \text{D}$$

Where

$$\text{EF} = [(P_2) * (G) * (365 \text{ days/yr}) * (V)] / [(P_1) * (T)]$$

$$P_1 = 14.7 \text{ psia (atmospheric pressure)}$$

$$P_2 = (\text{Pressure of Gas (psig)}) + 14.7$$

$$G = \% \text{ of Packed Vessel Volume that is Natural Gas}$$

$$V = \text{Volume of Dehydrator (ft}^3\text{)}$$

$$T = \text{Frequency of Desiccant Replacement (days)}$$

$$\text{CH}_4 \text{ Mole Fraction} = (\text{lbmole CH}_4) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CH}_4) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CH}_4 = (16 \text{ lb CH}_4) / (\text{lbmole CH}_4)$$

Data Requirements

1. Mole % CH₄
2. Volume of Dehydrator
3. Pressure of Natural Gas
4. Frequency of Desiccant Replacement
5. % of Packed Vessel Volume that is Natural Gas (45% will be assumed if no value is provided)

Method 15 – Natural Gas Dehydration Fugitive Emissions

Fugitive emission calculations using mass balance.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{Mass Balance}) - (\text{Vented Emissions})$$

Where

$$\text{Mass Balance} = D * [(\text{Input}) * (\text{In CO}_2 \text{ Mole Fraction}) - (\text{Output}) * (\text{Out CO}_2 \text{ Mole Fraction})]$$

$$\text{Vented Emissions} = \text{Method 13 or Method 14}$$

$$\text{Input} = \text{Input volume (scf/year)}$$

$$\text{Output} = \text{Output volume (scf/year)}$$

$$\text{In CO}_2 \text{ Mole Fraction} = \text{Input CO}_2 \text{ Mole Fraction} = (\text{lbmole CO}_2) / (\text{lbmole gas})$$

$$\text{Out CO}_2 \text{ Mole Fraction} = \text{Output CO}_2 \text{ Mole Fraction} = (\text{lbmole CO}_2) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CO}_2) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CO}_2 = (44 \text{ lb CO}_2) / (\text{lbmole CO}_2)$$

Data Requirements

1. Input volume (scf/year)
2. Output volume (scf/year)
3. Input Mole % CO₂
4. Output Mole % CO₂
5. Vented Emissions

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{Mass Balance}) - (\text{Vented Emissions})$$

Where

$$\text{Mass Balance} = D * [(\text{Input}) * (\text{In CH}_4 \text{ Mole Fraction}) - (\text{Output}) * (\text{Out CH}_4 \text{ Mole Fraction})]$$

$$\text{Vented Emissions} = \text{Method 13 or Method 14}$$

$$\text{Input} = \text{Input volume (scf/year)}$$

$$\text{Output} = \text{Output volume (scf/year)}$$

$$\text{In CH}_4 \text{ Mole Fraction} = \text{Input CH}_4 \text{ Mole Fraction} = (\text{lbmole CH}_4) / (\text{lbmole gas})$$

$$\text{Out CH}_4 \text{ Mole Fraction} = \text{Output CH}_4 \text{ Mole Fraction} = (\text{lbmole CH}_4) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CH}_4) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CH}_4 = (16 \text{ lb CH}_4) / (\text{lbmole CH}_4)$$

Data Requirements

1. Input volume (scf/year)
2. Output volume (scf/year)
3. Input Mole % CH₄
4. Output Mole % CH₄
5. Vented Emissions

Method 16 –Natural Gas Sweetening/Acid Gas Removal (Solid Material Units)

Vented emissions from refilling solid material (EPA 2003b).

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{EF}) * (\text{CO}_2 \text{ Mole Fraction}) * \text{D}$$

Where

$$\text{EF} = [(P_2) * (G) * (365 \text{ days/yr}) * (V)] / [(P_1) * (T)]$$

$$P_1 = 14.7 \text{ psia (atmospheric pressure)}$$

$$P_2 = (\text{Pressure of Gas (psig)}) + 14.7$$

$$G = \% \text{ of Packed Vessel Volume that is Natural Gas}$$

$$V = \text{Volume of Unit (ft}^3\text{)}$$

$$T = \text{Frequency of Solid Material Replacement (days)}$$

$$\text{CO}_2 \text{ Mole Fraction} = (\text{lbmole CO}_2) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CO}_2) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CO}_2 = (44 \text{ lb CO}_2) / (\text{lbmole CO}_2)$$

Data Requirements

1. Input Mole % CO₂
2. Volume of unit
3. Pressure of Natural Gas
4. Frequency of solid material replacement
5. % of Packed Vessel Volume that is Natural Gas (45% will be assumed if no value is provided)

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{EF}) * (\text{CH}_4 \text{ Mole Fraction}) * \text{D}$$

Where

$$\text{EF} = [(P_2) * (G) * (365 \text{ days/yr}) * (V)] / [(P_1) * (T)]$$

$$P_1 = 14.7 \text{ psia (atmospheric pressure)}$$

$$P_2 = (\text{Pressure of Gas (psig)}) + 14.7$$

$$G = \% \text{ of Packed Vessel Volume that is Natural Gas}$$

$$V = \text{Volume of Unit (ft}^3\text{)}$$

$$T = \text{Frequency of Solid Material Replacement (days)}$$

$$\text{CH}_4 \text{ Mole Fraction} = (\text{lbmole CH}_4) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CH}_4) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CH}_4 = (16 \text{ lb CH}_4) / (\text{lbmole CH}_4)$$

Data Requirements

1. Input Mole % CH₄
2. Volume of unit
3. Pressure of Natural Gas
4. Frequency of solid material replacement
5. % of Packed Vessel Volume that is Natural Gas (45% will be assumed if no value is provided)

Method 17 – Natural Gas Sweetening/Acid Gas Removal Fugitive Emissions (Solid Material Units)

Fugitive emission calculations using mass balance.

CO₂ emissions (tonnes/year) = (Mass Balance) – (Vented Emissions)

Where

Mass Balance = $D * [(Input) * (In\ CO_2\ Mole\ Fraction) - (Output) * (Out\ CO_2\ Mole\ Fraction)]$

Vented Emissions = Method 16

Input = Input volume (scf/year)

Output = Output volume (scf/year)

In CO₂ Mole Fraction = Input CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)

Out CO₂ Mole Fraction = Output CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)

D = (molar volume) * (Molecular Weight CO₂) * (tonne/2204.6lb)

Molar Volume = (1 lbmole gas)/(379.3 scf gas)

Molecular Weight CO₂ = (44 lb CO₂)/(lbmole CO₂)

Data Requirements

1. Input volume (scf/year)
2. Output volume (scf/year)
3. Input Mole % CO₂
4. Output Mole % CO₂
5. Vented Emissions

CH₄ emissions (tonnes/year) = (Mass Balance) – (Vented Emissions)

Where

Mass Balance = $D * [(Input) * (In\ CH_4\ Mole\ Fraction) - (Output) * (Out\ CH_4\ Mole\ Fraction)]$

Vented Emissions = Method 16

Input = Input volume (scf/year)

Output = Output volume (scf/year)

In CH₄ Mole Fraction = Input CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)

Out CH₄ Mole Fraction = Output CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)

D = (molar volume) * (Molecular Weight CH₄) * (tonne/2204.6lb)

Molar Volume = (1 lbmole gas)/(379.3 scf gas)

Molecular Weight CH₄ = (16 lb CH₄)/(lbmole CH₄)

Data Requirements

1. Input volume (scf/year)
2. Output volume (scf/year)
3. Input Mole % CH₄
4. Output Mole % CH₄
5. Vented Emissions

Method 18 – Natural Gas Sweetening/Acid Gas Removal Mass Balance (Non-solid Material Units)

Fugitive emissions from natural gas sweetening or acid gas removal.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = D * [(\text{Input}) * (\text{In CO}_2 \text{ Mole Fraction}) - (\text{Output}) * (\text{Out CO}_2 \text{ Mole Fraction})]$$

Where

Input = Input volume (scf/year)
 Output = Output volume (scf/year)
 In CO₂ Mole Fraction = Input CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)
 Out CO₂ Mole Fraction = Output CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)
 D = (molar volume)*(Molecular Weight CO₂)*(tonne/2204.6lb)
 Molar Volume = (1 lbmole gas)/(379.3 scf gas)
 Molecular Weight CO₂ = (44 lb CO₂)/(lbmole CO₂)

Data Requirements

1. Input volume (scf/year)
2. Output volume (scf/year)
3. Input Mole % CO₂
4. Output Mole % CO₂

$$\text{CH}_4 \text{ emissions (tonnes/year)} = D * [(\text{Input}) * (\text{In CH}_4 \text{ Mole Fraction}) - (\text{Output}) * (\text{Out CH}_4 \text{ Mole Fraction})]$$

Where

Input = Input volume (scf/year)
 Output = Output volume (scf/year)
 In CH₄ Mole Fraction = Input CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)
 Out CH₄ Mole Fraction = Output CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)
 D = (molar volume)*(Molecular Weight CH₄)*(tonne/2204.6lb)
 Molar Volume = (1 lbmole gas)/(379.3 scf gas)
 Molecular Weight CH₄ = (16 lb CH₄)/(lbmole CH₄)

Data Requirements

1. Input volume (scf/year)
2. Output volume (scf/year)
3. Input Mole % CH₄
4. Output Mole % CH₄

Method 19 – Other Natural Gas Processing

Vented and fugitive emissions from other natural gas processing.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = D * [(\text{Input}) * (\text{In CO}_2 \text{ Mole Fraction}) - (\text{Output}) * (\text{Out CO}_2 \text{ Mole Fraction})]$$

Where

Input = Input volume (scf/year)
 Output = Output volume (scf/year)
 In CO₂ Mole Fraction = Input CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)
 Out CO₂ Mole Fraction = Output CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)
 D = (molar volume)*(Molecular Weight CO₂)*(tonne/2204.6lb)
 Molar Volume = (1 lbmole gas)/(379.3 scf gas)
 Molecular Weight CO₂ = (44 lb CO₂)/(lbmole CO₂)

Data Requirements

1. Input volume (scf/year)
2. Output volume (scf/year)
3. Input Mole % CO₂
4. Output Mole % CO₂

$$\text{CH}_4 \text{ emissions (tonnes/year)} = D * [(\text{Input}) * (\text{In CH}_4 \text{ Mole Fraction}) - (\text{Output}) * (\text{Out CH}_4 \text{ Mole Fraction})]$$

Where

Input = Input volume (scf/year)
 Output = Output volume (scf/year)
 In CH₄ Mole Fraction = Input CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)
 Out CH₄ Mole Fraction = Output CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)
 D = (molar volume)*(Molecular Weight CH₄)*(tonne/2204.6lb)
 Molar Volume = (1 lbmole gas)/(379.3 scf gas)
 Molecular Weight CH₄ = (16 lb CH₄)/(lbmole CH₄)

Data Requirements

1. Input volume (scf/year)
2. Output volume (scf/year)
3. Input Mole % CH₄
4. Output Mole % CH₄

Method 20 – Natural Gas Compressor Startups

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{Total Volume of Gas Vented}) * (\text{CO}_2 \text{ Mole Fraction}) * D$$

Where

CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)
 D = (molar volume)*(Molecular Weight CO₂)*(tonne/2204.6lb)
 Molar Volume = (1 lbmole gas)/(379.3 scf gas)
 Molecular Weight CO₂ = (44 lb CO₂)/(lbmole CO₂)

Data Requirements

1. Total volume of gas vented (scf)
2. Mole %CO₂

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{Total Volume of Gas Vented}) * (\text{CH}_4 \text{ Mole Fraction}) * D$$

Where

CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)
 D = (molar volume)*(Molecular Weight CH₄)*(tonne/2204.6lb)
 Molar Volume = (1 lbmole gas)/(379.3 scf gas)
 Molecular Weight CH₄ = (16 lb CH₄)/(lbmole CH₄)

Data Requirements

1. Total volume of gas vented (scf)
2. Mole %CH₄

Method 21 – Natural Gas Compressor Blowdowns

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{Total Volume of Gas Vented}) * (\text{CO}_2 \text{ Mole Fraction}) * D$$

Where

$$\text{CO}_2 \text{ Mole Fraction} = (\text{lbmole CO}_2) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CO}_2) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CO}_2 = (44 \text{ lb CO}_2) / (\text{lbmole CO}_2)$$

Data Requirements

1. Total volume of gas vented (scf)
2. Mole %CO₂

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{Total Volume of Gas Vented}) * (\text{CH}_4 \text{ Mole Fraction}) * D$$

Where

$$\text{CH}_4 \text{ Mole Fraction} = (\text{lbmole CH}_4) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CH}_4) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CH}_4 = (16 \text{ lb CH}_4) / (\text{lbmole CH}_4)$$

Data Requirements

1. Total volume of gas vented (scf)
2. Mole %CH₄

Method 22 – Natural Gas Compressor Seals

Fugitive emission calculations for natural gas compressor seals.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{CO}_2 \text{ EF}) * (\text{CO}_2 \text{ Mole Fraction} \setminus 0.03) * (\text{Seals}) * (\text{Usage})$$

Where

$$\text{CO}_2 \text{ EF} = \text{See Table 10}$$

$$\text{CO}_2 \text{ Mole Fraction} = (\text{lbmole CO}_2) / (\text{lbmole gas})$$

$$\text{Seals} = \text{Number seals}$$

$$\text{Usage} = \text{Annual Usage (hours/year)}$$

Data Requirements

1. Mole % CO₂
2. Number of compressor seals
3. Annual usage (hours/year)

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ EF}) * (\text{CH}_4 \text{ Mole Fraction} \setminus 0.788) * (\text{Seals}) * (\text{Usage})$$

Where

$$\text{CH}_4 \text{ EF} = \text{See Table 10}$$

$$\text{CH}_4 \text{ Mole Fraction} = (\text{lbmole CH}_4) / (\text{lbmole gas})$$

$$\text{Seals} = \text{Number of seals}$$

$$\text{Usage} = \text{Annual Usage (hours/year)}$$

Data Requirements

1. Mole % CH₄
2. Number of compressor seals
3. Annual usage (hours/year)

Table 10: Compressor Seals

| Device Type | CH ₄ (tonnes/component ¹ -hr) | % Methane Assumption | CO ₂ (tonnes/component ¹ -hr) | % CO ₂ Assumption |
|--------------------------|--|-------------------------|--|---------------------------------|
| Reciprocating Seal | 9.925E-04 ² | 78.8 | 1.039E-04 ² | 3 |
| Centrifugal Seal | 1.035E-03 ² | 78.8 | 1.083E-04 ² | 3 |
| Rotary Seal ³ | 1.035E-03 ² | 78.8 | 1.083E-04 ² | 3 |
| Screw Seal ³ | 1.035E-03 ² | 78.8 | 1.083E-04 ² | 3 |
| Vane Seal ³ | 1.035E-03 ² | 78.8 | 1.083E-04 ² | 3 |

1. Leak rate for when the compressor is pressurized.

2. EPA (1996a)

3. Assumed Rotary, Screw, and Vane seals emit at the same rate as Centrifugal seals.

Method 23 – Natural Gas Gathering System Pipelines

Fugitive emission calculations for natural gas gathering system pipelines (before the gas meter).

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{CO}_2 \text{ EF}) * (\text{CO}_2 \text{ Mole Fraction} \backslash 0.03) * (\text{Miles}) + (\text{Oxidation CO}_2 \text{ EF}) * (\text{Miles})$$

Where

CO₂ EF = See Table 11

CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)

Oxidation CO₂ EF = See Table 10

Miles = miles of natural gas pipeline

Data Requirement

1. Mole % CO₂
2. Mile of natural gas pipeline

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ EF}) * (\text{CH}_4 \text{ Mole Fraction} \backslash 0.788) * (\text{Miles})$$

Where

CH₄ EF = See Table 11

CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)

Miles = miles of natural gas pipeline

Data Requirements

1. Mole % CH₄
2. Miles of natural gas pipeline

Table 11: Natural Gas Gathering Pipelines

| Type | CH ₄ (tonnes/mile-yr) | % Methane Assumption | CO ₂ (tonnes/mile-yr) | % CO ₂ Assumption | Oxidation CO ₂ (tonnes/mile-yr) |
|--------------------|-------------------------------------|-------------------------|-------------------------------------|---------------------------------|---|
| Gathering Pipeline | 0.374 ¹ | 78.8 | 7.682E-02 ¹ | 3 | 3.833E-02 ¹ |

1. API (2004)

Method 24 – Natural Gas Gathering System Maintenance Activities

CO₂ emissions (tonnes/year) = (Total Volume of Gas Vented)*(CO₂ Mole Fraction)*D

Where

CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)
 D = (molar volume)*(Molecular Weight CO₂)*(tonne/2204.6lb)
 Molar Volume = (1 lbmole gas)/(379.3 scf gas)
 Molecular Weight CO₂ = (44 lb CO₂)/(lbmole CO₂)

Data Requirements

1. Total volume of gas vented (scf/year)
2. Mole % CO₂

CH₄ emissions (tonnes/year) = (Total Volume of Gas Vented)*(CH₄ Mole Fraction)*D

Where

CH₄ Mole Fraction = (lbmole CH₄)/(lbmole gas)
 D = (molar volume)*(Molecular Weight CH₄)*(tonne/2204.6lb)
 Molar Volume = (1 lbmole gas)/(379.3 scf gas)
 Molecular Weight CH₄ = (16 lb CH₄)/(lbmole CH₄)

Data Requirements

1. Total volume of gas vented (scf/year)
2. Mole % CH₄

Method 25 – Pipeline Pigging

Vented emission calculations for natural gas pipeline pigging (EPA 2005).

CO₂ emissions (tonnes/year) = (CO₂ EF)*(CO₂ Mole Fraction\0.03)*(Openings)

Where

CO₂ EF = See Table 12
 CO₂ Mole Fraction = (lbmole CO₂)/(lbmole gas)
 Openings = Number of time launcher/receiver is opened

Data Requirements

1. Mole % CO₂
2. Number of launcher/receiver openings

Emission Factor Calculation

$$\text{Equation} = V * [(P_1) * (T_2)] / [(P_2) * (T_1)]$$

Where

V = pig launcher/receiver volume
 P₁ = gathering line pressure (psia)
 P₂ = 14.7 psia (standard surface pressure)
 T₁ = temperature of the pig launcher/receiver
 T₂ = 60°F (standard surface temperature)

Assumptions (from EPA 2005)

$$V = 11.5 \text{ ft}^3 \text{ (for an 18 in line)}$$

$$P_1 = 315 \text{ psia}$$

$$T_1 = 60^\circ\text{F}$$

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ EF}) * (\text{CH}_4 \text{ Mole Fraction} \backslash 0.788) * (\text{Openings})$$

Where

$$\text{CH}_4 \text{ EF} = \text{See Table 12}$$

$$\text{CH}_4 \text{ Mole Fraction} = (\text{lbmole CH}_4) / (\text{lbmole gas})$$

$$\text{Openings} = \text{Number of time launcher/receiver is opened}$$

Data Requirements

1. Mole %CH₄
2. Number of launcher/receiver openings

Table 12: Pigging

| Device Type | CH ₄ (tonnes/opening) | % Methane Assumption | CO ₂ (tonnes/opening) | % CO ₂ Assumption |
|-------------|-------------------------------------|-------------------------|-------------------------------------|---------------------------------|
| Pigging | 3.716E-03 ¹ | 78.8 | 3.89E-04 ¹ | 3 |

1. EPA (2005)

Method 26 – Tank Cleaning (Separators and Storage Tanks)

Vented emission calculations for the cleaning of crude oil storage tanks or separation units.

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (V) * (\text{CO}_2 \text{ Mole Fraction}) * (0.1) * (\text{Events}) * D$$

Where

$$V = \text{Volume of tank (ft}^3\text{)}$$

$$0.1 = \text{Common air district rule that vapors must be reduced at least 90\% before opening}$$

$$\text{CO}_2 \text{ Mole Fraction} = (\text{lbmole CO}_2) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CO}_2) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CO}_2 = (44 \text{ lb CH}_4) / (\text{lbmole CO}_2)$$

$$\text{Events} = \text{Number of degassing events}$$

Data Requirements

1. Size of tank (bbl/ft³)
2. Mole % CO₂ in vapor head space
3. Number of degassing events

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (V) * (\text{CH}_4 \text{ Mole Fraction}) * (0.1) * (\text{Events}) * D$$

Where

$$V = \text{Volume of tank (ft}^3\text{)}$$

$$0.1 = \text{Common air district rule that vapors must be reduced at least 90\% before opening}$$

$$\text{CH}_4 \text{ Mole Fraction} = (\text{lbmole CH}_4) / (\text{lbmole gas})$$

$$D = (\text{molar volume}) * (\text{Molecular Weight CH}_4) * (\text{tonne}/2204.6\text{lb})$$

$$\text{Molar Volume} = (1 \text{ lbmole gas}) / (379.3 \text{ scf gas})$$

$$\text{Molecular Weight CH}_4 = (16 \text{ lb CH}_4) / (\text{lbmole CH}_4)$$

$$\text{Events} = \text{Number of degassing events}$$

Data Requirements

1. Size of tank (bbl/ft³)
2. Mole % CH₄ in vapor head space
3. Number of degassing events

Method 27 – Crude Oil Separation and Storage Tanks

Fugitive emission calculations for crude oil separation and storage tanks. Default CH₄ and CO₂ mole percents are 43% and 4% respectively (HARC, 2006).

$$\text{CO}_2 \text{ emissions (tonnes/year)} = (\text{TOG}) * (\% \text{ CO}_2)$$

Where

TOG = (Working Loss TOG)+(Breathing Loss TOG)+(Flashing Loss TOG)
 % CO₂ = percent CO₂ in the head space vapor concentration

Data Requirements

1. Working Losses (tons/year)
2. Breathing Losses (tons/year)
3. Flashing Losses (tons/year)
4. % CO₂ in the head space vapor concentration

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{TOG}) * (\% \text{ CH}_4)$$

Where

TOG = (Working Loss TOG)+(Breathing Loss TOG)+(Flashing Loss TOG)
 % CH₄ = percent CH₄ in the head space vapor concentration

Data Requirements

1. Working Losses (tons/year)
2. Breathing Losses (tons/year)
3. Flashing Losses (tons/year)
4. % CH₄ in the head space vapor concentration

Method 28 – Sumps and Pits

Fugitive emission calculations for sumps and pits.

$$\text{CH}_4 \text{ emissions (tonnes/year)} = (\text{CH}_4 \text{ EF}) * (\text{Area}) * (\text{Days})$$

Where

CH₄ EF = See Table 13
 Area = area of the sump or pit
 Days = Number of Days in Use

Data Requirements

1. Area of sump or pit
2. Sump or pit level (primary, secondary, tertiary)
3. Crude Oil API
4. Number of days sump is in use

Table 13: Sumps

| Type | CH ₄ (tonnes/ft ² -day) |
|--------------------|--|
| Light Crude | |
| Primary Sump | 1.297E-05 ¹ |
| Secondary Sump | 1.814E-06 ¹ |
| Tertiary Sump | 9.070E-07 ¹ |
| Heavy Crude | |
| Primary Sump | 9.480E-06 ¹ |
| Secondary Sump | 4.672E-06 ¹ |
| Tertiary Sump | 5.90E-07 ¹ |

Carbon Limits is a consulting company with long standing experience in supporting energy efficiency measures in the petroleum industry. In particular, our team works in close collaboration with industries, government, and public bodies to identify and address inefficiencies in the use of natural gas and through this to achieve reductions in greenhouse gas emissions and other air pollutants.

Executive Summary

Natural gas-driven pneumatic controllers are used widely in the oil and natural gas industry to control liquid level, temperature, and pressure during the production, processing, transmission, and storage of natural gas and petroleum products. However, these devices release methane into the atmosphere. Pneumatic controllers are the second-largest source of methane from the US oil and gas industry, behind only component leaks, according to US EPA's Greenhouse Gas Inventory.

US Federal rules require that new continuous-bleed controllers be *low-bleed* (defined as designed to emit less than six standard cubic feet/hour) at production sites and compressor stations and be *zero-bleed* at processing plants. Unfortunately, recent measurements have demonstrated that many controllers currently in field use are emitting more than would be expected based on design specifications.

This study was undertaken to determine whether cost-effective non-emitting technologies are available to eliminate this major emissions source. We find that these technologies have evolved considerably over the past decade and are now available and actively in use in oil and gas fields in the United States and Canada. Two technologies are mature, proven, and in relatively wide use, and as we discuss in this report, these technologies provide a cost-effective way to eliminate emissions of methane and other pollutants from pneumatic controllers.

Major findings include:

- Zero emission technologies can virtually eliminate emissions from pneumatic devices.
- A number of technologies are available. The two most promising, which this report focuses on, are electronic controllers – both solar and grid powered – and instrument air.

Electronic controllers can be installed both at sites connected to the electric grid and at sites isolated from the grid.

Instrument air technology is a well-established, mature solution to run pneumatic control systems and is widely applied globally. The technology requires a reliable power supply, either from the grid or from generators on the site.

- Currently, electronic controllers are generally used at smaller sites while instrument air is used at larger sites, due to the technical limitations of air compressors. These two technologies are on the market today, from multiple suppliers.
- Due to the market conditions, providers of electronic controllers have so far focused mainly on the development of solutions for small sites in remote locations. There thus seems to be much less field experience with using electronic controllers at medium and large sites; however, no technical barriers were identified for this type of installation.
- A number of other zero emission solutions are available today with more limited applicability (e.g. self-contained devices) or fewer documented implementations (e.g. solar-powered instrument air). Depending on the site specificities, these options can represent useful alternatives to instrument air or electronic controllers.
- Operators have successfully installed hundreds of systems. They report positive experiences on both new and retrofit sites, valuing zero emission solutions for their low maintenance costs and reliability.
- An economic analysis, assuming conservative average emission factors for pneumatic controllers, was performed for 2032 site configurations with 1 to 40 controllers (excluding emergency

CARBON LIMITS

shutdown devices). Both retrofit and new installations, with and without electricity on-site, were considered.

- Zero emission solutions have abatement costs below the social cost of methane used by US EPA (\$1354/tCH₄, mean value calculated for 2020 with a 3% discount rate in 2016 USD) in the vast majority of the site configurations considered (2008 out of 2032 site configurations).
- The abatement costs, calculated as described above, exceed the social cost of methane used by US EPA primarily at very small sites – those with less than three controllers (excluding emergency shutdown devices). However, if higher emission factors, as reported from recent field measurements, are used, the abatement costs at even the very small sites will fall below the social cost of methane.

Overall, we find that zero emission solutions are available today and are cost effective to implement in nearly every situation.

The following table presents a summary of both the technical applicability and economic attractiveness of the different zero emission technologies under different categories of sites. Though this analysis does not provide a detailed evaluation of the distribution of the sites in the US for each of the below categories, existing studies have suggested that the vast majority of the sites have less than 20 controllers.

| Type of site | | Both retrofit and new sites | | | | | | |
|--|---|--|---|---|---|---|--------------|---|
| | | Number of controllers (excl. ESDs) | | 4-20 | | 21-40 | | |
| | | 1-3 | | Yes | No | Yes | No | |
| Electricity on-site? | | Yes | No | Yes | No | Yes | No | |
| Main options: Electric controller Instrument air | Description (of the most economic option which is technically feasible) | Grid connected electric controller | Solar powered electric controller | Grid connected electric controller | Solar powered electric controller | Instrument air | | |

All the data are presented in metric tons

All monetary figures are presented in US dollars, denoted as \$

Social Cost of Methane: This report uses the social cost of methane, as reported by US EPA in recent regulatory analyses, as a benchmark for the cost-effectiveness of measures to abate methane emissions. We use the mean value calculated at the 3% discount rate for emissions in year 2020. EPA calculates this as \$1300 per metric ton in 2012 USD. We have converted this to \$1354 per metric ton in 2016 USD, using a cumulative rate of inflation of 4.2%.

1. Introduction

1.1 What is the problem?

Natural gas-driven pneumatic controllers are used widely in the oil and natural gas industry to control liquid level, temperature, and pressure during the production, processing, transmission, and storage of natural gas and petroleum products. However, these devices vent methane into the atmosphere. Pneumatic controllers are the second-largest source of methane from the US oil and gas industry, behind only component leaks, according to US EPA's Greenhouse Gas Inventory [1].

Over the last few years, regulators have worked to reduce the emission of methane and volatile organic compounds (VOCs) from pneumatic controllers. US Federal rules require that new continuous-bleed controllers be *low-bleed* (defined as designed to emit less than 6 scfh) at production sites and compressor stations and *zero-bleed* at processing plants. Wyoming goes further to include intermittent-vent controllers in its requirement that *all* new controllers are designed to emit less than 6 scfh. It also requires the replacement of existing high-emitting controllers in some areas and caps allowable emissions in other areas. Recently Colorado required that existing high-continuous-bleed controllers be replaced with low-bleed controllers statewide, and other states are currently considering similar measures. Finally, some operators have reported voluntary replacements of high-bleed controllers with low-bleed controllers to programs such as US EPA's Natural Gas STAR.

Unfortunately, recent measurement studies [2,3,4] have reported higher emissions from low-bleed controllers than expected. Some controllers that are considered low-bleed according to manufacturer specifications actually bleed above the low-bleed threshold of 6 scfh. Indeed, a number of controllers appear to malfunction, emitting significantly more than they are designed to emit.

Moreover, as a class, intermittent-vent controllers, which are largely unregulated, far outnumber continuous-bleed controllers, and EPA estimates that emissions from intermittent-vent controllers are considerably higher than emissions from continuous-bleed controllers [1]. Recent work has demonstrated that some controllers designed to emit intermittently fail and begin leaking natural gas continually [2,5].

Given the wide range of applications of pneumatic controllers, their typical installation in remote, unmanned sites, and the limited resources of air quality regulators, it is very challenging for air quality regulators to ensure compliance to emissions standards for pneumatic controllers. Currently, new continuous-bleed controllers are in compliance with EPA rules, if they are designed to emit below the EPA threshold of six cubic feet per hour. In practice, they may emit more depending on installation parameters (such as the pressure of the supply-gas), malfunctions, or even tampering, e.g. production workers modify controllers bleed rates when they believe that it will improve reliability [9]. Finally, it is inherently difficult to quantify the emissions from intermittent-vent controllers, as their actuation frequency is variable and may change over time.

1.2 Objective of this project

Zero emission technologies have the potential to virtually eliminate this emission source. They have evolved extensively over the last few years, as operators have gained experience using them. Yet, although zero emission technologies are often mentioned in best practices documentation and reports, there is very limited information on overall applicability and costs (with the exception of instrument air).

CARBON LIMITS

This report documents how zero emission technologies are being used in gas and oil fields, and discusses the zero emissions technologies that are suitable for wide usage in common applications at oil and gas production facilities and compressor stations. The main objectives include:

- Presentation of zero emission technologies that are currently available on the market.
- Discussion of the applicability and the technical barriers to the implementation of these technologies.
- Estimates of implementation and methane abatement costs of these technologies for new installations and retrofits.

1.3 Approach and methodology

In addition to a comprehensive literature review, this report relies on interviews with a number of relevant stakeholders and a detailed cost-benefit analysis.

Interviews: Seventeen interviews were conducted. Nine were with technology providers, and eight with both small and large oil and gas companies. The interviews gathered information on field experience with the implementation of zero emission technologies, in particular on their applicability, technical barriers experienced, and actual costs and benefits.

Cost-benefit analysis of zero emission technology implementation: Based on the information gathered during the interviews, literature reviews, and online equipment quotes, a cost-benefit analysis was performed covering a wide range of possible site configurations.

The cost-benefit analysis is presented in section 4 of this report. Prior to that, section 2 includes an introduction to controller typologies, followed by a brief literature review of emissions from controllers. Section 3 presents the different zero emission controller technologies and includes a description of field experiences with these technologies. The report concludes with a brief overview of existing applicability and costs under a range of circumstances.

2. Gas Driven Pneumatic controllers – What are we talking about?

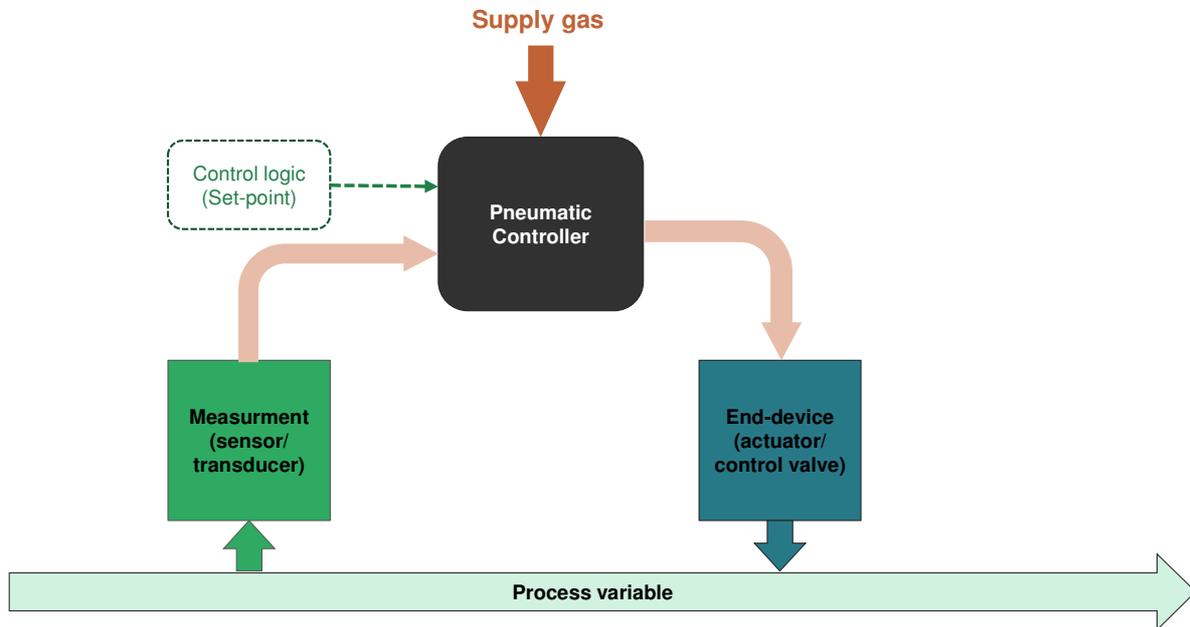

2.1 Definition

A process controller is a device that senses a physical state and then operates automatically to regulate that state¹, based on an established set-point in its control logic. Process controllers can regulate a variety of physical parameters – or *process variables* – including fluid pressure, liquid level, fluid temperature, and differential pressure. An example of a common type is a separator dump valve controller, which operates when it senses that liquid has reached a certain level. Process controllers can be electric, hydraulic, pneumatic or a combination of them. An example of a combination controller would be an electrohydraulic controller operating an electric valve to send liquid pressure to a hydraulic end-device.

Pneumatic controllers convert an input signal to a pneumatic pressure output using gas pressure. The end-device, i.e. the control valve, is adjusted by the actuator in response to signal from the controller. A pneumatic controller uses gas pressure to open or close a mechanical device, such as a valve, when it senses the need to regulate a process condition such as liquid level, pressure, temperature, or flow.

¹ In complex control systems, other process control variables might be modulated to regulate the *state* of that process variable.

Figure 1: Pneumatic Controller - concept sketch

2.2 Typology of controllers

Different typologies have been used in the literature to classify controllers, based on:

- The controller application (i.e. what the controller is used for, such as to control liquid level, pressure, or temperature)
- The emission pattern of the controller (continuous-bleed or intermittent vent)
- The end service (i.e. the way the controller regulate the parameter, such as *on/off* service or *throttle* service)

Controller application

Pneumatic controllers are widely used in upstream oil and gas operations, most commonly to regulate fluid level in separators and tanks, temperature of heaters and fans, pressure of vessels, and differential pressure of lines.

Emission pattern of the controllers

Pneumatic controllers can be designed to release supply-gas continuously or intermittently. Pneumatic controllers are thus classified as **continuous-bleed** or **intermittent-vent** (equivalent to intermittent bleed in all EPA documents), depending on whether or not they are *designed* to emit continuously.

In this study,

- emissions occurring from intermittent-vent controllers, where there is a physical barrier between the supply-gas and the end-device, are referred to as **vent**; and
- emissions from continuous-bleed controllers, where the supply-gas provides required pressure to the end-device while the excess amount of gas is emitted, are referred to as **bleed**.

CARBON LIMITS

The continuous-bleed controllers are classified into high-bleed and low-bleed in this report, depending on whether or not the controller is deemed to have a bleed rate above or below 6 scfh, in line with EPA regulations.²

The typology used in this report differs from the one presented in Allen et al. [2] where controllers are classified depending on their measured emissions pattern as opposed to their designed emissions pattern.

End-service typology

The end-device can be in *on/off* service or *throttle* service, depending on the process requirements. An example of on/off service is a dump-valve that controls the level of a vessel. In the “on” state, the valve is completely open to “dump” liquid. When the desired level has been achieved, the valve completely closes to its “off” state. An example of throttle service is a pressure control valve, which increases or decreases the flow of gas as needed to maintain line pressure at a fixed value. Both continuous-bleed and intermittent-vent controllers are commonly used to perform both on/off and throttling services.

A summary of pneumatic controller typology is presented in the table below. As this study focuses on eliminating emissions from these devices, only the emission pattern typology is used in the rest of the report.

Table 1: Summary of controller typology (mainly based on [6])

| | | Type of Service | |
|--------------------------|---|---|--|
| | | On/Off | Throttling |
| Emission characteristics | Intermittent-vent | <ul style="list-style-type: none"> - Gas vented at de-actuation - Designed to emit no gas between de-actuation instances - De-actuation frequency depends on process variability | <ul style="list-style-type: none"> - Gas vented when end-device needs to throttle-off - Designed to emit no gas between throttle-off instances - Throttling frequency depends on process fluctuations |
| | High-bleed continuous controller | <ul style="list-style-type: none"> - Gas emitted continuously with higher bleed rates when end-device needs “off” service - Nevertheless, the average bleed amount is constant - Bleed rates are by definition deemed to be higher than 6 scfh | <ul style="list-style-type: none"> - Gas emitted continuously with higher bleed rates end-device needs to throttle-off - Nevertheless, the average bleed amount is constant - Bleed rates are by definition deemed to be higher than 6 scfh |
| | Low-bleed continuous controller | <ul style="list-style-type: none"> - Gas emitted continuously with higher bleed rates when end-device needs “off” service - Nevertheless, the average bleed amount is constant - Bleed rates are by definition deemed to be lower than 6 scfh | <ul style="list-style-type: none"> - Gas emitted continuously with higher bleed rates end-device needs to throttle-off - Nevertheless, the average bleed amount is constant - Bleed rates are by definition deemed to be lower than 6 scfh |

2.3 Number of controllers and emission factors – Brief literature review.

Important work has been taking place over the last few years to measure and understand methane and VOC emissions from pneumatic controllers. This work includes measurement surveys [2,3,4,7], count of controllers per facility [1,2,8], and engineering calculations [8]. The methodology and the sampling approach vary significantly between different sources of information; thus comparisons should be made with particular care [8].

² It should be noted that the bleed rate is not a specification of the controller only, but also depends on the pressure and flow-rate of the supply-gas in addition to the size of the restriction orifice.

How many controllers per site?

The number of controllers per site varies depending on the number of wells and more generally the number and type of equipment used. Recent studies have demonstrated that the vast majority of sites have less than 20 controllers.

Most of the existing studies have focused only on emitting controllers [3,5,7], thus underestimating the number of controllers reported for each site, since some intermittent-bleed controllers actuate infrequently (e.g., controllers for emergency shut-down valves) and are unlikely to do so while a site is being surveyed. Two studies have performed a thorough count of the number of controllers per site [2,8]. The distribution of controller functions reported by these studies varied, perhaps due to differences in the types of sites sampled in the studies, but the overall distribution of controller counts at production sites were quite similar (Figures 2 and 3):

- Very small and medium sites (with less than 20 controllers) account for the vast majority (97%) of the sites evaluated in both studies (Figure 2)
- These sites represent 85% of the controllers (Figure 3)

Figure 2: Share of the sites depending on the total number of controllers per site

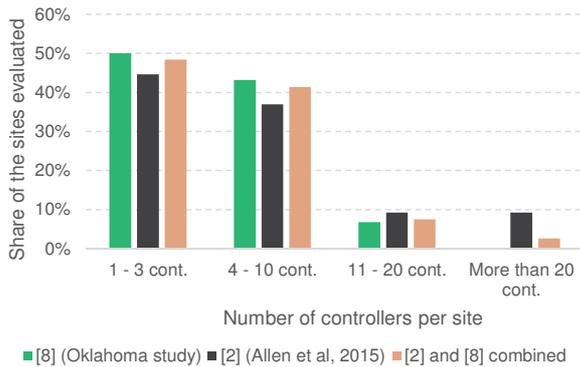

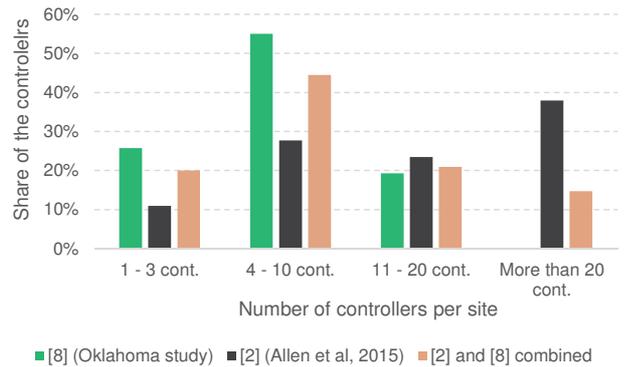

Figure 3: Share of the controllers depending on the total number of controllers per site

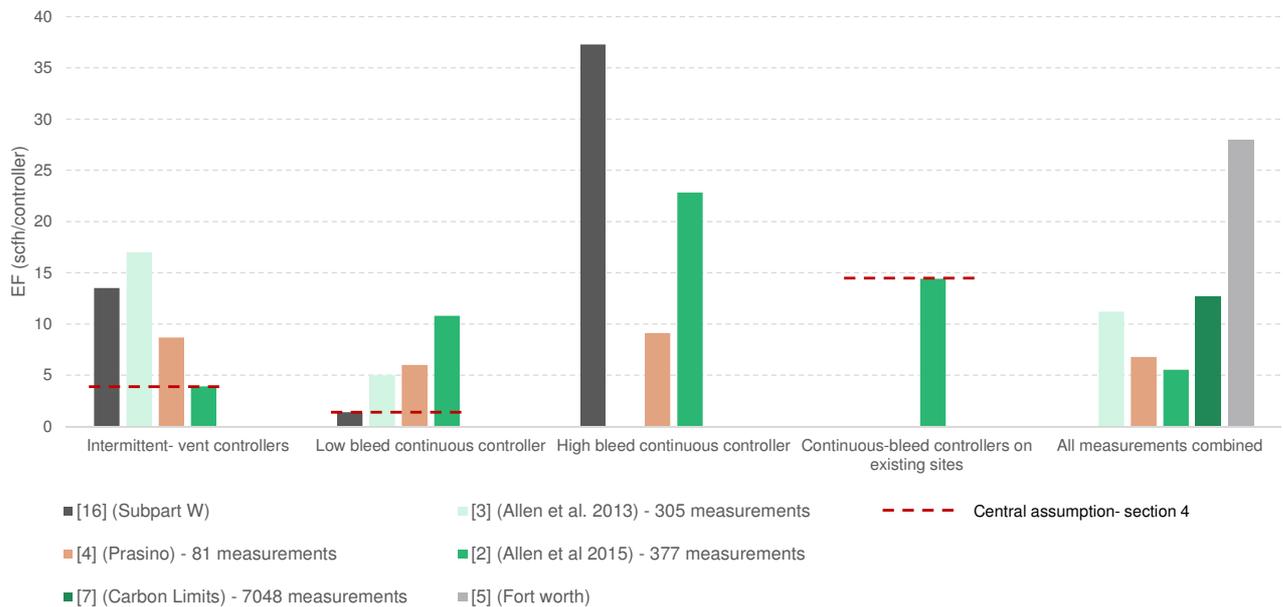

How much do controllers emit?

Despite the important work performed over the last few years, there is still significant uncertainty regarding emissions factors from controllers. The following figure summarizes the current emission estimates available for the different categories of controllers.

CARBON LIMITS

Figure 4: Emissions factors by controller category from different information sources³

A number of important conclusions can be drawn from the review of existing publications:

- Emissions from controllers vary between controller models and, for some models, for the same controller model between sites [2,4,7]
- A small subset of the controllers account for the vast majority of the emissions [2,7]
- Overall, recent research has demonstrated that a number of controllers behave differently than originally designed. In particular,
 - Average emission rates exceed the manufacturers' specifications [4], including some controllers designated low-bleed which emit above the threshold rate of 6 scfh [4,7]
 - Some controllers designed to emit intermittently fail and begin emitting natural gas continually [2,5]

In the analysis presented in the report, we have very conservatively adopted the lowest of the above average EFs for low-bleed in new installations and for intermittent-vent controllers. For continuous bleed controllers at existing sites, we have used the results of the recent measurement [2]. This average is consistent with a mix of low- and high-bleed in the field. The EFs are illustrated in Figure 4 and are described further in Section 4.1.

Do controllers from smaller sites emit more?

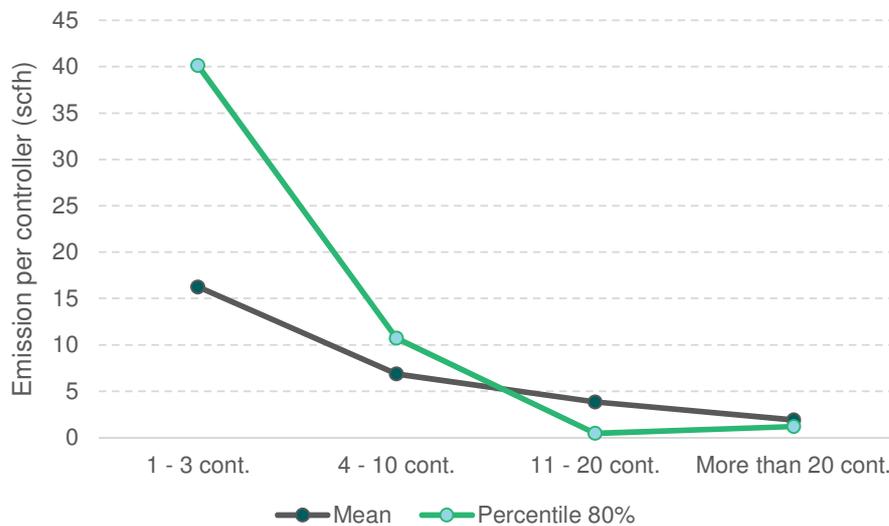

There is very little information available on how emission factors vary depending on the site's size. Analysis of recent measurements [2] suggests, however, that controllers are likely to emit much more in small than in large sites.

The following graph, plotting the mean and the eightieth percentile emission factors, shows a clear downward trend as the number of controllers per site increases. This trend could potentially be explained by the difference in terms of maintenance practices for small sites (typically unmanned and in remote area) and larger sites. In the follow-up analysis, a constant emission factor is assumed for both small and large sites.

³ The data from [3] and [4] have been categorized and presented as described in [8]. The data from [2] have been categorized based on the "company classification into EPA category" (excluding ESD) and not based on the measured emission typology.

CARBON LIMITS

Figure 5: Average emission factors depending on the number of controllers per site [2]

3. Zero emission technologies – Description and technical applicability

This section provides an overview of a number of zero emission technologies available as an alternative to gas driven pneumatic controllers, based primarily on interviews and on a general literature review. A technology is considered “zero emission” if there is no methane or VOC emissions associated with its utilization.

3.1 Overview of the zero emission technology presented.

Five different technologies have been reviewed: Electronic controllers, instrument air provided by compressors (with electric power from the grid or existing on-site generation), solar-powered instrument air, vent recovery, and self-contained pneumatic controllers. Of these five different zero emission technologies, two – electronic controllers and instrument air – have reached a reliable level of maturity and are widely applicable. The remaining three technologies are either less mature (solar-powered instrument) or are applicable only in certain circumstances (self-contained pneumatic controllers and vent recovery).

The economic feasibility of the two mature and widely applicable technologies, electronic controllers and instrument air, is evaluated in detail in section 4 of this report.

The following table presents a brief summary of the different technologies evaluated.

Table 2: overview of the zero emission technologies presented

| Technology | Maturity of the technology | Technical applicability limitations | Main strengths |
|---|---|--|--|
| Electronic controllers (ref section 3.2) | The technology has reached a reliable level of maturity, with hundreds of installations identified throughout this study. | Operators interviewed continue to use pneumatic ESDs. Some limitations with large numbers of controllers or high power demand chemical injection pumps. | <ul style="list-style-type: none"> • Can operate off grid • Reduced maintenance costs, in particular compared to wet gas driven controllers • Enables or simplifies automation of systems |

CARBON LIMITS

| | | | |
|--|--|--|--|
| Instrument air (ref section 3.3) | Extensive global experience for many years | Requires a reliable source of power Limited to installations with an air compressor > 5 HP | <ul style="list-style-type: none"> Reliability Reduced maintenance costs, in particular compared to wet gas driven controllers |
| Solar-powered Instrument air (ref section 3.4) | Less than 100 installations identified | Compressor up to ~20 scfh | <ul style="list-style-type: none"> Operates off grid Reduced maintenance costs, in particular compared to wet gas driven controllers |
| Vent Recovery (ref section 3.4) | The study identified less than 100 installations, with uncertain performance | Requires the presence of a VRU or a gas engine on site | <ul style="list-style-type: none"> Reliability |
| Self-contained pneumatic controllers (aka “Bleed to Pressure” or integral controllers) (ref section 3.4) | Although this solution has been deployed since early 2000s and is considered a relatively well-developed technology, controllers of this type are only available for certain specific applications | Applicability is limited by a number of conditions (e.g. pressure differential, downstream pressure, etc.) | <ul style="list-style-type: none"> Low-cost solution |

3.2 Electronic controllers (solar powered and grid powered)

Electronic controllers adjust the position of the end-device by sending an electric signal to an electric actuator or positioner (as compared to pneumatic controllers which send a pneumatic signal to a pneumatic actuator or positioner). A motor powers the electric actuator to adjust the control valve to the desired position.

This section provides a description of the benefits, costs, and applicability of electronic controllers to both new sites and existing sites, where retrofits would be required. The description is based mainly on interviews with four oil and gas production companies that have installed these systems in their operations (from 3 to 40 installations per operator interviewed), complemented by interviews with technology providers.

Description of the technology

Electronic controllers can be installed both at sites connected to the electric grid, and at remote sites isolated from the grid. These systems typically include a control panel, electric actuators, electronic controllers, control valves, relevant switches (e.g. pressure, level or temperature switch) and a power source – connection to the grid, solar panels and batteries, or power generation on site. An electronic control system is generally designed to completely replace all pneumatically powered devices with electronic controls (with the exception of ESD, see below).

Electrically powered sites: Electronic controllers can be powered using 120 VAC or 220 VAC input from the grid or from on-site generation (three-phase power is not needed).

Remote sites: Solar control systems are driven by solar power cells that actuate mechanical devices using electric power. Systems can be customized for every application; those installed to date include up to three solar panels and eight batteries [9]. Use of solar-powered chemical injection pumps has become widespread over the past years.

CARBON LIMITS

Rationale for the use of electronic controllers:

For the operators interviewed, the two main drivers for project implementation were (i) to reduce methane and VOC emissions and conserve gas otherwise emitted and (ii) to reduce maintenance costs. Electronic systems have much lower maintenance costs than traditional gas-driven controller systems [10], in particular if the gas used is not perfectly dry and sweet.

Higher operating costs are also experienced for gas driven controller systems on sites where there is a need to purchase fuel gas from another source or use imported propane. These include sites with overly sour or wet gas, or with drastic drop in gas supply due to low gas/oil ratio (GOR) /low production.

Investment Costs

Each electronic control system is designed on a case-by-case basis. The investment costs depend on the number of controllers/pumps, but also on other factors such as pressure differential, pipeline diameter, and methanol volume requirement, which varies according to such factors as climate and production patterns⁴. The following table summarizes typical equipment costs for the cases evaluated:

Figure 6- Calscan pictures- Bear solar control system: Top: solar panel and control panel, bottom: Electric Actuator

Table 3: Electronic controllers – Typical investment costs for main equipment

| Main items | Approximate unit costs USD |
|--|----------------------------|
| Level Controller & Level Control Valve | 4000 |
| Pressure Controller & Control Valve | 4000 |
| Chemical injection Pump | 6000 |
| Control panel | 4000 |
| Solar panel (140W unit) | 500 |
| Battery (100 Ah unit) | 500 |

The operators interviewed experienced fairly smooth installations, with installation costs decreasing as they gained experience with the technology⁵. The installation costs vary by site, estimated at between \$5000 and \$8000 per well site. For a retrofit project, the well needs to be shut in for one or two days; retrofit will generally take place when other maintenance is scheduled, to take advantage of that shut-down time.

⁴ Chemical injection pumps (e.g. methanol pumps) usually are the most important power consumer. Sites requiring high volumes of methanol volume injection would cause higher costs for scaled-up solar panel and batteries.

⁵ After the first few sites installations.

CARBON LIMITS

Maintenance costs

The major maintenance costs include the replacement of batteries and panels. Most batteries last three to six years, while solar panels last twenty to thirty years. The operators interviewed highlighted that they experienced minimal maintenance costs on the sites converted to electronic controllers over the last five years.

Benefits of electronic controllers

Operators highlighted a number of benefits:

- Revenue from the sale of gas: Electronic controllers eliminate methane and VOC emissions and thus increase the volume of gas available for sale.
- Automation: Electronic control systems can provide additional benefits by enabling or simplifying the installation of automation systems (SCADA, Supervisory Control and Data Acquisition), though these systems are not required in order to use electronic controllers. This can potentially reduce the need for site inspections, reducing those costs for operators. For example, an alarm can be programmed to warn the operator if the dump has been open for more than 10 min. The system can be as sophisticated or as simple as required. (Note that we have not included any estimate of these cost reductions in the calculations of cost-effectiveness discussed in Section 4.)
- Reliability: As highlighted above, operators report that the electronic system is more reliable than a gas driven pneumatic control system, as operation of the latter with even slightly wet gas can lead to condensation issues, which over time will impact the performance of the system. One operator reported corrosion issues with sour gas used for pneumatic controllers and pumps.

Technical challenges with electronic controllers

- Snow: One operator reported that snow can be a problem with solar panel and battery lifetime.
- Theft or damage: Solar panels have reportedly been stolen or used as targets for shooting.
- Chemical injection pumps: Pumps consume far more energy than controllers/actuators. Sites with a large number of pumps or with pumps with high energy or power demand may represent a challenge for 100% solar powered electric systems. In addition, shortly after completion, some wells may require high volumes of methanol injection, and powering pumps to inject this high volume can strain these systems. Some of the operators interviewed reported that this technical barrier can be solved by bringing a portable stand-alone generator to the site for a few weeks to ensure that the power requirement is met.
- Safety considerations: Due to the very low voltage of the system, the safety risks are considered acceptable by the operator who evaluated this risk.

Applicability of electronic controllers

According to interviews with operators, this solution can technically be implemented on any well site. Generally, for the sites with these systems in place, the pressure differential is up to 2000 psi and the pipe diameters are between 2- 3 inches, but the system can be designed for larger pressure drops and larger diameters as required.

The only general limitation is the incremental costs. According to the operators, given the current gas prices, implementation costs are not compensated by the value of the gas saved. The project can be economical when other factors such as lower maintenance costs improve the return on investment.

Note on Emergency Shut-Down Valves (ESD): As a rule, electric controllers/actuators will stay in position if the system fails and power is lost, wires are cut, or other failures occur. This differs from some other solutions that can be designed so that valves close (or open) if the system fails (for example if the supply gas pressure is lost). Although Calscan is developing a “fail safe” electric ESD, operators have reportedly been using pneumatic or hydraulic ESD valves, as they are “fail-safe”.

CARBON LIMITS

Sunlight: In northern latitudes (e.g. northern Alberta) and when the energy demand is high (e.g. several pumps), solar panels may not generate enough power, in particular for chemical injection pumps. Other power sources such as thermal electric generators or methanol fuel cells have been used in pilot implementations.

Electronic controllers at medium and large sites: Due to the market conditions, providers have so far focused mainly on the development of solutions for small sites in remote locations. There thus seems to be much less field experience with using electronic controllers at medium and large sites. No technical barriers were identified for the installation of electronic controllers in sites with available electricity. Given the recent progress in both solar panel technologies and large battery solutions, solar-powered solutions may also be appropriate for large sites without available power. However, we are not aware of any such installations. Therefore, to be conservative, we do not examine the use of electronic controllers at large sites without electricity available.

Medium or large sites may also be the result of a combination of a number of small sites (e.g. several well pads). In practice, several small independent electronic controller installations can thus be installed on one medium to large site.

Suppliers

The following table presents a non-exhaustive list of relevant providers:

Table 4: Non-exhaustive list of relevant providers:

| Name of the suppliers | Website | Offer | Comments |
|----------------------------|---|---|---|
| Calscan | http://www.calscan.net/products_bearcontrol.html | Provide full customized system | Calscan's Bear Solar Electric Control System is designed mainly for well head separators, but it can also be used in other applications. It includes solar panels, batteries, electric actuators, control valves, switches, control panels and other control equipment. |
| Spartan | http://www.spartancontrols.com/ | Provide full customized system | Spartan designs electronic control systems assembling a number of components including Emerson/Fisher electronic controllers and actuators. |
| Ameresco | http://www.amerescosolar.com/solar-power-solutions-oil-and-gas-industry | Provide full customized systems | Ameresco Solar designs customized off-grid solar power systems. |
| Emerson/ Fisher | | Manufacture elec. controllers and actuators | Different brands under Emerson Process Management (including Fisher, EIM) supply electronic and electro-pneumatic control components (controllers, positioners, actuators, control valves, transducers, etc.) |
| Exlar | http://exlar.com/ | Manufacture elec. actuators | Exlar currently offer electric actuators that can replace pneumatic actuators. |

3.3 Instrument air

Instrument air controllers are systems where pressurized natural gas is replaced with compressed air as a source of energy and signaling medium for pneumatic controllers and pneumatic actuators. Since controllers use air, instead of natural gas, they only vent air to the atmosphere, eliminating emissions from pneumatic controllers. Instrument air controllers are applicable to both new sites and existing sites; however, the technology can only be implemented when a reliable power supply is available.

CARBON LIMITS

This section provides a description of the benefits, the costs, and the applicability of instrument air controllers and is mainly based on interviews with oil companies, reviewing their recent experience installing instrument air systems.

Description of the technology

Instrument air technology is a well-established mature solution to run pneumatic control systems and is widely applied globally. In many countries (e.g. Norway, Iran, Kazakhstan [11]), the majority of the pneumatic control systems run on instrument air.

Systems typically include:

- Heavy-duty industrial air compressors. Two compressors are generally installed for redundancy, but for cost reasons, an operator has reported using only one.
- Air dryers - part of the air compressor package.
- Wet air receiver tank - part of the air compressor package.
- Dry air receiver tank - helps provide a buffer to secure longer system autonomy in the event of a power outage or demand surge.

Investment costs

Interviewers highlighted that the investment costs for instrument air installation vary significantly from site to site, depending on the layout and the type of equipment already on site. Investment costs can be classified as follows:

- Air compressor package: This includes the purchase of the main equipment (compressors, dryers and air receiver tanks). The size of compressors, dryers, and other equipment depends on the number of pneumatic controllers to be supplied with compressed air, and on their specifications (i.e., their demand for compressed air). A small compressor station would require around 5 HP of air compression capacity, while a larger facility would require up to 20 HP. This system can be purchased as individual components or as a package, for between \$20,000 and \$70,000 [12].
- Mechanical & installation costs: Mechanical and civil work may be required, depending on the layout of the existing facility. These costs are often higher for older facilities and can include:
 - Pipe cleaning and upgrades.
 - Trenching and tubing installation, since large sites may have several independent natural gas supply systems for controllers and pumps, and air would need to be piped through the full site.
- Electrical/instrumentation equipment and supplies: Depending on the site and the specific project requirement, this category may include:
 - Remote terminal unit or SCADA system installation or upgrade. The control system for some plants (e.g. shutdown/start-up, safety systems etc.) may have to be upgraded to accommodate the air compressor package.
 - Upgrades and wiring needed to add the additional electrical loads from the air compressor motors.
 - Repair/replacement of a controller in case of malfunctioning controller.
- Engineering/consulting: The site might require additional expenditures for electrical engineering and consulting.

Although air compressors and their auxiliary equipment represent a large part of the CAPEX, the engineering, preparation and installation costs can comprise up to 70% of the total upfront investment. Installation and preparation costs may include electrical and instrumentation supplies, mechanical and civil works, additional wiring, piping, valves and fittings. These costs are higher for older facilities that are not capable of handling the extra power, or don't have a suitable layout for utilities. Overall, the total cost for a project varies between \$50,000 and \$250,000 [10].

CARBON LIMITS

Maintenance costs

Maintenance costs typically include:

- Power consumption
- Air compressor servicing, generally every 6 months.

Benefits of instrument air controllers

Operators highlight a number of benefits:

- Revenue from the sale of gas: Instrument air eliminates methane and VOC emissions and thus increases the volume of gas available for sale.
- Reliability: The instrument air system is a highly reliable alternative to a natural gas driven pneumatic system for grid-connected facilities.
- Reduced maintenance costs: Although there are some additional operating costs with the deployment of air systems, some maintenance expenses are cut as a result of stopping the use of natural gas, particularly wellhead gas (or separator gas). Due to fluctuations in the GOR, some operators reported gas shortages on-site and thus they had to use other sources, such as propane, or to purchase gas from an adjacent field. Maintenance costs due to liquids condensing in the system or sour gas damage are also avoided by replacing untreated natural gas with air.

Applicability of instrument air controllers

Two main applicability limitations were identified during the interviews:

Size of the installation:

Instrument air controllers require heavy duty industrial air compressor packages designed for continuous duty (24/7). This in effect precludes the use of air compressors smaller than 5 HP, since available 2-3 HP air compressor packages present reliability problems. One operator reported that the one-year lifetime of a smaller compressors makes them unacceptable, so a minimum of 5 HP is assumed.

Access to power

Instrument air systems may only be used in locations with access to a sufficient and consistent supply of electrical power. Operators have used instrument air at:

- Grid connected sites.
- Sites with onsite power generation. Many sites (e.g. compressor plants) have power generation for other purposes: lighting, automation and control systems, etc. The same system can also be used for instrument air if generation capacity is available. We note that a sufficient, reliable, good quality gas stream is required for power generation. Wet or sour gas may not always be used for on-site power generation, depending on the specification of generator engines, etc.

In theory, diesel powered instrument air could be installed; however, this project identified no concrete examples of this technology. One operator stated he considered, and then rejected, the use of diesel to run air compressors, due to the high costs and low perceived environmental benefits.

3.4 Other technologies

This section reviews other “zero emission” technologies at various stages of maturity. In general these technical options are either (i) not widely applicable (such as self-contained controllers and vent gas recovery) or (ii) fewer than 100 installations were identified as part of this project (such as solar powered instrument air).

CARBON LIMITS

Solar powered instrument air

This study identified about 40 installations of small, energy efficient motor-compressors powered by solar panels/batteries, to replace natural gas with instrument air as the pneumatic medium. TRIDO industries, the technology provider interviewed as part of this study, indicated that these systems have a maximum capacity of ~20 scfh, making them suitable for some small to medium sites which use a few low-emitting controllers. High-bleed controllers have to be retrofitted to reduce air consumption in order to reach the feasible level. Despite the lack of extensive deployment so far, an attraction of this solution lies in the fact that controllers and actuators do not need to be replaced.

Instrument air powered by other power sources

Other power sources, such as thermal electric generators or methanol fuel cells, have been used in pilot implementations to power traditional instrument air systems.

Vent Gas Recovery

Re-routing to VRU

Vapor Recovery Units (VRUs) have a long, well-established track record in the upstream oil and gas industry to recover VOCs and methane from vented sources. Typically, they consist of capturing and piping equipment, a de-liquefaction drum, and compressor(s) to inject the recovered gas into pipelines. In theory, all vent lines can be connected to the VRU, including pneumatic controllers' lines.

Nevertheless, there have been limited implementations (only one example identified in this study) of well-site vent gas recovery projects using the recovered gas from pneumatic controllers in non-engine applications. SlipStream®, as further presented below, is a technology that facilitates recovery of the gas and use of it in gas-fired engines. Another technology, Cata-Dyne™, utilizes the recovered gas as a feed to a small, flameless appliance that converts natural gas or propane into infrared radiant heat that is usable if industrial heating is required.

SlipStream®

Spartan's SlipStream® system captures vented hydrocarbons and uses them as a supplementary fuel source for natural gas-fired engines, reducing fuel consumption. This technology can thus be applied only to sites with gas-fired engines, e.g. compressor engines. Despite concerns about costs, one operator emphasized specifically the reliability of the technology, as it reportedly does not interfere with normal operations. Nevertheless, if the volume of gas emitted by the combined vents (including the controllers) exceeds the engine fuel requirements, natural gas would still be vented or otherwise controlled.

Self-contained (aka Bleed-to-Pressure or Integral Pneumatic Controllers)

Self-contained systems are designed to contain the gas typically vented from controllers and then discharge it to the control valve's downstream piping, thus resulting in zero emission.

A number of operational requirements limit the applicability of self-contained systems, the most important of which is the need for a high differential pressure across the control valve [6,13]. For instance, GE's Bleed-to-Pressure system requires more than 80 psi, and both GE and VRG Controls require a downstream pressure of maximum 300 psi [13]. Also, sour or untreated gas could cause disturbances in the operation of self-contained controllers. Nevertheless, if applicable, the technology may be cost-effective or economical in cases where the total baseline emissions are high.⁶

Due to the limited applicability or the lack of widespread field experience, the technologies described above are not further analyzed in this report. However, depending on the site specifics, these options may

⁶ A technology provider [reports](#) an average of less than \$3000 per Bleed-to-Pressure control system, leading to a payback period of less than 2 years for replacing 8 controllers.

CARBON LIMITS

be applicable and cost-effective, and can represent useful alternatives to instrument air or electronic controllers; thus they are presented as potential alternative options in section 4.4.

4. Cost effectiveness of electronic controllers and instrument air

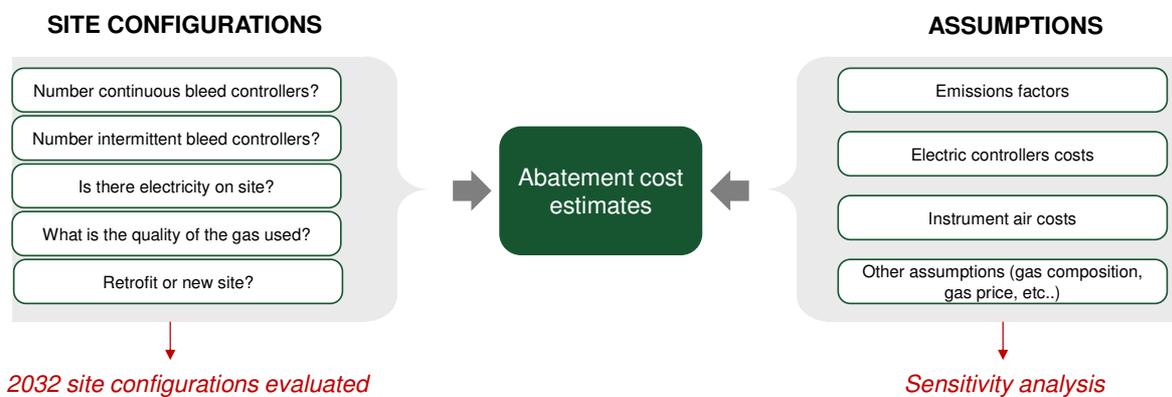

This section presents an analysis of the *cost-effectiveness* – net cost in USD per ton of avoided pollution – of employing the two main zero emission technologies, air-driven pneumatic controllers and electronic controllers, instead of natural gas-driven pneumatic controllers at new and existing sites. These results are applicable at both oil and gas production sites (well pads) and compressor stations.

4.1 Analytical approach

The cost-effectiveness of zero emission technologies will vary with the number and type of controllers at a site, in addition to many other factors, as we discuss below. Given the variety of site configurations (number and type of controllers per site, connection to the grid, type of gas handled) across the US, and the lack of information on the frequency of occurrence of these configurations, we opted to carry out cost-effectiveness assessments for both electronic and instrument air controllers for a broad spectrum of permutations of those site configuration parameters.

A number of assumptions have been made for the analysis. Key assumptions are discussed in the section below; all assumptions are detailed in the Appendix.

Figure 7: Overview of the methodology

For each permutation of the site configuration parameters, a CH₄ abatement cost (cost per metric ton of avoided pollution) was estimated.

For this analysis, a zero emission technology implementation is considered

- “economical” if the CH₄ abatement cost is negative (i.e. if the project NPV is positive)
- “cost effective” if the CH₄ abatement cost (net cost per ton of abated pollution) is lower than the social cost of methane that EPA has used in recent regulatory analyses [19] (Social cost of methane for 2020, calculated with a 3% discount rate, \$1354 (2016 USD)).⁷

⁷ EPA reports that the 2020 social cost of methane (mean value at 3% discount rate) is \$1300 / metric ton of methane in 2012 USD; this is adjusted to \$1354 / metric ton of methane in 2016 USD using a 4.2% cumulative inflation rate.

CARBON LIMITS

The following sections provide more insight on:

- The abatement cost calculation
- The main assumptions
- The site configurations evaluated.

Abatement cost calculation – methodology

For each site configuration, the following were estimated:

- The CAPEX and OPEX of the zero emission technology implementation (either electronic controllers or instrument air)
- The CAPEX and OPEX of the baseline scenario (i.e. the cost incurred by the operator if the conventional pneumatic technology had been used instead of zero emission systems)
- The emissions of CH₄ and VOC under the baseline scenario

Since methane and VOC emissions will be zero if the zero emission technology is used, the abatement cost (in \$/t CH₄) is then estimated as follows:

$$\text{Abatement cost} = - \frac{NPV(\text{Cash flow}_{\text{zero emission project}} - \text{Cash flow}_{\text{baseline scenario}})}{NPV(\text{Emission}_{\text{baseline scenario}})}$$

This approach, and its underlying assumptions, is compared to the annualized cost approach typically used by EPA in the appendix.

Main assumptions

The following table provides a list of the main assumptions applied. A full list of assumptions is available in the Appendix.

Table 5: Central assumptions

| Description | Central Assumption | Comment |
|---|-------------------------------|--|
| Gas price | 2 \$/Mscf | The value of recovered gas has been assumed to be similar for all emission sources, independent of the composition of the gas. Gas values from 1 to 3 \$/Mcf have been assessed in sensitivity analyses. |
| Discount rate | 7% | A 7% per year real term discount rate has been assumed. A sensitivity is presented for a 3% per year real term discount rate. This approach is consistent with EPA/BLM practice. |
| Remaining lifetime for a new project | 15 years | The lifetime for new controller installation is assumed to be 15 years in line with EPA practice. |
| Remaining lifetime for retrofit project | 10 years | The remaining lifetime for existing sites is assumed to be 10 years. A sensitivity is presented for a 5 years remaining lifetime. |
| Gas composition | 0.0167 tCH ₄ /Mscf | Gas composition assumptions for dry gas (wet gas assumptions are presented in the Appendix) |
| | 0.0046 tVOC/Mscf | |

Average emissions factors assumptions

The emission factors used for this analysis are conservative averages based on the literature review (See section 2.3). The following table presents the emission factors used and the rationale for each value.

Table 6: Emission factors assumptions – central assumptions

| Description | Central Assumption | Comment |
|--|--------------------|---|
| Continuous-bleed controller(s) – retrofit sites only | 14.4 scfh | This emission factor is applied for all the continuous bleed controllers on retrofit sites. |

CARBON LIMITS

| | | |
|--|-----------|---|
| | | Assumption based on [2] (Company classification into EPA categories excluding ESD) |
| Low bleed continuous controller (s) | 1.39 scfh | This emission factor is applied for all the continuous bleed controllers on new sites. Current federal regulation (OOOO) requires that new continuous bleed controllers be low bleed. Assumption based on [16], most conservative average value between [16], [3], [4] and [2] |
| Intermittent-vent controller(s) | 4.4 scfh | Assumption based on [2], most conservative average value between [16], [3], [4] and [2] |
| Chemical injection Pumps | 13.3 scfh | Assumption based on [16], most conservative average value between [4], [7] and [16] |
| ESD | 0.41 scfh | Assumption based on [2], average of the controllers classified as ESD |

While measurements show that emission factors vary widely in the field, using conservative average emission factors, we are able to calculate conservative (i.e. high) abatement costs for widespread adoption of zero-emitting technologies. Sensitivity analyses are presented in the section 4.2 to reflect the field variability, which impact the site specific abatement costs.

Site configurations evaluated

As described above, we performed economic modeling on a total of 2032 permutations of site configuration parameters, covering a wide range of possible combinations of site parameters.

The following parameter inputs were used to construct the site configurations:

- Total number of controllers – from 1 to 40 controllers.
- A varying mix of continuous-bleed and intermittent-vent controllers (from 0% to 100% of intermittent-vent controllers).
- One emergency device (ESD) was added for every five controllers⁸ (rounded up).
- New site (construction of new facilities) or retrofit (upgrade of existing facilities).
- Access to electricity or not.
- Whether pneumatic driven controllers currently operate on dry gas or wet gas.

To simplify the presentation of the results, the 2032 possible site configurations were then grouped into 20 larger categories depending on the total number of controllers, the presence of electricity on site, and whether the site is new or would need to be retrofit with zero emission controllers. The following table presents a matrix of the 20 different categories of site configurations evaluated, with the number of sites in each category presented in green. Each cell of this table includes a number of site configurations depending on the number of intermittent-vent or continuous-bleed controllers and the type of gas used to power the controllers.

⁸ This number of ESDs has no impact on the final conclusion. Operators do not currently replace ESDs with electric controllers, so number and the emission factor of ESD have no effect on the cost-effectiveness of electric controllers. On the other hand, ESDs will generally be converted to instrument air, but the effect of including reasonable numbers of ESDs on the final cost-effectiveness is small due to the small air consumption of ESD. In this context, the assumption on the number of ESD did not affect the final number of sites with an abatement cost higher than the social cost of methane.

CARBON LIMITS

Table 7: Site configurations categories (number of site configurations presented in green)

| Number of Pumps | Number of controllers (excluding ESD) | New sites | | Retrofit | |
|-----------------|---------------------------------------|------------------|---------------|------------------|---------------|
| | | No elec. on site | Elec. on site | No elec. on site | Elec. on site |
| 0 | 1 to 3 controllers | 18 | 18 | 18 | 18 |
| | 4 to 10 controllers | 56 | 56 | 56 | 56 |
| | 11 to 20 controllers* | 98 | 98 | 98 | 98 |
| | 21 to 40 controllers* | | 164 | | 164 |
| 1 | 1 to 20 controllers* | 172 | 172 | 172 | 172 |
| | 21 to 40 controllers* | | 164 | | 164 |

* Based on the analysis presented in section 3, we did not model either technology for larger sites (≥21 controller excluding ESD) without electricity on-site

- Electronic controllers were modeled at sites of all sizes with electricity available, and smaller to medium sites (up to 20 controllers) with no electricity available. Medium and large sites with electricity on-site are presented, as no technical barriers were identified for the installation of electronic controllers in such installations. However, there seems to be much less field experience for these types of installations compared to smaller sites.
- Instrument air was presented at larger sites with electricity available. For sites smaller than 20 controllers, electronic controllers were always more cost efficient than instrument air (see below).

This approach reflects the current industry experience and practice as presented by the interviewees. It is, however, important to highlight that the threshold in terms of number of controllers (20 in the analysis), depends in reality on site-specific parameters, and should only be considered as an **illustrative** threshold based on information available.

4.2 Main findings – electronic controllers

The findings of the cost-benefit analysis for electronic controllers are presented in four different sections:

- First, the full cost-benefit analysis is presented for one site configuration, to illustrate the methodology by exploring one example in detail.
- Second, a sensitivity analysis is performed for the same site configuration to show the impact of the main assumptions.
- An overview of the results for all the site configurations evaluated is then presented.
- Finally, the impact of the emission factors assumptions is described.

Example of abatement cost estimate for one example site configuration

The following table presents a full analysis for an example site configuration. The project is the retrofit of an existing site with four different controllers (one continuous-bleed, two intermittent-vent, one ESD and no pump) which represents the most common number of controllers in [8,2]. The site is not connected to the grid and currently uses dry supply gas for the controllers.

Table 8 presents the CAPEX estimate for the conversion to electronic controllers. As the project is a retrofit project, the baseline CAPEX is zero.

The detailed assumptions for the size of the electronic system (such as number of solar panels and battery requirements) are presented in the appendix. Overall, the system is oversized and always includes, for example, 10 days of energy storage.

CARBON LIMITS

Table 8: CAPEX estimates for electronic controller implementation (central assumptions)

| Item | Assumption | # | Total USD |
|------------------------------------|------------------------|----|---------------|
| Controllers | \$ 4000/unit | 3 | 12 000 |
| Control Panel | \$ 4000/unit | 1 | 4 000 |
| 140 W Solar Panel | \$500 /Unit | 1 | 500 |
| 100 Amh battery | \$400 /Unit | 3 | 1 200 |
| Installation and engineering costs | 20% of equipment costs | NA | 3 540 |
| Total CAPEX | | | 21 240 |

Table 9: Emissions estimates (central assumptions, new sites)

| Whole gas emissions in scfh | EF assumption | # | Total |
|---------------------------------|---------------|---|-------------|
| Intermittent – vent controllers | 4.43 | 2 | 8.9 |
| Continuous –bleed controller | 14.4 | 1 | 14.4 |
| Total gas emissions | | | 23.3 |

In terms of OPEX, it is assumed that batteries are replaced every 4 years and solar panels every 10 years. Given the operators' reports of minimal maintenance for electronic controllers, it has thus been assumed, conservatively, that general maintenance costs for are similar to those for continuous-bleed controllers functioning properly⁹. We do not include any estimate of savings in inspection costs due to automation (conservative assumption). Table 9 above presents emission estimates for the baseline scenario and finally Table 10 includes the abatement costs estimated.

Table 10: Final results – central assumptions

| Item | Unit | Value USD |
|------------------------|---------------------------|------------|
| CAPEX | \$ | 21 240 |
| Value of the gas saved | \$/year | 408 |
| NPV of the OPEX | \$ | 1 672 |
| NPV | \$ | -19 266 |
| ABATEMENT COSTS | \$/tCH₄ | 751 |

As presented in Table 10, for the small and remote site configuration presented, the abatement costs is well below the social cost of methane as defined above. The abatement cost for same site configuration, but at a new facility, as opposed to a retrofit, is estimated to be \$847/ton CH₄. The difference is due to the difference in baseline costs and baseline emissions between new and retrofit sites (see below).

Info Box 1: Electric conversion of pneumatic pumps

Pumps at well sites and well pads are typically used for methanol, corrosion inhibitor, de-waxing agents, or soap injection. Federal regulation (OOOOa) rules already require that emissions from new and modified chemical injection pumps be controlled in a number of circumstances.

As highlighted in Section 3, conversion of chemical injection pumps to electric is both a mature and a cost effective technology.

In the analysis presented in this section, the conversion of one chemical injection pump per site is presented as a potential added benefit for the project developer. In cases with many pumps, or of major energy requirements for the pumps, the conversion of pumps to zero emission technologies could be assessed as a separate emission reduction project.

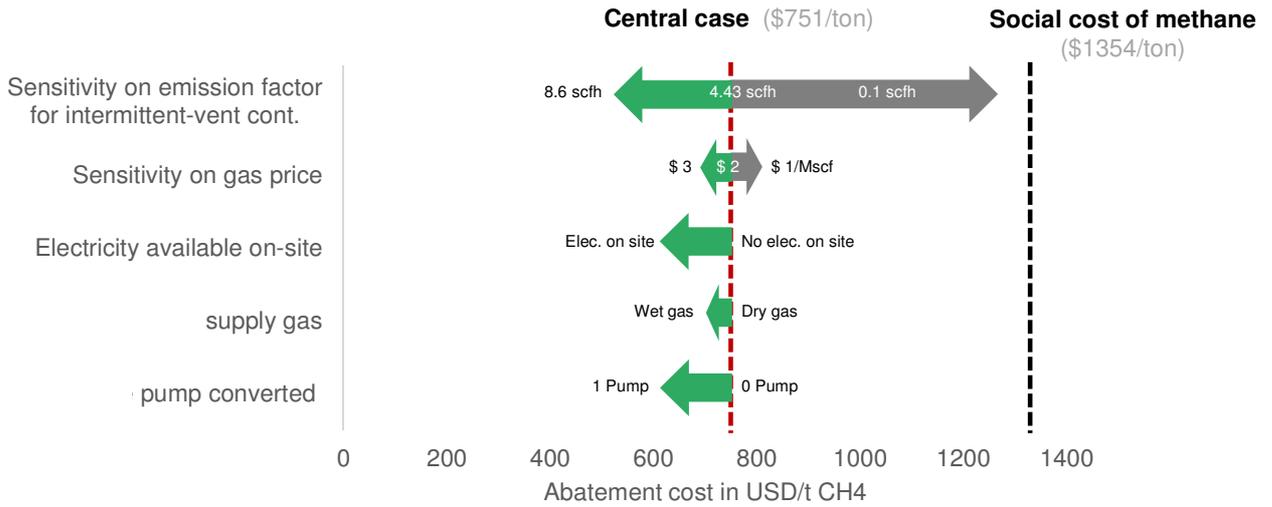

⁹ Which is lower than the maintenance costs for continuous bleed controllers operating with wet supply gas.

CARBON LIMITS

Sensitivity analysis for one example site configuration

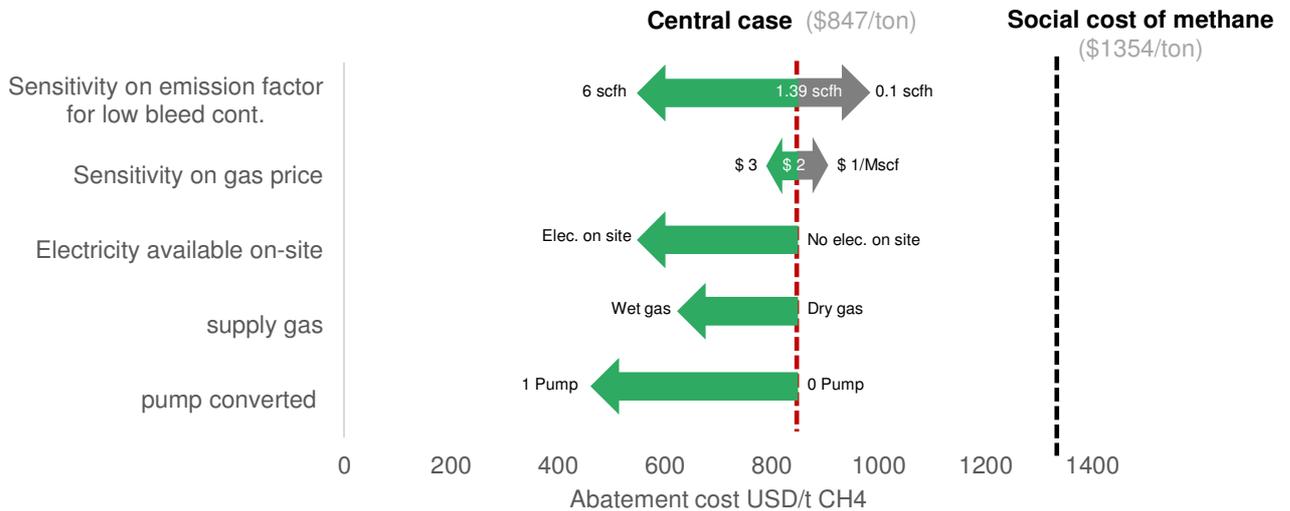

In this analysis, a number of assumptions have been made which impact the abatement cost. The following figures present sensitivity analyses for the site configuration described in the previous section, for both the retrofit case and the new site case. We examine the sensitivity of the abatement cost to changes to a few key sensitivities. A more exhaustive sensitivity analysis is presented in the appendix.

Figure 8: sensitivity analysis – electronic controllers - retrofit

The next figure presents a similar sensitivity for the same site configuration, but at a new facility as opposed to a retrofit.

Figure 9: sensitivity analysis – electronic controllers - new

The emission factor has by far the largest impact on the abatement cost and clearly heavily impacts the cost effectiveness of the option for retrofit sites. Excluding the emission factors, the other assumptions impact up to +33% of the abatement costs and no sensitivity leads to an abatement cost higher than the social cost of methane (see appendix).

CARBON LIMITS

In general terms, the abatement cost is more sensitive to changes for new sites than for retrofit sites. This is due to the fact that both the incremental costs and the emissions reductions are much smaller for new sites than for retrofit sites. A small change in either of these is thus relatively larger for new sites than for retrofit sites.

The following few paragraphs describes in more detail the impact of the main assumptions:

Electricity on site

The investment costs for sites without an electricity supply are higher than for sites with electricity due to the need to install solar panels and batteries. As a result, the abatement cost for site configurations with electricity is generally ten to one hundred percent lower than for site configurations without power. In a few site configurations the abatement cost is negative (i.e. NPV>0).

Wet versus dry supply gas

Operators have reported that the quality of the supply gas affects maintenance costs. Even slightly wet (or sour) gas can lead to condensation (or corrosion) issues, which over time will impact the performance of the system. The maintenance cost for sites with wet supply gas is estimated at \$200/year/controller [10] compared to \$80/year/controller for dry supply gas [18]. As a result, sites with wet gas have an abatement cost generally 5 to 100 % lower than sites with dry gas, and, in a few site configurations, the abatement cost is negative (i.e. NPV>0). Gas quality is also likely to impact the average emission rate. Due to the lack of quantitative data on this impact, however, this factor has not been taken into consideration during the analysis, but it would reduce the abatement costs of sites with wet gas even lower.

Chemical injection pumps

As pumps have high emissions factors, sites where one pump (or several) can be converted to electric power have much lower abatement costs than sites without. All the sites with one pump have an abatement cost lower than the social cost of methane.

New versus retrofit sites

The costs and the emissions abatement structures differ greatly for new and for retrofit sites. The main differences include:

- The incremental CAPEX (i.e. the difference between the zero emission technology CAPEX and the baseline CAPEX) for a retrofit site is usually much higher than for a new site.
- Given the current regulatory framework, it is assumed that new sites use low-bleed continuous controllers as a default, and we conservatively use the EPA emissions factor [1] for these controllers, despite measurements showing higher emissions for low-bleed controllers [3,4]. The emissions reduction for retrofit sites is higher than for new sites, as we use an emissions factor based on actual measurement [2] for continuous-bleed controllers at existing sites.

The first difference makes the abatement cost higher for retrofit sites than new sites, while the second difference has the opposite effect. Overall, in the vast majority of the site configurations evaluated, the abatement cost for new sites is higher than for the equivalent retrofit site configuration.

Overview of the results for all the site configurations

Overall, the abatement costs for electronic controller installations at 2032 site configurations were estimated during this project. Under the central assumptions, 20 of the 2032 site configurations evaluated have abatement costs higher than the social cost of methane, \$1354/t. The following table shows in red the number of site configurations with abatement costs higher than that figure for each category.

CARBON LIMITS

Table 11: Number of site configurations with abatement costs superior to the social cost of methane – central assumptions

| Number of Pumps | Number of controllers (excluding ESD) | New sites | | Retrofit | |
|-----------------|---------------------------------------|------------------|----------------|------------------|----------------|
| | | No elec. on site | Elec. On site | No elec. on site | Elec. On site |
| 0 | 1 to 3 controllers | 6 / 18 | 4 / 18 | 5 / 18 | 2 / 18 |
| | 4 to 10 controllers | 2 / 56 | 0 / 56 | 0 / 56 | 0 / 56 |
| | 11 to 20 controllers* | 0 / 98 | 0 / 98 | 0 / 98 | 0 / 98 |
| | 21 to 40 controllers* | | 0 / 164 | | 0 / 164 |
| 1 | 1 to 20 controllers* | 0 / 172 | 0 / 172 | 0 / 172 | 0 / 172 |
| | 21 to 40 controllers* | | 0 / 164 | | 0 / 164 |

* Sites with more than 10 controllers were presented for the installation of electronic controllers. However, there seems to be much less field experience for this type of installation, compared to smaller sites. Sites with more than 20 controllers and without electricity on-site were not modelled. Though no major technical barriers were identified, we could identify no examples of installations of solar powered electronic controllers on very large sites.

A number of conclusions can be drawn from this analysis. Under the central assumptions:

- For almost all the site configurations evaluated with four or more controllers (excluding ESDs), it is cost-effective to install electronic controllers.
- For all site configurations evaluated with one chemical injection pump, it is cost effective to install electronic controllers.

A site configuration is not cost effective if the volume of gas saved does not justify the cost of implementation. In general, for a given type of site configuration (wet/dry, on or off grid, new or existing, share of intermittent controllers), the cost-effectiveness improves (fewer \$/ton) with the number of controllers.

In addition, we can highlight the following patterns for the site configurations with abatement costs higher than the social cost of methane:

- For new facilities, these sites have only low-bleed continuous controllers (5 or fewer). The low bleed emission factor assumption has an important impact on the conclusion (see below).
- For retrofit facilities, these sites have only intermittent-vent controllers (3 or fewer). For retrofit sites, the emissions factor used for intermittent-vent controllers is less than that used for continuous bleed controllers (see section 4.1)

The full list of site configurations with an abatement cost higher than the social cost of methane is presented in the appendix.

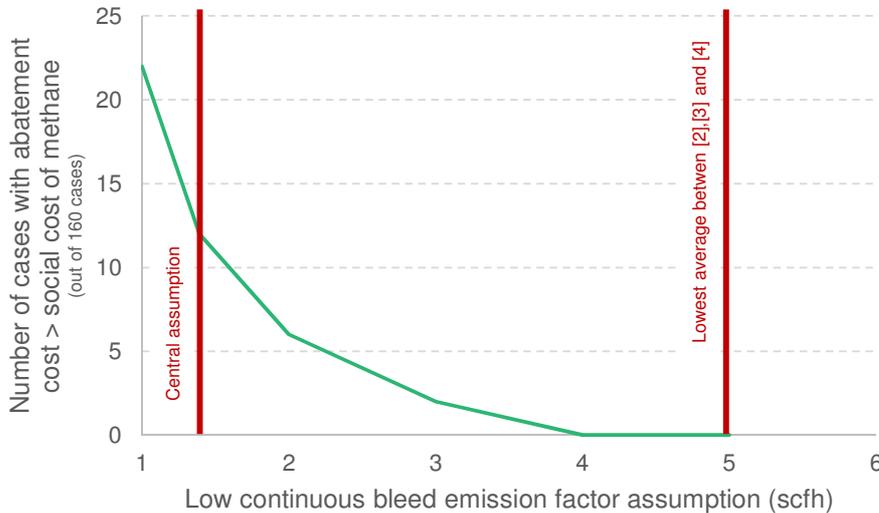

Impact of the emission factors assumptions

The results of the analysis are quite dependent on the emissions factors used for the various types of pneumatic controllers.

The following graph illustrates the impact of the continuous low-bleed emission factor on the cost effectiveness of new sites with at least one continuous low-bleed device. This represents 12 of the 19 site configurations deemed not cost effective. The central assumption for the low-bleed emission factor is 1.39 scfh. But an emission factor of 4 scfh would make all sites with at least one continuous bleed controller cost effective. It is interesting to compare this figure to the results of past measurement campaigns presented in the Figure 4, which suggest that average emission factors for low-bleed devices are likely higher than 5 scfh.

CARBON LIMITS

Figure 10: Impact of the continuous low bleed emission factor on the cost effectiveness of new sites with at least one continuous low bleed device.

In a site without an electricity supply and with just a single controller, an electronic controller is cost-effective if the emissions from that single controller are more than 4.4 scfh for a new site and more than 7.2 scfh for a retrofit site. The point of cost-effectiveness is lower for sites with 2 or more controllers, for sites using wet supply gas, or for sites with on-site electricity. These thresholds should be compared with emissions factors observed in Figure 5 for small and very small sites.

As mentioned above, while emissions from pneumatic controllers vary widely from device to device, this analysis uses average emissions factors based on recent measurements, aiming at evaluating the cost-effectiveness of using electronic controllers on a widespread basis.

To conclude, the analysis shows that conversion to electronic controllers would be cost effective in most site configurations even using conservative average emissions assumptions. If higher emissions assumptions are considered -- as reflected in recent field measurements -- virtually all site configurations evaluated would be fall below the social cost of methane

4.3 Main findings – Instrument air

As in the previous section, the finding of the analysis for instrument air is presented in three different sections:

- First, the full cost-benefit analysis is presented for one site configuration, to explain the methodology applied to one example.
- Secondly, a sensitivity analysis is performed for the same site configuration to illustrate the impact of the main assumptions.
- Finally, an overview of the results for all the site configurations evaluated is presented.

Contrary to electronic controllers, instrument air installation is only presented for site configurations with electricity available on-site.

Example of abatement cost estimate for one example site configuration

The following tables present a full analysis for an example site configuration. The project is retrofit of an existing site with 20 different controllers (5 continuous-bleed, 11 intermittent-vent, and 4 ESD). This configuration is illustrative; it is not known how representative it would be of larger sites. The site is

CARBON LIMITS

connected to the grid or has power already generated on site, and currently uses dry gas for the controllers.

The first table presents the CAPEX estimate for the instrument air project. The detailed assumptions for the size of the instrument air system (share of the air bypassed in dryer, share of the utility air supply,¹⁰ size of compressor, load of the compressor) are presented in the appendix. The approach in terms of system sizing proposed by Natural gas star has been applied [14], after having been quality checked against nine recently implemented projects. Overall, the system is oversized (as per the industry standard) and always includes, for example, one spare compressor. Equipment costs (including industrial grade compressors designed for 24/7 duty) have been assumed using online quotes.

As highlighted previously, installation costs for instrument air are highly site specific. Interviews have reported very low installation costs in particular when retrofitting many sites with similar designs. On the other side of the spectrum, operators have also reported high installation costs in cases where important investments, such as electric system upgrades and trenching between building or clusters of equipment, were required on the installations. The investment cost estimates presented below include some relatively conservative assumptions (i.e., high cost) in terms of equipment and installation costs. Some sensitivities are presented (appendix) to reflect the variability of the local circumstances.

Table 12: CAPEX estimates for instrument air controller implementation – central assumptions

| Item | Assumption | Sizing /# | Value USD |
|---|---|--|----------------|
| Controllers and installation costs for the controllers | NA | retrofit projects (it is assumed that controller can be re-used) | 0 |
| Compressor package (Assuming 2 compressors, air drying unit and wet air receiver unit) | See list of assumption in the appendix [12] | 10 HP | 32 000 |
| Other supplies costs (Instrumentation Supplies & Pipe/Valve/Fittings, electrical supplies, etc..) | 1400 \$/cont | 20 | 28 000 |
| Electrical, mechanical & civil Installation Costs, engineering | Retrofit: 100% New: 50% of equipment costs | NA | 60 000 |
| Total CAPEX | | | 120 000 |

In terms of OPEX, it is assumed that compressors are replaced every 6 years. In addition, 4% of the equipment costs are accounted for normal compressor maintenance (typically every 6 months). Other OPEX costs include, for example, electricity costs.

Table 13 presents the emissions estimates while Table 14 present the final results.

¹⁰ Because it is useful to have compressed air at a site for a variety of tasks and uses, operators typically oversize compressed air systems installed to drive pneumatic controllers. In this analysis, we assume that operators will do so, and consider the costs of the oversized system but do not make any estimate of the value of having compressed air available onsite. This approach is conservative (since operators do not strictly need oversize compression capacity for this purpose to use instrument air for pneumatic controllers), though the effect is not large.

CARBON LIMITS

Table 13: Emission estimates – central assumptions

| Emissions is scfh | EF assumption | # | total |
|-------------------------------|---------------|----|-------|
| Intermittent-vent Controllers | 4.43 | 11 | 48.7 |
| Continuous-bleed controllers | 14.43 | 5 | 72.1 |
| ESD | 0.41 | 4 | 1.64 |
| Total gas emissions | | | 122.5 |

Table 14: Final results for the site configuration analyzed – central assumptions

| Item | Unit | Value USD |
|------------------------|---------------------|-----------|
| CAPEX | \$ | 120 000 |
| Value of the gas saved | \$/year | 1073 |
| NPV (Opex) | \$ | 24 683 |
| NPV | \$ | -121 652 |
| ABATEMENT COSTS | \$/tCH ₄ | 972 |

The abatement cost for the same site configuration, but at a new facility, as opposed to a retrofit, is estimated to be \$886/ton CH₄. The difference is because the baseline costs are higher and the baseline emissions are lower for new sites than for retrofits.

Info Box 2: Conversion of pneumatic pumps to instrument air

Pneumatic pumps typically emit more per device than pneumatic controllers, so converting pumps to air can represent a large emission reduction and potentially reduce significantly the abatement cost of conversion. However converting pumps to instrument air is not always technically and/or economically feasible. For sites with access to reliable source of electricity, conversion to air is applicable and cost-effective for the majority of chemical injection pumps. However, even for grid-connected sites, conversion to instrument air is not always the preferred option, as electric pumps are proven effective and low-cost.

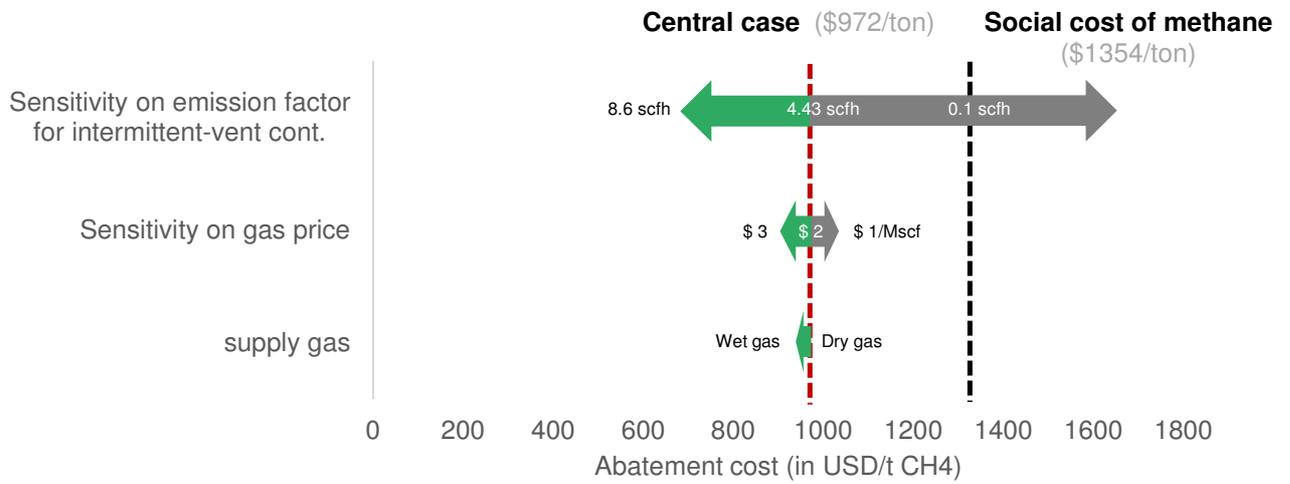

In summary, in a number of cases, emissions reduction for pumps could be considered as a separate project from controllers. In the follow up analysis, conversion of 1 pump to instrument air is only presented as part of the sensitivity analysis.

Sensitivity analysis for one example site configuration

The following figures present a sensitivity analysis for the same site configuration as in the section above. The CH₄ abatement cost for a few key sensitivities is compared to the abatement cost with the central assumptions. A more detailed sensitivity assessment is presented in the appendix.

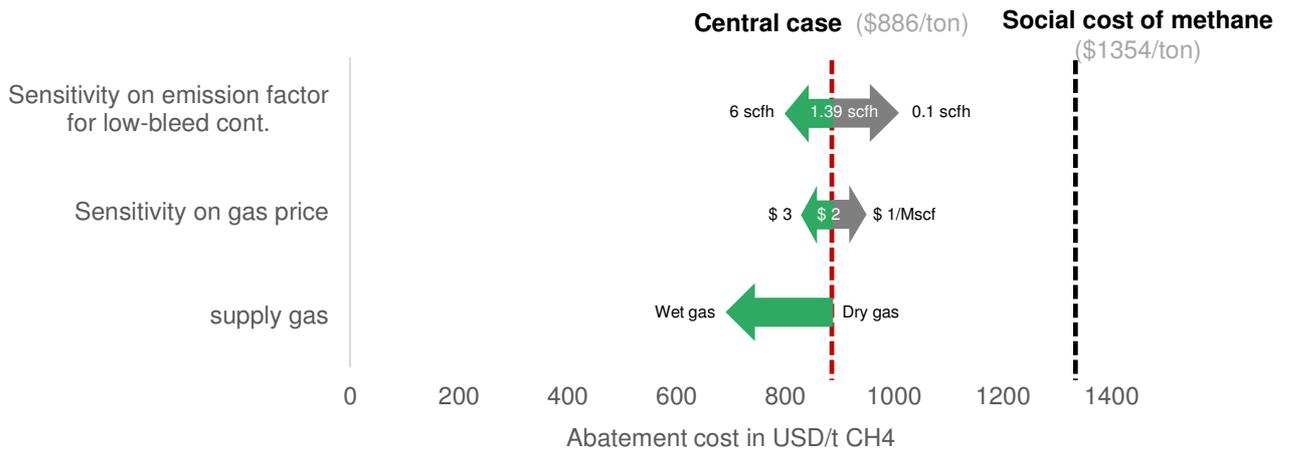

CARBON LIMITS

Figure 11: Sensitivity analysis – instrument air - retrofit

The next figure presents a similar sensitivity for the same site configuration but at a new facility.

Figure 12: Sensitivity analysis – instrument air - new site

As with the electronic controllers, the emission factor heavily impacts the attractiveness of the option. Excluding the emission factor, no other assumption affects the abatement cost per ton by more than 30% (see appendix).

Wet versus dry supply gas

As with electronic controllers, sites with wet gas have an abatement cost generally 5% to 50 % lower than sites with dry gas due to the difference in maintenance costs.

Overview of the results for all the site configurations

The overall abatement costs for about 328 site configurations, all with an electricity supply and no pneumatic pump conversions, were estimated, with a total number of controllers ranging from 21 to 50 (in various permutations of intermittent-vent and continuous-bleed controllers). Sites with fewer than 20 controllers are not presented, as conversion to electric is cheaper (on a per ton basis) in most of the site configurations with fewer than 20 controllers.

CARBON LIMITS

In terms of CAPEX, the total investment for retrofit sites varies between \$90,000 and \$230,000, while the investment (excluding controllers and their installation) for new sites varies between \$60,000 and \$120,000.

Under the central assumptions, 5 of the 328 site configurations evaluated have abatement costs higher than the social cost of methane. The following table shows in red the number of sites with abatement costs higher than \$1354 /tCH₄ for each category of sites.

Table 15: Number of site configurations with abatement costs higher than the social cost of methane – central assumptions

| Number of Pumps | Number of controllers (Excluding ESD) | New Sites | Retrofit |
|-----------------|---------------------------------------|-----------|----------|
| | | | |
| 0 | 21 to 25 controllers | 3 / 42 | 0 / 42 |
| | 26 to 30 controllers | 2 / 40 | 0 / 40 |
| | 31 to 40 controllers | 0 / 82 | 0 / 82 |

A number of conclusions can be drawn from this analysis. Under the central assumptions:

- For almost all the site configurations evaluated with more than 21 controllers (excluding ESDs), it is cost effective to install instrument air.
- For all the retrofit site configurations evaluated, it is cost effective to install instrument air.
- In a few of the new site configurations considered, it is not cost effective to install instrument air.

A site configuration is not cost effective if the volume of gas saved does not justify the cost of implementation. The new site configurations with abatement costs greater than the social cost of methane have a vast majority of low bleed continuous controllers, which we have conservatively assumed have very low emissions (1.39 scfh emission factor, see Section 4.1).

The full list of site configurations with abatement costs higher than the social cost of methane is presented in the appendix.

4.4 Summary of the analysis

As described in the section above, an economic analysis assuming conservative average emission factors was performed for 2032 permutations of site configurations with 1 to 50 controllers. Both retrofit and new installations, with or without electricity, were considered. A number of key conclusions can be drawn:

- Zero emission solutions had abatement costs below the social cost of methane (for 2020) described in the EPA 2015 Regulatory Impact Analysis in the vast majority of site configurations considered.
- The abatement costs exceeded the social cost of methane mostly for small sites – those with less than three controllers (excluding ESDs). If higher emission factors, as reflected in field measurements, are used, the abatement costs at even the very small sites fall below the social cost of methane.

The following figure presents a summary of both the technical applicability and economic attractiveness of the different zero emission technologies under different categories of sites. Though this analysis does not provide a detailed evaluation of the distribution of the sites in the US for each of the categories below, existing studies have suggested that the vast majority of the sites have less than 20 controllers.

CARBON LIMITS

Table 16: Summary table

| Type of site | | Both retrofit and new sites | | | | | | |
|--|---|--|---|---|---|---|--------------|---|
| | | Number of controllers (excl. ESDs) | | 4-20 | | 21-40 | | |
| | | Yes | No | Yes | No | Yes | No | |
| Main options: Electric controller Instrument air | Description (of the most economic option which is technically feasible) | Grid connected electric controller | Solar powered electric controller | Grid connected electric controller | Solar powered electric controller | Instrument air | | |
| | Number of cases not cost effective (i.e. abatement cost > social cost of methane) under central assumptions | 6 / 36 | 11 / 36 | 0 / 308 | 2 / 308 | 5 / 328 | | |
| | Cost effective for every site configuration if emissions factors are: [*] | > 5.6 scfh for retrofit > 2.8 scfh for new sites | > 7.2 scfh for retrofit > 4.4 scfh for new sites | > 3.6 scfh for retrofit > 1.4 scfh for new sites | > 4.2 scfh for retrofit > 1.8 scfh for new sites | > 4.5 scfh for retrofit > 1.8 scfh for new sites | | |
| Other options potentially applicable depending on the local conditions | Limited applicability | Vent gas recovery | ✓ | ✓ | ✓ | ✓ | ✓ | |
| | | Instrument air powered by gas | Not relevant | Not relevant | Not relevant | Not relevant | ✓ | |
| | | Self contained controllers | ✓ | ✓ | ✓ | ✓ | ✓ | |
| | Limited known implementations | Solar powered instrument air | Not relevant | ✓ | Not relevant | ✓ | X | |
| | | Electric controllers powered by other power sources (TEG, fuel cell) | Not relevant | Not relevant | Not relevant | Not relevant | Not relevant | ✓ |
| | | Large solar powered electric controller (no known implementations) | Not relevant | Not relevant | Not relevant | Not relevant | Not relevant | Potential solution,** but no example known. |

^{*} Emissions factors thresholds listed are determined for the site configuration with the highest abatement cost within the category.

^{**} Based on other solar applications.

The applicability of electronic controllers for small sites and instrument air for large sites reflects the current industry experience and practice as presented by the interviewees. It is, however, important to highlight that the threshold in terms of number of controllers (20 in the analysis), depends in reality on site-specific parameters, and should only be considered as an illustrative threshold based on information available.

Due to the market conditions, electronic controller providers have so far focused mainly on the development of solutions for small sites in remote locations. There thus seems to be much less field experience with using electronic controllers at medium and large sites; however, no technical barriers were identified for this type of installation.

These analyses indicate that the widespread adoption of zero-emitting technologies is cost effective in the vast majority of the site configurations considered. Furthermore, several factors listed should be considered:

- Conservative (low) average emissions factors have been used for low-bleed pneumatic controllers, even though recent research indicates that actual average emissions from those pneumatic controllers may be higher.
- Some of the important benefits of switching to zero-emitting technology, such as the ease of automation or remote operations associated with electrifying pneumatic controllers, are not included in our analysis of the cost-effectiveness of using zero emission technologies.
- Finally, pneumatic controllers emit natural gas, which includes (in varying amounts) other pollutants aside from methane, such as volatile organic compounds (VOCs), which are precursors to ground level smog, and toxic hazardous air pollutants (HAPs). Replacing natural-gas driven pneumatic controllers with zero-emitting technologies will eliminate emissions of these other

CARBON LIMITS

pollutants, in addition to emissions of methane, but we have not included the benefits of VOC or HAP abatement in our calculation of abatement costs for methane.

6.2 Other assumptions for the model

- General assumptions
 - Retrofitting is assumed to be performed during a planned maintenance, hence retrofit activities do not cause production losses; thus, no potential revenue losses are accounted for in the estimates presented.

CARBON LIMITS

- Electronic controllers:
 - In all the site configurations, it is assumed that ESDs are gas driven pneumatic controllers.
 - Electronic controllers can reduce the need for site inspections. The subsequent reduced labour costs have not, however, been taken into consideration in the analysis. (conservative assumption)
- Instrument air
 - CO₂ emissions from power consumption (for non-solar powered options) have been neglected; this represents a very small volume of emissions compared to the CH₄ emissions (typically a few per cent, assuming a GWP of methane of 21).

6.3 Detailed sensitivity analysis

In the analysis presented, a number of assumptions have been made which affect the abatement cost. The following sections present the detailed sensitivity analysis performed.

Electronic controller – Retrofit

The following table presents a sensitivity analysis for the site configuration described in the section 4.2 (site with four controllers). The CH₄ abatement costs for a few key sensitivities should be compared to the abatement costs under the central assumption: \$751/t CH₄. The abatement cost under all the sensitivities is below the social cost of methane.

Table 18: Sensitivity analysis – retrofit site with 4 controllers– results

| Name of the parameter | Central assumption | Sensitivity value | Abatement cost in \$/t CH ₄ |
|--|------------------------|------------------------|--|
| Number of pumps | 0 pump | 1 pump | 614 |
| Type of supply gas | Dry supply gas | Wet supply gas | 702 |
| Power on-site | No power on-site | Power on-site | 611 |
| Gas price | 2 \$/Mscf | 1 \$/Mscf | 811 |
| Gas price | | 3 \$/Mscf | 692 |
| Discount rate | 7% | 3% | 635 |
| Emission factors intermittent-vent cont. | 4.43 scfh | 8.6 scfh | 522 |
| | | 0.1 scfh | 1267 |
| Control Panel equipment cost | \$4000 | \$6000 | 845 |
| Installation Costs | 20% of Equipment Costs | 40% of Equipment Costs | 889 |
| Battery replacement freq. | 4 years | 2 years | 823 |
| Average peak sun | 4 hours | 2 hours | 775 |

Electronic controller – New

The following table presents a sensitivity analysis for the site configuration described in the section 4.2 (site with four controllers). The CH₄ abatement cost for a few key sensitivities should be compared to the abatement costs under the central assumption: \$847/t CH₄. The abatement costs for all the sensitivities are below the social cost of methane.

CARBON LIMITS

Table 19: Sensitivity analysis – New site with 4 controllers– results

| Name of the parameter | Central assumption | Sensitivity value | Abatement cost in \$/t CH ₄ |
|--|------------------------|------------------------|--|
| Number of pumps | 0 pump | 1 pump | 459 |
| Type of supply gas | Dry supply gas | Wet supply gas | 624 |
| Power on-site | No power on-site | Power on-site | 548 |
| Gas price | 2 \$/Mscf | 1 \$/Mscf | 906 |
| Gas price | | 3 \$/Mscf | 787 |
| Discount rate | 7% | 3% | 680 |
| Emission factors low bleed controllers | 1.39 scfh | 6 scfh | 547 |
| | | 0.1 scfh | 986 |
| Control Panel equipment cost | \$4000 | \$6000 | 1011 |
| Installation Costs | 20% of Equipment Costs | 40% of Equipment Costs | 1089 |
| Battery replacement freq. | 4 years | 2 years | 1046 |
| Average peak sun | 4 hours | 2 hours | 905 |
| Low Bleed Cont. - Equipment cost | \$2698 per controller | \$554 per controller | 993 |
| Intermittent Cont. - Equipment cost | \$2471 per controller | \$387 per controller | 1131 |

Instrument air – Retrofit

The following table presents a sensitivity analysis for the site configuration described in the section 4.3 (site with twenty controllers). The CH₄ abatement costs for a few key sensitivities should be compared to the abatement costs under the central assumption: \$972/t CH₄.

Table 20: Sensitivity analysis – retrofit site with 4 controllers– results

| Name of the parameter | Central assumption | Sensitivity value | Abatement cost in \$/t CH ₄ |
|---|--------------------------------------|--------------------------------------|--|
| Type of supply gas | Dry supply gas | Wet supply gas | 945 |
| Gas price | 2 \$/Mscf | 1 \$/Mscf | 1037 |
| Gas price | | 3 \$/Mscf | 908 |
| Discount rate | 7% | 3% | 848 |
| Emission factors intermittent-vent cont. | 4.43 scfh | 8.6 scfh | 679 |
| | | 0.1 scfh | 1656 |
| Other supplies costs | \$1400/controller | \$1800 /controller | 1100 |
| | | \$1000 /controller | 844 |
| Electrical, mechanical & civil installation costs | 100% of equipment and supplies costs | 150% of equipment and supplies costs | 1212 |
| | | 50% of equipment and supplies costs | 732 |

CARBON LIMITS

Instrument air – New site

The following table presents a sensitivity analysis for the site configuration described in the section 4.3 (site with twenty controllers). The CH₄ abatement costs for a few key sensitivities should be compared to the abatement costs under the central assumption: \$886/t CH₄.

Table 21: Sensitivity analysis – retrofit site with 4 controllers– results

| Name of the parameter | Central assumption | Sensitivity value | Abatement cost in \$/t CH ₄ |
|---|-------------------------------------|--------------------------------------|--|
| Type of supply gas | Dry supply gas | Wet supply gas | 690 |
| Gas price | 2 \$/Mscf | 1 \$/Mscf | 949 |
| Gas price | | 3 \$/Mscf | 824 |
| Discount rate | 7% | 3% | 734 |
| Other supplies costs | \$1000/controller | \$1200 /controller | 963 |
| Electrical, mechanical & civil installation costs | 50% of equipment and supplies costs | 100% of equipment and supplies costs | 1154 |
| Emission factors low bleed controllers | 1.39 scfh | 6 scfh | 800 |
| | | 0.1 scfh | 1011 |

6.4 List of site configurations with abatement cost superior to the social cost of methane

The following table presents a complete list of all the site configurations with an abatement cost higher than the social cost of methane.

Electronic controller – New sites

The abatement cost is presented for the central assumptions, but also (right column) for a low-bleed emission factor of 5 scfh (compared to 1.39 in the central assumption).

Table 22: Site configurations with abatement cost superior to \$1354/ton - Electric controller – New sites

| Site configuration ID | New/retrofit | Electricity on site? | Supply gas | Pump # | Continuous Cont. # | Intermittent Cont. # | ESD # | Abatement costs – central assumptions | Abatement costs – Higher EF assumption |
|-----------------------|--------------|----------------------|------------|--------|--------------------|----------------------|-------|---------------------------------------|--|
| 13 | New | Electricity | Wet | 0 | 1 | 0 | 1 | 1985 | 456 |
| 349 | New | Electricity | Dry | 0 | 1 | 0 | 1 | 2838 | 703 |

FOREWORD

This background technical support document (TSD) provides information relevant to the proposal of New Source Performance Standards (NSPS) for limiting VOC emissions from the Oil and Natural Gas Sector. The proposed standards were developed according to section 111(b)(1)(B) under the Clean Air Act, which requires EPA to review and revise, is appropriate, NSPS standards. The NSPS review allows EPA to identify processes in the oil and natural sector that are not regulated under the existing NSPS but may be appropriate to regulate under NSPS based on new information. This would include processes that emit the current regulated pollutants, VOC and SO₂, as well as any additional pollutants that are identified. This document is the result of that review process. Chapter 1 provides introduction on NSPS regulatory authority. Chapter 2 presents an overview of the oil and natural gas sector. Chapter 3 discusses the entire NSPS review process undertaken for this review. Finally, Chapters 4-8 provide information on previously unregulated emissions sources. Each chapter describes the emission source, the estimated emissions (on average) from these sources, potential control options identified to reduce these emissions and the cost of each control option identified. In addition, secondary impacts are estimated and the rationale for the proposed NSPS for each emission source is provided.

TABLE OF CONTENTS

| | |
|---|------|
| 1.0 NEW SOURCE PERFORMANCE BACKGROUND | 1-1 |
| 1.1 Statutory Authority | 1-1 |
| 1.2 History of Oil and Gas Source Category | 1-2 |

APPENDIX A

1.0 NEW SOURCE PERFORMANCE STANDARD BACKGROUND

Standards of performance for new stationary sources are established under section 111 of the Clean Air Act (42 U.S.C. 7411), as amended in 1977. Section 111 directs the Administrator to establish standards of performance for any category of new stationary sources of air pollution which "...causes or contributes significantly to air pollution which may reasonably be anticipated to endanger public health or welfare." This technical support document (TSD) supports the proposed standards, which would control volatile organic compounds (VOC) and sulfur dioxide (SO₂) emissions from the oil and natural gas sector.

1.1 Statutory Authority

Section 111 of the Clean Air Act (CAA) requires the Environmental Protection Agency Administrator to list categories of stationary sources, if such sources cause or contribute significantly to air pollution which may reasonably be anticipated to endanger public health or welfare. The EPA must then issue performance standards for such source categories. A performance standard reflects the degree of emission limitation achievable through the application of the "best system of emission reduction" (BSER) which the EPA determines has been adequately demonstrated. The EPA may consider certain costs and nonair quality health and environmental impact and energy requirements when establishing performance standards. Whereas CAA section 112 standards are issued for existing and new stationary sources, standards of performance are issued for new and modified stationary sources. These standards are referred to as new source performance standards (NSPS). The EPA has the authority to define the source categories, determine the pollutants for which standards should be developed, identify the facilities within each source category to be covered and set the emission level of the standards.

CAA section 111(b)(1)(B) requires the EPA to "at least every 8 years review and, if appropriate, revise" performance standards unless the "Administrator determines that such review is not appropriate in light of readily available information on the efficacy" of the standard. When conducting a review of an existing performance standard, the EPA has discretion to revise that standard to add emission limits for pollutants or emission sources not currently regulated for that source category.

In setting or revising a performance standard, CAA section 111(a)(1) provides that performance standards are to "reflect the degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction and any

non-air quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.” This level of control is referred to as the best system of emission reduction (BSER). In determining BSER, a technology review is conducted that identifies what emission reduction systems exist and how much the identified systems reduce air pollution in practice. For each control system identified, the costs and secondary air benefits (or disbenefits) resulting from energy requirements and non-air quality impacts such as solid waste generation are also evaluated. This analysis determines BSER. The resultant standard is usually a numerical emissions limit, expressed as a performance level (i.e., a rate-based standard or percent control), that reflects the BSER. Although such standards are based on the BSER, the EPA may not prescribe a particular technology that must be used to comply with a performance standard, except in instances where the Administrator determines it is not feasible to prescribe or enforce a standard of performance. Typically, sources remain free to elect whatever control measures that they choose to meet the emission limits. Upon promulgation, a NSPS becomes a national standard to which all new, modified or reconstructed sources must comply.

1.2 History of Oil and Natural Gas Source Category

In 1979, the EPA listed crude oil and natural gas production on its priority list of source categories for promulgation of NSPS (44 FR 49222, August 21, 1979). On June 24, 1985 (50 FR 26122), the EPA promulgated a NSPS for the source category that addressed volatile organic compound (VOC) emissions from leaking components at onshore natural gas processing plants (40 CFR part 60, subpart KKK). On October 1, 1985 (50 FR 40158), a second NSPS was promulgated for the source category that regulates sulfur dioxide (SO₂) emissions from natural gas processing plants (40 CFR part 60, subpart LLL). Other than natural gas processing plants, EPA has not previously set NSPS for a variety of oil and natural gas operations. These NSPS are relatively narrow in scope as they address emissions only at natural gas processing plants. Specifically, subpart KKK addresses VOC emissions from leaking equipment at onshore natural gas processing plants, and subpart LLL addresses SO₂ emissions from natural gas processing plants.

1.3 NSPS Review Process Overview

CAA section 111(b)(1)(B) requires EPA to review and revise, if appropriate, NSPS standards. First, the existing NSPS were evaluated to determine whether it reflects BSER for the emission affected sources. This review was conducted by examining control technologies currently in use and assessing whether

these technologies represent advances in emission reduction techniques compared to the technologies upon which the existing NSPS are based. For each new control technology identified, the potential emission reductions, costs, secondary air benefits (or disbenefits) resulting from energy requirements and non-air quality impacts such as solid waste generation are evaluated. The second step is evaluating whether there are additional pollutants emitted by facilities in the oil and natural gas sector that contribute significantly to air pollution and may reasonably be anticipated to endanger public health or welfare. The final review step is to identify additional processes in the oil and natural gas sector that are not covered under the existing NSPS but may be appropriate to develop NSPS based on new information. This would include processes that emit the current regulated pollutants, VOC and SO₂, as well as any additional pollutants that are identified. The entire review process is described in Chapter 3.

2.0 OIL AND NATURAL GAS SECTOR OVERVIEW

The oil and natural gas sector includes operations involved in the extraction and production of oil and natural gas, as well as the processing, transmission and distribution of natural gas. Specifically for oil, the sector includes all operations from the well to the point of custody transfer at a petroleum refinery. For natural gas, the sector includes all operations from the well to the customer. The oil and natural gas operations can generally be separated into four segments: (1) oil and natural gas production, (2) natural gas processing, (3) natural gas transmission and (4) natural gas distribution. Each of these segments is briefly discussed below.

Oil and natural gas production includes both onshore and offshore operations. Production operations include the wells and all related processes used in the extraction, production, recovery, lifting, stabilization, separation or treating of oil and/or natural gas (including condensate). Production components may include, but are not limited to, wells and related casing head, tubing head and “Christmas tree” piping, as well as pumps, compressors, heater treaters, separators, storage vessels, pneumatic devices and dehydrators. Production operations also include well drilling, completion and recompletion processes; which includes all the portable non-self-propelled apparatus associated with those operations. Production sites include not only the “pads” where the wells are located, but also include stand-alone sites where oil, condensate, produced water and gas from several wells may be separated, stored and treated. The production sector also includes the low pressure, small diameter, gathering pipelines and related components that collect and transport the oil, gas and other materials and wastes from the wells to the refineries or natural gas processing plants. None of the operations upstream of the natural gas processing plant (i.e. from the well to the natural gas processing plant) are covered by the existing NSPS. Offshore oil and natural gas production occurs on platform structures that house equipment to extract oil and gas from the ocean or lake floor and that process and/or transfer the oil and gas to storage, transport vessels or onshore. Offshore production can also include secondary platform structures connected to the platform structure, storage tanks associated with the platform structure and floating production and offloading equipment.

There are three basic types of wells: Oil wells, gas wells and associated gas wells. Oil wells can have “associated” natural gas that is separated and processed or the crude oil can be the only product processed. Once the crude oil is separated from the water and other impurities, it is essentially ready to be transported to the refinery via truck, railcar or pipeline. The oil refinery sector is considered

separately from the oil and natural gas sector. Therefore, at the point of custody transfer at the refinery, the oil leaves the oil and natural gas sector and enters the petroleum refining sector.

Natural gas is primarily made up of methane. However, whether natural gas is associated gas from oil wells or non-associated gas from gas or condensate wells, it commonly exists in mixtures with other hydrocarbons. These hydrocarbons are often referred to as natural gas liquids (NGL). They are sold separately and have a variety of different uses. The raw natural gas often contains water vapor, hydrogen sulfide (H₂S), carbon dioxide (CO₂), helium, nitrogen and other compounds. Natural gas processing consists of separating certain hydrocarbons and fluids from the natural gas to produce “pipeline quality” dry natural gas. While some of the processing can be accomplished in the production segment, the complete processing of natural gas takes place in the natural gas processing segment. Natural gas processing operations separate and recover natural gas liquids or other non-methane gases and liquids from a stream of produced natural gas through components performing one or more of the following processes: Oil and condensate separation, water removal, separation of natural gas liquids, sulfur and CO₂ removal, fractionation of natural gas liquid and other processes, such as the capture of CO₂ separated from natural gas streams for delivery outside the facility. Natural gas processing plants are the only operations covered by the existing NSPS.

The pipeline quality natural gas leaves the processing segment and enters the transmission segment. Pipelines in the natural gas transmission segment can be interstate pipelines that carry natural gas across state boundaries or intrastate pipelines, which transport the gas within a single state. While interstate pipelines may be of a larger diameter and operated at a higher pressure, the basic components are the same. To ensure that the natural gas flowing through any pipeline remains pressurized, compression of the gas is required periodically along the pipeline. This is accomplished by compressor stations usually placed between 40 and 100 mile intervals along the pipeline. At a compressor station, the natural gas enters the station, where it is compressed by reciprocating or centrifugal compressors.

In addition to the pipelines and compressor stations, the natural gas transmission segment includes underground storage facilities. Underground natural gas storage includes subsurface storage, which typically consists of depleted gas or oil reservoirs and salt dome caverns used for storing natural gas. One purpose of this storage is for load balancing (equalizing the receipt and delivery of natural gas). At an underground storage site, there are typically other processes, including compression, dehydration and flow measurement.

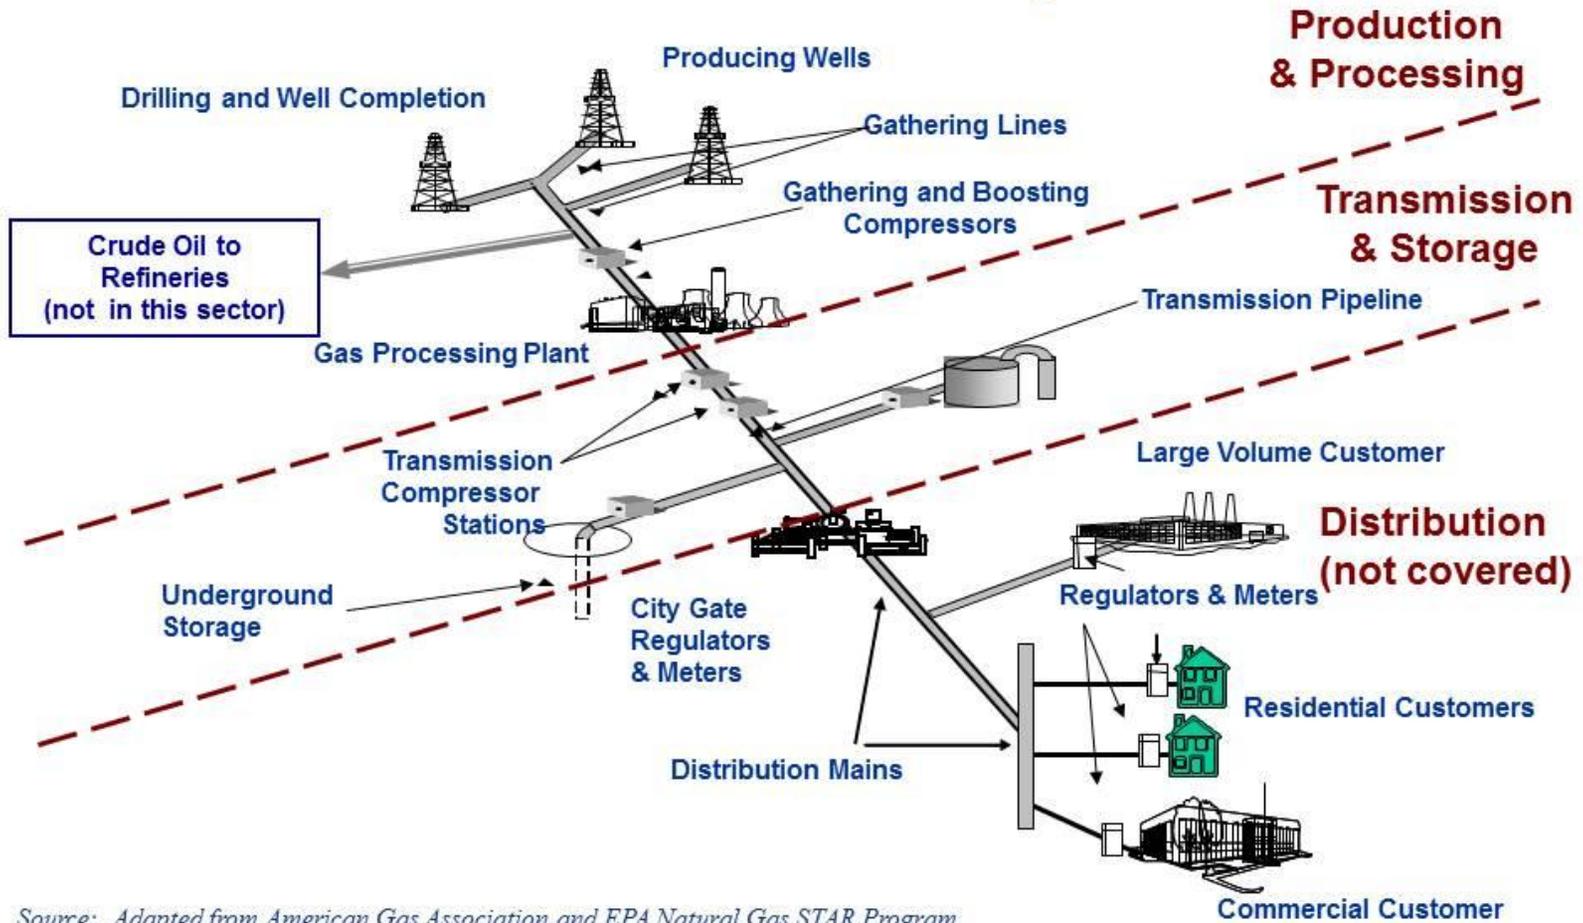

The distribution segment is the final step in delivering natural gas to customers. The natural gas enters the distribution segment from delivery points located on interstate and intrastate transmission pipelines to business and household customers. The delivery point where the natural gas leaves the transmission segment and enters the distribution segment is often called the “citygate.” Typically, utilities take ownership of the gas at the citygate. Natural gas distribution systems consist of thousands of miles of piping, including mains and service pipelines to the customers. Distribution systems sometimes have compressor stations, although they are considerably smaller than transmission compressor stations. Distribution systems include metering stations, which allow distribution companies to monitor the natural gas in the system. Essentially, these metering stations measure the flow of gas and allow distribution companies to track natural gas as it flows through the system.

Emissions can occur from a variety of processes and points throughout the oil and natural gas sector. Primarily, these emissions are organic compounds such as methane, ethane, VOC and organic hazardous air pollutants (HAP). The most common organic HAP are n-hexane and BTEX compounds (benzene, toluene, ethylbenzene and xylenes). Hydrogen sulfide and SO₂ are emitted from production and processing operations that handle and treat sour gasⁱ

In addition, there are significant emissions associated with the reciprocating internal combustion engines and combustion turbines that power compressors throughout the oil and natural gas sector. However, emissions from internal combustion engines and combustion turbines are covered by regulations specific to engines and turbines and, thus, are not addressed in this action.

ⁱ Sour gas is defined as natural gas with a maximum H₂S content of 0.25 gr/100 scf (4ppmv) along with the presence of CO₂

Oil and Natural Gas Operations

Figure 2-1. Oil and Natural Gas Operations

3.0 NEW SOURCE PERFORMANCE STANDARD REVIEW

As discussed in section 1.2, there are two NSPS that impact the oil and natural gas sector: (1) the NSPS for equipment leaks of VOC at natural gas processing plants (subpart KKK) and (2) the NSPS for SO₂ emissions from sweetening units located at natural gas processing plants (subpart LLL). Because they only address emissions from natural gas processing plants, these NSPS are relatively narrow in scope.

Section 111(b)(1) of the CAA requires the EPA to review and revise, if appropriate, NSPS standards. This review process consisted of the following steps:

1. Evaluation of the existing NSPS to determine whether they continue to reflect the BSER for the emission sources that they address;
2. Evaluation of whether there were additional pollutants emitted by facilities in the oil and natural gas sector that warrant regulation and for which there is adequate information to promulgate standards of performance; and
3. Identification of additional processes in the oil and natural gas sector for which it would be appropriate to develop performance standards, including processes that emit the currently regulated pollutants as well as any additional pollutants identified in step two.

The following sections detail each of these steps.

3.1 Evaluation of BSER for Existing NSPS

Consistent with the obligations under CAA section 111(b), control options reflected in the current NSPS for the Oil and Natural Gas source category were evaluated in order to distinguish if these options still represent BSER. To evaluate the BSER options for equipment leaks the following was reviewed: EPA's current leak detection and repair (LDAR) programs, the Reasonably Available Control Technology (RACT)/Best Available Control Technology (BACT)/Lowest Achievable Emission Rate (LAER) Clearinghouse (RBLC) database, and emerging technologies that have been identified by partners in the Natural Gas STAR program.¹

3.1.1 BSER for VOC Emissions from Equipment Leaks at Natural Gas Processing Plants

The current NSPS for equipment leaks of VOC at natural gas processing plants (40 CFR part 60, subpart KKK) requires compliance with specific provisions of 40 CFR part 60, subpart VV, which is a LDAR program, based on the use of EPA Method 21 to identify equipment leaks. In addition to the subpart VV requirements, the LDAR requirements in 40 CFR part 60, subpart VVa were also reviewed. This LDAR

program is considered to be more stringent than the subpart VV requirements, because it has lower component leak threshold definitions and more frequent monitoring, in comparison to the subpart VV program. Furthermore, subpart VVa requires monitoring of connectors, while subpart VV does not. Options based on optical gas imaging were also reviewed.

The currently required LDAR program for natural gas processing plants (40 CFR part 60, subpart KKK) is based on EPA Method 21, which requires the use of an organic vapor analyzer to monitor components and to measure the concentration of the emissions in identifying leaks. Although there have been advancements in the use of optical gas imaging to detect leaks from these same types of components, these instruments do not yet provide a direct measure of leak concentrations. The instruments instead provide a measure of a leak relative to an instrument specific calibration point. Since the promulgation of 40 CFR part 60, subpart KKK (which requires Method 21 leak measurement monthly), the EPA has updated the 40 CFR part 60 General Provisions to allow the use of advanced leak detection tools, such as optical gas imaging and ultrasound equipment as an alternative to the LDAR protocol based on Method 21 leak measurements (see 40 CFR 60.18(g)). The alternative work practice allowing use of these advanced technologies includes a provision for conducting a Method 21-based LDAR check of the regulated equipment annually to verify good performance.

In considering BSER for VOC equipment leaks at natural gas processing plants, four options were evaluated. One option evaluated consists of changing from a 40 CFR part 60, subpart VV-level program, which is what 40 CFR part 60, subpart KKK currently requires, to a 40 CFR part 60, subpart VVa program, which applies to new synthetic organic chemical plants after 2006. Subpart VVa lowers the leak definition for valves from 10,000 parts per million (ppm) to 500 ppm, and requires the monitoring of connectors. In our analysis of these impacts, it was estimated that, for a typical natural gas processing plant, the incremental cost effectiveness of changing from the current subpart VV-level program to a subpart VVa-level program using Method 21 is \$3,352 per ton of VOC reduction.

In evaluating 40 CFR part 60, subpart VVa-level LDAR at processing plants, the individual types of components (valves, connectors, pressure relief devices and open-ended lines) were also analyzed separately to determine cost effectiveness for individual components. Detailed discussions of these component-by-component analyses are provided in Chapter 8. Cost effectiveness ranged from \$144 per ton of VOC (for valves) to \$4,360 per ton of VOC (for connectors), with no change in requirements for pressure relief devices and open-ended lines.

Another option evaluated for gas processing plants was the use of optical gas imaging combined with an annual EPA Method 21 check (i.e., the alternative work practice for monitoring equipment for leaks at 40 CFR 60.18(g)). It was previously determined that the VOC reduction achieved by this combination of optical gas imaging and Method 21 would be equivalent to reductions achieved by the 40 CFR part 60, subpart VVa-level program. Based on the emission reduction level, the cost effectiveness of this option was estimated to be \$6,462 per ton of VOC reduction. This analysis was based on the facility purchasing an optical gas imaging system costing \$85,000. However, at least one manufacturer was identified that rents the optical gas imaging systems. That manufacturer rents the optical gas imaging system for \$3,950 per week. Using this rental cost in place of the purchase cost, the VOC cost effectiveness of the monthly optical gas imaging combined with annual Method 21 inspection visits is \$4,638 per ton of VOC reduction.ⁱ

A third option evaluated consisted of monthly optical gas imaging without an annual Method 21 check. The annual cost of the monthly optical gas imaging LDAR program was estimated to be \$76,581 based on camera purchase, or \$51,999 based on camera rental. However, it is not possible to quantify the VOC emission reductions achieved by an optical imaging program alone, therefore the cost effectiveness of this option could not be determined. Finally, a fourth option was evaluated that was similar to the third option, except that the optical gas imaging would be performed annually rather than monthly. For this option, the annual cost was estimated to be \$43,851, based on camera purchase, or \$18,479, based on camera rental.

Because the cost effectiveness of options 3 and 4 could not be estimated, these options could not be identified as BSER for reducing VOC leaks at gas processing plants. Because options 1 and 2 achieve equivalent VOC reduction and are both cost effective, both options 1 and 2 reflect BSER for LDAR for natural gas processing plants. As mentioned above, option 1 is the LDAR in 40 CFR part 60, subpart VVa and option 2 is the alternative work practice at 40 CFR 60.18(g) and is already available to use as an alternative to subpart VVa LDAR.

3.1.2 BSER for SO₂ Emissions from Sweetening Units at Natural Gas Processing Plants

For 40 CFR part 60, subpart LLL, control systems for SO₂ emissions from sweetening units located at natural gas processing plants were evaluated, including those followed by a sulfur recovery unit. Subpart

ⁱ Because optical gas imaging is used to view multiple pieces of equipment at a facility during one leak survey, options involving imaging are not amenable to a component by component analysis.

LLL provides specific standards for SO₂ emission reduction efficiency, on the basis of sulfur feed rate and the sulfur content of the natural gas.

According to available literature, the most widely used process for converting H₂S in acid gases (i.e., H₂S and CO₂) separated from natural gas by a sweetening process (such as amine treating) into elemental sulfur is the Claus process. Sulfur recovery efficiencies are higher with higher concentrations of H₂S in the feed stream due to the thermodynamic equilibrium limitation of the Claus process. The Claus sulfur recovery unit produces elemental sulfur from H₂S in a series of catalytic stages, recovering up to 97-percent recovery of the sulfur from the acid gas from the sweetening process. Further, sulfur recovery is accomplished by making process modifications or by employing a tail gas treatment process to convert the unconverted sulfur compounds from the Claus unit.

In addition, process modifications and tail gas treatment options were also evaluated at the time 40 CFR part 60, subpart LLL was proposed.ⁱⁱ As explained in the preamble to the proposed subpart LLL, control through sulfur recovery with tail gas treatment may not always be cost effective, depending on sulfur feed rate and inlet H₂S concentrations. Therefore, other methods of increasing sulfur recovery via process modifications were evaluated.

As shown in the original evaluation for the proposed subpart LLL, the performance capabilities and costs of each of these technologies are highly dependent on the ratio of H₂S and CO₂ in the gas stream and the total quantity of sulfur in the gas stream being treated. The most effective means of control was selected as BSER for the different stream characteristics. As a result, separate emissions limitations were developed in the form of equations that calculate the required initial and continuous emission reduction efficiency for each plant. The equations were based on the design performance capabilities of the technologies selected as BSER relative to the gas stream characteristics.ⁱⁱⁱ The emission limit for sulfur feed rates at or below 5 long tons per day, regardless of H₂S content, was 79 percent. For facilities with sulfur feed rates above 5 long tons per day, the emission limits ranged from 79 percent at an H₂S content below 10 percent to 99.8 percent for H₂S contents at or above 50 percent.

To review these emission limitations, a search was performed of the RBLC database¹ and state regulations. No State regulations were identified that included emission limitations more stringent than 40 CFR part 60, subpart LLL. However, two entries in the RBLC database were identified having SO₂

ⁱⁱ 49 FR 2656, 2659-2660 (1984).

ⁱⁱⁱ 49 FR 2656, 2663-2664 (1984).

emission reductions of 99.9 percent. One entry is for a facility in Bakersfield, California, with a 90 long ton per day sulfur recovery unit followed by an amine-based tailgas treating unit. The second entry is for a facility in Coden, Alabama, with a sulfur recovery unit with a feed rate of 280 long tons of sulfur per day, followed by selective catalytic reduction and a tail gas incinerator. However, neither of these entries contained information regarding the H₂S contents of the feed stream. Because the sulfur recovery efficiency of these large sized plants was greater than 99.8 percent, the original data was reevaluated. Based on the available cost information, a 99.9 percent efficiency is cost effective for facilities with a sulfur feed rate greater than 5 long tons per day and H₂S content equal to or greater than 50 percent. Based on this review, the maximum initial and continuous efficiency for facilities with a sulfur feed rate greater than 5 long tons per day and a H₂S content equal to or greater than 50 percent is raised to 99.9 percent.

The search of the RBLC database did not uncover information regarding costs and achievable emission reductions to suggest that the emission limitations for facilities with a sulfur feed rate less than 5 long tons per day or H₂S content less than 50 percent should be modified. Therefore, there were not any identifiable changes to the emissions limitations for facilities with sulfur feed rate and H₂S content less than 5 long tons per day and 50 percent, respectively.¹

3.2 Additional Pollutants

The two current NSPS for the Oil and Natural Gas source category address emissions of VOC and SO₂. In addition to these pollutants, sources in this source category also emit a variety of other pollutants, most notably, air toxics. However, there are NESHAP that address air toxics from the oil and natural gas sector, specifically 40 CFR subpart HH and 40 CFR subpart HHH.

In addition, processes in the Oil and Natural Gas source category emit significant amounts of methane. The 1990 - 2009 U.S. GHG Inventory estimates 2009 methane emissions from Petroleum and Natural Gas Systems (not including petroleum refineries) to be 251.55 MMtCO₂e (million metric tons of CO₂-equivalents (CO₂e)).^{iv} The emissions estimated from well completions and recompletions exclude a significant number of wells completed in tight sand plays, such as the Marcellus, due to availability of data when the 2009 Inventory was developed. The estimate in this proposal includes an adjustment for tight sand plays (being considered as a planned improvement in development of the 2010 Inventory).

^{iv} U.S. EPA. Inventory of U.S. Greenhouse Gas Inventory and Sinks. 1990 - 2009.
http://www.epa.gov/climatechange/emissions/downloads10/US-GHGInventory2010_ExecutiveSummary.pdf

This adjustment would increase the 2009 Inventory estimate by 76.74 MMtCO₂e. The total methane emissions from Petroleum and Natural Gas Systems, based on the 2009 Inventory, adjusted for tight sand plays and the Marcellus, is 328.29 MMtCO₂e.

Although this proposed rule does not include standards for regulating the GHG emissions discussed above, EPA continues to assess these significant emissions and evaluate appropriate actions for addressing these concerns. Because many of the proposed requirements for control of VOC emissions also control methane emissions as a co-benefit, the proposed VOC standards would also achieve significant reduction of methane emissions.

Significant emissions of oxides of nitrogen (NO_x) also occur at oil and natural gas sites due to the combustion of natural gas in reciprocating engines and combustion turbines used to drive the compressors that move natural gas through the system, and from combustion of natural gas in heaters and boilers. While these engines, turbines, heaters and boilers are co-located with processes in the oil and natural gas sector, they are not in the Oil and Natural Gas source category and are not being addressed in this action. The NO_x emissions from engines and turbines are covered by the Standards of Performance for Stationary Spark Internal Combustion Engines (40 CFR part 60, subpart JJJJ) and Standards of Performance for Stationary Combustion Turbines (40 CFR part 60, subpart KKKK), respectively.

An additional source of NO_x emissions would be pit flaring of VOC emissions from well completions. As discussed in Chapter 4 Well completions, pit flaring is one option identified for controlling VOC emissions. Because there is no way of directly measuring the NO_x produced, nor is there any way of applying controls other than minimizing flaring, flaring would only be required for limited conditions.

3.3 Additional Processes

The current NSPS only cover emissions of VOC and SO₂ from one type of facility in the oil and natural gas sector, which is the natural gas processing plant. This is the only type of facility in the Oil and Natural Gas source category where SO₂ is expected to be emitted directly; although H₂S contained in sour gas^v forms SO₂ as a product of oxidation when oxidized in the atmosphere or combusted in boilers and heaters in the field. These field boilers and heaters are not part of the Oil and Natural Gas source category and are generally too small to be regulated by the NSPS covering boilers (i.e., they have a heat

^v Sour gas is defined as natural gas with a maximum H₂S content of 0.25 gr/100 scf (4ppmv) along with the presence of CO₂.

input of less than 10 million British Thermal Units per hour). They may, however, be included in future rulemakings.

In addition to VOC emissions from gas processing plants, there are numerous sources of VOC throughout the oil and natural gas sector that are not addressed by the current NSPS. Pursuant to CAA section 111(b), a modification of the listed category will now include all segments of the oil and natural gas industry for regulation. In addition, VOC standards will now cover additional processes at oil and natural gas operations. These include NSPS for VOC from gas well completions and recompletions, pneumatic controllers, compressors and storage vessels. In addition, produced water ponds may also be a potentially significant source of emissions, but there is very limited information available regarding these emissions. Therefore, no options could be evaluated at this time. The remainder of this document presents the evaluation for each of the new processes to be included in the NSPS.

4.0 WELL COMPLETIONS AND RECOMPLETIONS

In the oil and natural gas sector, well completions and recompletions contain multi-phase processes with various sources of emissions. One specific emission source during completion and recompletion activities is the venting of natural gas to the atmosphere during flowback. Flowback emissions are short-term in nature and occur as a specific event during completion of a new well or during recompletion activities that involve re-drilling or re-fracturing an existing well. This chapter describes completions and recompletions, and provides estimates for representative wells in addition to nationwide emissions. Control techniques employed to reduce emissions from flowback gas venting during completions and recompletions are presented, along with costs, emission reductions, and secondary impacts. Finally, this chapter discusses considerations in developing regulatory alternatives for reducing flowback emissions during completions and recompletions.

4.1 Process Description

4.1.1 Oil and Gas Well Completions

All oil and natural gas wells must be “completed” after initial drilling in preparation for production. Oil and natural gas completion activities not only will vary across formations, but can vary between wells in the same formation. Over time, completion and recompletion activities may change due to the evolution of well characteristics and technology advancement. Conventional gas reservoirs have well defined formations with high resource allocation in permeable and porous formations, and wells in conventional gas reservoirs have generally not required stimulation during production. Unconventional gas reservoirs are more dispersed and found in lower concentrations and may require stimulation (such as hydraulic fracturing) to extract gas.¹

Well completion activities include multiple steps after the well bore hole has reached the target depth. These steps include inserting and cementing-in well casing, perforating the casing at one or more producing horizons, and often hydraulically fracturing one or more zones in the reservoir to stimulate production. Surface components, including wellheads, pumps, dehydrators, separators, tanks, and gathering lines are installed as necessary for production to begin. The flowback stage of a well completion is highly variable but typically lasts between 3 and 10 days for the average well.²

Developmental wells are drilled within known boundaries of a proven oil or gas field, and are located near existing well sites where well parameters are already recorded and necessary surface equipment is in place. When drilling occurs in areas of new or unknown potential, well parameters such as gas composition, flow rate, and temperature from the formation need to be ascertained before surface facilities required for production can be adequately sized and brought on site. In this instance, exploratory (also referred to as “wildcat”) wells and field boundary delineation wells typically either vent or combust the flowback gas.

One completion step for improving gas production is to fracture the reservoir rock with very high pressure fluid, typically a water emulsion with a proppant (generally sand) that “props open” the fractures after fluid pressure is reduced. Natural gas emissions are a result of the backflow of the fracture fluids and reservoir gas at high pressure and velocity necessary to clean and lift excess proppant to the surface. Natural gas from the completion backflow escapes to the atmosphere during the reclamation of water, sand, and hydrocarbon liquids during the collection of the multi-phase mixture directed to a surface impoundment. As the fracture fluids are depleted, the backflow eventually contains a higher volume of natural gas from the formation. Due to the additional equipment and resources involved and the nature of the backflow of the fracture fluids, completions involving hydraulic fracturing have higher costs and vent substantially more natural gas than completions not involving hydraulic fracturing.

Hydraulic fracturing can and does occur in some conventional reservoirs, but it is much more common in “tight” formations. Therefore, this analysis assumes hydraulic fracturing is performed in tight sand, shale, and coalbed methane formations. This analysis defines tight sand as sandstones or carbonates with an in situ permeability (flow rate capability) to gas of less than 0.1 millidarcy.ⁱ

“Energized fractures” are a relatively new type of completion method that injects an inert gas, such as carbon dioxide or nitrogen, before the fracture fluid and proppant. Thus, during initial flowback, the gas stream will first contain a high proportion of the injected gas, which will gradually decrease overtime.

4.1.2 Oil and Gas Well Recompletions

Many times wells will need supplementary maintenance, referred to as recompletions (these are also referred to as workovers). Recompletions are remedial operations required to maintain production or minimize the decline in production. Examples of the variety of recompletion activities include

ⁱ A darcy (or darcy unit) and millidarcies (mD) are units of permeability. Converted to SI units, 1 darcy is equivalent to $9.869233 \times 10^{-13} \text{ m}^2$ or $0.9869233 \text{ (}\mu\text{m)}^2$. This conversion is usually approximated as $1 \text{ (}\mu\text{m)}^2$.

completion of a new producing zone, re-fracture of a previously fractured zone, removal of paraffin buildup, replacing rod breaks or tubing tears in the wellbore, and addressing a malfunctioning downhole pump. During a recompletion, portable equipment is conveyed back to the well site temporarily and some recompletions require the use of a service rig. As with well completions, recompletions are highly specialized activities, requiring special equipment, and are usually performed by well service contractors specializing in well maintenance. Any flowback event during a recompletion, such as after a hydraulic fracture, will result in emissions to the atmosphere unless the flowback gas is captured.

When hydraulic re-fracturing is performed, the emissions are essentially the same as new well completions involving hydraulic fracture, except that surface gas collection equipment will already be present at the wellhead after the initial fracture. The backflow velocity during re-fracturing will typically be too high for the normal wellhead equipment (separator, dehydrator, lease meter), while the production separator is not typically designed for separating sand.

Backflow emissions are not a direct result of produced water. Backflow emissions are a result of free gas being produced by the well during well cleanup event, when the well also happens to be producing liquids (mostly water) and sand. The high rate backflow, with intermittent slugs of water and sand along with free gas, is typically directed to an impoundment or vessels until the well is fully cleaned up, where the free gas vents to the atmosphere while the water and sand remain in the impoundment or vessels. Therefore, nearly all of the backflow emissions originate from the recompletion process but are vented as the backflow enters the impoundment or vessels. Minimal amounts of emissions are caused by the fluid (mostly water) held in the impoundment or vessels since very little gas is dissolved in the fluid when it enters the impoundment or vessels.

4.2. Emission Data and Emissions Factors

4.2.1 Summary of Major Studies and Emission Factors

Given the potential for significant emissions from completions and recompletions, there have been numerous recent studies conducted to estimate these emissions. In the evaluation of the emissions and emission reduction options for completions and recompletions, many of these studies were consulted. Table 4-1 presents a list of the studies consulted along with an indication of the type of information contained in the study.

4.2.2 Representative Completion and Recompletion Emissions

As previously mentioned, one specific emission source during completion and recompletion activities is the venting of natural gas to the atmosphere during flowback. Flowback emissions are short-term in nature and occur as a specific event during the completion of a new well or during recompletion activities that involve re-drilling or re-fracturing of an existing well. For this analysis, well completion and recompletion emissions are estimated as the venting of emissions from the well during the initial phases of well preparation or during recompletion maintenance and/or re-fracturing of an existing well.

As previously stated, this analysis assumes wells completed/recompleted with hydraulic fracturing are found in tight sand, shale, or coal bed methane formations. A majority of the available emissions data for recompletions is for vertically drilled wells. It is projected that in the future, a majority of completions and recompletions will predominantly be performed on horizontal wells. However, there is not enough history of horizontally drilled wells to make a reasonable estimation of the difference in emissions from recompletions of horizontal versus vertical wells. Therefore, for this analysis, no distinction was made between vertical and horizontal wells.

As shown in Table 4-1, methane emissions from oil and natural gas operations have been measured, analyzed and reported in studies spanning the past few decades. The basic approach for this analysis was to approximate methane emissions from representative oil and gas completions and recompletions and then estimate volatile organic compounds (VOC) and hazardous air pollutants (HAP) using a representative gas composition.²⁶ The specific gas composition ratios used for gas wells were 0.1459 pounds (lb) VOC per lb methane (lb VOC/lb methane) and 0.0106 lb HAP/lb methane. The specific gas composition ratios used for oil wells were 0.8374 pounds lb VOC/lb methane and 0.0001 lb HAP/lb methane.

The EPA's analysis to estimate methane emissions conducted in support of the Greenhouse Gas Mandatory Reporting Rule (Subpart W), which was published in the *Federal Register* on November 30, 2010 (75 FR 74458), was the foundation for methane emission estimates from natural gas completions with hydraulic fracturing and recompletions with hydraulic fracturing. Methane emissions from oil well completions, oil well recompletions, natural gas completions without hydraulic fracturing, and natural gas recompletions without hydraulic fracturing were derived directly from the EPA's Inventory of Greenhouse Gas Emissions and Sinks: 1990-2008 (Inventory).⁴ A summary of emissions for a representative model well completion or recompletion is found in Table 4-2.

Table 4-2. Uncontrolled Emissions Estimates from Oil and Natural Gas Well Completions and Recompletions

| Well Completion Category | Emissions (Mcf/event) | Emissions (tons/event) | | |
|--|-----------------------|------------------------|------------------|------------------|
| | Methane | Methane ^a | VOC ^b | HAP ^c |
| Natural Gas Well Completion without Hydraulic Fracturing | 38.6 | 0.8038 | 0.12 | 0.009 |
| Natural Gas Well Completion with Hydraulic Fracturing | 7,623 | 158.55 | 23.13 | 1.68 |
| Oil Well Completions | 0.34 | 0.0076 | 0.00071 | 0.0000006 |
| Natural Gas Well Recompletion without Hydraulic Fracturing | 2.59 | 0.0538 | 0.0079 | 0.0006 |
| Natural Gas Well Recompletion with Hydraulic Fracturing | 7,623 | 158.55 | 23.13 | 1.68 |
| Oil Well Recompletions | 0.057 | 0.00126 | 0.001 | 0.0000001 |

Minor discrepancies may exist due to rounding.

- a. Reference 4, Appendix B., pgs 84-89. The conversion used to convert methane from volume to weight is 0.0208 tons methane is equal to 1 Mcf of methane. It is assumed methane comprises 83.081 percent by volume of natural gas from gas wells and 46.732 percent by volume of methane from oil wells.
- b. Assumes 0.1459 lb VOC /lb methane for natural gas wells and 0.8374 lb VOC/lb methane for oil wells.
- c. Assumes 0.0106 lb HAP/lb methane for natural gas wells and 0.0001 lb HAP/lb methane for oil wells.

4.3 Nationwide Emissions from New Sources

4.3.1 Overview of Approach

The first step in this analysis is to estimate nationwide emissions in absence of the proposed rulemaking, referred to as the baseline emissions estimate. In order to develop the baseline emissions estimate, the number of completions and recompletions performed in a typical year was estimated and then multiplied by the expected uncontrolled emissions per well completion listed in Table 4-2. In addition, to ensure no emission reduction credit was attributed to sources already controlled under State regulations, it was necessary to account for the number of completions/recompletions already subject to State regulations as detailed below. In order to estimate the number of wells that are already controlled under State regulations, existing well data was analyzed to estimate the percentage of currently controlled wells. This percentage was assumed to also represent the wells that would have been controlled in absence of a federal regulation and applied to the number of well completions estimated for future years.

4.3.2 Number of Completions and Recompletions

The number of new well completions was estimated using the National Energy Modeling System (NEMS). NEMS is a model of U.S. energy economy developed and maintained by the Energy Information Administration (EIA). NEMS is used to produce the Annual Energy Outlook, a reference publication that provides detailed forecasts of the energy economy from the current year to 2035. EIA is legally required to make the NEMS source code available and fully documented for the public. The source code and accompanying documentation is released annually when a new Annual Energy Outlook is produced. Because of the availability of NEMS, numerous agencies, national laboratories, research institutes, and academic and private-sector researchers have used NEMS to analyze a variety of issues. NEMS models the dynamics of energy markets and their interactions with the broader U.S. economy. The system projects the production of energy resources such as oil, natural gas, coal, and renewable fuels, the conversion of resources through processes such as refining and electricity generation, and the quantity and prices for final consumption across sectors and regions.

New well completion estimates are based on predictions from the NEMS Oil and Gas Supply Model, drawing upon the same assumptions and model used in the Annual Energy Outlook 2011 Reference Case. New well completions estimates were based on total successful wells drilled in 2015 (the year of analysis for regulatory impacts) for the following well categories: natural gas completions without hydraulic fracturing, natural gas completions with hydraulic fracturing, and oil well completions.

Successful wells are assumed to be equivalent to completed wells. Meanwhile, it was assumed that new dry wells would be abandoned and shut in and would not be completed. Therefore estimates of the number of dry wells were not included in the activity projections or impacts discussion for exploratory and developmental wells. Completion estimates are based on successful developmental and exploratory wells for each category defined in NEMS that includes oil completions, conventional gas completions and unconventional gas completions. The NEMS database defines unconventional reservoirs as those in shale, tight sand, and coalbed methane formations and distinguishes those from wells drilled in conventional reservoirs. Since hydraulic fracturing is most common in unconventional formations, this analysis assumes new successful natural gas wells in shale, tight sand, and coalbed methane formations are completed with hydraulic fracturing. New successful natural gas wells in conventional formations are assumed to be completed without hydraulic fracturing.

The number of natural gas recompletions with hydraulic fracturing (also referred to as a re-fracture), natural gas recompletions without hydraulic fracturing and oil well recompletions was based on well count data found in the HPDI[®] database.^{ii, iii} The HPDI database consists of oil and natural gas well information maintained by a private organization that provides parameters describing the location, operator, and production characteristics. HPDI[®] collects information on a well basis such as the operator, state, basin, field, annual gas production, annual oil production, well depth, and shut-in pressure, all of which is aggregated from operator reports to state governments. HPDI was used to estimate the number of recompleted wells because the historical well data from HPDI is a comprehensive resource describing existing wells. Well data from 2008 was used as a base year since it was the most recent available data at the time of this analysis and is assumed to represent the number of recompletions that would occur in a representative year. The number of hydraulically fractured natural gas recompletions was estimated by estimating each operator and field combination found in the HPDI database and multiplying by 0.1 to represent 10 percent of the wells being re-fractured annually (as assumed in Subpart W's Technical Supporting Document3). This results in 14,177 total natural gas recompletions with hydraulic fracturing in the U.S. for the year 2008; which is assumed to depict a representative year. Non-fractured

ⁱⁱ HPDI, LLC is a private organization specializing in oil and gas data and statistical analysis. The HPDI database is focused on historical oil and gas production data and drilling permit data.

ⁱⁱⁱ For the State of Pennsylvania, the most recent drilling information available from HPDI was for 2003. Due to the growth of oil and gas operations occurring in the Marcellus region in Pennsylvania, this information would not accurately represent the size of the industry in Pennsylvania for 2006 through 2008. Therefore, information from the Pennsylvania's Department of Environmental Protection was used to estimate well completion activities for this region. Well data from remaining states were based on available information from HPDI. From

<<http://www.marcellusreporting.state.pa.us/OGREReports/Modules/DataExports/DataExports.aspx>

recompletions were based on well data for 2008 in HPDI. The number of estimated well completions and recompletions for each well source category is listed in Table 4-3.

4.3.3 Level of Controlled Sources in Absence of Federal Regulation

As stated previously, to determine the impact of a regulation, it is first necessary to determine the current level of emissions from the sources being evaluated, or baseline emissions. To more accurately estimate baseline emissions for this analysis, and to ensure no emission reduction credit was attributed for sources already being controlled, it was necessary to evaluate the number of completions and recompletions already subject to regulation. Therefore, the number of completions and recompletions already being controlled in the absence of federal regulation was estimated based on the existing State regulations that require control measures for completions and recompletions. Although there may be regulations issued by other local ordinances for cities and counties throughout the U.S., wells impacted by these regulations were not included in this analysis because well count data are not available on a county or local ordinance level. Therefore, the percentage calculated based on the identified State regulations should be considered a conservative estimate.

In order to determine the number of completions and recompletions that are already controlled under State regulations, EIA historical well count data was analyzed to determine the percentage of new wells currently undergoing completion and recompletion in the States identified as having existing controls.^{iv} Colorado (CO) and Wyoming (WY) were the only States identified as requiring controls on completions prior to NSPS review. The State of Wyoming's Air Quality Division (WAQD) requires operators to complete wells without flaring or venting where the following criteria are met: (1) the flowback gas meets sales line specifications and (2) the pressure of the reservoir is high enough to enable REC. If the above criteria are not met, then the produced gas is to be flared.²⁷ The WAQD requires that, "emissions of VOC and HAP associated with the flaring and venting of hydrocarbon fluids (liquids and gas) associated with well completion and recompletion activities shall be eliminated to the extent practicable by routing the recovered liquids into storage tanks and routing the recovered gas into a gas sales line or collection system." Similar to WY, the Colorado Oil and Gas Conservation Commission (COGCC) requires REC for both oil and natural gas wells.²⁸ It was assumed for this analysis that the ratio of natural wells in CO and WY to the total number of wells in the U.S. represents the percentage of controlled wells for well completions. The ratio of wells in WY to the number of total nationwide wells

^{iv} See EIA's The Number of Producing Wells, http://www.eia.gov/dnav/ng/ng_prod_wells_s1_a.htm

Table 4-3: Estimated Number of Total Oil and Natural Gas Completions and Recompletions for a Typical Year

| Well Completion Category | Estimated Number of Total Completions and Recompletions^a | Estimated Number of Controlled Completions and Recompletions | Estimated Number of Uncontrolled Completions and Recompletions^b |
|---|--|---|---|
| Natural Gas Well Completions without Hydraulic Fracturing [*] | 7,694 | | 7,694 |
| Exploratory Natural Gas Well Completions with Hydraulic Fracturing ^{**} | 446 | | 446 |
| Developmental Natural Gas Well Completions with Hydraulic Fracturing ^c | 10,957 | 1,644 | 9,313 |
| Oil Well Completions ^d | 12,193 | | 12,193 |
| Natural Gas Well Recompletions without Hydraulic Fracturing | 42,342 | | 42,342 |
| Natural Gas Well Recompletions with Hydraulic Fracturing ^{††} | 14,177 | 2,127 | 12,050 |
| Oil Well Recompletions [†] | 39,375 | | 39,375 |

- a. Natural gas completions and recompletions without hydraulic fracturing are assumed to be uncontrolled at baseline.
- b. Fifteen percent of natural gas well completions with hydraulic fracturing are assumed as controlled at baseline.
- c. Oil well completions and recompletions are assumed to be uncontrolled at baseline.
- d. Fifteen percent of natural gas well recompletions with hydraulic fracturing are assumed to be controlled at baseline.

was assumed to represent the percentage of controlled well recompletions as it was the only State identified as having regulations directly regulated to recompletions.

From this review it was estimated that 15 percent of completions and 15 percent of recompletions are controlled in absence of federal regulation. It is also assumed for this analysis that only natural gas wells undergoing completion or recompletion with hydraulic fracturing are controlled in these States. Completions and recompletions that are performed without hydraulic fracturing, in addition to oil well completions and recompletions were assumed to not be subject to State regulations and therefore, were assumed to not be regulated at baseline. Baseline emissions for the controlled completions and recompletions covered by regulations are assumed to be reduced by 95 percent from the use of both REC and combustion devices that may be used separately or in tandem, depending on the individual State regulation.^v The final activity factors for uncontrolled completions and uncontrolled recompletions are also listed in Table 4-3.

4.3.4 Emission Estimates

Using the estimated emissions, number of uncontrolled and controlled wells at baseline, described above, nationwide emission estimates for oil and gas well completions and recompletions in a typical year were calculated and are summarized in Table 4-4. All values have been independently rounded to the nearest ton for estimation purposes. As the table indicates, hydraulic fracturing significantly increases the magnitude of emissions. Completions and recompletions without hydraulic fracturing have lower emissions, while oil completions and recompletions have even lower emissions in comparison.

4.4 Control Techniques

4.4.1 Potential Control Techniques

Two techniques were considered that have been proven to reduce emissions from well completions and recompletions: REC and completion combustion. One of these techniques, REC, is an approach that not only reduces emissions but delivers natural gas product to the sales meter that would typically be vented. The second technique, completion combustion, destroys the organic compounds. Both of these techniques are discussed in the following sections, along with estimates of the impacts of their application for a representative well. Nationwide impacts of chosen regulatory options are discussed in

^v Percentage of controls by flares versus REC were not determined, so therefore, the count of controlled wells with REC versus controlled wells with flares was not determined and no secondary baseline emission impacts were calculated.

Table 4-4. Nationwide Baseline Emissions from Uncontrolled Oil and Gas Well Completions and Recompletions

| Well Completion Category | Uncontrolled Methane Emissions per event (tpy) | Number of Uncontrolled Wells ^a | Baseline Nationwide Emissions (tons/year) ^a | | |
|--|--|---|--|------------------|------------------|
| | | | Methane ^b | VOC ^c | HAP ^d |
| Natural Gas Well Completions without Hydraulic Fracturing | 0.8038 | 7,694 | 6,185 | 902 | 66 |
| Exploratory Natural Gas Well Completions with Hydraulic Fracturing | 158.55 | 446 | 70,714 | 10,317 | 750 |
| Developmental Natural Gas Well Completions with Hydraulic Fracturing | 158.55 | 9,313 | 1,476,664 | 215,445 | 15,653 |
| Oil Well Completions | 0.0076 | 12,193 | 93 | 87 | .008 |
| Natural Gas Well Recompletions without Hydraulic Fracturing | 0.0538 | 42,342 | 2,279 | 332 | 24 |
| Natural Gas Well Recompletions with Hydraulic Fracturing | 158.55 | 12,050 | 1,910,549 | 278,749 | 20,252 |
| Oil Well Recompletions | 0.00126 | 39,375 | 50 | 47 | .004 |

Minor discrepancies may be due to rounding.

- a. Baseline emissions include emissions from uncontrolled wells plus five percent of emissions from controlled sources. The Baseline emission reductions listed in the Regulatory Impacts (Table 4-9) represents only emission reductions from uncontrolled sources.
- b. The number of controlled and uncontrolled wells estimated based on State regulations.
- c. Based on the assumption that VOC content is 0.1459 pounds VOC per pound methane for natural gas wells and 0.8374 pounds VOC per pound methane for oil wells This estimate accounts for 5 percent of emissions assumed as vented even when controlled. Does not account for secondary emissions from portion of gas that is directed to a combustion device.
- d. Based on the assumption that HAP content is 0.0106 pounds HAP per pound methane for natural gas wells and 0.0001 pounds HAP per pound methane for oil wells. This estimate accounts for 5 percent of emissions assumed as vented even when controlled. Does not account for secondary emissions from portion of gas that is directed to a combustion device.

section 4.5.

4.4.2 Reduced Emission Completions and Recompletions

4.4.2.1 Description

Reduced emission completions, also referred to as “green” or “flareless” completions, use specially designed equipment at the well site to capture and treat gas so it can be directed to the sales line. This process prevents some natural gas from venting and results in additional economic benefit from the sale of captured gas and, if present, gas condensate. Additional equipment required to conduct a REC may include additional tankage, special gas-liquid-sand separator traps, and a gas dehydrator.²⁹ In many cases, portable equipment used for RECs operate in tandem with the permanent equipment that will remain after well drilling is completed. In other instances, permanent equipment is designed (e.g. oversized) to specifically accommodate initial flowback. Some limitations exist for performing RECs since technical barriers fluctuate from well to well. Three main limitations include the following for RECs:

- Proximity of pipelines. For exploratory wells, no nearby sales line may exist. The lack of a nearby sales line incurs higher capital outlay risk for exploration and production companies and/or pipeline companies constructing lines in exploratory fields. The State of Wyoming has set a precedent by stating proximity to gathering lines for wells is not a sufficient excuse to avoid RECs unless they are deemed exploratory, or the first well drilled in an area that has never had oil and gas well production prior to that drilling instance (i.e., a wildcat well).³⁰ In instances where formations are stacked vertically and horizontal drilling could take place, it may be possible that existing surface REC equipment may be located near an exploratory well, which would allow for a REC.
- Pressure of produced gas. During each stage of the completion/recompletion process, the pressure of flowback fluids may not be sufficient to overcome the sales line backpressure. This pressure is dependent on the specific sales line pressure and can be highly variable. In this case, combustion of flowback gas is one option, either for the duration of the flowback or until a point during flowback when the pressure increases to flow to the sales line. Another control option is compressor applications. One application is gas lift which is accomplished by withdrawing gas from the sales line, boosting its pressure, and routing it down the well

casing to push the fracture fluids up the tubing. The increased pressure facilitates flow into the separator and then the sales line where the lift gas becomes part of the normal flowback that can be recovered during a REC. Another potential compressor application is to boost pressure of the flowback gas after it exits the separator. This technique is experimental because of the difficulty operating a compressor on widely fluctuating flowback rate.

- Inert gas concentration. If the concentration of inert gas, such as nitrogen or carbon dioxide, in the flowback gas exceeds sales line concentration limits, venting or combustion of the flowback may be necessary for the duration of flowback or until the gas energy content increases to allow flow to the sales line. Further, since the energy content of the flowback gas may not be high enough to sustain a flame due to the presence of the inert gases, combustion of the flowback stream would require a continuous ignition source with its own separate fuel supply.

4.4.2.2. Effectiveness

RECs are an effective emissions reduction method for only natural gas completions and recompletions performed with hydraulic fracturing based on the estimated flowback emissions described in Section 4.2. The emissions reductions vary according to reservoir characteristics and other parameters including length of completion, number of fractured zones, pressure, gas composition, and fracturing technology/technique. Based on several experiences presented at Natural Gas STAR technology transfer workshops, this analysis assumes 90 percent of flowback gas can be recovered during a REC.³¹ Any amount of gas that cannot be recovered can be directed to a completion combustion device in order to achieve a minimum 95 percent reduction in emissions.

4.4.2.3 Cost Impacts

All completions incur some costs to a company. Performing a REC will add to these costs. Equipment costs associated with RECs vary from well to well. High production rates may require larger equipment to perform the REC and will increase costs. If permanent equipment, such as a glycol dehydrator, is already installed or is planned to be in place at the well site as normal operations, costs may be reduced as this equipment can be used or resized rather than installing a portable dehydrator for temporary use during the completion. Some operators normally install equipment used in RECs, such as sand traps and three-phase separators, further reducing incremental REC costs.

Costs of performing a REC are projected to be between \$700 and \$6,500 per day, with representative well completion flowback lasting 3 to 10 days.² This cost range is the incremental cost of performing a REC over a traditional completion, where typically the gas is vented or combusted because there is an absence of REC equipment. Since RECs involve techniques and technologies that are new and continually evolving, and these cost estimates are based on the state of the industry in 2006 (adjusted to 2008 US dollars).^{vi} Cost data used in this analysis are qualified below:

- \$700 per day (equivalent to \$806 per day in 2008 dollars) represents completion and recompletion costs where key pieces of equipment, such as a dehydrator or three phase separator, are already found on site and are of suitable design and capacity for use during flowback.
- \$6,500 per day (equivalent to \$7,486 in 2008 dollars) represents situations where key pieces of equipment, such as a dehydrator or three-phase separator, are temporarily brought on site and then relocated after the completion.

Costs were assessed based on an average of the above data (for costs and number of days per completion), resulting in an average incremental cost for a REC of \$4,146 per day (2008 dollars) for an average of 7 days per completion. This results in an overall incremental cost of \$29,022 for a REC versus an uncontrolled completion. An additional \$691 (2008 dollars) was included to account for transportation and placement of equipment, bringing total incremental costs estimated at \$29,713. Reduced emission completions are considered one-time events per well; therefore annual costs were conservatively assumed to be the same as capital costs. Dividing by the expected emission reductions, cost-effectiveness for VOC is \$1,429 per ton, with a methane co-benefit of \$208 per ton. Table 4-5 provides a summary of REC cost-effectiveness.

Monetary savings associated with additional gas captured to the sales line was also estimated based on a natural gas price of \$4.00^{vii} per thousand cubic feet (Mcf).³² It was assumed that all gas captured would be included as sales gas. Therefore, assuming that 90 percent of the gas is captured and sold, this equates

^{vi} The Chemical Engineering Cost Index was used to convert dollar years. For REC, the 2008 value equals 575.4 and the 2006 value equals 499.6.

^{vii} The average market price for natural gas in 2010 was approximately \$4.16 per Mcf. This is much less compared to the average price in 2008 of \$7.96 per Mcf. Due to the volatility in the price, a conservative savings of \$4.00 per Mcf estimate was projected for the analysis in order to not overstate savings. The value of natural gas condensate recovered during the REC would also be significant depending on the gas composition. This value was not incorporated into the monetary savings in order to not overstate savings.

Table 4-5. Reduced Emission Completion and Recompletion Emission Reductions and Cost Impacts Summary

| Well Completion Category | Emission Reduction Per Completion/Recompletion (tons/year) ^a | | | Total Cost Per Completion/Recompletion ^b (\$/event) | VOC Cost Effectiveness (\$/ton) ^c | | Methane Cost Effectiveness (\$/ton) | |
|---|---|---------|-----|--|--|--------------|-------------------------------------|--------------|
| | VOC | Methane | HAP | | without savings | with savings | without savings | with savings |
| Natural Gas Completions and Recompletions with Hydraulic Fracturing | 20.8 | 142.7 | 1.5 | 29,713 | 1,429 | net savings | 208 | net savings |

Minor discrepancies may be due to rounding.

- a. This represents a ninety percent reduction from baseline for the average well.
- b. Total cost for reduced emission completion is expressed in terms of incremental cost versus a completion that vents emissions. This is based on an average incremental cost of \$4,146 per day for an average length of completion flowback lasting 7 days and an additional \$691 for transportation and set up.
- c. Cost effectiveness has been rounded to the nearest dollar.

to a total recovery of 8,258 Mcf of natural gas per completion or recompletion with hydraulic fracturing. The estimated value of the recovered natural gas for a representative natural gas well with hydraulic fracturing is approximately \$33,030. In addition we estimate an average of 34 barrels of condensate is recovered per completion or recompletion. Assuming a condensate value of \$70 per barrel (bbl), this result is an income due to condensate sales around \$2,380.³³ When considering these savings from REC, for a completion or recompletion with hydraulic fracturing, there is a net savings on the order of \$5,697 per completion.

4.4.2.4 Secondary Impacts

A REC is a pollution prevention technique that is used to recover natural gas that would otherwise be emitted. No secondary emissions (e.g., nitrogen oxides, particulate matter, etc.) would be generated, no wastes should be created, no wastewater generated, and no electricity needed. Therefore, there are no secondary impacts expected due to REC.

4.4.3 Completion Combustion Devices

4.4.3.1 Description

Completion combustion is a high-temperature oxidation process used to burn combustible components, mostly hydrocarbons, found in waste streams.³⁴ Completion combustion devices are used to control VOC in many industrial settings, since the completion combustion device can normally handle fluctuations in concentration, flow rate, heating value, and inert species content.³⁵ Completion combustion devices commonly found on drilling sites are rather crude and portable, often installed horizontally due to the liquids that accompany the flowback gas. These flares can be as simple as a pipe with a basic ignition mechanism and discharge over a pit near the wellhead. However, the flow directed to a completion combustion device may or may not be combustible depending on the inert gas composition of flowback gas, which would require a continuous ignition source. Sometimes referred to as pit flares, these types of combustion devices do not employ an actual control device, and are not capable of being tested or monitored for efficiency. They do provide a means of minimizing vented gas and is preferable to venting. For the purpose of this analysis, the term completion combustion device represents all types of combustion devices including pit flares.

4.4.3.2 Effectiveness

The efficiency of completion combustion devices, or exploration and production flares, can be expected to achieve 95 percent, on average, over the duration of the completion or recompletion. If the energy content of natural gas is low, then the combustion mechanism can be extinguished by the flowback gas. Therefore, it is more reliable to install an igniter fueled by a consistent and continuous ignition source. This scenario would be especially true for energized fractures where the initial flowback concentration will be extremely high in inert gases. This analysis assumes use of a continuous ignition source with an independent external fuel supply is assumed to achieve an average of 95 percent control over the entire flowback period. Additionally, because of the nature of the flowback (i.e., with periods of water, condensate, and gas in slug flow), conveying the entire portion of this stream to a flare or other control device is not always feasible. Because of the exposed flame, open pit flaring can present a fire hazard or other undesirable impacts in some situations (e.g., dry, windy conditions, proximity to residences, etc.). As a result, we are aware that owners and operators may not be able to flare unrecoverable gas safely in every case.

Federal regulations require industrial flares meet a combustion efficiency of 98 percent or higher as outlined in 40 CFR 60.18. This statute does not apply to completion combustion devices. Concerns have been raised on applicability of 40 CFR 60.18 within the oil and gas industry including for the production segment.^{30, 36, 37} The design and nature of completion combustion devices must handle multiphase flow and stream compositions that vary during the flowback period. Thus, the applicability criterion that specifies conditions for flares used in highly industrial settings may not be appropriate for flares typically used to control emissions from well completions and recompletions.

4.4.3.3 Cost Impacts

An analysis depicting the cost for wells including completion combustion devices was conducted for the Petroleum Services Association of Canada (PSAC)³⁸ in 2009 by N.L. Fisher Supervision and Engineering, Ltd.^{viii} The data corresponds to 34 gas wells for various types of formations, including coal bed methane and shale. Multiple completion methods were also examined in the study including hydraulic and energized fracturing. Using the cost data points from these natural gas well completions,

^{viii} It is important to note that outliers were excluded from the average cost calculation. Some outliers estimated the cost of production flares to be as low as \$0 and as high as \$56,000. It is expected that these values are not representative of typical flare costs and were removed from the data set. All cost data found in the PSAC study were aggregated values of the cost of production flares and other equipment such as tanks. It is possible the inclusion of the other equipment is not only responsible for the outliers, but also provides a conservatively high estimate for completion flares.

an average completion combustion device cost is approximately \$3,523 (2008 dollars).^{ix} As with the REC, because completion combustion devices are purchased for these one-time events, annual costs were conservatively assumed to be equal to the capital costs.

It is assumed that the cost of a continuous ignition source is included in the combustion completion device cost estimations. It is understood that multiple completions and recompletions can be controlled with the same completion combustion device, not only for the lifetime of the combustion device but within the same yearly time period. However, to be conservative, costs were estimated as the total cost of the completion combustion device itself, which corresponds to the assumption that only one device will control one completion per year. The cost impacts of using a completion combustion device to reduce emissions from representative completions/recompletions are provided in Table 4-6. Completion combustion devices have a cost-effectiveness of \$161 per ton VOC and a co-benefit of \$23 per ton methane for completions and recompletions with hydraulic fracturing.

4.4.3.4 Secondary Impacts

Noise and heat are the two primary undesirable outcomes of completion combustion device operation. In addition, combustion and partial combustion of many pollutants also create secondary pollutants including nitrogen oxides (NO_x), carbon monoxide (CO), sulfur oxides (SO_x), carbon dioxide (CO₂), and smoke/particulates (PM). The degree of combustion depends on the rate and extent of fuel mixing with air and the temperature maintained by the flame. Most hydrocarbons with carbon-to-hydrogen ratios greater than 0.33 are likely to smoke.³⁴ Due to the high methane content of the gas stream routed to the completion combustion device, it suggests that there should not be smoke except in specific circumstances (e.g., energized fractures). The stream to be combusted may also contain liquids and solids that will also affect the potential for smoke. Soot can typically be eliminated by adding steam. Based on current industry trends in the design of completion combustion devices and in the decentralized nature of completions, virtually no completion combustion devices include steam assistance.³⁴

Reliable data for emission factors from flare operations during natural gas well completions are limited. Guidelines published in AP-42 for flare operations are based on tests from a mixture containing

^{ix} The Chemical Engineering Cost Index was used to convert dollar years. For the combustion device the 2009 value equals 521.9. The 2009 average value for the combustion device is \$3,195.

**Table 4-6. Emission Reduction and Cost-effectiveness Summary
for Completion Combustion Devices**

| Well Completion Category | Emission Reduction Per Completion/Workover (tons/year) ^a | | | Total Capital Cost Per Completion Event (\$)* | VOC Cost Effectiveness | Methane Cost Effectiveness |
|--|---|---------|-----------|---|------------------------|----------------------------|
| | VOC | Methane | HAP | | (\$/ton) ^b | (\$/ton) |
| Natural Gas Well Completions without Hydraulic Fracturing | 0.11 | 0.76 | 0.0081 | 3,523 | 31,619 | 4,613 |
| Natural Gas Well Completions with Hydraulic Fracturing | 21.9 | 150.6 | 1.597 | | 160 | 23 |
| Oil Well Completions | 0.01 | 0.007 | 0.0000007 | | 520,580 | 488,557 |
| Natural Gas Well Re Completions without Hydraulic Fracturing | 0.007 | 0.051 | 0.0005 | | 472,227 | 68,889 |
| Natural Gas Well Re Completions with Hydraulic Fracturing | 21.9 | 150.6 | 1.597 | | 160 | 23 |
| Oil Well Re Completions | 0.00 | 0.001 | 0.0000001 | | 3,134,431 | 2,941,615 |

Minor discrepancies may be due to rounding.

- a. This assumes one combustion device will control one completion event per year. This should be considered a conservative estimate, since it is likely multiple completion events will be controlled with the same combustion unit in any given year. Costs are stated in 2008 dollars.

80 percent propylene and 20 percent propane.³⁴ These emissions factors, however, are the best indication for secondary pollutants from flare operations currently available. These secondary emission factors are provided in Table 4-7.

Since this analysis assumed pit flares achieve 95 percent efficiency over the duration of flowback, it is likely the secondary emission estimations are lower than actuality (i.e. AP-42 assumes 98 percent efficiency). In addition due, to the potential for the incomplete combustion of natural gas across the pit flare plume, the likelihood of additional NO_x formulating is also likely. The degree of combustion is variable and depends on the on the rate and extent of fuel mixing with air and on the flame temperature. Moreover, the actual NO_x (and CO) emissions may be greatly affected when the raw gas contains hydrocarbon liquids and water. For these reasons, the nationwide impacts of combustion devices discussed in Section 4.5 should be considered minimum estimates of secondary emissions from combustion devices.

4.5 Regulatory Options

The REC pollution prevention approach would not result in emissions of CO, NO_x, and PM from the combustion of the completion gases in the flare, and would therefore be the preferred option. As discussed above, REC is only an option for reducing emissions from gas well completions/workovers with hydraulic fracturing. Taking this into consideration, the following regulatory alternatives were evaluated:

- Regulatory Option 1: Require completion combustion devices for conventional natural gas well completions and recompletions;
- Regulatory Option 2: Require completion combustion devices for oil well completions and recompletions;
- Regulatory Option 3: Require combustion devices for all completions and recompletions;
- Regulatory Option 4: Require REC for all completions and recompletions of hydraulically fractured wells;
- Regulatory Option 5: Require REC and combustion operational standards for natural gas well completions with hydraulic fracturing, with the exception of exploratory, and delineation wells;
- Regulatory Option 6: Require combustion operational standards for exploratory and delineation wells; and

Table 4-7. Emission Factors from Flare Operations from AP-42 Guidelines Table 13.4-1^a

| Pollutant | Emission Factor (lb/10⁶ Btu) |
|--------------------------------|--|
| Total Hydrocarbon ^b | 0.14 |
| Carbon Monoxide | 0.37 |
| Nitrogen Oxides | 0.068 |
| Particular Matter ^c | 0-274 |
| Carbon Dioxide ^d | 60 |

- a. Based on combustion efficiency of 98 percent.
- b. Measured as methane equivalent.
- c. Soot in concentration values: nonsmoking flares, 0 micrograms per liter (µg/L); lightly smoking flares, 40 µg/L; average smoking flares, 177 µg/L; and heavily smoking flares, 274 µg/L.
- d. Carbon dioxide is measured in kg CO₂/MMBtu and is derived from the carbon dioxide emission factor obtained from 40 CFR Part 98, subpart Y, Equation Y-2.

- Regulatory Option 7: Require REC and combustion operational standards for all natural gas well recompletions with hydraulic fracturing.

The following sections discuss these regulatory options.

4.5.1 Evaluation of Regulatory Options

The first two regulatory options (completion combustion devices for conventional natural gas well completions and recompletions and completion combustion devices for oil well completions and recompletions) were evaluated first. As shown in Table 4-6, the cost effectiveness associated with controlling conventional natural gas and oil well completions and recompletions ranges from \$31,600 per ton VOC to over \$3.7 million per ton VOC. Therefore, Regulatory Options 1 and 2 were rejected due to the high cost effectiveness.

The next regulatory option, to require completion combustion devices for all completions and recompletions, was considered. Under Regulatory Option 3, all of the natural gas emitted from the well during flowback would be destroyed by sending flowback gas through a combustion unit. Not only would this regulatory option result in the destruction of a natural resource with no recovery of salable gas, it also would result in an increase in emissions of secondary pollutants (e.g., nitrogen oxides, carbon monoxide, etc.). Therefore, Regulatory Option 3 was also rejected.

The fourth regulatory option would require RECs for all completions and recompletions of hydraulically fractured wells. As stated previously, RECs are not feasible for all well completions, such as exploratory wells, due to their distance from sales lines, etc. Further, RECs are also not technically feasible for each well at all times during completion and recompletion activities due to the variability of the pressure of produced gas and/or inert gas concentrations. Therefore, Regulatory Option 4 was rejected.

The fifth regulatory option was to require an operational standard consisting of a combination of REC and combustion for natural gas well completions with hydraulic fracturing. As discussed for Regulatory Option 4, RECs are not feasible for every well at all times during completion or recompletion activities due to variability of produced gas pressure and/or inert gas concentrations. In order to allow for wellhead owners and operators to continue to reduce emissions when RECs are not feasible due to well characteristics (e.g, wellhead pressure or inert gas concentrations), Regulatory Option 5 also allows for the use of a completion combustion device in combination with RECs.

Under Regulatory Option 5, a numerical limit was considered, but was rejected in favor of an operational standard. Under section 111(h)(2) of the CAA, EPA can set an operational standard which represents the best system of continuous emission reduction, provided the following criteria are met:

“(A) a pollutant or pollutants cannot be emitted through a conveyance designed and constructed to emit or capture such pollutant, or that any requirement for, or use of, such a conveyance would be inconsistent with any Federal, State, or local law, or

(B) the application of measurement methodology to a particular class of sources is not practicable due to technological or economic limitations.”

As discussed in section 4.4.3, emissions from a completion combustion device cannot be measured or monitored to determine efficiency making an operational standard appropriate. Therefore, an operational standard under this regulatory option consists of a combination of REC and a completion combustion device to minimize the venting of natural gas and condensate vapors to the atmosphere, but allows venting in lieu of combustion for situations in which combustion would present safety hazards, other concerns, or for periods when the flowback gas is noncombustible due to high concentrations of inert gases. Sources would also be required, under this regulatory option, to maintain documentation of the overall duration of the completion event, duration of recovery using REC, duration of combustion, duration of venting, and specific reasons for venting in lieu of combustion. It was also evaluated whether Regulatory Option 5 should apply to all well completions, including exploratory and delineation wells.

As discussed previously, one of the technical limitations of RECs is that they are not feasible for use at some wells due to their proximity to pipelines. Section 111(b)(2) of the CAA allows EPA to “...distinguish among classes, types, and sizes within categories of new sources for the purpose of establishing...” performance standards. Due to their distance from sales lines, and the relatively unknown characteristics of the formation, completion activities occurring at exploratory or delineation wells were considered to be a different “type” of activity than the types of completion activities occurring at all other gas wells. Therefore, two subcategories of completions were identified: *Subcategory 1* wells are all natural gas wells completed with hydraulic fracturing that do not fit the definition of exploratory or delineation wells. *Subcategory 2* wells are natural gas wells that meet the following definitions of exploratory or delineation wells:

- Exploratory wells are wells outside known fields or the first well drilled in an oil or gas field where no other oil and gas production exists or
- Delineation wells means a well drilled in order to determine the boundary of a field or producing reservoir.

Based on this subcategorization, Regulatory Option 5 would apply to the Subcategory 1 wells and a sixth regulatory option was developed for Subcategory 2 wells.

Regulatory Option 6 requires an operational standard for combustion for the Subcategory 2 wells. As described above, REC is not an option for exploratory and delineation wells due to their distance from sales lines. As with the Regulatory Option 5, a numerical limitation is not feasible. Therefore, this regulatory option requires an operational standard where emissions are minimized using a completion combustion device during completion activities at Subcategory 2 wells, with an allowance for venting in situations where combustion presents safety hazards or other concerns or for periods when the flowback gas is noncombustible due to high concentrations of inert gases. Consistent with Regulatory Option 5, records would be required to document the overall duration of the completion event, the duration of combustion, the duration of venting, and specific reasons for venting in lieu of combustion.

The final regulatory option was considered for recompletions. Regulatory Option 7 requires an operational standard for a combination of REC and a completion combustion device for all recompletions with hydraulic fracturing performed on new and existing natural gas wells. Regulatory Option 7 has the same requirements as Regulatory Option 5. Subcategorization similar to Regulatory Option 5 was not necessary for recompletions because it was assumed that RECs would be technically feasible for recompletions at all types of wells since they occur at wells that are producing and thus proximity to a sales line is not an issue. While evaluating this regulatory option, it was considered whether or not recompletions at existing wells should be considered modifications and subject to standards.

The affected facility under the New Source Performance Standards (NSPS) is considered to be the wellhead. Therefore, a new well drilled after the proposal date of the NSPS would be subject to emission control requirements. Likewise, wells drilled prior to the proposal date of the NSPS would not be subject to emission control requirements unless they underwent a modification after the proposal date. Under section 111(a) of the Clean Air Act, the term “modification” means:

“any physical change in, or change in the method of operation of, a stationary source which increases the amount of any air pollutant emitted by such source or which results in the emission of any air pollutant not previously emitted.”

The wellhead is defined as the piping, casing, tubing, and connected valves protruding above the earth’s surface for an oil and/or natural gas well. The wellhead ends where the flow line connects to a wellhead valve. In order to fracture an existing well during recompletion, the well would be re-perforated, causing physical change to the wellbore and casing and therefore a physical change to the wellhead, the affected facility. Additionally, much of the emissions data on which this analysis is based demonstrates that hydraulic fracturing results in an increase in emissions. Thus, recompletions using hydraulic fracturing result in an increase in emissions from the existing well producing operations. Based on this understanding of the work performed in order to recomplete the well, it was determined that a recompletion would be considered a modification under CAA section 111(a) and thus, would constitute a new wellhead affected facility subject to NSPS. Therefore, Regulatory Option 7 applies to recompletions using hydraulic fracturing at new and existing wells.

In summary, Regulatory Options 1, 2, 3, and 4 were determined to be unreasonable due to cost considerations, other impacts or technical feasibility and thereby rejected. Regulatory Options 5, 6, and 7 were determined to be applicable to natural gas wells and were evaluated further.

4.5.2 Nationwide Impacts of Regulatory Options

This section provides an analysis of the primary environmental impacts (i.e., emission reductions), cost impacts and secondary environmental impacts related to Regulatory Options 5, 6, and 7 which were selected as viable options for setting standards for completions and recompletions.

4.5.2.1 Primary Environmental Impacts of Regulatory Options

Regulatory Options 5, 6, and 7 were selected as options for setting standards for completions and regulatory options as follows:

- Regulatory Option 5: Operational standard for completions with hydraulic fracturing for Subcategory 1 wells (i.e., wells which do not meet the definition of exploratory or delineation wells), which requires a combination of REC with combustion, but allows for venting during specified situations.

- Regulatory Option 6: An operational standard for completions with hydraulic fracturing for exploratory and delineation wells (i.e., Subcategory 2 wells) which requires completion combustion devices with an allowance for venting during specified situations.
- Regulatory Option 7: An operational standard equivalent to Regulatory Option 5 which applies to recompletions with hydraulic fracturing at new and existing wells.

The number of completions and recompletions that would be subject to the regulatory options listed above was presented in Table 4-3. It was estimated that there would be 9,313 uncontrolled developmental natural gas well completions with hydraulic fracturing subject to Regulatory Option 5. Regulatory Option 6 would apply to 446 uncontrolled exploratory natural gas well completions with hydraulic fracturing, and 12,050 uncontrolled recompletions at existing wells would be subject to Regulatory Option 7.^x

Table 4-8 presents the nationwide emission reduction estimates for each regulatory option. It was estimated that RECs in combination with the combustion of gas unsuitable for entering the gathering line, can achieve an overall 95 percent VOC reduction over the duration of the completion operation. The 95 percent recovery was estimated based on 90 percent of flowback being captured to the sales line and assuming an additional 5 percent of the remaining flowback would be sent to the combustion device. Nationwide emission reductions were estimated by applying this 95 percent VOC reduction to the uncontrolled baseline emissions presented in Table 4-4.

4.5.2.2 Cost Impacts

Cost impacts of the individual control techniques (RECs and completion combustion devices) were presented in section 4.4. For Regulatory Option 6, the costs for completion combustion devices presented in Table 4-6 for would apply to Subcategory 2 completions. The cost per completion event was estimated to be \$3,523. Applied to the 446 estimated Subcategory 2 completions, the nationwide costs were estimated to be \$1.57 million. Completion combustion devices are assumed to achieve an overall 95 percent combustion efficiency. Since the operational standards for Regulatory Options 5 and 7 include both REC and completion combustion devices, an additional cost impact analysis was

^x The number of uncontrolled recompletions at new wells is not included in this analysis. Based on the assumption that wells are recompleted once every 10 years, any new wells that are drilled after the date of proposal of the standard would not likely be recompleted until after the year 2015, which is the date of this analysis. Therefore, impacts were not estimated for recompletion of new wells, which will be subject to the standards.

Table 4-8. Nationwide Emission and Cost Analysis of Regulatory Option

| Well Completion Category | Number of Sources subject to NSPS ^a | Annual Cost Per Completion Event (\$) ^b | Nationwide Emission Reductions (tpy) ^c | | | VOC Cost Effectiveness (\$/ton) | | Methane Cost Effectiveness (\$/ton) | | Total Nationwide Costs (million \$/year) | | |
|--|--|--|---|-----------|--------|---------------------------------|--------------|-------------------------------------|--------------|--|------------------------|---------------------|
| | | | VOC | Methane | HAP | without savings | with savings | without savings | with savings | Capital Cost | Annual without savings | Annual with savings |
| Regulatory Option 5 (operational standard for REC and combustion) | | | | | | | | | | | | |
| Subcategory 1: Natural gas Completions with Hydraulic Fracturing | 9,313 | 33,237 | 204,134 | 1,399,139 | 14,831 | 1,516 | net savings | 221 | net savings | 309.5 | 309.5 | (20.24) |
| Regulatory Option 6 (operational standard for combustion) | | | | | | | | | | | | |
| Subcategory 2: Natural gas Completions with Hydraulic Fracturing | 446 | 3,523 | 9,801 | 67,178 | 712 | 160 | 160 | 23 | 23 | 1.57 | 1.57 | 1.57 |
| Regulatory Option 7 (operational standard for REC and combustion) | | | | | | | | | | | | |
| Natural Gas Well Recompletions with Hydraulic Fracturing | 12,050 | 33,237 | 264,115 | 1,810,245 | 19,189 | 1,516 | net savings | 221 | net savings | 400.5 | 400.5 | (26.18) |

Minor discrepancies may be due to rounding.

- a. Number of sources in each well completion category that are uncontrolled at baseline as presented in Table 4-3.
- b. Costs per event for Regulatory Options 5 and 7 are calculated by adding the costs for REC and completion combustion device presented in Tables 4-5 and 4-6, respectively. Cost per event for Regulatory Option 6 is presented for completion combustion devices in Table 4-6.
- c. Nationwide emission reductions calculated by applying the 95 percent emission reduction efficiency to the uncontrolled nationwide baseline emissions in Table 4-4.

performed to analyze the nationwide cost impacts of these regulatory options. The total incremental cost of the operational standard for Subcategory 1 completions and for recompletions is estimated at around \$33,237, which includes the costs in Table 4-5 for the REC equipment and transportation in addition to the costs in Table 4-6 for the completion combustion device. Applying the cost for the combined REC and completion combustion device to the estimated 9,313 Subcategory 1 completions, the total nationwide cost was estimated to be \$309.5 million, with a net annual savings estimated around \$20 million when natural gas savings are considered. A cost of \$400.5 million was estimated for recompletions, with an overall savings of around \$26 million when natural gas savings are considered. The VOC cost effectiveness for Regulatory Options 5 and 7 was estimated at around \$1,516 per ton, with a methane co-benefit of \$221 per ton.

4.5.2.3 Secondary Impacts

Regulatory Options 5, 6 and 7 all require some amount of combustion; therefore the estimated nationwide secondary impacts are a direct result of combusting all or partial flowback emissions. Although, it is understood the volume of gas captured, combusted and vented may vary significantly depending on well characteristics and flowback composition, for the purpose of estimating secondary impacts for Regulatory Options 5 and 7, it was assumed that ninety percent of flowback is captured and an additional five percent of the remaining gas is combusted. For both Subcategory 1 natural gas well completions with hydraulic fracturing and for natural gas well recompletions with hydraulic fracturing, it is assumed around 459 Mcf of natural gas is combusted on a per well basis. For Regulatory Option 6, Subcategory 2 natural gas completions with hydraulic fracturing, it is assumed that 95 percent (8,716 Mcf) of flowback emissions are consumed by the combustion device. Tons of pollutant per completion event was estimated assuming 1,089.3 Btu/scf saturated gross heating value of the "raw" natural gas and applying the AP-42 emissions factors listed in Table 4-7.

From category 1 well completions and from recompletions, it is estimated 0.02 tons of NO_x are produced per event. This is based on assumptions that 5 percent of the flowback gas is combusted by the combustion device. From category 2 well completions, it is estimated 0.32 tons of NO_x are produced in secondary emissions per event. This is based on the assumption 95 percent of flowback gas is combusted by the combustion device. Based on the estimated number of completions and recompletions, the proposed regulatory options are estimated to produce around 507 tons of NO_x in secondary emissions nationwide from controlling all or partial flowback by combustion. Table 4-9 summarizes the estimated secondary emissions of the selected regulatory options.

Table 4-9 Nationwide Secondary Impacts of Selected Regulatory Options^a

| Pollutant | Regulatory Options 5 ^b | | Regulatory Option 6 ^c | | Regulatory Options 7 ^b | |
|--------------------|--|---|--|---|--|---|
| | Subcategory 1 Natural Gas Well Completions with Hydraulic Fracturing | | Subcategory 2 Natural Gas Well Completions with Hydraulic Fracturing | | Natural Gas Well Recompletions with Hydraulic Fracturing | |
| | tons per event ^d | Nationwide Annual Secondary Emissions (tons/year) | tons per event ^d | Nationwide Annual Secondary Emissions (tons/year) | tons per event ^d | Nationwide Annual Secondary Emissions (tons/year) |
| Total Hydrocarbons | 0.03 | 326 | 0.66 | 296 | 0.03 | 422 |
| Carbon Monoxide | 0.09 | 861 | 1.76 | 783 | 0.09 | 1,114 |
| Nitrogen Oxides | 0.02 | 158 | 0.32 | 144 | 0.02 | 205 |
| Particulate Matter | 0.00000002 | 0.0002 | 0.011 | 5 | 0.00000002 | 0.0003 |
| Carbon Dioxide | 33.06 | 307,863 | 628 | 280,128 | 33.06 | 398,341 |

- a. Nationwide impacts are based on AP-42 Emission Guidelines for Industrial Flares as outlined in Table 4-7. As such, these emissions should be considered the minimum level of secondary emissions expected.
- b. The operational standard (Regulatory Options 5 and 7) combines REC and combustion is assumed to capture 90 percent of flowback gas. Five percent of the remaining flowback is assumed to be consumed in the combustion device. Therefore, it is estimated 459 Mcf is sent to the combustion device per completion event. This analysis assumes there are 9,313 Subcategory 1 wells and 12,050 recompletions.
- c. Assumes 8,716 Mcf of natural gas is sent to the combustion unit per completion. This analysis assumes 446 exploratory wells fall into this category.
- d. Based on 1,089.3 Btu/scf saturated gross heating value of the "raw" natural gas.

5.0 PNEUMATIC CONTROLLERS

The natural gas industry uses a variety of process control devices to operate valves that regulate pressure, flow, temperature, and liquid levels. Most instrumentation and control equipment falls into one of three categories: (1) pneumatic; (2) electrical; or (3) mechanical. Of these, only pneumatic devices are direct sources of air emissions. Pneumatic controllers are used throughout the oil and natural gas sector as part of the instrumentation to control the position of valves. This chapter describes pneumatic devices including their function and associated emissions. Options available to reduce emissions from pneumatic devices are presented, along with costs, emission reductions, and secondary impacts. Finally, this chapter discusses considerations in developing regulatory alternatives for pneumatic devices.

5.1 Process Description

For the purpose of this document, a pneumatic controller is a device that uses natural gas to transmit a process signal or condition pneumatically and that may also adjust a valve position based on that signal, with the same bleed gas and/or a supplemental supply of power gas. In the vast majority of applications, the natural gas industry uses pneumatic controllers that make use of readily available high-pressure natural gas to provide the required energy and control signals. In the production segment, an estimated 400,000 pneumatic devices control and monitor gas and liquid flows and levels in dehydrators and separators, temperature in dehydrator regenerators, and pressure in flash tanks. There are around 13,000 gas pneumatic controllers located in the gathering, boosting and processing segment that control and monitor temperature, liquid, and pressure levels. In the transmission segment, an estimated 85,000 pneumatic controllers actuate isolation valves and regulate gas flow and pressure at compressor stations, pipelines, and storage facilities.¹

Pneumatic controllers are automated instruments used for maintaining a process condition such as liquid level, pressure, pressure differential, and temperature. In many situations across all segments of the oil and gas industry, pneumatic controllers make use of the available high-pressure natural gas to operate control of a valve. In these “gas-driven” pneumatic controllers, natural gas may be released with every valve movement and/or continuously from the valve control pilot. The rate at which the continuous release occurs is referred to as the bleed rate. Bleed rates are dependent on the design and operating characteristics of the device. Similar designs will have similar steady-state rates when operated under similar conditions. There are three basic designs: (1) continuous bleed devices are used to modulate flow, liquid level, or pressure, and gas is vented continuously at a rate that may vary over time; (2) snap-

acting devices release gas only when they open or close a valve or as they throttle the gas flow; and (3) self-contained devices release gas to a downstream pipeline instead of to the atmosphere. This analysis assumes self-contained devices that release natural gas to a downstream pipeline instead of to the atmosphere have no emissions. Furthermore, it is recognized “closed loop” systems are applicable only in instances with very low pressure² and may not be suitable to replace many applications of bleeding pneumatic devices. Therefore, these devices are not further discussed in this analysis.

Snap-acting controllers are devices that only emit gas during actuation and do not have a continuous bleed rate. The actual amount of emissions from snap-acting devices is dependent on the amount of natural gas vented per actuation and how often it is actuated. Bleed devices also vent an additional volume of gas during actuation, in addition to the device’s bleed stream. Since actuation emissions serve the device’s functional purpose and can be highly variable, the emissions characterized for high-bleed and low-bleed devices in this analysis (as described in section 5.2.2) account for only the continuous flow of emissions (i.e. the bleed rate) and do not include emissions directly resulting from actuation. Snap-acting controllers are assumed to have zero bleed emissions. Most applications (but not all), snap-acting devices serve functionally different purposes than bleed devices. Therefore, snap-acting controllers are not further discussed in this analysis.

In addition, not all pneumatic controllers are gas driven. At sites without electrical service sufficient to power an instrument air compressor, mechanical or electrically powered pneumatic devices can be used. These “non-gas driven” pneumatic controllers can be mechanically operated or use sources of power other than pressurized natural gas, such as compressed “instrument air.” Because these devices are not gas driven, they do not directly release natural gas or VOC emissions. However, electrically powered systems have energy impacts, with associated secondary impacts related to generation of the electrical power required to drive the instrument air compressor system. Instrument air systems are feasible only at oil and natural gas locations where the devices can be driven by compressed instrument air systems and have electrical service sufficient to power an air compressor. This analysis assumes that natural gas processing plants are the only facilities in the oil and natural gas sector highly likely to have electrical service sufficient to power an instrument air system, and that most existing gas processing plants use instrument air instead of gas driven devices.⁹ The application of electrical controls is further elaborated in Section 5.3.

5.2 Emissions Data and Information

5.2.1 Summary of Major Studies and Emissions

In the evaluation of the emissions from pneumatic devices and the potential options available to reduce these emissions, numerous studies were consulted. Table 5-1 lists these references with an indication of the type of relevant information contained in each study.

5.2.2 Representative Pneumatic Device Emissions

Bleeding pneumatic controllers can be classified into two types based on their emissions rates: (1) high-bleed controllers and (2) low-bleed controllers. A controller is considered to be high-bleed when the continuous bleed emissions are in excess of 6 standard cubic feet per hour (scfh), while low-bleed devices bleed at a rate less than or equal to 6 scfh.ⁱ

For this analysis, EPA consulted information in the appendices of the Natural Gas STAR Lessons Learned document on pneumatic devices, Subpart W of the Greenhouse Gas Reporting rule, as well as obtained updated data from major vendors of pneumatic devices. The data obtained from vendors included emission rates, costs, and any other pertinent information for each pneumatic device model (or model family). All pneumatic devices that a vendor offered were itemized and inquiries were made into the specifications of each device and whether it was applicable to oil and natural gas operations. High-bleed and low-bleed devices were differentiated using the 6 scfh threshold.

Although by definition, a low-bleed device can emit up to 6 scfh, through this vendor research, it was determined that the typical low-bleed device available currently on the market emits lower than the maximum rate allocated for the device type. Specifically, low-bleed devices on the market today have emissions from 0.2 scfh up to 5 scfh. Similarly, the available bleed rates for a high bleed device vary significantly from venting as low as 7 scfh to as high as 100 scfh.^{3,ii} While the vendor data provides useful information on specific makes and models, it did not yield sufficient information about the

ⁱ The classification of high-bleed and low-bleed devices originated from a report by Pacific Gas & Electric (PG&E) and the Gas Research Institute (GRI) in 1990 titled "Unaccounted for Gas Project Summary Volume." This classification was adopted for the October 1993 Report to Congress titled "Opportunities to Reduce Anthropogenic Methane Emissions in the United States". As described on page 2-16 of the report, "devices with emissions or 'bleed' rates of 0.1 to 0.5 cubic feet per minute are considered to be 'high-bleed' types (PG&E 1990)." This range of bleed rates is equivalent to 6 to 30 cubic feet per hour.

ⁱⁱ All rates are listed at an assumed supply gas pressure of 20 psig.

**Table 5-1. Major Studies Reviewed for Consideration
of Emissions and Activity Data**

| Report Name | Affiliation | Year of Report | Number of Devices | Emissions Information | Control Information |
|--|----------------------------------|-----------------------|--------------------------|------------------------------|----------------------------|
| Greenhouse Gas Mandatory Reporting Rule and Technical Supporting Document ³ | EPA | 2010 | Nationwide | X | |
| Inventory of Greenhouse Gas Emissions and Sinks: 1990-2009 ^{4,5} | EPA | 2011 | Nationwide/ Regional | X | |
| Methane Emissions from the Natural Gas Industry ^{6,7,8,9} | Gas Research Institute / EPA | 1996 | Nationwide | X | |

| Natural Gas STAR Program ¹ | EPA | 2000-2010 | | X | X |

prevalence of each model type in the population of devices; which is an important factor in developing a representative emission factor. Therefore, for this analysis, EPA determined that best available emissions estimates for pneumatic devices are presented in Table W-1A and W-1B of the Greenhouse Gas Mandatory Reporting Rule for the Oil and Natural Gas Industry (Subpart W). However, for the natural gas processing segment, a more conservative approach was assumed since it has been determined that natural gas processing plants would have sufficient electrical service to upgrade to non-gas driven controls. Therefore, to quantify representative emissions from a bleed-device in the natural gas processing segment, information from Volume 12 of the EPA/GRI reportⁱⁱⁱ was used to estimate the methane emissions from a single pneumatic device by type.

The basic approach used for this analysis was to first approximate methane emissions from the average pneumatic device type in each industry segment and then estimate VOC and hazardous air pollutants (HAP) using a representative gas composition.¹³ The specific ratios from the gas composition were 0.278 pounds VOC per pound methane and 0.0105 pounds HAP per pound methane in the production and processing segments, and 0.0277 pounds VOC per pound methane and 0.0008 pounds HAP per pound methane in the transmission segment. Table 5-2 summarizes the estimated bleed emissions for a representative pneumatic controller by industry segment and device type.

5.3 Nationwide Emissions from New Sources

5.3.1 Approach

Nationwide emissions from newly installed natural gas pneumatic devices for a typical year were calculated by estimating the number of pneumatic devices installed in a typical year and multiplying by the estimated annual emissions per device listed in Table 5-2. The number of new pneumatic devices installed for a typical year was determined for each segment of the industry including natural gas production, natural gas processing, natural gas transmission and storage, and oil production. The methodologies that determined the estimated number of new devices installed in a typical year is provided in section 5.3.2 of this chapter.

5.3.2 Population of Devices Installed Annually

In order to estimate the average number of pneumatic devices installed in a typical year, each industry

ⁱⁱⁱ Table 4-11. page 56. epa.gov/gasstar/tools/related.html

Table 5-2. Average Bleed Emission Estimates per Pneumatic Device in the Oil and Natural Gas Sector (tons/year)^a

| Industry Segment | High-Bleed | | | Low-Bleed | | |
|---|------------|-------|-------|-----------|-------|--------|
| | Methane | VOC | HAP | Methane | VOC | HAP |
| Natural Gas Production ^b | 6.91 | 1.92 | 0.073 | 0.26 | 0.072 | 0.003 |
| Natural Gas Transmission and Storage ^c | 3.20 | 0.089 | 0.003 | 0.24 | 0.007 | 0.0002 |
| Oil Production ^d | 6.91 | 1.92 | 0.073 | 0.26 | 0.072 | 0.003 |
| Natural Gas Processing ^e | 1.00 | 0.28 | 0.01 | 1.00 | 0.28 | 0.01 |

Minor discrepancies may be due to rounding.

- a. The conversion factor used in this analysis is 1 thousand cubic feet of methane (Mcf) is equal to 0.0208 tons methane. Minor discrepancies may be due to rounding.
- b. Natural Gas Production methane emissions are derived from Table W-1A and W-1B of Subpart W.
- c. Natural gas transmission and storage methane emissions are derived from Table W-3 of Subpart W.
- d. Oil production methane emissions are derived from Table W-1A and W-1B of Subpart W. It is assumed only continuous bleed devices are used in oil production.
- e. Natural gas processing sector methane emissions are derived from Volume 12 of the 1996 GRI report.⁹ Emissions from devices in the processing sector were determined based on data available for snap-acting and bleed devices, further distinction between high and low bleed could not be determined based on available data.

segment was analyzed separately using the best data available for each segment. The number of facilities estimated in absence of regulation was undeterminable due to the magnitude of new sources estimated and the lack of sufficient data that could indicate the number of controllers that would be installed in states that may have regulations requiring low bleed controllers, such as in Wyoming and Colorado.

For the natural gas production and oil production segments, the number of new pneumatics installed in a typical year was derived using a multiphase analysis. First, data from the US Greenhouse Gas Inventory: Emission and Sinks 1990-2009 was used to establish the ratio of pneumatic controllers installed per well site on a regional basis. These ratios were then applied to the number of well completions estimated in Chapter 4 for natural gas well completions with hydraulic fracturing, natural gas well completions without hydraulic fracturing and for oil well completions. On average, one pneumatic device was assumed to be installed per well completion for a total of 33,411 pneumatic devices. By applying the estimated 51 percent of bleed devices (versus snap acting controllers), it is estimated that an average of 17,040 bleed-devices would be installed in the production segment in a typical year.

The number of pneumatic controllers installed in the transmission segment was approximated using the Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2009. The number of new devices installed in a given year was estimated by subtracting the prior year (e.g. 2007) from the given year's total (e.g. 2008). This difference was assumed to be the number of new devices installed in the latter year (e.g. Number of new devices installed during 2008 = Pneumatics in 2008 – Pneumatics in 2007). A 3-year average was calculated based on the number of new devices installed in 2006 through 2008 in order to determine the average number of new devices installed in a typical year.

Once the population counts for the number of pneumatics in each segment were established, this population count was further refined to account for the number of snap-acting devices that would be installed versus a bleed device. This estimate of the percent of snap-acting and bleed devices was based on raw data found in the GRI study, where 51 percent of the pneumatic controllers are bleed devices in the production segment, and 32 percent of the pneumatic controllers are bleed devices in the transmission segment.⁹ The distinction between the number of high-bleed and low-bleed devices was not estimated because this analysis assumes it is not possible to predict or ensure where low bleeds will be used in the future. Table 5-3 summarizes the estimated number of new devices installed per year.

Table 5-3. Estimated Number of Pneumatic Devices Installed in an Typical Year

| Industry Segment | Number of New Devices Estimated for a Typical Year ^a | | |
|---|---|---------------|--------|
| | Snap-Acting | Bleed-Devices | Total |
| Natural Gas and Oil Production ^b | 16,371 | 17,040 | 33,411 |
| Natural Gas Transmission and Storage ^c | 178 | 84 | 262 |

- a. National averages of population counts from the Inventory were refined to include the difference in snap-acting and bleed devices based on raw data found in the GRI/EPA study. This is based on the assumption that 51 percent of the pneumatic controllers are bleed devices in the production segment, while 32 percent are bleed devices in the transmission segment.
- b. The number of pneumatics was derived from a multiphase analysis. Data from the US Greenhouse Gas Inventory: Emission and Sinks 1990-2009 was used to establish the number of pneumatics per well on a regional basis. These ratios were applied to the number of well completions estimated in Chapter 4 for natural gas wells with hydraulic fracturing, natural gas wells without hydraulic fracturing and for oil wells.
- c. The number of pneumatics estimated for the transmission segment was approximated from comparing a 3 year average of new devices installed in 2006 through 2008 in order to establish an average number of pneumatics being installed in this industry segment in a typical year. This analysis was performed using the Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2009.

For the natural gas processing segment, this analysis assumes that existing natural gas plants have already replaced pneumatic controllers with other types of controls (i.e. an instrument air system) and any high-bleed devices that remain are safety related. As a result, the number of new pneumatic bleed devices installed at existing natural gas processing plants was estimated as negligible. A new greenfield natural gas processing plant would require multiple control loops. In Chapter 8 of this document, it is estimated that 29 new and existing processing facilities would be subject to the NSPS for equipment leak detection. In order to quantify the impacts of the regulatory options represented in section 5.5 of this Chapter, it is assumed that half of these facilities are new sites that will install an instrument air system in place of multiple control valves. This indicates about 15 instrument air systems will be installed in a representative year.

5.3.3 Emission Estimates

Nationwide baseline emission estimates for pneumatic devices for new sources in a typical year are summarized in Table 5-4 by industry segment and device type. This analysis assumed for the nationwide emission estimate that all bleed-devices have the high-bleed emission rates estimated in Table 5-2 per industry segment since it cannot be predicted which sources would install a low bleed versus a high bleed controller.

5.4 Control Techniques

Although pneumatic devices have relatively small emissions individually, due to the large population of these devices installed on an annual basis, the cumulative VOC emissions for the industry are significant. As a result, several options to reduce emissions have been developed over the years. Table 5-5 provides a summary of these options for reducing emissions from pneumatic devices including: instrument air, non-gas driven controls, and enhanced maintenance.

Given the various control options and applicability issues, the replacement of a high-bleed with a low-bleed device is the most likely scenario for reducing emissions from pneumatic device emissions. This is also supported by States such as Colorado and Wyoming that require the use of low-bleed controllers in place of high-bleed controllers. Therefore, low-bleed devices are further described in the following section, along with estimates of the impacts of their application for a representative device and nationwide basis. Although snap-acting devices have zero bleed emissions, this analysis assumes the

Table 5-4. Nationwide Baseline Emissions from Representative Pneumatic Device Installed in a Typical Year for the Oil and Natural Gas Industry (tons/year)^a

| Industry Segment | Baseline Emissions from Representative New Unit (tpy) | | | Number of New Bleed Devices Expected Per Year | Nationwide Baseline Emissions from Bleeding Pneumatic (tpy) ^b | | |
|--------------------------------------|---|---------|--------|---|--|---------|-------|
| | VOC | Methane | HAP | | VOC | Methane | HAP |
| Oil and Gas Production | 1.9213 | 6.9112 | 0.0725 | 17,040 | 32,739 | 117,766 | 1,237 |

Minor discrepancies may be due to rounding.

- a. Emissions have been based on the bleed rates for a high-bleed device by industry segment. Minor discrepancies may be due to rounding.
- b. To estimate VOC and HAP, weight ratios were developed based on methane emissions per device. The specific ratios used were 0.278 pounds VOC per pound methane and 0.0105 pounds HAP per pound methane in the production and processing segments, and 0.0277 pounds VOC per pound methane and 0.0008 pounds HAP per pound methane in the transmission segment.

Table 5-5. Alternative Control Options for Pneumatic Devices

| Option | Description | Applicability/Effectiveness | Estimated Cost Range |
|---|--|--|---|
| Install Low Bleed Device in Place of High Bleed Device | Low-bleed devices provide the same functional control as a high-bleed device, while emitting less continuous bleed emissions. | Applicability may depend on the function of instrumentation for an individual device on whether the device is a level, pressure, or temperature controller. | Low-bleed devices are, on average, around \$165 more than high bleed versions. |
| Convert to Instrument Air ¹⁴ | Compressed air may be substituted for natural gas in pneumatic systems without altering any of the parts of the pneumatic control. In this type of system, atmospheric air is compressed, stored in a tank, filtered and then dried for instrument use. For utility purposes such as small pneumatic pumps, gas compressor motor starters, pneumatic tools and sand blasting, air would not need to be dried. Instrument air conversion requires additional equipment to properly compress and control the pressured air. This equipment includes a compressor, power source, air dehydrator and air storage vessel. | Replacing natural gas with instrument air in pneumatic controls eliminates VOC emissions from bleeding pneumatics. It is most effective at facilities where there are a high concentration of pneumatic control valves and an operator present. Since the systems are powered by electric compressors, they require a constant source of electrical power or a back-up natural gas pneumatic device. These systems can achieve 100 percent reduction in emissions. | A complete cost analysis is provided in Section 5.4.2. System costs are dependent on size of compressor, power supply needs, labor and other equipment. |
| Mechanical and Solar Powered Systems in place of Bleed device ¹⁵ | Mechanical controls operate using a simple design comprised of levers, hand wheels, springs and flow channels. The most common mechanical control device is the liquid-level float to the drain valve position with mechanical linkages. Electricity or small electrical motors (including solar powered) have been used to operate valves. Solar control systems are driven by solar power cells that actuate mechanical devices using electric power. As such, solar cells require some type of back-up power or storage to ensure reliability. | Application of mechanical controls is limited because the control must be located in close proximity to the process measurement. Mechanical systems are also incapable of handling larger flow fluctuations. Electric powered valves are only reliable with a constant supply of electricity. Overall, these options are applicable in niche areas but can achieve 100 percent reduction in emissions where applicable. | Depending on supply of power, costs can range from below \$1,000 to \$10,000 for entire systems. |
| Enhanced Maintenance ¹⁶ | Instrumentation in poor condition typically bleeds 5 to 10 scf per hour more than representative conditions due to worn seals, gaskets, diaphragms; nozzle corrosion or wear, or loose control tube fittings. This may not impact the operations but does increase emissions. | Enhanced maintenance to repair and maintain pneumatic devices periodically can reduce emissions. Proper methods of maintaining a device are highly variable and could incur significant costs. | Variable based on labor, time, and fuel required to travel to many remote locations. |

devices are not always used in the same functional application as bleed devices and are, therefore, not an appropriate form of control for all bleed devices. It is assumed snap-acting, or no-bleed, devices meet the definition of a low-bleed. This concept is further detailed in Section 5.5 of this chapter. Since this analysis has assumed areas with electrical power have already converted applicable pneumatic devices to instrument air systems, instrument air systems are also described for natural gas processing plants only. Given applicability, efficiency and the expected costs of the other options identified in Table 5-5 (i.e. mechanical controls and enhanced maintenance), were not further conducted for this analysis.

5.4.1 Low-Bleed Controllers

5.4.1.1 Emission Reduction Potential

As discussed in the above sections, low-bleed devices provide the same functional control as a high-bleed device, but have lower continuous bleed emissions. As summarized in Table 5-6, it is estimated on average that 6.6 tons of methane and 1.8 tons of VOC will be reduced annually in the production segment from installing a low-bleed device in place of a high-bleed device. In the transmission segment, the average achievable reductions per device are estimated around 3.7 tons and 0.08 tons for methane and VOC, respectively. As noted in section 5.2, a low-bleed controller can emit up to 6 scfh, which is higher than the expected emissions from the typical low-bleed device available on the current market.

5.4.1.1 Effectiveness

There are certain situations in which replacing and retrofitting are not feasible, such as instances where a minimal response time is needed, cases where large valves require a high bleed rate to actuate, or a safety isolation valve is involved. Based on criteria provided by the Natural Gas STAR Program, it is assumed about 80 percent of high-bleed devices can be replaced with low-bleed devices throughout the production and transmission and storage industry segments.¹ This corresponds to 13,632 new high-bleed devices in the production segment (out of 17,040) and 67 new high-bleed devices in the transmission and storage segment (out of 84) that can be replaced with a new low-bleed alternative. For high-bleed devices in natural gas processing, this analysis assumed that the replaceable devices have already been replaced with instrument air and the remaining high-bleed devices are safety related for about half of the existing processing plants.

Table 5-6. Estimated Annual Bleed Emission Reductions from Replacing a Representative High-Bleed Pneumatic Device with a Representative Low-Bleed Pneumatic Device

| Segment/Device Type | Emissions (tons/year) ^a | | |
|--------------------------------------|------------------------------------|-------|-------|
| | Methane | VOC | HAP |
| Oil and Natural Gas Production | 6.65 | 1.85 | 0.07 |
| Natural Gas Transmission and Storage | 2.96 | 0.082 | 0.002 |

Minor discrepancies may be due to rounding.

- a. Average emission reductions for each industry segment based on the typical emission flow rates from high-bleed and low-bleed devices as listed in Table 5-2 by industry segment.

Applicability may depend on the function of instrumentation for an individual device on whether the device is a level, pressure, or temperature controller. High-bleed pneumatic devices may not be applicable for replacement with low-bleed devices because a process condition may require a fast or precise control response so that it does not stray too far from the desired set point. A slower-acting controller could potentially result in damage to equipment and/or become a safety issue. An example of this is on a compressor where pneumatic devices may monitor the suction and discharge pressure and actuate a re-cycle when one or the other is out of the specified target range. Other scenarios for fast and precise control include transient (non-steady) situations where a gas flow rate may fluctuate widely or unpredictably. This situation requires a responsive high-bleed device to ensure that the gas flow can be controlled in all situations. Temperature and level controllers are typically present in control situations that are not prone to fluctuate as widely or where the fluctuation can be readily and safely accommodated by the equipment. Therefore, such processes can accommodate control from a low-bleed device, which is slower-acting and less precise.

Safety concerns may be a limitation issue, but only in specific situations because emergency valves are not bleeding controllers since safety is the pre-eminent consideration. Thus, the connection between the bleed rate of a pneumatic device and safety is not a direct one. Pneumatic devices are designed for process control during normal operations and to keep the process in a normal operating state. If an Emergency Shut Down (ESD) or Pressure Relief Valve (PRV) actuation occurs,^{iv} the equipment in place for such an event is spring loaded, or otherwise not pneumatically powered. During a safety issue or emergency, it is possible that the pneumatic gas supply will be lost. For this reason, control valves are deliberately selected to either fail open or fail closed, depending on which option is the failsafe.

5.4.1.2 Cost Impacts

As described in Section 5.2.2, costs were based on the vendor research described in Section 5.2 as a result of updating and expanding upon the information given in the appendices of the Natural Gas STAR Lessons Learned document on pneumatic devices.¹ As Table 5-7 indicates, the average cost for a low bleed pneumatic is \$2,553, while the average cost for a high bleed is \$2,338.^v Thus, the incremental cost of installing a low-bleed device instead of a high-bleed device is on the order of \$165 per device. In order to analyze cost impacts, the incremental cost to install a low-bleed instead of a high-bleed was

^{iv} ESD valves either close or open in an emergency depending on the fail safe configuration. PRVs always open in an emergency.

^v Costs are estimated in 2008 U.S. Dollars.

Table 5-7. Cost Projections for the Representative Pneumatic Devices^a

| Device | Minimum cost (\$) | Maximum cost (\$) | Average cost (\$) | Low-Bleed Incremental Cost (\$) |
|-----------------------|--------------------------|--------------------------|--------------------------|--|
| High-bleed controller | 366 | 7,000 | 2,388 | \$165 |
| Low-bleed controller | 524 | 8,852 | 2,553 | |

a. Major pneumatic devices vendors were surveyed for costs, emission rates, and any other pertinent information that would give an accurate picture of the present industry.

annualized for a 10 year period using a 7 percent interest rate. This equated to an annualized cost of around \$23 per device for both the production and transmission segments.

Monetary savings associated with additional gas captured to the sales line was estimated based on a natural gas value of \$4.00 per Mcf.^{vi,17} The representative low-bleed device is estimated to emit 6.65 tons, or 319 Mcf, (using the conversion factor of 0.0208 tons methane per 1 Mcf) of methane less than the average high-bleed device per year. Assuming production quality gas is 82.8 percent methane by volume, this equals 385.5 Mcf natural gas recovered per year. Therefore, the value of recovered natural gas from one pneumatic device in the production segment equates to approximately \$1,500. Savings were not estimated for the transmission segment because it is assumed the owner of the pneumatic controller generally is not the owner of the natural gas. Table 5-8 provides a summary of low-bleed pneumatic cost effectiveness.

5.4.1.3 Secondary Impacts

Low-bleed pneumatic devices are a replacement option for high-bleed devices that simply bleed less natural gas that would otherwise be emitted in the actuation of pneumatic valves. No wastes should be created, no wastewater generated, and no electricity needed. Therefore, there are no secondary impacts expected due to the use of low-bleed pneumatic devices.

5.4.2 Instrument Air Systems

5.4.2.1 Process Description

The major components of an instrument air conversion project include the compressor, power source, dehydrator, and volume tank. The following is a description of each component as described in the Natural Gas STAR document, *Lessons Learned: Convert Gas Pneumatic Controls to Instrument Air*:

- Compressors used for instrument air delivery are available in various types and sizes, from centrifugal (rotary screw) compressors to reciprocating piston (positive displacement) types. The size of the compressor depends on the size of the facility, the number of control devices operated by the system, and the typical bleed rates of these devices. The compressor is usually driven by an electric motor that turns on and off, depending on the pressure in the volume tank.

^{vi} The average market price for natural gas in 2010 was approximately \$4.16 per Mcf. This is much less compared to the average price in 2008 of \$7.96 per Mcf. Due to the volatility in the value, a conservative savings of \$4.00 per Mcf estimate was projected for the analysis in order to not overstate savings.

**Table 5-8. Cost-effectiveness for Low-Bleed Pneumatic Devices
versus High Bleed Pneumatics**

| Segment | Incremental Capital Cost Per Unit (\$) ^a | Total Annual Cost Per Unit (\$/yr) ^b | | VOC Cost Effectiveness (\$/ton) | | Methane Cost Effectiveness (\$/ton) | |
|--|---|---|-----------------|---------------------------------------|-----------------|---|-----------------|
| | | without savings | with savings | without savings | with savings | without savings | with savings |
| Oil and Natural Gas Production | 165 | 23.50 | -1,519 | 13 | net savings | 4 | net savings |
| Natural Gas Transmission and Storage | 165 | 23.50 | 23.50 | 286 | 286 | 8 | 8 |

- a. Incremental cost of a low bleed device versus a high bleed device as summarized in Table 5-7.
- b. Annualized cost assumes a 7 percent interest rate over a 10 year equipment lifetime.

For reliability, a full spare compressor is normally installed. A minimum amount of electrical service is required to power the compressors.

- A critical component of the instrument air control system is the power source required to operate the compressor. Since high-pressure natural gas is abundant and readily available, gas pneumatic systems can run uninterrupted on a 24-hour, 7-day per week schedule. The reliability of an instrument air system, however, depends on the reliability of the compressor and electric power supply. Most large natural gas plants have either an existing electric power supply or have their own power generation system. For smaller facilities and in remote locations, however, a reliable source of electric power can be difficult to assure. In some instances, solar-powered battery-operated air compressors can be cost effective for remote locations, which reduce both methane emissions and energy consumption. Small natural gas powered fuel cells are also being developed.
- Dehydrators, or air dryers, are also an integral part of the instrument air compressor system. Water vapor present in atmospheric air condenses when the air is pressurized and cooled, and can cause a number of problems to these systems, including corrosion of the instrument parts and blockage of instrument air piping and controller orifices.
- The volume tank holds enough air to allow the pneumatic control system to have an uninterrupted supply of high pressure air without having to run the air compressor continuously. The volume tank allows a large withdrawal of compressed air for a short time, such as for a motor starter, pneumatic pump, or pneumatic tools, without affecting the process control functions.

Compressed air may be substituted for natural gas in pneumatic systems without altering any of the parts of the pneumatic control. The use of instrument air eliminates natural gas emissions from natural gas powered pneumatic controllers. All other parts of a gas pneumatic system will operate the same way with instrument air as they do with natural gas. The conversion of natural gas pneumatic controllers to instrument air systems is applicable to all natural gas facilities with electrical service available.¹⁴

5.4.2.2 Effectiveness

The use of instrument air eliminates natural gas emissions from the natural gas driven pneumatic devices; however, the system is only applicable in locations with access to a sufficient and consistent

supply of electrical power. Instrument air systems are also usually installed at facilities where there is a high concentration of pneumatic control valves and the presence of an operator that can ensure the system is properly functioning.¹⁴

5.4.2.3 Cost Impacts

Instrument air conversion requires additional equipment to properly compress and control the pressured air. The size of the compressor will depend on the number of control loops present at a location. A control loop consists of one pneumatic controller and one control valve. The volume of compressed air supply for the pneumatic system is equivalent to the volume of gas used to run the existing instrumentation – adjusted for air losses during the drying process. The current volume of gas usage can be determined by direct metering if a meter is installed. Otherwise, an alternative rule of thumb for sizing instrument air systems is one cubic foot per minute (cfm) of instrument air for each control loop.¹⁴ As the system is powered by electric compressors, the system requires a constant source of electrical power or a back-up pneumatic device. Table 5-9 outlines three different sized instrument air systems including the compressor power requirements, the flow rate provided from the compressor, and the associated number of control loops.

The primary costs associated with conversion to instrument air systems are the initial capital expenditures for installing compressors and related equipment and the operating costs for electrical energy to power the compressor motor. This equipment includes a compressor, a power source, a dehydrator and a storage vessel. It is assumed that in either an instrument air solution or a natural gas pneumatic solution, gas supply piping, control instruments, and valve actuators of the gas pneumatic system are required. The total cost, including installation and labor, of three representative sizes of compressors were evaluated based on assumptions found in the Natural Gas STAR document, “Lessons Learned: Convert Gas Pneumatic Controls to Instrument Air”¹⁴ and summarized in Table 5-10.^{vii}

For natural gas processing, the cost-effectiveness of the three representative instrument air system sizes was evaluated based on the emissions mitigated from the number of control loops the system can provide and not on a per device basis. This approach was chosen because we assume new processing plants will need to provide instrumentation of multiple control loops and size the instrument air system accordingly. We also assume that existing processing plants have already upgraded to instrument air

^{vii} Costs have been converted to 2008 US dollars using the Chemical Engineering Cost Index.

Table 5-9. Compressor Power Requirements and Costs for Various Sized Instrument Air Systems^a

| Compressor Power Requirements ^b | | | Flow Rate | Control Loops |
|--|----|------|-----------|------------------|
| Size of Unit | hp | kW | (cfm) | Loops/Compressor |
| small | 10 | 13.3 | 30 | 15 |
| medium | 30 | 40 | 125 | 63 |
| large | 75 | 100 | 350 | 175 |

- a. Based on rules of thumb stated in the Natural Gas STAR document, *Lessons Learned: Convert Gas Pneumatic Controls to Instrument Air*¹⁴
- b. Power is based on the operation of two compressors operating in parallel (each assumed to be operating at full capacity 50 percent of the year).

Table 5-10 Estimated Capital and Annual Costs of Various Sized Representative Instrument Air Systems

| Instrument Air System Size | Compressor | Tank | Air Dryer | Total Capital^a | Annualized Capital^b | Labor Cost | Total Annual Costs^c | Annualized Cost of Instrument Air System |
|-----------------------------------|-------------------|-------------|------------------|----------------------------------|---------------------------------------|-------------------|---------------------------------------|---|
| Small | \$3,772 | \$754 | \$2,262 | \$16,972 | \$2,416 | \$1,334 | \$8,674 | \$11,090 |
| Medium | \$18,855 | \$2,262 | \$6,787 | \$73,531 | \$10,469 | \$4,333 | \$26,408 | \$36,877 |
| Large | \$33,183 | \$4,525 | \$15,083 | \$135,750 | \$19,328 | \$5,999 | \$61,187 | \$80,515 |

- a. Total Capital includes the cost for two compressors, tank, an air dryer and installation. Installation costs are assumed to be equal to 1.5 times the cost of capital. Equipment costs were derived from the Natural Gas Star Lessons Learned document and converted to 2008 dollars from 2006 dollars using the Chemical Engineering Cost Index.
- b. The annualized cost was estimated using a 7 percent interest rate and 10 year equipment life.
- c. Annual Costs include the cost of electrical power as listed in Table 5-9 and labor.

unless the function has a specific need for a bleeding device, which would most likely be safety related.⁹ Table 5-11 summarizes the cost-effectiveness of the three sizes of representative instrument air systems.

5.4.2.4 Secondary Impacts

The secondary impacts from instrument air systems are indirect, variable and dependent on the electrical supply used to power the compressor. No other secondary impacts are expected.

5.5 Regulatory Options

The affected facility definition for pneumatic controllers is defined as a single natural gas pneumatic controller. Therefore, pneumatic controllers would be subject to a New Source Performance Standard (NSPS) at the time of installation. The following Regulatory alternatives were evaluated:

- Regulatory Option 1: Establish an emissions limit equal to 0 scfh.
- Regulatory Option 2: Establish an emissions limit equal to 6 scfh.

5.5.1 Evaluation of Regulatory Options

By establishing an emission limit of 0 scfh, facilities would most likely install instrument air systems to meet the threshold limit. This option is considered cost effective for natural gas processing plants as summarized in Table 5-11. A major assumption of this analysis, however, is that processing plants are constructed at a location with sufficient electrical service to power the instrument air compression system. It is assumed that facilities located outside of the processing plant would not have sufficient electrical service to install an instrument air system. This would significantly increase the cost of the system at these locations, making it not cost effective for these facilities to meet this regulatory option. Therefore, Regulatory Option 1 was accepted for natural gas processing plants and rejected for all other types of facilities.

Regulatory Option 2 would establish an emission limit equal to the maximum emissions allowed for a low-bleed device in the production and transmissions and storage industry segments. This would most likely be met by the use of low-bleed controllers in place of a high-bleed controller, but allows flexibility in the chosen method of meeting the requirement. In the key instances related to pressure control that would disallow the use of a low-bleed device, specific monitoring and recordkeeping criteria

Table 5-11 Cost-effectiveness of Representative Instrument Air Systems in the Natural Gas Processing Segment

| System Size | Number of Control Loops | Annual Emissions Reduction ^a (tons/year) | | | Value of Product Recovered (\$/year) ^b | Annualized Cost of System | | VOC Cost-effectiveness (\$/ton) | | Methane Cost-effectiveness (\$/ton) | |
|-------------|-------------------------|---|-----------------|------|---|---------------------------|--------------|---------------------------------|--------------|-------------------------------------|--------------|
| | | VOC | CH ₄ | HAP | | without savings | with savings | without savings | with savings | without savings | with savings |
| Small | 15 | 4.18 | 15 | 0.16 | 3,484 | 11,090 | 7,606 | 2,656 | 1,822 | 738 | 506 |
| Medium | 63 | 17.5 | 63 | 0.66 | 14,632 | 36,877 | 22,245 | 2,103 | 1,269 | 585 | 353 |
| Large | 175 | 48.7 | 175 | 1.84 | 40,644 | 80,515 | 39,871 | 1,653 | 819 | 460 | 228 |

Minor discrepancies may be due to rounding.

- a. Based on the emissions mitigated from the entire system, which includes multiple control loops.
- b. Value of recovered product assumes natural gas processing is 82.8 percent methane by volume. A natural gas price of \$4 per Mcf was assumed.

would be required to ensure the device function dictates the precision of a high bleed device. Therefore, Regulatory Option 2 was accepted for locations outside of natural gas processing plants.

5.5.2 Nationwide Impacts of Regulatory Options

Table 5-12 summarizes the costs impacts of the selected regulatory options by industry segment. Regulatory Option 1 for the natural gas processing segment is estimated to affect 15 new processing plants with nationwide annual costs discounting savings of \$166,000. When savings are realized the net annual cost is reduced to around \$114,000. Regulatory Option 2 has nationwide annual costs of \$320,000 for the production segment and around \$1,500 in the natural gas transmission and storage segment. When annual savings are realized in the production segment there is a net savings of \$20.7 million in nationwide annual costs.

Table 5-12 Nationwide Cost and Emission Reduction Impacts for Selected Regulatory Options by Industry Segment

| Industry Segment | Number of Sources subject to NSPS* | Capital Cost Per Device/IAS (\$)** | Annual Costs (\$/year) | | Nationwide Emission Reductions (tpy)† | | | VOC Cost Effectiveness (\$/ton) | | Methane Cost Effectiveness (\$/ton) | | Total Nationwide Costs (\$/year) | | |
|---|------------------------------------|------------------------------------|------------------------|--------------|---------------------------------------|---------|-----|---------------------------------|--------------|-------------------------------------|--------------|----------------------------------|------------------------|---------------------|
| | | | without savings | with savings | VOC | Methane | HAP | without savings | with savings | without savings | with savings | Capital Cost | Annual without savings | Annual with savings |
| Regulatory Option 1 (emission threshold equal to 0 scfh) | | | | | | | | | | | | | | |
| Natural Gas Processing | 15 | 16,972 | 11,090 | 7,606 | 63 | 225 | 2 | 2,656 | 1,822 | 738 | 506 | 254,576 | 166,351 | 114,094 |
| Regulatory Option 2 (emission threshold equal to 6 scfh) | | | | | | | | | | | | | | |
| Oil and Natural Gas Production | 13,632 | 165 | 23 | (1,519) | 25,210 | 90,685 | 952 | 13 | net savings | 4 | net savings | 2,249,221 | 320,071 | (20,699,918) |
| Natural Gas Transmission and Storage | 67 | 165 | 23 | 23 | 6 | 212 | 0.2 | 262 | 262 | 7 | 7 | 11,039 | 1,539 | 1,539 |

Minor discrepancies may be due to rounding.

- a. The number of sources subject to NSPS for the natural gas processing and the natural gas transmission and storage segments represent the number of new devices expected per year reduced by 20 percent. This is consistent with the assumption that 80 percent of high bleed devices can be replaced with a low bleed device. It is assumed all new sources would be installed as a high bleed for these segments. For the natural gas processing segment the number of new sources represents the number of Instrument Air Systems (IAS) that is expected to be installed, with each IAS expected to power 15 control loops (or replace 15 pneumatic devices).
- b. The capital cost for regulatory option 2 is equal to the incremental cost of a low bleed device versus a new high bleed device. The capital cost of the IAS is based on the small IAS as summarized in Table 5-10.
- c. Nationwide emission reductions vary based on average expected emission rates of bleed devices typically used in each segment industry segment as summarized in Tables 5-2.

6.0 COMPRESSORS

Compressors are mechanical devices that increase the pressure of natural gas and allow the natural gas to be transported from the production site, through the supply chain, and to the consumer. The types of compressors that are used by the oil and gas industry as prime movers are reciprocating and centrifugal compressors. This chapter discusses the air pollutant emissions from these compressors and provides emission estimates for reducing emission from these types of compressors. In addition, nationwide emissions estimates from new sources are estimated. Options for controlling pollutant emissions from these compressors are presented, along with costs, emission reductions, and secondary impacts. Finally, this chapter discusses considerations in developing regulatory alternatives for both reciprocating and centrifugal compressors.

6.1 Process Description

6.1.1 Reciprocating Compressors

In a reciprocating compressor, natural gas enters the suction manifold, and then flows into a compression cylinder where it is compressed by a piston driven in a reciprocating motion by the crankshaft powered by an internal combustion engine. Emissions occur when natural gas leaks around the piston rod when pressurized natural gas is in the cylinder. The compressor rod packing system consists of a series of flexible rings that create a seal around the piston rod to prevent gas from escaping between the rod and the inboard cylinder head. However, over time, during operation of the compressor, the rings become worn and the packing system will need to be replaced to prevent excessive leaking from the compression cylinder.

6.1.2 Centrifugal Compressors

Centrifugal compressors use a rotating disk or impeller to increase the velocity of the gas where it is directed to a divergent duct section that converts the velocity energy to pressure energy. These compressors are primarily used for continuous, stationary transport of natural gas in the processing and transmission systems. Many centrifugal compressors use wet (meaning oil) seals around the rotating shaft to prevent natural gas from escaping where the compressor shaft exits the compressor casing. The wet seals use oil which is circulated at high pressure to form a barrier against compressed natural gas leakage. The circulated oil entrains and absorbs some compressed natural gas which is released to the

atmosphere during the seal oil recirculation process. Alternatively, dry seals can be used to replace the wet seals in centrifugal compressors. Dry seals prevent leakage by using the opposing force created by hydrodynamic grooves and springs. The opposing forces create a thin gap of high pressure gas between the rings through which little gas can leak. The rings do not wear or need lubrication because they are not in contact with each other. Therefore, operation and maintenance costs are lower for dry seals in comparison to wet seals.

6.2 Emissions Data and Emission Factors

6.2.1 Summary of Major Studies and Emissions Factors

There are a few studies that have been conducted that provide leak estimates from reciprocating and centrifugal compressors. These studies are provided in Table 6-1, along with the type of information contained in the study.

6.2.2 Representative Reciprocating and Centrifugal Compressor Emissions

The methodology for estimating emission from reciprocating compressor rod packing was to use the methane emission factors referenced in the EPA/GRI study¹ and use the methane to pollutant ratios developed in the gas composition memorandum.² The emission factors in the EPA/GRI document were expressed in thousand standard cubic feet per cylinder (Mscf/cyl), and were multiplied by the average number of cylinder per reciprocating compressor at each oil and gas industry segment. The volumetric methane emission rate was converted to a mass emission rate using a density of 41.63 pounds of methane per thousand cubic feet. This conversion factor was developed assuming that methane is an ideal gas and using the ideal gas law to calculate the density. A summary of the methane emission factors is presented in Table 6-2. Once the methane emissions were calculated, ratios were used to estimate volatile organic compounds (VOC) and hazardous air pollutants (HAP). The specific ratios that were used for this analysis were 0.278 pounds VOC per pound of methane and 0.105 pounds HAP per pound of methane for the production and processing segments, and 0.0277 pounds VOC per pound of methane and 0.0008 pounds HAP per pound of methane for the transmission and storage segments. A summary of the reciprocating compressor emissions are presented in Table 6-3.

The compressor emission factors for wet seals and dry seals are based on data used in the GHG inventory. The wet seals methane emission factor was calculated based on a sampling of 48 wet seal centrifugal compressors. The dry seal methane emission factor was based on data collected by the

Natural Gas STAR Program. The methane emissions were converted to VOC and HAP emissions using the same gas composition ratios that were used for reciprocating engines.⁴ A summary of the emission factors are presented in Table 6-2 and the individual compressor emission are shown in Table 6-3 for each of the oil and gas industry segments.

6.3 Nationwide Emissions from New Sources

6.3.1 Overview of Approach

The number of new affected facilities in each of the oil and gas sectors was estimated using data from the U.S. Greenhouse Gas Inventory,^{5,6} with some exceptions. This basis was used whenever the total number of existing facilities was explicitly estimated as part of the Inventory, so that the difference between two years can be calculated to represent the number of new facilities. The Inventory was not used to estimate the new number of reciprocating compressor facilities in gas production, since more recent information is available in the comments received to subpart W of the mandatory reporting rule. Similarly, the Inventory was not used to estimate the new number of reciprocating compressor facilities in gas gathering, since more recent information is available in comments received as comments to subpart W of the mandatory reporting rule. For both gas production and gas gathering, information received as comments to subpart W of the mandatory reporting rule was combined with additional EPA estimates and assumptions to develop the estimates for the number of new affected facilities.

Nationwide emission estimates for new sources were then determined by multiplying the number of new sources for each oil and gas segment by the expected emissions per compressor using the emission data in Table 6-3. A summary of the number of new reciprocating and centrifugal compressors for each of the oil and gas segments is presented in Table 6-4.

6.3.2 Activity Data for Reciprocating Compressors

6.3.2.1 Wellhead Reciprocating Compressors

The number of wellhead reciprocating compressors was estimated using data from industry comments on Subpart W of the Greenhouse Gas Mandatory Reporting Rule.⁷ The 2010 U.S. GHG Inventory reciprocating compressor activity data was not considered in the analysis because it does not distinguish between wellhead and gathering and boosting compressors. Therefore, using data submitted to EPA during the subpart W comment period from nine basins supplied by the El Paso Corporation,⁸ the

Table 6-4. Approximate Number of New Sources in the Oil and Gas Industry in 2008

| Industry Segment | Number of New Reciprocating Compressors | Number of New Centrifugal Compressors |
|-------------------------|--|--|
| Wellheads | 6,000 | 0 |
| Gathering and Boosting | 210 | 0 |
| Processing | 209 | 16 |
| Transmission | 20 | 14 |
| Storage | 4 | |

average number of new wellhead compressors per new well was calculated using the 315 well head compressors provided in the El Paso comments and 3,606 wells estimated in the Final Subpart W onshore production threshold analysis. This produced an average of 0.087 compressors per wellhead. The average wellhead compressors per well was multiplied by the total well completions (oil and gas) determined from the HPDI® database⁹ between 2007 and 2008, which came to 68,000 new well completions. Using this methodology, the estimated number of new reciprocating compressors at production pads was calculated to be 6,000 for 2008. A summary of the number of new reciprocating compressors located at well pads is presented in Table 6-4.

6.3.2.2 Gathering and Boosting Reciprocating Compressors

The number of gathering & boosting reciprocating compressors was also estimated using data from industry comments on Subpart W. DCP Midstream stated on page 3 of its 2010 Subpart W comments that it operates 48 natural gas processing plants and treaters and 700 gathering system compressor stations. Using this data, there were an average of 14.583 gathering and boosting compressor stations per processing plant. The number of new gathering and boosting compressors was determined by taking the average difference between the number of processing plants for each year in the 2010 U.S. Inventory, which references the total processing plants in the Oil and Gas Journal. This was done for each year up to 2008. An average was taken of only the years with an increase in processing plants, up to 2008. The resulting average was multiplied by the 14.583 ratio of gathering and boosting compressor stations to processing plants and the 1.5 gathering and boosting compressors per station yielding 210 new source gathering and boosting compressor stations and is shown in Table 6-4.

6.3.2.3 Processing Reciprocating Compressors

The number of new processing reciprocating compressors at processing facilities was estimated by averaging the increase of reciprocating compressors at processing plants in the greenhouse gas inventory data for 2007, 2008, and 2009.^{10,11} The estimated number of existing reciprocating compressors in the processing segment was 4,458, 4,781, and 4,876 for the years 2007, 2008, and 2009 respectively. This calculated to be 323 new reciprocating compressors between 2007 and 2008, and 95 new reciprocating compressors between 2008 and 2009. The average difference was calculated to be 209 reciprocating compressors and was used to estimate the number of new sources in Table 6-4.

6.3.2.4 Transmission and Storage Reciprocating Compressors

The number of new transmission and storage reciprocating compressors was estimated using the differences in the greenhouse gas inventory^{12,13} data for 2007, 2008, and 2009 and calculating an average of those differences. The estimated number of existing reciprocating compressors at transmission stations was 7,158, 7,028, and 7,197 for the years 2007, 2008, and 2009 respectively. This calculated to be -130 new reciprocating compressors between 2007 and 2008, and 169 new reciprocating compressors between 2008 and 2009. The average difference was calculated to be 20 reciprocating compressors and was used to estimate the number of new sources at transmission stations. The number of existing reciprocating compressors at storage stations was 1,144, 1,178, and 1,152 for the years 2007, 2008, and 2009 respectively. This calculated to be 34 new reciprocating compressors between 2007 and 2008, and -26 new reciprocating compressors between 2008 and 2009. The average difference was calculated to be 4 reciprocating compressors and was used to estimate the number of new sources at storage stations in Table 6-4.

6.3.3 Activity Data for Centrifugal Compressors

The number of new centrifugal compressors in 2008 for the processing and transmission/storage segments was determined by taking the average difference between the centrifugal compressor activity data for each year in the 2008 U.S. Inventory. For example, the number of compressors in 1992 was subtracted from the number of compressors in 1993 to determine the number of new centrifugal compressors in 1993. This was done for each year up to 2008. An average was taken of only the years with an increase in centrifugal compressors, up to 2008, to determine the number of new centrifugal compressors in 2008. The result was 16 and 14 new centrifugal compressors in the processing and transmission segments respectively. A summary of the estimates for new centrifugal compressor is presented in Table 6-4.

6.3.4 Emission Estimates

Nationwide baseline emission estimates for new reciprocating and centrifugal compressors are summarized in Table 6-5 by industry segment.

Table 6-5. Nationwide Baseline Emissions for New Reciprocating and Centrifugal Compressors

| Industry Segment/ Compressor Type | Nationwide baseline Emissions (tons/year) | | |
|--------------------------------------|--|-------|--------|
| | Methane | VOC | HAP |
| <i>Reciprocating Compressors</i> | | | |
| Production (Well Pads) | 1,186 | 330 | 12.4 |
| Gathering & Boosting | 2,587 | 719 | 27.1 |
| Processing | 4,871 | 1,354 | 51.0 |
| Transmission | 529 | 14.6 | 0.435 |
| Storage | 113 | 3.13 | 0.0929 |
| <i>Centrifugal Compressors</i> | | | |
| Processing | 3,640 | 329 | 11.8 |
| Transmission/Storage | 1,768 | 48.9 | 1.45 |

6.4 Control Techniques

6.4.1 Potential Control Techniques

The potential control options reviewed for reducing emissions from reciprocating compressors include control techniques that limit the leaking of natural gas past the piston rod packing. This includes replacement of the compressor rod packing, replacement of the piston rod, and the refitting or realignment of the piston rod.

The replacement of the rod packing is a maintenance task performed on reciprocating compressors to reduce the leakage of natural gas past the piston rod. Over time the packing rings wear and allow more natural gas to escape around the piston rod. Regular replacement of these rings reduces methane and VOC emissions. Therefore, this control technique was determined to be an appropriate option for reciprocating compressors.

Like the packing rings, piston rods on reciprocating compressors also deteriorate. Piston rods, however, wear more slowly than packing rings, having a life of about 10 years.¹⁴ Rods wear “out-of-round” or taper when poorly aligned, which affects the fit of packing rings against the shaft (and therefore the tightness of the seal) and the rate of ring wear. An out-of-round shaft not only seals poorly, allowing more leakage, but also causes uneven wear on the seals, thereby shortening the life of the piston rod and the packing seal. Replacing or upgrading the rod can reduce reciprocating compressor rod packing emissions. Also, upgrading piston rods by coating them with tungsten carbide or chrome reduces wear over the life of the rod. This analysis assumes operators will choose, at their discretion, when to replace the rod and hence, does not consider this control technique to be a practical control option for reciprocating compressors. A summary of these techniques are presented in the following sections.

Potential control options to reduce emissions from centrifugal compressors include control techniques that limit the leaking of natural gas across the rotating shaft, or capture and destruction of the emissions using a flare. A summary of these techniques are presented in the following sections.

A control technique for limiting or reducing the emission from the rotating shaft of a centrifugal compressor is a mechanical dry seal system. This control technique uses rings to prevent the escape of natural gas across the rotating shaft. This control technique was determined to be a viable option for reducing emission from centrifugal compressors.

For centrifugal compressors equipped with wet seals, a flare was considered to be a reasonable option for reducing emissions from centrifugal compressors. Centrifugal compressors require seals around the rotating shaft to prevent natural gas from escaping where the shaft exits the compressor casing. “Beam” type compressors have two seals, one on each end of the compressor, while “over-hung” compressors have a seal on only the “inboard” (motor end) side. These seals use oil, which is circulated under high pressure between three rings around the compressor shaft, forming a barrier against the compressed gas leakage. The center ring is attached to the rotating shaft, while the two rings on each side are stationary in the seal housing, pressed against a thin film of oil flowing between the rings to both lubricate and act as a leak barrier. The seal also includes “O-ring” rubber seals, which prevent leakage around the stationary rings. The oil barrier allows some gas to escape from the seal, but considerably more gas is entrained and absorbed in the oil under the high pressures at the “inboard” (compressor side) seal oil/gas interface, thus contaminating the seal oil. Seal oil is purged of the absorbed gas (using heaters, flash tanks, and degassing techniques) and recirculated back to the seal. As a control measure, the recovered gas would then be sent to a flare or other combustion device.

6.4.2 Reciprocating Compressor Rod Packing Replacement

6.4.2.1 Description

Reciprocating compressor rod packing consists of a series of flexible rings that fit around a shaft to create a seal against leakage. As the rings wear, they allow more compressed gas to escape, increasing rod packing emissions. Rod packing emissions typically occur around the rings from slight movement of the rings in the cups as the rod moves, but can also occur through the “nose gasket” around the packing case, between the packing cups, and between the rings and shaft. If the fit between the rod packing rings and rod is too loose, more compressed gas will escape. Periodically replacing the packing rings ensures the correct fit is maintained between packing rings and the rod.

6.4.2.2 Effectiveness

As discussed above, regular replacement of the reciprocating compressor rod packing can reduce the leaking of natural gas across the piston rod. The potential emission reductions were calculated by comparing the average rod packing emissions with the average emissions from newly installed and worn-in rod packing. Since the estimate for newly installed rod packing was intended for larger processing and transmission compressors, this analysis uses the estimate to calculate reductions from only gathering

and boosting compressors and not wellhead compressor which are known to be smaller. The calculation for gathering and boosting reductions is shown in Equation 1.

$$R_{WP}^{G\&B} = \frac{Comp_{New}^{G\&B} (E_{G\&B} - E_{New}) \times C \times O \times 8760}{10^6} \quad \text{Equation 1}$$

where,

$R_{WP}^{G\&B}$ = Potential methane emission reductions from gathering and boosting compressors switching from wet seals to dry seals, in million cubic feet per year (MMcf/year);

$Comp_{New}^{G\&B}$ = Number of new gathering and boosting compressors;

$E_{G\&B}$ = Methane emission factor for gathering and boosting compressors in Table 6-2, in cubic feet per hour per cylinder;

E_{New} = Average emissions from a newly installed rod packing, assumed to be 11.5 cubic feet per hour per cylinder¹⁵ for this analysis;

C = Average number of cylinders for gathering and boosting compressors in Table 6-2;

O = Percent of time during the calendar year the average gathering and boosting compressor is in the operating and standby pressurized modes, 79.1%;

8760 = Number of days in a year;

10^6 = Number of cubic feet in a million cubic feet.

For wellhead reciprocating compressors, this analysis calculates a percentage reduction using the transmission emission factor from the 1996 EPA/GRI report and the minimum emissions rate from a newly installed rod packing to determine methane emission reductions. The calculation for wellhead compressor reductions is shown in Equation 2 below.

$$R_{Well} = \frac{Comp_{New}^{Well} (E_{Well}) \times C \times O \times 8760}{10^6} \left(\frac{E_{Trans} - E_{New}}{E_{Trans}} \right) \quad \text{Equation 2}$$

where,

R_{Well} = Potential methane emission reductions from wellhead compressors switching from wet seals to dry seals, in million cubic feet per year (MMcf/year);

$Comp_{New}^{Well}$ = Number of new wellhead compressors;

E_{Well} = Methane emission factor for wellhead compressors from Table 6-2, cubic feet per hour per cylinder;

C = Average number of cylinders for wellhead compressors in Table 6-2;

O = Percent of time during the calendar year the average gathering and boosting compressor is in the operating and standby pressurized modes, 100%;

E_{Trans} = Methane emissions factor for transmission compressors from Table 6-2 in cubic feet per hour per cylinder;

E_{New} = Average emissions from a newly installed rod packing, assumed to be 11.5 cubic feet per hour per cylinder¹⁶ for this analysis;

8760 = Number of days in a year;

10^6 = Number of cubic feet in a million cubic feet.

The emission reductions for the processing, transmission, and storage segments were calculated by multiplying the number of new reciprocating compressors in each segment by the difference between the average rod packing emission factors in Table 6-2 by the average emission factor from newly installed rod packing. This calculation, shown in the Equation 3 below, was performed for each of the natural gas processing, transmission, and storage/LNG sectors.

$$R_{PTS} = \frac{Comp_{New}^{PTS} (E_{G\&B} - E_{New}) \times C \times O \times 8760}{10^6} \quad \text{Equation 3}$$

where,

R_{PTS} = Potential methane emission reductions from processing, transmission, or storage compressors switching from wet seals to dry seals, in million cubic feet per year (MMcf/year);

$Comp_{New}^{PTS}$ = Number of new processing, transmission, or storage compressors;

$E_{G\&B}$ = Methane emission factor for processing, transmission, or storage compressors in Table 6-2, in cubic feet per hour per cylinder;

E_{New} = Average emissions from a newly installed rod packing, assumed to be 11.5 cubic feet per hour per cylinder¹⁷ for this analysis;

C = Average number of cylinders for processing, transmission, or storage compressors in Table 6-2;

O = Percent of time during the calendar year the average processing, transmission, or storage compressor is in the operating and standby pressurized modes, 89.7%, 79.1%, 67.5% respectively;

8760 = Number of days in a year;

10^6 = Number of cubic feet in a million cubic feet.

A summary of the potential emission reductions for reciprocating rod packing replacement for each of the oil and gas segments is shown in Table 6-6. The emissions of VOC and HAP were calculated using the methane emission reductions calculated above the gas composition¹⁸ for each of the segments.

Reciprocating compressors in the processing sector were assumed to be used to compress production gas.

Table 6-6. Estimated Annual Reciprocating Compressor Emission Reductions from Replacing Rod Packing

| Oil & Gas Segment | Number of New Sources Per Year | Individual Compressor Emission Reductions (tons/compressor-year) | | | Nationwide Emission Reductions (tons/year) | | |
|------------------------|--------------------------------|--|--------|---------|--|-------|--------|
| | | Methane | VOC | HAP | Methane | VOC | HAP |
| Production (Well Pads) | 6,000 | 0.158 | 0.0439 | 0.00165 | 947 | 263 | 9.91 |
| Gathering & Boosting | 210 | 6.84 | 1.90 | 0.0717 | 1,437 | 400 | 15.1 |
| Processing | 375 | 18.6 | 5.18 | 0.195 | 3,892 | 1,082 | 40.8 |
| Transmission | 199 | 21.7 | 0.600 | 0.0178 | 423 | 11.7 | 0.348 |
| Storage | 9 | 21.8 | 0.604 | 0.0179 | 87.3 | 2.42 | 0.0718 |

6.4.2.3 Cost Impacts

Costs for the replacement of reciprocating compressor rod packing were obtained from a Natural Gas Star Lessons Learned document¹⁹ which estimated the cost to replace the packing rings to be \$1,620 per cylinder. It was assumed that rod packing replacement would occur during planned shutdowns and maintenance and therefore, no travel costs will be incurred for implementing the rod packing replacement program. In addition, no costs were included for monitoring because the rod packing placement is based on number of hours that the compressor operates. The replacement of rod packing for reciprocating compressors occurs on average every four years based on industry information from the Natural Gas STAR Program.²⁰ The cost impacts are based on the replacement of the rod packing 26,000 hours that the reciprocating compressor operates in the pressurized mode. The number of hours used for the cost impacts was determined using a weighted average of the annual percentage that the reciprocating compressors are pressurized for all of the new sources. This weighted hours, on average, per year the reciprocating compressor is pressurized was calculated to be 98.9 percent. This percentage was multiplied by the total number of hours in 3 years to obtain a value of 26,000 hours. This calculates to an average of 3 years for production compressors, 3.8 years for gathering and boosting compressors, 3.3 years for processing compressors, 3.8 years for transmission compressors, and 4.4 years for storage compressors using the operating factors in Table 6-2. The calculated years were assumed to be the equipment life of the compressor rod packing and were used to calculate the capital recovery factor for each of the segments. Assuming an interest rate of 7 percent, the capital recovery factors were calculated to be 0.3848, 0.3122, 0.3490, 0.3122, and 0.2720 for the production, gathering and boosting, processing, transmission, and storage sectors, respectively. The capital costs were calculated using the average rod packing cost of \$1,620 and the average number of cylinders per segment in Table 6-2. The annual costs were calculated using the capital cost and the capital recovery factors. A summary of the capital and annual costs for each of the oil and gas segments is shown in Table 6-7.

Monetary savings associated with the amount of gas saved with reciprocating compressor rod packing replacement was estimated using a natural gas price of \$4.00 per Mcf.²¹ This cost was used to calculate the annual cost with gas savings using the methane emission reductions in Table 6-6. The annual cost with savings is shown in Table 6-7 for each of the oil and gas segments. The cost effectiveness for the reciprocating rod packing replacement option is presented in Table 6-7. There is no gas savings cost benefits for transmission and storage facilities, because they do not own the natural gas that is

Table 6-7. Cost Effectiveness for Reciprocating Compressor Rod Packing Replacement

| Oil and Gas Segment | Capital Cost (\$2008) | Annual Cost per Compressor (\$/compressor-year) | | VOC Cost Effectiveness (\$/ton) | | Methane Cost Effectiveness (\$/ton) | |
|----------------------|-----------------------|---|--------------|---------------------------------|--------------|-------------------------------------|--------------|
| | | Without savings | With savings | Without savings | With savings | Without savings | With savings |
| Production | \$6,480 | \$2,493 | \$2,457 | \$56,847 | \$56,013 | \$15,802 | \$15,570 |
| Gathering & Boosting | \$5,346 | \$1,669 | \$83 | \$877 | \$43 | \$244 | \$12 |
| Processing | \$4,050 | \$1,413 | -\$2,903 | \$273 | -\$561 | \$76 | -\$156 |
| Transmission | \$5,346 | \$1,669 | N/A | \$2,782 | N/A | \$77 | N/A |
| Storage | \$7,290 | \$2,276 | N/A | \$3,766 | N/A | \$104 | N/A |

compressed at their compressor stations.

6.4.2.4 Secondary Impacts

The reciprocating compressor rod packing replacement is an option that prevents the escape of natural gas from the piston rod. No wastes should be created, no wastewater generated, and no electricity maintenance and therefore, no travel costs will be incurred for implementing the rod packing replacement program. In addition, no costs were included for monitoring because the rod packing

6.4.3 Centrifugal Compressor Dry Seals

6.4.3.1 Description

Centrifugal compressor dry seals operate mechanically under the opposing force created by hydrodynamic grooves and springs. The hydrodynamic grooves are etched into the surface of the rotating ring affixed to the compressor shaft. When the compressor is not rotating, the stationary ring in the seal housing is pressed against the rotating ring by springs. When the compressor shaft rotates at high speed, compressed gas has only one pathway to leak down the shaft, and that is between the rotating and stationary rings. This gas is pumped between the rings by grooves in the rotating ring. The opposing force of high-pressure gas pumped between the rings and springs trying to push the rings together creates a very thin gap between the rings through which little gas can leak. While the compressor is operating, the rings are not in contact with each other, and therefore, do not wear or need lubrication. O-rings seal the stationary rings in the seal case.

Dry seals substantially reduce methane emissions. At the same time, they significantly reduce operating costs and enhance compressor efficiency. Economic and environmental benefits of dry seals include:

- **Gas Leak Rates.** During normal operation, dry seals leak at a rate of 6 scfm methane per compressor.²² While this is equivalent to a wet seal's leakage rate at the seal face, wet seals generate additional emissions during degassing of the circulating oil. Gas separated from the seal oil before the oil is re-circulated is usually vented to the atmosphere, bringing the total leakage rate for tandem wet seals to 47.7 scfm methane per compressor.^{23,24}
- **Mechanically Simpler.** Dry seal systems do not require additional oil circulation components and treatment facilities.

- **Reduced Power Consumption.** Because dry seals have no accessory oil circulation pumps and systems, they avoid “parasitic” equipment power losses. Wet seal systems require 50 to 100 kW per hour, while dry seal systems need about 5 kW of power per hour.
- **Improved Reliability.** The highest percentage of downtime for a compressor using wet seals is due to seal system problems. Dry seals have fewer ancillary components, which translates into higher overall reliability and less compressor downtime.
- **Lower Maintenance.** Dry seal systems have lower maintenance costs than wet seals because they do not have moving parts associated with oil circulation (e.g., pumps, control valves, relief valves, and the seal oil cost itself).
- **Elimination of Oil Leakage from Wet Seals.** Substituting dry seals for wet seals eliminates seal oil leakage into the pipeline, thus avoiding contamination of the gas and degradation of the pipeline.

Centrifugal compressors were found in the processing and transmission sectors based on information in the greenhouse gas inventory.²⁵ Therefore, it was assumed that new compressors would be located in these sectors only.

6.4.3.2 Effectiveness

The control effectiveness of the dry seals was calculated by subtracting the dry seal emissions from a centrifugal compressor equipped with wet seals. The centrifugal compressor emission factors in Table 6-2 were used in combination with an operating factor of 43.6 percent for processing centrifugal compressors and 24.2 percent for transmission centrifugal compressors. The operating factors are used to account for the percent of time in a year that a compressor is in the operating mode. The operating factors for the processing and transmission sectors are based on data in the EPA/GRI study.²⁶ The wet seals emission factor is an average of 48 different wet seal centrifugal compressors. The dry seal emission factor is based on information from the Natural Gas STAR Program.²⁷ A summary of the emission reduction from the replacement of wet seals with dry seals is shown in Table 6-8.

6.4.3.3 Cost Impacts

The price difference between a brand new dry seal and brand new wet seal centrifugal compressor is insignificant relative to the cost for the entire compressor. General Electric (GE) stated that a natural gas transmission pipeline centrifugal compressor with dry seals cost between \$50,000 and \$100,000 more than the same centrifugal compressor with wet seals. However, this price difference is only about 1 to 3

Table 6-8. Estimated Annual Centrifugal Compressor Emission Reductions from Replacing Wet Seals with Dry Seals

| Oil & Gas Segment | Number of New Sources Per Year | Individual Compressor Emission Reductions (ton/compressor-year) | | | Nationwide Emission Reductions (ton/year) | | |
|----------------------|--------------------------------|---|------|--------|---|------|------|
| | | Methane | VOC | HAP | Methane | VOC | HAP |
| Transmission/Storage | 16 | 199 | 18.0 | 0.643 | 3,183 | 287 | 10.3 |
| Storage | 14 | 110 | 3.06 | 0.0908 | 1,546 | 42.8 | 1.27 |

percent of the total cost of the compressor. The price of a brand new natural gas transmission pipeline centrifugal compressor between 3,000 and 5,000 horsepower runs between \$2 million to \$5 million depending on the number of stages, desired pressure ratio, and gas throughput. The larger the compressor, the less significant the price difference is between dry seals and wet seals. This analysis assumes the additional capital cost for a dry seal compressor is \$75,000. The annual cost was calculated as the capital recovery of this capital cost assuming a 10-year equipment life and 7 percent interest which came to \$10,678 per compressor. The Natural Gas STAR Program estimated that the operation and maintenance savings from the installation of dry seals is \$88,300 in comparison to wet seals. Monetary savings associated with the amount of gas saved with the replacement of wet seals with dry seals for centrifugal compressors was estimated using a natural gas price of \$4.00 per Mcf.²⁸ This cost was used to calculate the annual cost with gas savings using the methane emission reductions in Table 6-8. A summary of the capital and annual costs for dry seals is presented in Table 6-9. The methane and VOC cost effectiveness for the dry seal option is also shown in Table 6-9. There is no gas savings cost benefits for transmission and storage facilities, because it is assumed the owners of the compressor station may not own the natural gas that is compressed at the station.

6.4.3.4 Secondary Impacts

Dry seals for centrifugal compressors are an option that prevents the escape of natural gas across the rotating compressor shaft. No wastes should be created, no wastewater generated, and no electricity needed. Therefore, there are no secondary impacts expected due to the installation of dry seals on centrifugal compressors.

6.4.4 Centrifugal Compressor Wet Seals with a Flare

6.4.4.1 Description

Another control option used to reduce pollutant emissions from centrifugal compressors equipped with wet seals is to route the emissions to a combustion device or capture the emissions and route them to a fuel system. A wet seal system uses oil that is circulated under high pressure between three rings around the compressor shaft, forming a barrier against the compressed gas. The center ring is attached to the rotating shaft, while the two rings on each side are stationary in the seal housing, pressed against a thin film of oil flowing between the rings to both lubricate and act as a leak barrier. Compressed gas becomes absorbed and entrained in the fluid barrier and is removed using a heater, flash tank, or other degassing technique so that the oil can be recirculated back to the wet seal. The removed gas is either

Table 6-9. Cost Effectiveness for Centrifugal Compressor Dry Seals

| Oil and Gas Segment | Capital Cost (\$2008) | Annual Cost per Compressor (\$/compressor-yr) | | VOC Cost Effectiveness (\$/ton) | | Methane Cost Effectiveness (\$/ton) | |
|----------------------|-----------------------|---|--------------------------|---------------------------------|--------------------------|-------------------------------------|--------------------------|
| | | without savings | with O&M and gas savings | without savings | with O&M and gas savings | without savings | with O&M and gas savings |
| Processing | \$75,000 | \$10,678 | -\$123,730 | \$595 | -\$6,892 | \$54 | -\$622 |
| Transmission/Storage | \$75,000 | \$10,678 | -\$77,622 | \$3,495 | -\$25,405 | \$97 | -\$703 |

combusted or released to the atmosphere. The control technique investigated in this section is the use of wet seals with the removed gas sent to an enclosed flare.

6.4.4.2 Effectiveness

Flares have been used in the oil and gas industry to combust gas streams that have VOC and HAP. A flare typically achieves 95 percent reduction of these compounds when operated according to the manufacturer instructions. For this analysis, it was assumed that the entrained gas from the seal oil that is removed in the degassing process would be directed to a flare that achieves 95 percent reduction of methane, VOC, and HAP. The wet seal emissions in Table 6-5 were used along with the control efficiency to calculate the emissions reductions from this option. A summary of the emission reductions is presented in Table 6-10.

6.4.4.3 Cost Impacts

The capital and annual cost of the enclosed flare was calculated using the methodology in the EPA Control Cost Manual.²⁹ The heat content of the gas stream was calculated using information from the gas composition memorandum.³⁰ A summary of the capital and annual costs for wet seals routed to a flare is presented in Table 6-11. The methane and VOC cost effectiveness for the wet seals routed to a flare option is also shown in Table 6-12. There is no cost saving estimated for this option because the recovered gas is combusted.

6.4.4.4 Secondary Impacts

There are secondary impacts with the option to use wet seals with a flare. The combustion of the recovered gas creates secondary emissions of hydrocarbons, nitrogen oxide (NO_x), carbon dioxide (CO₂), and carbon monoxide (CO) emissions. A summary of the estimated secondary emission are presented in Table 6-11. No other wastes should be created or wastewater generated.

6.5 Regulatory Options

The affected facility definition for a reciprocating compressor is defined as a piece of equipment that increases the pressure of a process gas by positive displacement, employing linear movement of the driveshaft. A centrifugal compressor is defined as a piece of equipment that compresses a process gas by means of mechanical rotating vanes or impellers. Therefore these types of compressor would be

Table 6-10. Estimated Annual Centrifugal Compressor Emission Reductions from Wet Seals Routed to a Flare

| Transmission/Storage | \$67,918 | \$103,371 | N/A | \$31,133 | N/A | \$862 | N/A |

subject to a New Performance Standard (NSPS) at the time of installation. The following Regulatory options were evaluated:

- Regulatory Option 1: Require replacement of the reciprocating compressor rod packing based on 26,000 hours of operation while the compressor is pressurized.
- Regulatory Option 2: Require all centrifugal compressors to be equipped with dry seals.
- Regulatory Option 3: Require centrifugal compressors equipped with a wet seal to route the recovered gas emissions to a combustion device.

6.5.1 Evaluation of Regulatory Options

The first regulatory option for replacement of the reciprocating compressor rod packing based on the number of hours that the compressor operates in the pressurized mode was described in Section 6.4.1. The VOC cost effectiveness from \$56,847 for reciprocating compressors located at production pads to \$273 for reciprocating compressors located at processing plants. The VOC cost effectiveness for the gathering and boosting, transmission, and storage segments were \$877, \$2,782, and 3,766 respectively. Based on these cost effectiveness values, Regulatory Option 1 was accepted for the processing, gathering and boosting, transmission, and storage segments and rejected for the production segment.

The second regulatory option would require all centrifugal compressors to be equipped with dry seals. As presented in Section 6.4.2, dry seals are effective at reducing emissions from the rotating shaft of a centrifugal compressor. Dry seals also reduce operation and maintenance costs in comparison to wet seals. In addition, a vendor reported in 2003 that 90 percent of new compressors that were sold by the company were equipped with dry seals. Another vendor confirmed in 2010 that the rate at which new compressor sales have dry seals is still 90 percent; thus, it was assumed that from 2003 onward, 90 percent of new compressors are equipped with dry seals. The VOC cost effectiveness of dry seals was calculated to be \$595 for centrifugal compressors located at processing plants, and \$3,495 for centrifugal compressors located at transmission or storage facilities. Therefore, Regulatory Option 2 was accepted as a regulatory option for centrifugal compressors located at processing, transmission, or storage facilities.

The third regulatory option would allow the use of wet seals if the recovered gas emissions were routed to a flare. Centrifugal compressors with wet seals are commonly used in high pressure applications over 3,000 pounds per square inch (psi). None of the applications in the oil and gas industry operate at these

pressures. Therefore, it does not appear that any facilities would be required to operate a centrifugal compressor with wet seals. The VOC control effectiveness for the processing and transmission/storage segments were \$5,299 and \$31,133 respectively. Therefore, Regulatory Option 3 was rejected due to the high VOC cost effectiveness.

6.5.2 Nationwide Impacts of Regulatory Options

Tables 6-13 and 6-14 summarize the impacts of the selected regulatory options by industry segment. Regulatory Option 1 is estimated to affect 210 reciprocating compressors at gathering and boosting stations, 209 reciprocating compressors at processing plants, 20 reciprocating compressors at transmission facilities, and 4 reciprocating compressors at underground storage facilities. A summary of the capital and annual costs and emission reductions for this option is presented in Table 6-13.

Regulatory Option 2 is expected to affect 16 centrifugal compressors in the processing segment and 14 centrifugal compressors in the transmission and storage segments. A summary of the capital and annual costs and emission reductions for this option is presented in Table 6-14.

Table 6-13. Nationwide Cost Impacts for Regulatory Option 1

| Oil & Gas Segment | Number of New Sources Per Year | Nationwide Emission Reductions (tons/year) | | | Total Nationwide Costs | | |
|----------------------|--------------------------------|--|---------|--------|------------------------|-------------------------------------|----------------------------------|
| | | VOC | Methane | HAP | Capital Cost (\$) | Annual Cost without savings (\$/yr) | Annual Cost with savings (\$/yr) |
| Gathering & Boosting | 210 | 400 | 1,437 | 15.1 | \$1,122,660 | \$350,503 | \$17,337 |
| Processing | 209 | 1,082 | 3,892 | 40.8 | \$846,450 | \$295,397 | -\$606,763 |
| Transmission | 20 | 11.7 | 423 | 0.348 | \$104,247 | \$32,547 | \$32,547 |
| Storage | 4 | 2.42 | 87.3 | 0.0718 | \$29,160 | \$9,104 | \$9,104 |

Table 6-14. Nationwide Cost Impacts for Regulatory Option 2

| Oil & Gas Segment | Number of New Sources Per Year | Nationwide Emission Reductions ¹ (tons/year) | | | Total Nationwide Costs ^a | | |
|------------------------|--------------------------------|--|---------|--------|-------------------------------------|-----------------------------------|----------------------------------|
| | | VOC | Methane | HAP | Capital Cost (\$) | Annual Cost w/o Savings (\$/year) | Annual Cost w/ Savings (\$/year) |
| Production (Well Pads) | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Gathering & Boosting | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Processing | 16 | 118 | 422 | 4.42 | \$100,196 | \$14,266 | -\$120,144 |
| Transmission/Storage | 14 | 3.24 | 117 | 0.0962 | \$50,098 | \$7,133 | -\$37,017 |

- a. The nationwide emission reduction and nationwide costs are based on the emission reductions and costs for 2 centrifugal compressors with wet seals located at a processing facility and 1 centrifugal compressor equipped with wet seal located at a transmission or storage facility.

7.0 STORAGE VESSELS

Storage vessels, or storage tanks, are sources of air emissions in the oil and natural gas sector. This chapter provides a description of the types of storage vessels present in the oil and gas sector, and provides emission estimates for a typical storage vessel as well as nationwide emission estimates. Control techniques employed to reduce emissions from storage vessels are presented, along with costs, emission reductions, and secondary impacts. Finally, this chapter provides a discussion of considerations used in developing regulatory alternatives for storage vessels.

7.1 Process Description

Storage vessels in the oil and natural gas sector are used to hold a variety of liquids, including crude oil, condensates, produced water, etc. Underground crude oil contains many lighter hydrocarbons in solution. When the oil is brought to the surface and processed, many of the dissolved lighter hydrocarbons (as well as water) are removed through a series of high-pressure and low-pressure separators. Crude oil under high pressure conditions is passed through either a two phase separator (where the associated gas is removed and any oil and water remain together) or a three phase separator (where the associated gas is removed and the oil and water are also separated). At the separator, low pressure gas is physically separated from the high pressure oil. The remaining low pressure oil is then directed to a storage vessel where it is stored for a period of time before being shipped off-site. The remaining hydrocarbons in the oil are released from the oil as vapors in the storage vessels. Storage vessels are typically installed with similar or identical vessels in a group, referred to in the industry as a tank battery.

Emissions of the remaining hydrocarbons from storage vessels are a function of working, breathing (or standing), and flash losses. Working losses occur when vapors are displaced due to the emptying and filling of storage vessels. Breathing losses are the release of gas associated with daily temperature fluctuations and other equilibrium effects. Flash losses occur when a liquid with entrained gases is transferred from a vessel with higher pressure to a vessel with lower pressure, thus allowing entrained gases or a portion of the liquid to vaporize or flash. In the oil and natural gas production segment, flashing losses occur when live crude oils or condensates flow into a storage vessel from a processing vessel operated at a higher pressure. Typically, the larger the pressure drop, the more flash emissions will occur in the storage stage. Temperature of the liquid may also influence the amount of flash emissions.

The volume of gas vapor emitted from a storage vessel depends on many factors. Lighter crude oils flash more hydrocarbons than heavier crude oils. In storage vessels where the oil is frequently cycled and the overall throughput is high, working losses are higher. Additionally, the operating temperature and pressure of oil in the separator dumping into the storage vessel will affect the volume of flashed gases coming out of the oil.

The composition of the vapors from storage vessels varies, and the largest component is methane, but also includes ethane, butane, propane, and hazardous air pollutants (HAP) such as benzene, toluene, ethylbenzene, xylene (collectively referred to as BTEX), and n-hexane.

7.2 Emissions Data

7.2.1 Summary of Major Studies and Emissions

Given the potentially significant emissions from storage vessels, there have been numerous studies conducted to estimate these emissions. Many of these studies were consulted to evaluate the emissions and emission reduction options for emissions from storage vessels. Table 7-1 presents a summary of these studies, along with an indication of the type of information available in each study.

7.2.2 Representative Storage Vessel Emissions

Due to the variability in the sizes and throughputs, model tank batteries were developed to represent the ranges of sizes and population distribution of storage vessels located at tank batteries throughout the sector. Model tank batteries were not intended to represent any single facility, but rather a range of facilities with similar characteristics that may be impacted by standards. Model tank batteries were developed for condensate tank batteries and crude oil tank batteries. Average VOC emissions were then developed and applied to the model tank batteries.

7.2.2.1 Model Condensate Tank Batteries

During the development of the national emissions standards for HAP (NESHAP) for oil and natural gas production facilities (40 CFR part 63, subpart HH), model plants were developed to represent condensate tank batteries across the industry.¹ For this current analysis, the most recent inventory data available was the 2008 U.S. Greenhouse Gas Emissions Inventory.^{2,3} Therefore, 2008 was chosen to represent the base year for this impacts analysis. To estimate the current condensate battery population and distribution across the model plants, the number of tanks represented by the model plants was scaled

Table 7-1. Major Studies Reviewed for Consideration of Emissions and Activity Data

from 1992 (the year for which that the model plants were developed under the NESHAP) to 2008 for this analysis. Based on this approach, it was estimated that there were a total of 59,286 existing condensate tanks in 2008. Condensate throughput data from the U.S. Greenhouse Gas Emissions Inventory was used to scale up from 1992 the condensate tank populations for each model condensate tank battery under the assumption that an increase in condensate production would be accompanied by a proportional increase in number of condensate tanks. The inventory data indicate that condensate production increased from a level of 106 million barrels per year (MMbbl/yr) in 1992 to 124 MMbbl/yr in 2008. This increase in condensate production was then distributed across the model condensate tank batteries in the same proportion as was done for the NESHAP. The model condensate tank batteries are presented in Table 7-2.

7.2.2.2 *Model Crude Oil Tank Batteries*

According to the Natural Gas STAR program,⁵ there were 573,000 crude oil storage tanks in 2003. According to the U.S. Greenhouse Gas Emissions Inventory, crude oil production decreased from 1,464 MMbbl/yr in 2003 to 1,326 MMbbl/yr (a decrease of approximately 9.4 percent) in 2008. Therefore, it was assumed that the number of crude oil tanks in 2008 were approximately 90.6 percent of the number of tanks identified in 2003. Therefore, for this analysis it was assumed that there were 519,161 crude oil storage tanks in 2008. During the development of the NESHAP, model crude oil tank batteries were not developed and a crude oil tank population was not estimated. Therefore, it was assumed that the percentage distribution of crude oil storage tanks across the four model crude oil tank battery classifications was the same as for condensate tank batteries. Table 7-3 presents the model crude oil tank batteries.

7.2.2.3 *VOC Emissions from Condensate and Crude Oil Storage Vessels*

Once the model condensate and crude oil tank battery distributions were developed, VOC emissions from a representative storage vessel were estimated. Emissions from storage vessels vary considerably depending on many factors, including, but not limited to, throughput, API gravity, Reid vapor pressure, separator pressure, etc. The American Petroleum Institute (API) has developed a software program called E&P TANKS which contains a dataset of more than 100 storage vessels from across the country.⁸ A summary of the information contained in the dataset, as well as the output from the E&P TANKS program, is presented in Appendix A of this document. According to industry representatives, this

Table 7-2. Model Condensate Tank Batteries

| Parameter | Model Condensate Tank Battery | | | |
|---|--------------------------------------|----------|----------|-----------|
| | E | F | G | H |
| Condensate throughput (bbl/day) ^a | 15 | 100 | 1,000 | 5,000 |
| Condensate throughput (bbl/yr) ^a | 5,475 | 36,500 | 365,000 | 1,825,000 |
| Number of fixed-roof product storage vessels ^a | | | | |
| 210 barrel capacity | 4 | 2 | | |
| 500 barrel capacity | | 2 | 2 | |
| 1,000 barrel capacity | | | 2 | 4 |
| Estimated tank battery population (1992) ^a | 12,000 | 500 | 100 | 70 |
| Estimated tank battery population (2008) ^b | 14,038 | 585 | 117 | 82 |
| Total number of storage vessels (2008) ^b | 56,151 | 2,340 | 468 | 328 |
| Percent of number of storage vessels in model condensate tank battery | 94.7% | 3.95% | 0.789% | 0.552% |
| Percent of throughput per model condensate tank battery ^a | 26% | 7% | 15% | 51% |
| Total tank battery condensate throughput (MMbbl/yr) ^c | 32.8 | 9.11 | 18.2 | 63.8 |
| Condensate throughput per model condensate battery (bbl/day) | 6.41 | 42.7 | 427 | 2,135 |
| Condensate throughput per storage vessel (bbl/day) | 1.60 | 10.7 | 106.8 | 534 |

Minor discrepancies may be due to rounding.

- a. Developed for NESHAP (Reference 1).
- b. Population of tank batteries for 2008 determined based on condensate throughput increase from 106 MMbbl/yr in 1992 to 124 MMbbl/yr in 2008 (References 2,3).
- c. 2008 condensate production rate of 124 MMbbl/yr distributed across model tank batteries using same relative ratio as developed for NESHAP (Reference 1).

Table 7-3. Model Crude Oil Tank Batteries

| Parameter | Model Crude Oil Tank Battery | | | |
|--|-------------------------------------|----------|----------|----------|
| | E | F | G | H |
| Percent of number of condensate storage vessels in model size range ^a | 94.7% | 3.95% | 0.789% | 0.552% |
| Number of storage vessels ^b | 491,707 | 20,488 | 4,098 | 2,868 |
| Percent of throughput across condensate tank batteries | 26% | 7% | 15% | 51% |
| Crude oil throughput per model plant category (MMbbl/yr) | 351 | 97.5 | 195 | 683 |
| Crude oil throughput per storage vessel (bbl/day) | 1.96 | 13.0 | 130 | 652 |

Minor discrepancies may be due to rounding.

- a. Same relative percent of storage vessel population developed for model condensate tank batteries. Refer to Table 7-2.
- b. Calculated by applying the percent of number of condensate storage vessels in model size range to total number of crude oil storage vessels (519,161 crude oil storage vessels estimated for 2008) (Reference 5).
- c. Same relative percent of throughput developed for model condensate tank batteries. Refer to Table 7-2.

dataset in combination with the output of the E&P TANKS program is representative of the various VOC emissions from storage vessels across the country.⁹

The more than 100 storage vessels provided with the E&P TANKS program, which had varying characteristics, were modeled with a constant throughput (based on the assumption that emissions would increase in proportion with throughput) and the relationship of these different characteristics and emissions was studied. While many of the characteristics impacted emissions, a correlation was found to exist between API gravity and emissions. The average API gravity for all storage vessels in the data set was approximately 40 degrees. Therefore, we selected an API gravity of 40 degrees as a parameter to distinguish between lower emitting storage vessels and higher emitting storage vessels.ⁱ While the liquid type was not specified for the storage vessels modeled in the study, it was assumed that condensate storage vessels would have higher emissions than crude oil storage vessels. Therefore, based on this study using the E&P TANKS program, it was assumed for this analysis that liquids with API gravity equal to or greater than 40 degrees should be classified as condensate and liquids with API gravity less than 40 degrees should be classified as crude oil.

The VOC emissions from all storage vessels in the analysis are presented in Appendix A. Table 7-4 presents a summary of the average VOC emissions from all storage vessels as well as the average VOC emissions from the storage vessels identified as being condensate storage vessels and those identified as being crude oil storage vessels. As shown in Table 7-4, the storage vessels were modeled at a constant throughput of 500 bpd.ⁱⁱ An average emission factor was developed for each type of liquid. The average of condensate storage vessel VOC emissions was modeled to be 1,046 tons/year or 11.5 lb VOC/bbl and the average of crude oil storage vessel VOC emissions was modeled to be 107 tons/year or 1.18 lb VOC/bbl. These emission factors were then applied to each of the two sets of model storage vessels in Tables 7-2 and 7-4 to develop the VOC emissions from the model tank batteries. These are presented in Table 7-5.

ⁱ The range of VOC emissions within the 95 percent confidence interval for storage vessels with an API gravity greater than 40 degrees was from 667 tons/year to 1425 tons/year. The range for API gravity less than 40 degrees was 76 tons/year to 138.

ⁱⁱ This throughput was originally chosen for this analysis to be equal to the 500 bbl/day throughput cutoff in subpart HH. While not part of the analysis described in this document, one of the original objectives of the E&P TANKS analysis was to assess the level of emissions associated with a storage vessel with a throughput below this cutoff. Due to the assumption that emissions increase and decrease in proportion with throughput, it was decided that using a constant throughput of 500 bbl/day would still provide the information necessary to determine VOC emissions from model condensate and crude oil storage vessels for this document.

Table 7-4. Summary of Data from E&P TANKS Modeling

| Parameter^a | | Average of Dataset | Average of Storage Vessels with API Gravity > 40 degrees | Average of Storage Vessels with API Gravity ≤ 40 degrees |
|------------------------------|--------------------------|---------------------------|--|---|
| Throughput Rate (bbl) | | 500 | 500 | 500 |
| API Gravity | | 40.6 | 52.8 | 30.6 |
| VOC | Emissions (tons/year) | 531 | 1046 | 107 |
| | Emission factor (lb/bbl) | 5.8 | 11.5 | 1.18 |

a. Information from analysis of E&P Tanks dataset, refer to Appendix A.

Table 7-5. Model Storage Vessel VOC Emissions

| Parameter | Model Tank Battery | | | |
|--|--------------------|------|-----|------|
| | E | F | G | H |
| Model Condensate Tank Batteries | | | | |
| Condensate throughput per storage vessel (bbl/day) | 1.60 | 10.7 | 107 | 534 |
| VOC Emissions (tons/year) ^b | 3.35 | 22.3 | 223 | 1117 |
| Model Crude Oil Tank Batteries | | | | |
| Crude Oil throughput per storage vessel (bbl/day) ^c | 2.0 | 13 | 130 | 652 |
| VOC Emissions (tons/year) ^d | 0.4 | 2.80 | 28 | 140 |

- a. Condensate throughput per storage vessel from table 7-2.
- b. Calculated using the VOC emission factor for condensate storage vessels of 11.5 lb VOC/bbl condensate.
- c. Crude oil throughput per storage vessel from table 7-3.
- d. Calculated using the VOC emission factor for crude oil storage vessels of 1.18 lb VOC/bbl crude oil.

7.3 Nationwide Baseline Emissions from New or Modified Sources

7.3.1 Overview of Approach

The first step in this analysis is to estimate nationwide emissions in absence of a federal rulemaking, referred to as the nationwide baseline emissions estimate. In order to develop the baseline emissions estimate, the number of new storage vessels expected in a typical year was calculated and then multiplied by the expected uncontrolled emissions per storage vessels presented in Table 7-5. In addition, to ensure no emission reduction credit was attributed to new sources that would already be required to be controlled under State regulations, it was necessary to account for the number of storage vessels already subject to State regulations as detailed below.

7.3.2 Number of New Storage Vessels Expected to be Constructed or Reconstructed

The number of new storage vessels expected to be constructed was determined for the year 2015 (the year of analysis for the regulatory impacts). To do this, it was assumed that the number of new or modified storage vessels would increase in proportion with increases in production. The Energy Information Administration (EIA), published crude oil production rates up to the year 2011.¹⁰ Therefore, using the forecast function in Microsoft Excel®, crude oil production was predicted for the year 2015.ⁱⁱⁱ From 2009 to 2015,^{iv} the expected growth of crude oil production was projected to be 8.25 percent (from 5.36 bpd to 5.80 bpd). Applying this expected growth to the number of existing storage vessels results in an estimate of 4,890 new or modified condensate storage vessels and 42,811 new or modified crude oil storage vessels. The number of new or modified condensate and crude oil storage vessels expected to be constructed or reconstructed is presented in Table 7-6.

7.3.3 Level of Controlled Sources in Absence of Federal Regulation

As stated previously, to determine the impact of a regulation, it was first necessary to determine the current level of emissions from the sources being evaluated, or baseline emissions. To more accurately estimate baseline emissions for this analysis, and to ensure no emission reduction credit was attributed

ⁱⁱⁱ The crude oil production values published by the EIA include leased condensate. Therefore, the increase in crude oil production was assumed to be valid for both crude oil and condensate tanks for the purpose of this analysis.

^{iv} For the purposes of estimating growth, the crude oil production rate in the year 2008 was considered an outlier for production and therefore was not used in this analysis.

Table 7-6. Nationwide Baseline Emissions for Storage Vessels

| | Model Tank Battery | | | | |
|--|---------------------------|----------|----------|----------|--------------|
| | E | F | G | H | Total |
| Model Condensate Tank Batteries | | | | | |
| Total number of storage vessels (2008) | 56,151 | 2,340 | 468 | 328 | 59,286 |
| Total projected number of new or modified storage vessels (2015) ^a | 4,630 | 193 | 39 | 27 | 4,889 |
| Number of uncontrolled storage vessels in absence of federal regulation ^b | 1,688 | 70 | 14 | 10 | 1,782 |
| Uncontrolled VOC Emissions from storage vessel at model tank battery ^c | 3.35 | 22.3 | 223 | 1,117 | 1,366 |
| Total Nationwide Uncontrolled VOC Emissions | 5,657 | 1,572 | 3,143 | 11,001 | 21,373 |
| Model Crude Oil Tank Batteries | | | | | |
| Total number of storage vessels (2008) | 491,707 | 20,488 | 4,098 | 2,868 | 519,161 |
| Total projected number of new or modified storage vessels (2015) ^a | 40,548 | 1,689 | 338 | 237 | 42,812 |
| Number of uncontrolled storage vessels in absence of federal regulation ^b | 14,782 | 616 | 123 | 86 | 15,607 |
| Uncontrolled VOC Emissions from storage vessel at model tank battery ^c | 0.4 | 2.80 | 28 | 140 | 171 |
| Total Nationwide Uncontrolled VOC Emissions | 6,200 | 1,722 | 3,444 | 12,055 | 23,421 |

Minor discrepancies may be due to rounding

- a. Calculated by applying the expected 8.25 percent industry growth to the number of storage vessels in 2008.
- b. Calculated by applying the estimated 36 percent of storage vessels that are uncontrolled in the absence of a Federal Regulation to the total projected number of new or modified storage vessels in 2015.
- c. VOC Emissions from individual storage vessel at model tank battery, see Table 7-5.

for sources already being controlled, it was necessary to determine which storage vessels were already being controlled. To do this, the 2005 National Emissions Inventory (NEI) was used. Storage vessels in the oil and natural gas sector were identified under the review of the maximum achievable control technology (MACT) standards.¹¹ There were 5,412 storage vessels identified in the NEI, and of these, 1,973 (or 36 percent) were identified as being uncontrolled. Therefore, this percent of storage vessels that would not require controls under State regulations was applied to the number of new or modified storage vessels results in an estimate of 1,782 new or modified condensate storage vessels and 15,607 new or modified crude oil storage vessels. These are also presented in Table 7-6.

7.3.4 Nationwide Emission Estimates for New or Modified Storage Vessels

Nationwide emissions estimates are presented in Table 7-6 for condensate storage vessels and crude oil storage vessels. Model storage vessel emissions were multiplied by the number of expected new or modified storage vessels that would be uncontrolled in the absence of a federal regulation. As shown in Table 7-6, the baseline nationwide emissions are estimated to be 21,373 tons/year for condensate storage vessels and 23,421 tons/year for crude oil storage vessels.

7.4 Control Techniques

7.4.1 Potential Control Techniques

In analyzing controls for storage vessels, we reviewed control techniques identified in the Natural Gas STAR program and state regulations. We identified two ways of controlling storage vessel emissions, both of which can reduce VOC emissions by 95 percent. One option would be to install a vapor recovery unit (VRU) and recover all the vapors from the storage vessels. The other option would be to route the emissions from the storage vessels to a combustor. These control technologies are described below along with their effectiveness as they apply to storage vessels in the oil and gas sector, cost impacts associated with the installation and operation of these control technologies, and any secondary impacts associated with their use.

7.4.2 Vapor Recovery Units

7.4.2.1 Description

Typically, with a VRU, hydrocarbon vapors are drawn out of the storage vessel under low pressure and are piped to a separator, or suction scrubber, to collect any condensed liquids, which are typically

recycled back to the storage vessel. Vapors from the separator flow through a compressor that provides the low-pressure suction for the VRU system. Vapors are then either sent to the pipeline for sale or used as on-site fuel.⁵

7.4.2.2 *Effectiveness*

Vapor recovery units have been shown to reduce VOC emissions from storage vessels by approximately 95 percent.**Error! Bookmark not defined.**A VRU recovers hydrocarbon vapors that potentially can be used as supplemental burner fuel, or the vapors can be condensed and collected as condensate that can be sold.If natural gas is recovered, it can be sold as well, as long as a gathering line is available to convey the recovered salable gas product to market or to further processing. A VRU also does not have secondary air impacts, as described below. However, a VRU cannot be used in all instances. Some conditions that affect the feasibility of VRU are: availability of electrical service sufficient to power the compressor; fluctuations in vapor loading caused by surges in throughput and flash emissions from the storage vessel; potential for drawing air into condensate storage vessels causing an explosion hazard; and lack of appropriate destination or use for the vapor recovered.

7.4.2.3 *Cost Impacts*

Cost data for a VRU was obtained from an Initial Economic Impact Analysis (EIA) prepared for proposed state-only revisions to a Colorado regulation.Cost information contained in the EIA was assumed to be giving in 2007 dollars.⁷Therefore costs were escalated to 2008 dollars using the CE Indices for 2007 (525.4) and 2008 (575.4).¹² According to the EIA, the purchased equipment cost of a VRU was estimated to be \$85,423 (escalated to 2008 dollars from \$75,000 in 2007 dollars). Total capital investment, including freight and design and installation was estimated to be \$98,186. These cost data are presented in Table 7-7. Total annual costs were estimated to be \$18,983/year.

7.4.2.4 *Secondary Impacts*

A VRU is a pollution prevention technique that is used to recover natural gas that would otherwise be emitted. No secondary emissions (e.g., nitrogen oxides, particulate matter, etc.) would be generated, no wastes should be created, no wastewater generated, and no electricity needed. Therefore, there are no secondary impacts expected due to the use of a VRU.

Table 7-7. Total Capital Investment and Total Annual Cost of a Vapor Recovery Unit

| Cost Item^a | Capital Costs (\$) | Non-Recurring, One-time Costs (\$) | Total Capital Investment (\$)^b | O&M Costs (\$) | Savings due to Fuel Sales (\$/yr) | Annualized Total Cost (\$/yr)^c |
|--|---------------------------|---|--|---------------------------|--|--|
| VRU | \$78,000 | | | | | |
| Freight and Design | | \$1,500 | | | | |
| VRU Installation | | \$10,154 | | | | |
| Maintenance | | | | \$8,553 | | |
| Recovered natural gas | | | | | (\$1,063) | |
| Subtotal Costs (2007) | \$78,000 | \$11,654 | | \$8,553 | (\$1,063) | |
| Subtotal Costs (2008) ^d | \$85,423 | \$12,763 | \$98,186 | \$9,367 | (\$1,164) | |
| Annualized costs (using 7% interest, 15 year equipment life) | \$9,379 | \$1,401 | | n/a | n/a | \$18,983 |

Minor discrepancies may be due to rounding

- a. Assume cost data provided is for the year 2007. Reference 7.
- b. Total Capital Investment is the sum of the subtotal costs for capital costs and nonrecurring one-time costs.
- c. Total Annual Costs is the sum of the annualized capital and recurring costs, O&M costs, and savings due to fuel sales.
- d. Costs are escalated to 2008 dollars using the CE Indices for 2007 (525.4) and 2008 (575.4). Reference 12.

7.4.3 Combustors

7.4.3.1 Description and Effectiveness

Combustors are also used to control emissions from condensate and crude oil storage vessels. The type of combustor used is a high-temperature oxidation process used to burn combustible components, mostly hydrocarbons, found in waste streams.¹³ Combustors are used to control VOC in many industrial settings, since the combustor can normally handle fluctuations in concentration, flow rate, heating value, and inert species content.¹⁴ For this analysis, the types of combustors installed for the oil and gas sector are assumed to achieve 95 percent efficiency.⁷ Combustors do not have the same operational issues as VRUs, however secondary impacts are associated with combustors as discussed below.

7.4.3.2 Cost Impacts

Cost data for a combustor was also obtained from the Initial EIA prepared for proposed state-only revisions to the Colorado regulation.⁷ As performed for the VRU, costs were escalated to 2008 dollars using the CE Indices for 2007 (525.4) and 2008 (575.4).¹² According to the EIA, the purchased equipment cost of a combustor, including an auto igniter and surveillance system was estimated to be \$23,699 (escalated to 2008 dollars from \$21,640 in 2007 dollars). Total capital investment, including freight and design and installation was estimated to be \$32,301. These cost data are presented in Table 7-8. Total annual costs were estimated to be \$8,909/year.

7.4.3.3 Secondary Impacts

Combustion and partial combustion of many pollutants also create secondary pollutants including nitrogen oxides, carbon monoxide, sulfur oxides, carbon dioxide, and smoke/particulates. Reliable data for emission factors from combustors on condensate and crude oil storage vessels are limited. Guidelines published in AP-42 for flare operations are based on tests from a mixture containing 80 percent propylene and 20 percent propane.¹³ These emissions factors, however, are the best indication for secondary pollutants from combustors currently available. The secondary emissions per storage vessel are provided in Table 7-9.

Table 7-8. Total Capital Investment and Total Annual Cost of a Combustor

| Cost Item^a | Capital Costs (\$) | Non-Recurring, One-time Costs (\$) | Total Capital Investment (\$)^b | O&M Costs (\$) | Annualized Total Cost (\$/yr)^c |
|--|---------------------------|---|--|---------------------------|--|
| Combustor | \$16,540 | | | | |
| Freight and Design | | \$1,500 | | | |
| Combustor Installation | | \$6,354 | | | |
| Auto Igniter | \$1,500 | | | | |
| Surveillance System ^d | \$3,600 | | | | |
| Pilot Fuel | | | | \$1,897 | |
| Maintenance | | | | \$2,000 | |
| Data Management | | | | \$1,000 | |
| Subtotal Costs (2007) | \$21,640 | \$7,854 | | \$4,897 | |
| Subtotal Costs (2008) ^e | \$23,699 | \$8,601 | \$32,301 | \$5,363 | |
| Annualized costs (using 7% interest, 15 year equipment life) | \$2,602 | \$944 | | n/a | \$8,909 |

Minor discrepancies may be due to rounding

- a. Assume cost data provided is for the year 2007. Reference 7.
- b. Total Capital Investment is the sum of the subtotal costs for capital costs and nonrecurring one-time costs.
- c. Total Annual Costs is the sum of the annualized capital and recurring costs, O&M costs, and savings due to fuel sales.
- d. Surveillance system identifies when pilot is not lit and attempt to relight it, documents the duration of time when the pilot is not lit, and notifies and operator that repairs are necessary.
- e. Costs are escalated to 2008 dollars using the CE Indices for 2007 (525.4) and 2008 (575.4). Reference 12.

Table 7-9. Secondary Impacts for Combustors used to Control Condensate and Crude Oil Storage Vessels

| Pollutant | Emission Factor | Units | Emissions per Storage Vessel (tons/year)^a |
|------------------|------------------------|--|---|
| THC | 0.14 | lb/MMBtu | 0.0061 |
| CO | 0.37 | lb/MMBtu | 0.0160 |
| CO ₂ | 60 | Kg/MMBtu ^b | 5.62 |
| NO _x | 0.068 | lb/MMBtu | 2.95E-03 |
| PM | 40 | µg/l (used lightly smoking flares due to criteria that flares should not have visible emissions i.e. should not smoke) | 5.51E-05 |

- a. Converted using average saturated gross heating value of the storage vessel vapor (1,968 Btu/scf) and an average vapor flow rate of 44.07 Mcf per storage vessel. See Appendix A.
- b. CO₂ emission factor obtained from 40 CFR Part 98, subpart Y, Equation Y-2.

7.5 Regulatory Options and Nationwide Impacts of Regulatory Options

7.5.1 Consideration of Regulatory Options for Condensate and Crude Oil Storage Vessels

The VOC emissions from storage vessels vary significantly, depending on the rate of liquid entering and passing through the vessel (i.e., its throughput), the pressure of the liquid as it enters the atmospheric pressure storage vessel, the liquid's volatility and temperature of the liquid. Some storage vessels have negligible emissions, such as those with very little throughput and/or handling heavy liquids entering at atmospheric pressure. Therefore, in order to determine the most cost effective means of controlling the storage vessels, a cutoff was evaluated to limit the applicability of the standards to these storage vessels. Rather than require a cutoff in terms of emissions that would require a facility to conduct an emissions test on their storage vessel, a throughput cutoff was evaluated. It was assumed that facilities would have storage vessel throughput data readily available. Therefore, we evaluated the costs of controlling storage vessels with varying throughputs to determine which throughput level would provide the most cost effective control option.

The standard would require an emission reduction of 95 percent, which, as discussed above, could be achieved with a VRU or a combustor. A combustor is an option for tank batteries because of the operational issues associated with a VRU as discussed above. However the use of a VRU is preferable to a combustor because a combustor destroys, rather than recycles, valuable resources and there are secondary impacts associated with the use of a combustor. Therefore, the cost impacts associated a VRU installed for the control of storage vessels were evaluated.

To conduct this evaluation, emission factor data from a study prepared for the Texas Environmental Research Consortium¹⁵ was used to represent emissions from the different throughputs being evaluated. For condensate storage vessels, an emission factor of 33.3 lb VOC/bbl was used and for crude oil storage vessels, an emission factor of 1.6 lb VOC/bbl was used. Using the throughput for each control option, an equivalent emissions limit was determined. Table 7-10 presents the following regulatory options considered for condensate storage vessels:

- Regulatory Option 1: Control condensate storage vessels with a throughput greater than 0.5 bbl/day (equivalent emissions of 3.0 tons/year);

Table 7-10. Options for Throughput Cutoffs for Condensate Storage Vessels

| Regulatory Option | Throughput Cutoff (bbl/day) | Equivalent Emissions Cutoff (tons/year)^a | Emission Reduction (tons/year)^b | Annual Costs for VRU (\$/yr)^c | Cost Effectiveness (\$/ton) | Number of impacted units^d |
|--------------------------|------------------------------------|--|---|---|------------------------------------|---|
| 1 | 0.5 | 3.0 | 2.89 | \$18,983 | \$6,576 | 1782 |
| 2 | 1 | 6.1 | 5.77 | \$18,983 | \$3,288 | 94 |
| 3 | 2 | 12.2 | 11.55 | \$18,983 | \$1,644 | 94 |
| 4 | 5 | 30.4 | 28.87 | \$18,983 | \$658 | 24 |

Minor discrepancies may be due to rounding

- a. Emissions calculated using emission factor of 33.3 lb VOC/bbl condensate and the throughput associated with each option.
- b. Calculated using 95 percent reduction
- c. Refer to Table 7-7 for VRU Annual Costs.
- d. Number of impacted units determined by evaluating which of the model tank batteries and storage vessel populations associated with each model tank battery (refer to Table 7-6) would be subject to each regulatory option. A storage vessel at a model tank battery was considered to be impacted by the regulatory option if its throughput and emissions were greater than the cutoffs for the option.

- Regulatory Option 2: Control condensate storage vessels with a throughput greater than 1 bbl/day (equivalent emissions of 6 tons/year);
- Regulatory Option 3: Control condensate storage vessels with a throughput greater than 2 bbl/day (equivalent emissions of 12 tons/year);
- Regulatory Option 1: Control condensate storage vessels with a throughput greater than 5.0 bbl/day (equivalent emissions of 30 tons/year);

As shown in Table 7-10, Regulatory Option 1 is not cost effective for condensate storage vessels with a throughput of 0.5 bbl/day. Therefore Regulatory Option 1 is rejected. Since the cost effectiveness associated with Regulatory Option 2 is acceptable (\$3,288/ton), this option was selected. As shown in Table 7-5, Model Condensate Storage Vessel Categories F, G, and H have throughputs greater than 1 bbl/day and emissions greater than 6 tons/year. Therefore, for the purposes of determining impacts, the populations of new and modified condensate storage vessels associated with categories F, G, and H are assumed to be required to reduce their emissions by 95 percent, a total of 94 new or modified condensate storage vessels.

A similar evaluation was performed for crude oil vessels and is presented in Table 7-11 for the following regulatory options:

- Regulatory Option 1: Control crude oil storage vessels with a throughput greater than 1 bbl/day (equivalent emissions of 0.3 tons/year);
- Regulatory Option 2: Control condensate storage vessels with a throughput greater than 5 bbl/day (equivalent emissions of 1.5 tons/year);
- Regulatory Option 3: Control condensate storage vessels with a throughput greater than 20 bbl/day (equivalent emissions of 6 tons/year);
- Regulatory Option 1: Control condensate storage vessels with a throughput greater than 50 bbl/day (equivalent emissions of 15 tons/year);

As shown in Table 7-11, Regulatory Options 1 and 2 are not cost effective crude oil storage vessels with a throughput of 1 and 5 bbl/day, respectively. Therefore Regulatory Options 1 and 2 are rejected. Since the cost effectiveness associated with Regulatory Option 3 is acceptable (\$3,422/ton), this option was selected. As shown in Table 7-5, Model Crude Oil Storage Vessel Categories G and H have throughputs greater than 20 bbl/day and emissions greater than 6 tons/year. Therefore, for the purposes of determining impacts, the populations of new and modified crude oil storage vessels associated with categories G

Table 7-11. Options for Throughput Cutoffs for Crude Oil Storage Vessels

| Regulatory Option | Throughput Cutoff (bbl/day) | Equivalent Emissions Cutoff (tons/year)^a | Emission Reduction (tons/year)^b | Annual Costs for VRU (\$/yr)^c | Cost Effectiveness (\$/ton) | Number of impacted units^d |
|--------------------------|------------------------------------|--|---|---|------------------------------------|---|
| 1 | 1 | 0.3 | 0.28 | \$18,983 | \$68,432 | 15607 |
| 2 | 5 | 1.5 | 1.4 | \$18,983 | \$13,686 | 825 |
| 3 | 20 | 5.8 | 5.55 | \$18,983 | \$3,422 | 209 |
| 4 | 50 | 14.6 | 13.87 | \$18,983 | \$1,369 | 209 |

Minor discrepancies may be due to rounding

- a. Emissions calculated using emission factor of 1.6 lb VOC/bbl condensate and the throughput associated with each option.
- b. Calculated using 95 percent reduction
- c. Refer to Table 7-7 for VRU Annual Costs.
- d. Number of impacted units determined by evaluating which of the model tank batteries and storage vessel populations associated with each model tank battery (refer to Table 7-6) would be subject to each regulatory option. A storage vessel at a model tank battery was considered to be impacted by the regulatory option if its throughput and emissions were greater than the cutoffs for the option.

and H are assumed to be required to reduce their emissions by 95 percent, a total of 209 new or modified condensate storage vessels.

7.5.2 Nationwide Impacts of Regulatory Options

This section provides an analysis of the primary environmental impacts (i.e., emission reductions), cost impacts and secondary environmental impacts related to Regulatory Option 2 for condensate storage vessels and Regulatory Option 3 for crude oil storage vessels which were selected as viable options for setting standards for storage vessels. In addition, combined impacts for a typical storage vessel are presented.

7.5.3 Primary Environmental Impacts of Regulatory Options

Regulatory Option 2 (condensate storage vessels) and 3 (crude oil storage vessels) were selected as options for setting standards for storage vessels as follows:

- Regulatory Option 2 (Condensate Storage Vessels): Reduce emissions from condensate storage vessels with an average throughput greater than 1 bbl/day.
- Regulatory Option 3 (Crude Oil Storage Vessels): Reduce emissions from crude oil storage vessels with an average throughput greater than 20 bbl/day.

The number of storage vessels that would be subject to the regulatory options listed above are presented in Tables 7-10 and 7-11. It was estimated that there would be 94 new or modified condensate storage vessels not otherwise subject to State regulations and impacted by Regulatory Option 2 (condensate storage vessels). As shown in Table 7-11, 209 new or modified crude oil storage vessels not otherwise subject to State regulations would be impacted by Regulatory Option 3 (crude oil storage tanks).

Table 7-12 presents the nationwide emission reduction estimates for each regulatory option. Emissions reductions were estimated by applying 95 percent control efficiency to the VOC emissions presented in Table 7-6 for each storage vessel in the model condensate and crude oil tank batteries and multiplying by the number of impacted storage vessels. For Regulatory Option 2 (condensate storage vessels), the total nationwide VOC emission reduction was estimated to be 15,061 tons/year and 14,710 tons/year for Regulatory Option 3 (crude oil storage vessels).

Table 7-12. Nationwide Impacts of Regulatory Options

| Model Tank Battery | Number of Sources subject to Regulatory Option ^a | VOC Emissions for a Typical Storage Vessel (tons/year) | Capital Cost for Typical Storage Vessel ^b (\$) | Annual Cost for a Typical Storage Vessel ^b (\$/yr) | | Nationwide Emission Reductions (tons/year) ^c | | VOC Cost Effectiveness (\$/ton) | | Methane Cost Effectiveness (\$/ton) | | Total Nationwide Costs (million \$/year) | | |
|--|---|--|---|---|---------------|---|----------------------|---------------------------------|--------------|-------------------------------------|--------------|--|------------------------|---------------------|

Minor discrepancies may be due to rounding

- a. Number of storage vessels in each model tank battery (refer to Table 7-6) determined to be subject to the regulatory option as outlined in Table 7-10.
- b. It was assumed for the purposes of estimating nationwide impacts that 50 percent of facilities would install a combustor and 50 percent a VRU. This accounts for the operational difficulties of using a VRU. Capital and Annual Costs determined using the average of costs presented in Tables 7-7 and 7-8.
- c. Nationwide emission reductions calculated by applying a 95 percent emissions reduction to the VOC emissions for a typical storage vessel multiplied by the number of sources subject to the regulatory option.
- d. Methane Reductions calculated by applying the average Methane to VOC factor from the E&P Tanks Study (see Appendix A). Methane:VOC = 0.219
- e. For purposes of evaluating NSPS impact, impacts were determined for an average storage vessel by calculating total VOC emissions from all storage vessels and dividing by the total number of impacted storage vessels to obtain the average VOC emissions per storage vessel.

7.5.4 Cost Impacts

Cost impacts of the individual control techniques (VRU and combustors) were presented in Section 7.4. For both regulatory options, it was assumed that 50 percent of facilities would install a combustor and 50 percent a VRU. This accounts for the operational difficulties of using a VRU. Therefore, the average capital cost of control for each storage vessel was estimated to be \$65,243 (the average of the total capital investment for a VRU of \$98,186 and \$32,301 for a combustor from Tables 7-7 and 7-8, respectively). Similarly, the average annual cost for a typical storage vessel was estimated to be \$14,528/yr (average of the total annual cost for a VRU of \$20,147/yr and \$8,909/yr for a combustor from Tables 7-7 and 7-8, respectively) without including any cost savings due to fuel sales and \$13,946/yr (average of the total annual cost for a VRU of \$18,983/yr and \$8,909/yr for a combustor from Tables 7-7 and 7-8, respectively) including cost savings.

Nationwide capital and annual costs were calculated by applying the number of storage vessels subject to the regulatory option. As shown in Table 7-12, the nationwide capital cost of Regulatory Option 2 (condensate storage vessels) was estimated to be \$6.14 million and for Regulatory Option 3 (crude oil storage vessels) nationwide capital cost was estimated to be \$13.6 million. Total annual costs without fuel savings were estimated to be \$1.37 million/yr for Regulatory Option 2 (condensate storage vessels) and \$3.04 million/yr for Regulatory Option 3 (crude oil storage vessels). Total annual costs with fuel savings were estimated to be \$1.31 million/yr for Regulatory Option 2 (condensate storage vessels) and \$2.91 million/yr for Regulatory Option 3 (crude oil storage vessels).

For purposes of evaluating the impact of a federal standard, impacts were determined for an average storage vessel by calculating the total VOC emissions from all storage vessels and dividing by the total number of impacted storage vessels (304) to obtain the average VOC emissions per storage vessel (103 tons/year). Therefore, the nationwide annual costs were estimated to be \$4.41 million/yr. A total nationwide VOC emission reduction of 29,746 tons/year results in a cost effectiveness of \$149/ton.

7.5.5 Nationwide Secondary Emission Impacts

Regulatory Options 2 (condensate storage vessels) and 3 (crude oil storage vessels) allow for the use of a combustor; therefore the estimated nationwide secondary impacts are a result of combusting 50 percent of all storage vessel emissions. The secondary impacts for controlling a single storage vessel using a combustor are presented in Table 7-9. Nationwide secondary impacts are calculated by

Table 7-13. Nationwide Secondary Combined Impacts for Storage Vessels

| Pollutant | Emissions per Storage Vessel (tons/year)^a | Nationwide Emissions (tons/year)^b |
|------------------|---|---|
| THC | 0.0061 | 0.927 |
| CO | 0.0160 | 2.43 |
| CO ₂ | 5.62 | 854 |
| NO _x | 2.95E-03 | 0.448 |
| PM | 5.51E-05 | 0.0084 |

- a. Emissions per storage vessel presented in Table 7-9.
- b. Nationwide emissions calculated by assuming that 50 percent of the 304 impacted storage vessels would install a combustor.

multiplying 50 percent of the estimated number of impacted storage vessels (152) by the secondary emissions and are presented in Table 7-13.

8.0 EQUIPMENT LEAKS

Leaks from components in the oil and natural gas sector are a source of pollutant emissions. This chapter explains the causes for these leaks, and provides emission estimates for “model” facilities in the various segments of the oil and gas sector. In addition, nationwide equipment leak emission estimates from new sources are estimated. Programs that are designed to reduce equipment leak emissions are explained, along with costs, emission reductions, and secondary impacts. Finally, this chapter discusses considerations in developing regulatory alternatives for equipment leaks.

8.1 Equipment Leak Description

There are several potential sources of equipment leak emissions throughout the oil and natural gas sector. Components such as pumps, valves, pressure relief valves, flanges, agitators, and compressors are potential sources that can leak due to seal failure. Other sources, such as open-ended lines, and sampling connections may leak for reasons other than faulty seals. In addition, corrosion of welded connections, flanges, and valves may also be a cause of equipment leak emissions. The following subsections describe potential equipment leak sources and the magnitude of the volatile emissions from typical facilities in the oil and gas industry.

Due to the large number of valves, pumps, and other components within oil and natural gas production, processing, and/or transmission facilities, total equipment leak VOC emissions from these components can be significant. Tank batteries or production pads are generally small facilities as compared with other oil and gas operations, and are generally characterized by a small number of components. Natural gas processing plants, especially those using refrigerated absorption, and transmission stations tend to have a large number of components.

8.2. Equipment leak Emission Data and Emissions Factors

8.2.1 Summary of Major Studies and Emission Factors

Emissions data from equipment leaks have been collected from chemical manufacturing and petroleum production to develop control strategies for reducing HAP and VOC emissions from these sources.^{1,2,3} In the evaluation of the emissions and emission reduction options for equipment leaks, many of these studies were consulted. Table 8-1 presents a list of the studies consulted along with an indication of the type of information contained in the study.

8.2.2 Model Plants

Facilities in the oil and gas sector can consist of a variety of combinations of process equipment and components. This is particularly true in the production segment of the industry, where “surface sites” can vary from sites where only a wellhead and associated piping is located to sites where a substantial amount of separation, treatment, and compression occurs. In order to conduct analyses to be used in evaluating potential options to reduce emissions from leaking equipment, a model plant approach was used. The following sections discuss the creation of these model plants.

Information related to equipment counts was obtained from a natural gas industry report. This document provided average equipment counts for gas production, gas processing, natural gas transmission and distribution. These average counts were used to develop model plants for wellheads, well pads, and gathering line and boosting stations in the production segment of the industry, for a natural gas processing plant, and for a compression/transmission station in the natural gas transmission segment. These equipment counts are consistent with those contained in EPA’s analysis to estimate methane emissions conducted in support of the Greenhouse Gas Mandatory Reporting Rule (subpart W), which was published in the *Federal Register* on November 30, 2010 (75 FR 74458). These model plants are discussed in the following sections.

8.2.2.1 Oil and Natural Gas Production

Oil and natural gas production varies from site-to site. Many production sites may include only a wellhead that is extracting oil or natural gas from the ground. Other production sites consist of wellheads attached to a well pad. A well pad is a site where the production, extraction, recovery, lifting, stabilization, separation and/or treating of petroleum and/or natural gas (including condensate) occurs. These sites include all equipment (including piping and associated components, compressors, generators, separators, storage vessels, and other equipment) associated with these operations. A well pad can serve one well on a pad or several wells on a pad. A wellhead site consisting of only the wellhead and affiliated piping is not considered to be a well pad. The number of wells feeding into a well pad can vary from one to as many as 7 wells. Therefore, the number of components with potential for equipment leaks can vary depending on the number of wells feeding into the production pad and the amount of processing equipment located at the site.

In addition to wellheads and well pads, model plants were developed for gathering lines and boosting stations. The gathering lines and boosting stations are sites that collect oil and gas from well pads and direct them to the gas processing plants. These stations have similar equipment to well pads; however they are not directly connected to the wellheads.

The EPA/GRI report provided the average number of equipment located at a well pad and the average number of components for each of these pieces of equipment.⁴The type of production equipment located at a well pad include: gas wellheads, separators, meters/piping, gathering compressors, heaters, and dehydrators. The types of components that are associated with this equipment include: valves, connectors, open-ended lines, and pressure relief valves. Four model plants were developed for well pads and are presented in Table 8-2. These model plants were developed starting with one, three, five and seven wellheads, and adding the average number of other pieces of equipment per wellhead. Gathering compressors are not included at well pads and were included in the equipment for gathering lines and boosting stations.

Component counts for each of the equipment items were calculated using the average component counts for gas production equipment in the Eastern U.S and the Western U.S. for the EPA/GRI document. A summary of the component counts for oil and gas production well pads is presented in Table 8-3.

Gathering line and boosting station model plants were developed using the average equipment counts for oil and gas production. The average equipment count was assigned Model Plant 2 and Model Plants 1 and 3 were assumed to be equally distributed on either side of the average equipment count. Therefore, Model Plant 1 can be assumed to be a small gathering and boosting station, and Model Plant 3 can be assumed to be a large gathering and boosting station. A summary of the model plant production equipment counts for gathering lines and boosting stations is provided in Table 8-4.

Component counts for each of the equipment items were calculated using the average component counts for gas production equipment in the Eastern U.S and the Western U.S. from the EPA/GRI document. The components for gathering compressors were included in the model plant total counts, but the compressor seals were excluded. Compressor seals are addressed in a Chapter 6 of this document. A summary of the component counts for oil and gas gathering line and boosting stations are presented in Table 8-5.

8.2.2.2 *Oil and Natural Gas Processing*

Natural gas processing involves the removal of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both. The types of process equipment used to separate the liquids are separators, glycol dehydrators, and amine treaters. In addition, centrifugal and/or reciprocating compressors are used to pressurize and move the gas from the processing facility to the transmission stations.

New Source Performance Standards (NSPS) have already been promulgated for equipment leaks at new natural gas processing plants (40 CFR Part 60, subpart KKK), and were assumed to be the baseline emissions for this analysis. Only one model plant was developed for the processing sector. A summary of the model plant production components counts for an oil and gas processing facility is provided in Table 8-6.

8.2.2.3 *Natural Gas Transmission/Storage*

Natural gas transmission/storage stations are facilities that use compressors that move natural gas at elevated pressure from production fields or natural gas processing facilities, in transmission pipelines, to natural gas distribution pipelines, or into storage. In addition, transmission stations may include equipment for liquids separation, natural gas dehydration, and tanks for the storage of water and hydrocarbon liquids. Residue (sales) gas compression operated by natural gas processing facilities are included in the onshore natural gas processing segment and are excluded from this segment. This source category also does not include emissions from gathering lines and boosting stations. Component counts were obtained from the EPA/GRI report and are presented in Table 8-7.

8.3 Nationwide Emissions from New Sources

8.3.1 Overview of Approach

Nationwide emissions were calculated by using the model plant approach for estimating emissions. Baseline model plant emissions for the natural gas production, processing, and transmission sectors were calculated using the component counts and the component gas service emission factors.⁵ Annual emissions were calculated assuming 8,760 hours of operation each year. The emissions factors are provided for total organic compounds (TOC) and include non-VOCs such as methane and ethane. The emission factors for the production and processing sectors that were used to estimate the new source emissions are presented in Table 8-8. Emission factors for the transmission sector are presented in

Table 8-6. Average Component Count for Oil and Gas Processing Model Plant

(EPA-453/R-95-017)

Table 8-9. Emissions for VOC, hazardous air pollutants (HAP), and methane were calculated using TOC weight fractions.⁶ A summary of the baseline emissions for each of the sectors are presented in Table 8-10.

8.3.2 Activity Data

Data from oil and gas technical documents and inventories were used to estimate the number of new sources for each of the oil and gas sectors. Information from the Energy Information Administration (EIA) was used to estimate the number of new wells, well pads, and gathering and boosting stations. The number of processing plants and transmission/storage facilities was estimated using data from the Oil and Gas Journal, and the EPA Greenhouse Gas Inventory. A summary of the steps used to estimate the new sources for each of the oil and gas sectors is presented in the following sections.

8.3.2.1 Well Pads

The EIA provided a forecast of the number of new conventional and unconventional gas wells for the Year 2015 for both exploratory and developmental wells. The EIA projected 19,097 conventional and unconventional gas wells in 2015. The number of wells was converted to number of well pads by dividing the total number of wells by the average number of wells serving a well pad which is estimated to be 5. Therefore, the number of new well pads was estimated to be 3,820. The facilities were divided into the model plants assuming a normal distribution of facilities around the average model plant (Model Plant 2).

8.3.2.2 Gathering and Boosting

The number of new gathering and boosting stations was estimated using the current inventory of gathering compressors listed in the EPA Greenhouse Gas Inventory. The total number of gathering compressors was listed as 32,233 in the inventory. The GRI/EPA document does not include a separate list of compressor counts for gathering and boosting stations, but it does list the average number of compressors in the gas production section. It was assumed that this average of 4.5 compressors for gas production facilities is applicable to gathering and boosting stations. Therefore, using the inventory of 32,233 compressors and the average number of 4.5 compressors per facility, we estimated the number of gathering and boosting stations to be 7,163. To estimate the number of new gathering and boosting stations, we used the same increase of 3.84 percent used to estimate well pads to estimate the number of new gathering and boosting stations. This provided an estimate of 275 new gathering and boosting

Table 8-9 Oil and Gas Transmission/Storage Average Emissions Factors

Table 8-10. Baseline Emissions for the Oil and Gas Production, Processing, and Transmission/Storage Model Plants

| Oil and Gas Sector | Model Plant | TOC Emissions (Tons/yr) | Methane Emissions (Tons/yr) | VOC Emissions (Tons/yr) | HAP Emissions (Tons/yr) |
|---------------------------|--------------------|------------------------------------|--|------------------------------------|------------------------------------|
| Well Pads | 1 | 0.482 | 0.335 | 0.0930 | 0.00351 |
| | 2 | 13.3 | 9.24 | 2.56 | 0.0967 |
| | 3 | 139 | 96.5 | 26.8 | 1.01 |
| Gathering & Boosting | 1 | 30.5 | 21.2 | 5.90 | 0.222 |
| | 2 | 50.6 | 35.2 | 9.76 | 0.368 |
| | 3 | 70.6 | 49.1 | 13.6 | 0.514 |
| Processing | 1 | 74.0 | 51.4 | 14.3 | 0.539 |
| Transmission/Storage | 1 | 108.1 | 98.1 | 2.71 | 0.0806 |

stations that would be affected sources under the proposed NSPS. The new gathering and boosting stations were assumed to be normally distributed around the average model plant (Model Plant 2).

8.3.2.3 Processing Facilities

The number of new processing facilities was estimated using gas processing data from the Oil and Gas Journal. The Oil and Gas Journal Construction Survey currently shows 6,303 million cubic feet of gas per day (MMcf/day) additional gas processing capacity in various stages of development. The OGJ Gas Processing Survey shows that there is 26.9 trillion cubic feet per year (tcf/year) in existing capacity, with a current throughput of 16.6 tcf/year or 62 percent utilization rate. If the utilization rate remains constant, the new construction would add approximately 1.4 tcf/year to the processing system. This would be an increase of 8.5 percent to the processing sector. The recent energy outlook published by the EIA predicts a 1.03 tcf/year increase in natural gas processing from 21.07 to 22.104 tcf/year. This would be an annual increase of 5 percent over the next five years.

The EPA Greenhouse Gas Inventory estimates the number of existing processing facilities to be 577 plants operating in the U.S. Based on the projections provided in Oil and Gas Journal and EIA, it was assumed that the processing sector would increase by 5 percent annually. Therefore the number of new sources was estimated to be 29 new processing facilities in the U.S.

8.3.2.4 Transmission/Storage Facilities

The number of new transmission and storage facilities was estimated using the annual growth rate of 5 percent used for the processing sector and the estimated number of existing transmission and storage facilities in the EPA Greenhouse Inventory. The inventory estimates 1,748 transmission stations and 400 storage facilities for a total of 2,148. Therefore, the number of new transmission/storage facilities was estimated to be 107.

8.3.3 Emission Estimates

Nationwide emission estimates for the new sources for well pads, gathering and boosting, processing, and transmission/storage are summarized in Table 8-11. For well pads and gathering and boosting stations, the numbers of new facilities were assumed to be normally distributed across the range of model plants.

Table 8-11. Nationwide Baseline Emissions for New Sources

| Oil and Gas Sector | Model Plant | Number of New Facilities | TOC Emissions (tons/yr) | Methane Emissions (tons/yr) | VOC Emissions (tons/yr) | HAP Emissions (tons/yr) |
|---------------------------|--------------------|---------------------------------|--------------------------------|------------------------------------|--------------------------------|--------------------------------|
| Well Pads | 1 | 605 | 292 | 203 | 56.3 | 2.12 |
| | 2 | 2,610 | 34,687 | 24,116 | 6,682 | 252 |
| | 3 | 605 | 84,035 | 58,389 | 16,214 | 612 |
| | Total | 3,820 | 119,014 | 82,708 | 22,952 | 866 |
| Gathering & Boosting | 1 | 44 | 1,312 | 912 | 254 | 9.55 |
| | 2 | 187 | 9,513 | 6,618 | 1,835 | 69.2 |
| | 3 | 44 | 3,106 | 2,160 | 598 | 22.6 |
| | Total | 275 | 13,931 | 9,690 | 2,687 | 101 |
| Processing | 1 | 29 | 2,146 | 1,490 | 415 | 15.6 |
| Transmission/Storage | 1 | 107 | 11,567 | 10,497 | 290 | 8.62 |

8.4 Control Techniques

8.4.1 Potential Control Techniques

EPA has determined that leaking equipment, such as valves, pumps, and connectors, are a significant source of VOC and HAP emissions from oil and gas facilities. The following section describes the techniques used to reduce emissions from these sources.

The most effective control technique for equipment leaks is the implementation of a leak detection and repair program (LDAR). Emissions reductions from implementing an LDAR program can potentially reduce product losses, increase safety for workers and operators, decrease exposure of hazardous chemicals to the surrounding community, reduce emissions fees, and help facilities avoid enforcement actions. The elements of an effective LDAR program include:

- Identifying Components;
- Leak Definition;
- Monitoring Components;
- Repairing Components; and
- Recordkeeping.

The primary source of equipment leak emissions from oil and gas facilities are from valves and connectors, because these are the most prevalent components and can number in the thousands. The major cause of emissions from valves and connectors is a seal or gasket failure due to normal wear or improper maintenance. A leak is detected whenever the measured concentration exceeds the threshold standard (i.e., leak definition) for the applicable regulation. Leak definitions vary by regulation, component type, service (e.g., light liquid, heavy liquid, gas/vapor), and monitoring interval. Most NSPS regulations have a leak definition of 10,000 ppm, while many NESHAP regulations use a 500-ppm or 1,000-ppm leak definition. In addition, some regulations define a leak based on visual inspections and observations (such as fluids dripping, spraying, misting or clouding from or around components), sound (such as hissing), and smell.

For many NSPS and NESHAP regulations with leak detection provisions, the primary method for monitoring to detect leaking components is EPA Reference Method 21 (40 CFR Part 60, Appendix A). Method 21 is a procedure used to detect VOC leaks from process equipment using toxic vapor analyzer (TVA) or organic vapor analyzer (OVA). In addition, other monitoring tools such as; infrared camera, soap solution, acoustic leak detection, and electronic screening device, can be used to monitor process components.

In optical gas imaging, a live video image is produced by illuminating the view area with laser light in the infrared frequency range. In this range, hydrocarbons absorb the infrared light and are revealed as a dark image or cloud on the camera. The passive infrared cameras scan an area to produce images of equipment leaks from a number of sources. Active infrared cameras point or aim an infrared beam at a potential source to indicate the presence of equipment leaks. The optical imaging camera is easy to use and very efficient in monitoring many components in a short amount of time. However, the optical imaging camera cannot quantify the amount or concentration of equipment leak. To quantify the leak, the user would need to measure the concentration of the leak using a TVA or OVA. In addition, the optical imaging camera has a high upfront capital cost of purchasing the camera.

Acoustic leak detectors measure the decibel readings of high frequency vibrations from the noise of leaking fluids from equipment leaks using a stethoscope-type device. The decibel reading, along with the type of fluid, density, system pressure, and component type can be correlated into leak rate by using algorithms developed by the instrument manufacturer. The acoustic detector does not decrease the monitoring time because components are measured separately, like the OVA or TVA monitoring. The accuracy of the measurements using the acoustic detector can also be questioned due to the number of variables used to determine the equipment leak emissions.

Monitoring intervals vary according to the applicable regulation, but are typically weekly, monthly, quarterly, and yearly. For connectors, the monitoring interval can be every 1, 2, 4, or 8 years. The monitoring interval depends on the component type and periodic leak rate for the component type. Also, many LDAR requirements specify weekly visual inspections of pumps, agitators, and compressors for indications of liquids leaking from the seals. For each component that is found to be leaking, the first attempt at repair is to be made no later than five calendar days after each leak is detected. First attempts at repair include, but are not limited to, the following best practices, where practicable and appropriate:

- Tightening of bonnet bolts;

- Replacement of bonnet bolts;
- Tightening of packing gland nuts; and
- Injection of lubricant into lubricated packing.

Once the component is repaired; it should be monitored daily over the next several days to ensure the leak has been successfully repaired. Another method that can be used to repair component is to replace the leaking component with “leakless” or other technologies.

The LDAR recordkeeping requirement for each regulated process requires that a list of all ID numbers be maintained for all equipment subject to an equipment leak regulation. A list of components that are designated as “unsafe to monitor” should also be maintained with an explanation/review of conditions for the designation. Detailed schematics, equipment design specifications (including dates and descriptions of any changes), and piping and instrumentation diagrams should also be maintained with the results of performance testing and leak detection monitoring, which may include leak monitoring results per the leak frequency, monitoring leakless equipment, and non-periodic event monitoring.

Other factors that can improve the efficiency of an LDAR program that are not addressed by the standards include training programs for equipment monitoring personnel and tracking systems that address the cost efficiency of alternative equipment (e.g., competing brands of valves in a specific application).

The first LDAR option is the implementation of a subpart VVa LDAR program. This program is similar to the VV monitoring, but finds more leaks due to the lower leak definition, thereby achieving better emission reductions. The VVa LDAR program requires the annual monitoring of connectors using an OVA or TVA (10,000 ppm leak definition), monthly monitoring of valves (500 ppm leak definition) and requires open-ended lines and pressure relief devices to operate with no detectable emissions (500 ppm leak definition). The monitoring of each of the equipment types were also analyzed as a possible option for reducing equipment leak emissions. The second option involves using the monitoring requirements in subpart VVa for each type of equipment which include: valves; connectors; pressure relief devices; and open-ended lines for each of the oil and gas sectors.

The third option that was investigated was the implementation of a LDAR program using an optical gas imaging system. This option is currently available as an alternative work practice (40 CFR Part 60, subpart A) for monitoring emissions from equipment leaks in subpart VVa. The alternative work practice requires monthly monitoring of all components using the optical gas imaging system and an

annual monitoring of all components using a Method 21 monitoring device. The Method 21 monitoring allows the facility to quantify emissions from equipment leaks, since the optical gas imaging system can only provide the magnitude of the equipment leaks.

A fourth option that was investigated is a modification of the 40 CFR Part 60, subpart A alternative work practice. The alternative work practice was modified by removing the required annual monitoring using a Method 21 instrument. This option only requires the monthly monitoring of components using the optical gas imaging system.

8.4.2 Subpart VVa LDAR Program

8.4.2.1 Description

The subpart VVa LDAR requires the monitoring of pumps, compressors, pressure relief devices, sampling connection systems, open-ended lines, valves, and connectors. These components are monitored with an OVA or TVA to determine if a component is leaking and measure the concentration of the organics if the component is leaking. Connectors, valves, and pressure relief devices have a leak definition of 500 parts per million by volume (ppmv). Valves are monitored monthly, connectors are monitored annually, and open-ended lines and pressure relief valves have no monitoring requirements, but are required to operate without any detectable emissions. Compressors are not included in this LDAR option and are regulated separately.

8.4.2.2 Effectiveness

The control effectiveness of the LDAR program is based on the frequency of monitoring, leak definition, frequency of leaks, percentage of leaks that are repaired, and the percentage of reoccurring leaks. A summary of the chemical manufacturing and petroleum refinery control effectiveness for each of the components is shown in Table 8-12. As shown in the table the control effectiveness for all of the components varies from 45 to 96 percent and is dependent on the frequency of monitoring and the leak definition. Descriptions of the frequency of monitoring and leak definition are described further below.

Monitoring Frequency: The monitoring frequency is the number of times each component is checked for leaks. For an example, quarterly monitoring requires that each component be checked for leaks 4 times per year, and annual monitoring requires that each component be checked for leaks once per year. As shown in Table 8-12, monthly monitoring provides higher control effectiveness than quarterly

Table 8-12. Control Effectiveness for an LDAR program at a Chemical Process Unit and a Petroleum Refinery

| Equipment Type and Service | Control Effectiveness (% Reduction) | | |
|--|--|---|---|
| | Monthly Monitoring 10,000 ppmv Leak Definition | Quarterly Monitoring 10,000 ppmv Leak Definition | 500 ppm Leak Definition ^a |
| Chemical Process Unit | | | |
| Valves – Gas Service ^b | 87 | 67 | 92 |
| Valves – Light Liquid Service ^c | 84 | 61 | 88 |
| Pumps – Light Liquid Service ^c | 69 | 45 | 75 |
| Connectors – All Services | --- | --- | 93 |
| Petroleum Refinery | | | |
| Valves – Gas Service ^b | 88 | 70 | 96 |
| Valves – Light Liquid Service ^c | 76 | 61 | 95 |
| Pumps – Light Liquid Service ^c | 68 | 45 | 88 |
| Connectors – All Services | --- | --- | 81 |

Source: Protocol for Equipment Leak Emission Estimates, EPA-453/R-95-017, Nov 1995.

- a. Control effectiveness attributable to the HON-negotiated equipment leak regulation (40 CFR 63, Subpart H) is estimated based on equipment-specific leak definitions and performance levels. However, pumps subject to the HON at existing process units have a 1,000 to 5,000 ppm leak definition, depending on the type of process.
- b. Gas (vapor) service means the material in contact with the equipment component is in a gaseous state at the process operating conditions.
- c. Light liquid service means the material in contact with the equipment component is in a liquid state in which the sum of the concentration of individual constituents with a vapor pressure above 0.3 kilopascals (kPa) at 20°C is greater than or equal to 20% by weight.

monitoring. This is because leaking components are found and repaired more quickly, which lowers the amount of emissions that are leaked to the atmosphere.

Leak Definition: The leak definition describes the local VOC concentration at the surface of a leak source that indicates that a VOC emission (leak) is present. The leak definition is an instrument meter reading based on a reference compound. Decreasing the leak definition concentration generally increases the number of leaks found during a monitoring period, which generally increases the number of leaks that are repaired.

The control effectiveness for the well pad, gathering and boosting stations, processing facilities, and transmissions and storage facilities were calculated using the LDAR control effectiveness and leak fraction equations for oil and gas production operation units in the EPA equipment leaks protocol document. The leak fraction equation uses the average leak rate (e.g., the component emission factor) and leak definition to calculate the leak fraction.⁷ This leak fraction is used in a steady state set of equations to determine the final leak rate after implementing a LDAR program.⁸ The initial leak rate and the final leak rate after implementing a LDAR program were then used to calculate the control effectiveness of the program. The control effectiveness for implementing a subpart VVa LDAR program was calculated to be 93.6 percent for valves, 95.9 percent for connectors, 100 percent for open-ended lines, and 100 percent for pressure relief devices.

8.4.2.3 Cost Impacts

Costs were calculated using a LDAR cost spreadsheet developed for estimating capital and annual costs for applying LDAR to the Petroleum Refinery and Chemical Manufacturing industry. The costs are based on the following assumptions:

- Subpart VVa monitoring frequency and leak definition were used for processing plants since they are already required to do subpart VV requirements. Connectors were assumed to be monitored over a 4-year period after initial annual compliance monitoring.
- Initial monitoring and setup costs are \$17.70 for valves, \$1.13 per connector, \$78.00 for pressure relief valve disks, \$3,852 for pressure relief valve disk holder and valves, and \$102 for open-ended lines.
- Subsequent monitoring costs are \$1.50 for valves and connectors, \$2.00 for pressure relief valve disks, and \$5.00 for pressure relief valve devices and open-ended lines.
- A wage rate of \$30.46 per hour was used to determine labor costs for repair.

- Administrative costs and initial planning and training costs are based on the Miscellaneous Organic NESHAP (MON) analysis. The costs were based on 340 hours for planning and training and 300 hours per year for reporting and administrative tasks at \$48.04 per hour.
- The capital cost also includes \$14,500 for a data collection system for maintaining the inventory and monitoring records for the components at a facility.
- Recovery credits were calculated assuming the methane reduction has a value of \$4.00 per 1000 standard cubic feet.

It was assumed that a single Method 21 monitoring device could be used at multiple locations for production pads, gathering and boosting stations, and transmission and storage facilities. To calculate the shared cost of the Method 21 device, the time required to monitor a single facility was estimated. For production pads and gathering and boosting stations, it was assumed that it takes approximately 1 minute to monitor a single component, and approximately 451 components would have to be monitored at an average facility in a month. This calculates to be 451 minutes or 7.5 hours per day. Assuming 20 working days in a typical month, a single Method 21 device could monitor 20 facilities. Therefore, the capital cost of the Method 21 device (\$6,500) was divided by 20 to get a shared capital cost of \$325 per facility. It was assumed for processing facilities that the full cost of the Method 21 monitoring device would apply to each individual plant. The transmission and storage segment Method 21 device cost was estimated using assuming the same 1 minute per component monitoring time. The average number of components that would need to be monitored in a month was estimated to be 1,440, which calculates to be 24 hours of monitoring time or 3 days. Assuming the same 20 day work month, the total number of facilities that could be monitored by a single Method 21 device is 7. Therefore, the shared cost of the Method 21 monitoring device was calculated to be \$929 per site.

A summary of the capital and annual costs and the cost effectiveness for each of the model plants in the oil and gas sectors are provided in Table 8-13. In addition to the full subpart VVa LDAR monitoring, a component by component LDAR analysis was performed for each of the oil and gas sectors using the component count for an average size facility. This Model Plant 2 for well pads, Model Plant 2 for gathering and boosting stations, and Model Plant 1 for processing plants and transmission and storage facilities.

Table 8-13. Summary of the Model Plant Cost Effectiveness for the Subpart VVa Option

| Model Plant | Annual Emission Reductions (tons/year) | | | Capital Cost (\$) | Annual Cost (\$/year) | | Cost Effectiveness (\$/ton) | | |
|--|---|---------|---------|----------------------|--------------------------|--------------|--------------------------------|-------------|----------|
| | VOC | HAP | Methane | | without savings | with savings | VOC | HAP | Methane |
| <i>Well Pads</i> | | | | | | | | | |
| 1 | 0.0876 | 0.00330 | 0.315 | \$15,418 | \$23,423 | \$23,350 | \$267,386 | \$7,088,667 | \$74,253 |
| 2 | 2.43 | 0.0915 | 8.73 | \$69,179 | \$37,711 | \$35,687 | \$15,549 | \$412,226 | \$4,318 |
| 3 | 25.3 | 0.956 | 91.3 | \$584,763 | \$175,753 | \$154,595 | \$6,934 | \$183,835 | \$1,926 |
| <i>Gathering and Boosting Stations</i> | | | | | | | | | |
| 1 | 5.58 | 0.210 | 20.1 | \$148,885 | \$57,575 | \$52,921 | \$10,327 | \$273,769 | \$2,868 |
| 2 | 9.23 | 0.348 | 33.2 | \$255,344 | \$84,966 | \$77,259 | \$9,203 | \$243,987 | \$2,556 |
| 3 | 12.9 | 0.486 | 46.4 | \$321,203 | \$105,350 | \$94,591 | \$8,174 | \$216,692 | \$2,270 |
| <i>Processing Plants</i> | | | | | | | | | |
| 1 | 13.5 | 0.508 | 48.5 | \$7,522 | \$45,160 | \$33,915 | \$3,352 | \$88,870 | \$931 |
| <i>Transmission/Storage Facilities</i> | | | | | | | | | |
| 1 | 2.62 | 0.0780 | 94.9 | \$94,482 | \$51,875 | N/A | \$19,769 | \$665,155 | \$546 |

Note: Transmission and storage facilities do not own the natural gas; therefore they do not receive any cost benefits from reducing the amount of natural gas as the result of equipment leaks.

The component costs were calculated using a LDAR cost spreadsheet developed for estimating capital and annual costs for applying LDAR to the Petroleum Refinery and Chemical Manufacturing industry. The costs are based on the following assumptions:

- Initial monitoring and setup costs are \$17.70 for valves, \$1.13 per connector, \$78.00 for pressure relief valve disks, \$3,852 for pressure relief valve disk holder and valves, and \$102 for open-ended lines.
- Subsequent monitoring costs are \$1.50 for valves and connectors, \$2.00 for pressure relief valve disks, and \$5.00 for pressure relief valve devices and open-ended lines.
- A wage rate of \$30.46 per hour was used to determine labor costs for repair.
- Administrative costs and initial planning and training costs are included for the component option and are based on the Miscellaneous Organic NESHAP (MON) analysis. The costs were based on 340 hours for planning and training and 300 hours per year for reporting and administrative tasks at \$48.04 per hour.
- The capital cost for purchasing a TVA or OVA monitoring system was estimated to be \$6,500.

The component control effectiveness for the subpart VVa component option were 93.6 percent for valves, 95.9 percent for connectors, 100 percent for open-ended lines, and 100 percent for pressure relief devices. These were the same control effectiveness's that were used for the subpart VVa facility option. The control effectiveness for the modified subpart VVa option with less frequent monitoring was estimated assuming the control effectiveness follows a hyperbolic curve or a $1/x$ relationship with the monitoring frequency. Using this assumption the component cost effectiveness's were determined to be 87.2 percent for valves, 81.0 percent for connectors, 100 percent for open-ended lines, and 100 percent for pressure relief devices. The assumption is believed to provide a conservative estimate of the control efficiency based on less frequent monitoring. A summary of the capital and annual costs and the cost effectiveness for each of the components for each of the oil and gas sectors are provided in Tables 8-14, 8-15, 8-16, and 8-17.

8.4.2.4 Secondary Impacts

The implementation of a LDAR program reduces pollutant emissions from equipment leaks. No secondary gaseous pollutant emissions or wastewater are generated during the monitoring and repair of equipment leaks. Therefore, there are no secondary impacts expected from the implementation of a LDAR program.

Table 8-14. Summary of Component Cost Effectiveness for Well Pads for the Subpart VVa Options

| Component | Average Number of Components | Monitoring Frequency (Times/yr) | Annual Emission Reductions (tons/year) | | | Capital Cost (\$) | Annual Cost (\$/yr) | Cost-effectiveness (\$/ton) | | |
|--|------------------------------|---------------------------------|--|---------|---------|-------------------|---------------------|-----------------------------|-------------|----------|
| | | | VOC | HAP | Methane | | | VOC | HAP | Methane |
| <i>Subpart VVa Option</i> | | | | | | | | | | |
| Valves | 235 | 12 | 1.84 | 0.0696 | 6.64 | \$11,175 | \$27,786 | \$15,063 | \$399,331 | \$4,183 |
| Connectors | 863 | 1/0.25 ^a | 0.308 | 0.0116 | 1.11 | \$7,830 | \$22,915 | \$74,283 | \$1,969,328 | \$20,628 |
| PRD | 10 | 0 | 0.164 | 0.00619 | 0.591 | \$48,800 | \$29,609 | \$180,537 | \$4,786,215 | \$50,135 |
| OEL | 29 | 0 | 0.108 | 0.00408 | 0.389 | \$9,458 | \$22,915 | \$211,992 | \$5,620,108 | \$58,870 |
| <i>Modified Subpart VVa– Less Frequent Monitoring</i> | | | | | | | | | | |
| Valves | 235 | 1 | 1.31 | 0.0496 | 4.73 | \$11,175 | \$23,436 | \$17,828 | \$472,640 | \$4,951 |
| Connectors | 863 | 1/0.125 ^b | 0.261 | 0.00983 | 0.938 | \$7,830 | \$22,740 | \$87,277 | \$2,313,795 | \$24,237 |
| PRD | 5 | 0 | 0.164 | 0.00619 | 0.591 | \$48,800 | \$29,609 | \$180,537 | \$4,786,215 | \$50,135 |
| OEL | 29 | 0 | 0.108 | 0.00408 | 0.389 | \$9,458 | \$22,915 | \$211,992 | \$5,620,108 | \$58,870 |

Minor discrepancies may be due to rounding.

- a. It was assumed that all the connectors are monitored in the first year for initial compliance and every 4 years thereafter.
- b. It was assumed that all the connectors are monitored in the first year for initial compliance and every 8 years thereafter.

Table 8-15. Summary of Component Cost Effectiveness for Gathering and Boosting Stations for the Subpart VVa Options

| Component | Average Number of Components | Monitoring Frequency (Times/yr) | Annual Emission Reductions (tons/year) | | | Capital Cost (\$) | Annual Cost (\$/yr) | Cost-effectiveness (\$/ton) | | |

Minor discrepancies may be due to rounding.

- a. It was assumed that all the connectors are monitored in the first year for initial compliance and every 4 years thereafter.
- b. It was assumed that all the connectors are monitored in the first year for initial compliance and every 8 years thereafter.

8.4.3 LDAR with Optical Gas Imaging

8.4.3.1 Description

The alternative work practice for equipment leaks in §60.18 of 40 CFR Part 60, subpart A allows the use of an optical gas imaging system to monitor leaks from components. This LDAR requires monthly monitoring and repair of components using an optical gas imaging system, and annual monitoring of components using a Method 21 instrument. This requirement does not have a leak definition because the optical gas imaging system can only measure the magnitude of a leak and not the concentration. However, this alternative work practice does not require the repair of leaks below 500 ppm. Compressors are not included in this LDAR option and are discussed in Chapter 6 of this document.

8.4.3.2 Effectiveness

No data was found on the control effectiveness of the alternative work practice. It is believed that this option would provide the same control effectiveness as the subpart VVa monitoring program. Therefore, the control effectiveness's for implementing an alternative work practice was assumed to be 93.6 percent for valves, 95.9 percent for connectors, 100 percent for open-ended lines, and 100 percent for pressure relief devices.

8.4.3.3 Cost Impacts

Costs were calculated using a LDAR cost spreadsheet developed for estimating capital and annual costs for applying LDAR to the Petroleum Refinery and Chemical Manufacturing industry. The costs are based on the following assumptions:

- Initial monitoring and setup costs are \$17.70 for valves, \$1.13 per connector, \$78.00 for pressure relief valve disks, \$3,852 for pressure relief valve disk holder and valves, and \$102 for open-ended lines.
- Monthly optical gas imaging monitoring costs are estimated to be \$0.50 for valves, connectors, pressure relief valve devices, and open-ended lines.
- Annual monitoring costs using a Method 21 device are estimated to be \$1.50 for valves and connectors, \$2.00 for pressure relief valve disks, and \$5.00 for pressure relief devices and open-ended lines.
- A wage rate of \$30.46 per hour was used to determine labor costs for repair.

- Administrative costs and initial planning and training costs are based on the Miscellaneous Organic NESHAP (MON) analysis. The costs were based on 340 hours for planning and training and 300 hours per year for reporting and administrative tasks at \$48.04 per hour.
- The capital cost also includes \$14,500 for a data collection system for maintaining the inventory and monitoring records for the components at a facility.
- Recovery credits were calculated assuming the methane reduction has a value of \$4.00 per 1000 standard cubic feet.

It was assumed that a single optical gas imaging and a Method 21 monitoring device could be used at multiple locations for production pads, gathering and boosting stations, and transmission and storage facilities. To calculate the shared cost of the optical gas imaging system and the Method 21 device, the time required to monitor a single facility was estimated. For production pads and gathering and boosting stations, it was assumed that 8 production pads could be monitored per day. This means that 160 production facilities could be monitored in a month. In addition, it was assumed 13 gathering and boosting station would service these wells and could be monitored during the same month for a total of 173 facilities. Therefore, the capital cost of the optical gas imaging system (Flir Model GF320, \$85,000) and the Method 21 device (\$6,500) was divided by 173 to get a shared capital cost of \$529 per facility. It was assumed for processing facilities that the full cost of the optical gas imaging system and the Method 21 monitoring device would apply to each individual plant. The transmission and storage segment Method 21 device cost was estimated assuming that one facility could be monitored in one hour, and the travel time between facilities was one hour. Therefore, in a typical day 4 transmission stations could be monitored in one day. Assuming the same 20 day work month, the total number of facilities that could be monitored by a single optical gas imaging system and Method 21 device is 80. Therefore, the shared cost of the Method 21 monitoring device was calculated to be \$1,144 per site.

A summary of the capital and annual costs and the cost effectiveness for each of the model plants in the oil and gas sector using the alternative work practice monitoring is provided in Table 8-18. A component cost effectiveness analysis for the alternative work practice was not performed, because the optical gas imaging system is not conducive to component monitoring, but is intended for facility-wide monitoring.

8.4.3.4 Secondary Impacts

The implementation of a LDAR program reduces pollutant emissions from equipment leaks. No secondary gaseous pollutant emissions or wastewater are generated during the monitoring and repair of

Table 8-18. Summary of the Model Plant Cost Effectiveness for the Optical Gas Imaging and Method 21 Monitoring Option

| Model Plant | Annual Emission Reductions (tons/year) | | | Capital Cost (\$) | Annual Cost (\$/year) | | Cost Effectiveness (\$/ton) | | |
|--|--|---------|---------|-------------------|-----------------------|--------------|-----------------------------|-------------|----------|
| | VOC | HAP | Methane | | without savings | with savings | VOC | HAP | Methane |
| Well Pads | | | | | | | | | |
| 1 | 0.0876 | 0.00330 | 0.315 | \$15,428 | \$21,464 | \$21,391 | \$245,024 | \$6,495,835 | \$68,043 |
| 2 | 2.43 | 0.0915 | 8.73 | \$64,858 | \$39,112 | \$37,088 | \$16,127 | \$427,540 | \$4,478 |
| 3 | 25.3 | 0.956 | 91.3 | \$132,891 | \$135,964 | \$114,807 | \$5,364 | \$142,216 | \$1,490 |
| Gathering and Boosting Stations | | | | | | | | | |
| 1 | 5.58 | 0.210 | 20.1 | \$149,089 | \$63,949 | \$59,295 | \$11,470 | \$304,078 | \$3,185 |
| 2 | 9.23 | 0.348 | 33.2 | \$240,529 | \$93,210 | \$85,503 | \$10,096 | \$267,659 | \$2,804 |
| 3 | 12.9 | 0.486 | 46.4 | \$329,725 | \$121,820 | \$111,060 | \$9,451 | \$250,567 | \$2,625 |
| Processing Plants | | | | | | | | | |
| 1 | 13.5 | 0.508 | 48.5 | \$92,522 | \$87,059 | \$75,813 | \$6,462 | \$171,321 | \$1,795 |
| Transmission/Storage Facilities | | | | | | | | | |
| 1 | 2.62 | 0.0780 | 94.9 | \$20,898 | \$51,753 | N/A | \$19,723 | \$663,591 | \$545 |

Minor discrepancies may be due to rounding.

Note: Transmission and storage facilities do not own the natural gas; therefore cost benefits from reducing the amount of natural gas as the result of equipment leaks was not estimated for the transmission segment..

equipment leaks. Therefore, there are no secondary impacts expected from the implementation of a LDAR program.

8.4.4 Modified Alternative Work Practice with Optical Gas Imaging

8.4.4.1 Description

The modified alternative work practice for equipment leaks in §60.18 of 40 CFR Part 60, subpart A allows the use of an optical gas imaging system to monitor leaks from components, but removes the requirement of the annual Method 21 device monitoring. Therefore, the modified work practice would require only monthly monitoring and repair of components using an optical gas imaging system. This requirement does not have a leak definition because the optical gas imaging system can only measure the magnitude of a leak and not the concentration. However, this alternative work practice does not require the repair of leaks below 500 ppm. Compressors are not included in this LDAR option and are regulated separately.

8.4.4.2 Effectiveness

No data was found on the control effectiveness of this modified alternative work practice. However, it is believed that this option would provide the similar control effectiveness and emission reductions as the subpart VVa monitoring program. Therefore, the control effectiveness's for implementing an alternative work practice was assumed to be 93.6 percent for valves, 95.9 percent for connectors, 100 percent for open-ended lines, and 100 percent for pressure relief devices.

8.4.4.3 Cost Impacts

Costs were calculated using a LDAR cost spreadsheet developed for estimating capital and annual costs for applying LDAR to the Petroleum Refinery and Chemical Manufacturing industry. The costs are based on the following assumptions:

- Initial monitoring and setup costs are \$17.70 for valves, \$1.13 per connector, \$78.00 for pressure relief valve disks, \$3,852 for pressure relief valve disk holder and valves, and \$102 for open-ended lines.
- Monthly optical gas imaging monitoring costs are estimated to be \$0.50 for valves, connectors, pressure relief valve devices, and open-ended lines.
- A wage rate of \$30.46 per hour was used to determine labor costs for repair.

- Administrative costs and initial planning and training costs are based on the Miscellaneous Organic NESHAP (MON) analysis. The costs were based on 340 hours for planning and training and 300 hours per year for reporting and administrative tasks at \$48.04 per hour.
- The shared capital cost for optical gas imaging system is \$491 for production and gathering and boosting, \$85,000 for processing, and \$1,063 for transmission for a FLIR Model GF320 optical gas imaging system.
- The capital cost also includes \$14,500 for a data collection system for maintaining the inventory and monitoring records for the components at a facility.
- Recovery credits were calculated assuming the methane reduction has a value of \$4.00 per 1000 standard cubic feet.

A summary of the capital and annual costs and the cost effectiveness for each of the model plants in the oil and gas sectors using the alternative work practice monitoring is provided in Table 8-19. A component cost effectiveness analysis for the alternative work practice was not performed, because the optical gas imaging system is not conducive to component monitoring, but is intended for facility-wide monitoring.

8.4.4.4 Secondary Impacts

The implementation of a LDAR program reduces pollutant emissions from equipment leaks. No secondary gaseous pollutant emissions or wastewater are generated during the monitoring and repair of equipment leaks. Therefore, there are no secondary impacts expected from the implementation of a LDAR program.

8.5 Regulatory Options

The LDAR pollution prevention approach is believed to be the best method for reducing pollutant emissions from equipment leaks. Therefore, the following regulatory options were considered for reducing equipment leaks from well pads, gathering and boosting stations, processing facilities, and transmission and storage facilities:

- Regulatory Option 1: Require the implementation of a subpart VVa LDAR program;
- Regulatory Option 2: Require the implementation of a component subpart VVa LDAR program;
- Regulatory Option 3: Require the implementation of the alternative work practice in §60.18 of 40 CFR Part 60;

Table 8-19. Summary of the Model Plant Cost Effectiveness for Monthly Gas Imaging Monitoring

| Model Plant | Annual Emission Reductions (tons/year) | | | Capital Cost (\$) | Annual Cost (\$/year) | | Cost Effectiveness (\$/ton) | | |
|---|--|-----|---------|-------------------|-----------------------|--------------|-----------------------------|-----|---------|
| | VOC | HAP | Methane | | without savings | with savings | VOC | HAP | Methane |
| <i>Well Pads</i> | | | | | | | | | |
| 1 | N/A | N/A | N/A | \$15,390 | \$21,373 | N/A | N/A | N/A | N/A |
| 2 | N/A | N/A | N/A | \$64,820 | \$37,049 | N/A | N/A | N/A | N/A |
| 3 | N/A | N/A | N/A | \$537,313 | \$189,174 | N/A | N/A | N/A | N/A |
| <i>Gathering and Boosting Stations</i> | | | | | | | | | |
| 1 | N/A | N/A | N/A | \$149,051 | \$59,790 | N/A | N/A | N/A | N/A |
| 2 | N/A | N/A | N/A | \$240,491 | \$86,135 | N/A | N/A | N/A | N/A |
| 3 | N/A | N/A | N/A | \$329,687 | \$11,940 | N/A | N/A | N/A | N/A |
| <i>Processing Plants</i> | | | | | | | | | |
| 1 | N/A | N/A | N/A | \$92,522 | \$76,581 | N/A | N/A | N/A | N/A |
| <i>Transmission/Storage Facilities</i> | | | | | | | | | |
| 1 | N/A | N/A | N/A | \$20,817 | \$45,080 | N/A | N/A | N/A | N/A |

Note: This option only provides the number and magnitude of the leaks. Therefore, the emission reduction from this program cannot be quantified and the cost effectiveness values calculated.

- Regulatory Option 4: Require the implementation of a modified alternative work practice in §60.18 of 40 CFR Part 60 that removes the requirement for annual monitoring using a Method 21 device.

The following sections discuss these regulatory options.

8.5.1 Evaluation of Regulatory Options for Equipment Leaks

8.5.1.1 Well pads

The first regulatory option of a subpart VVa LDAR program was evaluated for well pads, which include the wells, processing equipment (separators, dehydrators, acid gas removal), as well as any heaters and piping. The equipment does not include any of the compressors which will be regulated separately. For well pads the VOC cost effectiveness for the model plants ranged from \$267,386 per ton of VOC for a single well head facility to \$6,934 ton of VOC for a well pad servicing 48 wells. Because of the high VOC cost effectiveness, Regulatory Option 1 was rejected for well pads.

The second regulatory option that was evaluated for well pads was Regulatory Option 2, which would require the implementation of a component subpart VVa LDAR program. The VOC cost effectiveness of this option ranged from \$15,063 for valves to \$211,992 for open-ended lines. These costs were determined to be unreasonable and therefore this regulatory option was rejected.

The third regulatory option requires the implementation of a monthly LDAR program using an Optical gas imaging system with annual monitoring using a Method 21 device. The VOC cost effectiveness of this option ranged from \$5,364 per ton of VOC for Model Plant 3 to \$245,024 per ton of VOC for Model Plant 1. This regulatory option was determined to be not cost effective and was rejected.

The fourth regulatory option would require the implementation of a monthly LDAR program using an optical imaging instrument. The emission reductions from this option could not be quantified; therefore this regulatory option was rejected.

8.5.1.2 Gathering and Boosting Stations

The first regulatory option was evaluated for gathering and boosting stations which include the processing equipment (separators, dehydrators, acid gas removal), as well as any heaters and piping. The equipment does not include any of the compressors which will be regulated separately. The VOC cost effectiveness for the gathering and boosting model plants ranged from \$10,327 per ton of VOC for

Model Plant 1 to \$8,174 per ton of VOC for Model Plant 3. Regulatory Option 1 was rejected due to the high VOC cost effectiveness.

The second regulatory option that was evaluated for gathering and boosting stations was Regulatory Option 2. The VOC cost effectiveness of this option ranged from \$6,079 for valves to \$77,310 per ton of VOC for open-ended lines. These costs were determined to be unreasonable and therefore this regulatory option was also rejected.

The third regulatory option requires the implementation of a monthly LDAR program using an Optical gas imaging system with annual monitoring using a Method 21 device. The VOC cost effectiveness of this option was calculated to be \$10,724 per ton of VOC for Model Plant 1 and \$8,685 per ton of VOC for Model Plant 3. This regulatory option was determined to be not cost effective and was rejected.

The fourth regulatory option would require the implementation of a monthly LDAR program using an optical imaging instrument. The emission reductions from this option could not be quantified; therefore this regulatory option was rejected.

8.5.1.3 Processing Plants

The VOC cost effectiveness of the first regulatory option was calculated to be \$3,352 per ton of VOC. This cost effectiveness was determined to be reasonable and therefore this regulatory option was accepted.

The second option was evaluated for processing plants and the VOC cost effectiveness ranged from \$0 for open-ended lined and pressure relief devices to \$4,360 for connectors. Because the emission benefits and the cost effectiveness of Regulatory Option 1 were accepted, this option was not accepted.

The third regulatory option requires the implementation of a monthly LDAR program using an Optical gas imaging system with annual monitoring using a Method 21 device. The VOC cost effectiveness of this option was calculated to be \$6,462 per ton of VOC and was determined to be not cost effective. Therefore, this regulatory option was rejected.

The fourth regulatory option would require the implementation of a monthly LDAR program using an optical imaging instrument. The emission reductions from this option could not be quantified; therefore this regulatory option was rejected.

8.5.1.4 Transmission and Storage Facilities

The first regulatory option was evaluated for transmission and storage facilities which include separators and dehydrators, as well as any heaters and piping. The equipment does not include any of the compressors which will be regulated separately. This sector moves processed gas from the processing facilities to the city gates. The VOC cost effectiveness for Regulatory Option 1 was \$19,769 per ton of VOC. The high VOC cost effectiveness is due to the inherent low VOC concentration in the processed natural gas, therefore the VOC reductions from this sector are low in comparison to the other sectors. Regulatory Option 1 was rejected due to the high VOC cost effectiveness.

The second option was evaluated for transmission facilities and the VOC cost effectiveness ranged from \$24,762 for open-ended lined to \$243,525 for connectors. This option was not accepted because of the high cost effectiveness.

The third regulatory option that was evaluated for transmission and storage facilities was Regulatory Option 3. The VOC cost effectiveness of this option was calculated to be \$19,723 per ton of VOC. Again, because of the low VOC content of the processed gas, the regulatory option has a low VOC reduction. This cost was determined to be unreasonable and therefore this regulatory option was also rejected.

The fourth regulatory option would require the implementation of a monthly LDAR program using an optical imaging instrument. The emission reductions from this option could not be quantified; therefore this regulatory option was rejected.

8.5.2 Nationwide Impacts of Regulatory Options

Regulatory Option 1 was selected as an option for setting standards for equipment leaks at processing plants. This option would require the implementation of an LDAR program using the subpart VVa requirements. For production facilities, 29 facilities per year are expected to be affected sources by the NSPS regulation annually. Table 8-20 provides a summary of the expected emission reductions from the implementation of this option.

Table 8-20. Nationwide Emission and Cost Analysis of Regulatory Options

| Category | Estimated Number of Sources subject to NSPS | Facility Capital Cost (\$) | Nationwide Emission Reductions (tpy) | | | VOC Cost Effectiveness (\$/ton) | | Methane Cost Effectiveness (\$/ton) | | Total Nationwide Costs (million \$/year) | | |
|---|---|----------------------------|--------------------------------------|---------|------|---------------------------------|--------------|-------------------------------------|--------------|--|------------------------|---------------------|
| | | | VOC | Methane | HAP | without savings | with savings | without savings | with savings | Capital Cost | Annual without savings | Annual with savings |
| Regulatory Option 2 (Subpart VVa LDAR Program) | | | | | | | | | | | | |
| Processing Plants | 29 | \$7,522 | 392 | 1,407 | 14.7 | \$3,352 | \$2,517 | \$931 | \$699 | 0.218 | 1.31 | 0.984 |

Environmental hazards posed by the Los Angeles Basin urban oilfields: an historical perspective of lessons learned

G.V. Chilingar · B. Endres

Abstract Urban encroachment into areas historically reserved for oil and gas field operations is an ever-present problem within the Los Angeles Basin. The recent frenzy in real estate development has only intensified what can be characterized as a conflict in land usage. Subsurface mineral rights are severed from surface ownership, often resulting in developments being approved without adequate consideration of the underlying oil and gas field consequences. Also, surface operations are frequently co-located within residential areas without consideration of the health and safety consequences of emissions of toxics to air. This paper presents a review of the environmental, health and safety hazards posed by urban oilfield operations, with an emphasis upon the lessons learned from the “L.A. Basin: Original Urban Oilfield Legend” (see Castle and Yerkes 1976; Denton and others 2001; Endres and others 2002; Kouznetsov and others 1994; Katz and others 1994; Schumacher and Abrams 1994; and Schoell 1983). The Los Angeles Basin has provided the authors with one of the largest natural laboratories in the world for studying the consequences of these issues. The results presented are part of a long-term research program based upon the application of geoscience and petroleum engineering principles in obtaining a fundamental understanding of the root causes of the environmental hazards posed. Topics addressed include: (1) vertical migration of gas to the surface along faults and improperly completed or abandoned wellbores (e.g., due to poor cementing practices), (2) subsidence caused by the fluid

production and declining reservoir pressures, (3) soil and groundwater contamination resulting from historic oil and gas field operations, and (4) air toxics resulting from surface operations. A number of case histories are discussed that illustrate the seriousness of the problem. A clear case is made for the urgent need for closer coordination and education by the petroleum industry of the local government planning departments. These departments have the principal role in determining land use policies, acting as the lead agency in performing environmental site assessments (e.g., under the California Environmental Quality Act), and in establishing mitigation measures for dealing with the long-term environmental hazards. This paper establishes prudent practices on the part of oilfield operators for the monitoring and mitigation of these hazards.

Keywords Los Angeles oilfields · Gas migration · Toxic gases (hazard) · Subsidence-earthquakes · Methane

Introduction

The environmental hazards posed to the urban development by oil and gas field operations are numerous. These hazards must be properly evaluated and mitigation measures implemented in order to protect public safety. These hazards are caused by gas migration along faults, subsidence caused by the fluid removal with consequent formation of faults and fractures, and by improperly maintained wellbores.

The Los Angeles Basin, California, has over seventy oilfields that underlie extensive urban development. This setting has provided the authors an opportunity to study the long-term environment consequences of this mixed usage. These environmental hazards are not unique to the Los Angeles Basin, but relate to fundamental principles of gas migration, along faults and fracture zones, subsidence, and outgassing of oilfield gases that must be properly evaluated. This paper provides a detailed insight into these hazards, as well as lessons learned from the numerous

disasters that were not properly planned for. Methods for reducing risks and mitigation of hazards are discussed. Four aspects of these environment hazards are presented:

1. Oilfield gas migration into the near-surface deposits and aquifers.
2. Soil and groundwater contamination from upward migration of oilfields fluids, mainly gases.
3. Subsidence caused by oilfield fluid withdrawal and declining reservoir pressures.
4. Outgassing and release of air toxics from the oil- and gas-field operations.

These issues are interactive and must be evaluated in combination. Ignoring these issues could result in substantial legal liability upon the oilfield operator and upon those responsible for the public safety. Subsidence also results in the formation of faults and fracture zones, which are avenues for the migration of gases.

Gas migration in oilfield settings

The Los Angeles Basin has been plagued with numerous oilfield gas seeps that continue to present serious explosion and health risks to the residents. Oilfield gases have a propensity to migrate to the surface along faults and poorly completed and/or abandoned wellbores. Furthermore, the upward migrating gases will accumulate in the near-surface collector zones, often trapped and concealed within the permeable gravel and sand lenses.

The lower explosive limit (LEL) of the oilfield gases (composed primarily of methane) is approximately 5% by volume when mixed with 95% by volume of air. This translates into a serious explosion and fire hazard, especially where the gas is capable of migrating into a confined space such as a room or an electrical vault. In the Los Angeles Basin many homes and commercial structures have been constructed directly over old oil wells that have not been properly sealed, and no mitigation measures have been taken to seal out the seeping gases.

The March 24, 1985, Ross Department Store explosion

The first clear recognition of a very serious problem with oilfield gases migrating to the surface and causing an explosion hazard was the March 24, 1985, incident in the Fairfax area of Los Angeles which demolished the Ross Department Store and injured over 23 people (Cobarrubias 1985). Escaping oilfield gases burned for days through cracks in the sidewalks and within the parking lot surrounding the store located at 3rd Street and Ogden Drive, directly across the street from the Farmer's Market. Also, large quantities of gas were detected migrating to the surface under the Hancock Park Elementary School located on Fairfax Street near 3rd Street.

Near-surface soil gas studies revealed that the highest concentrations of gases were aligned in an elliptical pattern with the semi-major axis having an exact alignment with the Metropolitan Number 5 Slant Well operated from a nearby drilling island. A review of production records revealed that this well consistently produced the largest gas volumes of any operational well from the underlying Salt Lake Oilfield. Eventually, well records were obtained that revealed that the well casing had developed leaks as a result of corrosion holes located at a depth beginning at approximately 366 m, and extending deeper (Endres and others 1991; Khilyuk and others 2000).

Gas pathways to the surface included the 3rd Street Fault, that surfaced at the Ross Store location, and an old abandoned vertical well identified on the Division of Oil and Gas map for the area as Well Number 99. A vent well drilled into the parking lot of the Ross Store discovered a large pocket (collector zone) of trapped oilfield gas at a depth of approximately 15 m (Fig. 1). This collector zone had sufficient porosity and permeability to serve as a temporary trapping mechanism for the large quantities of upward migrating gases from the leaking wells to build to pressures of approximately 1.8 kg/cm². A clay layer served as a trapping mechanism until its threshold pressure was exceeded. Permanent soil gas probes were installed to a depth of approximately 4.6 m in order to perform ongoing monitoring of the upward migrating gases (Fig. 2).

Detailed gas fingerprinting, primarily utilizing isotopic gas characterization, was instrumental in providing 100% scientific proof (Fig. 3) that the explosion and fire were caused by the underlying Salt Lake Oilfield operations (Schoell and others 1993). Also, further investigation revealed that the gas seeps at the nearby La Brea Tar Pits result from upward migration of gases from the Salt Lake Oilfield along the 6th Street Fault (Jenden 1985). The 6th Street Fault slopes downward to the north and intercepts the oilfield reservoir at the location of the Metropolitan Number 5 well. Production Zone (viz., a very prolific gas zone). Gas fingerprinting has confirmed that the gas seeps at the La Brea Tar Pits match the leaking gases that caused the Ross Department Store explosion (Jenden 1985).

The City of Los Angeles methane ordinance

Following the Fairfax explosion and fires in 1985, the City of Los Angeles adopted a methane ordinance that was incorporated into the City of Los Angeles Building Code, Chapter 15, titled "Methane Seepage District Regulations." The stated purpose is for the control of methane intrusion emanating from petroliferous formations. These regulations apply largely to new construction, the boundaries of which are defined in the code, but are coincident with the boundaries of the Salt Lake Oilfield.

Existing commercial structures, including the Hancock Park Elementary School, were required to install gas detectors. These requirements for gas detection in existing buildings, however, were limited to the commercial

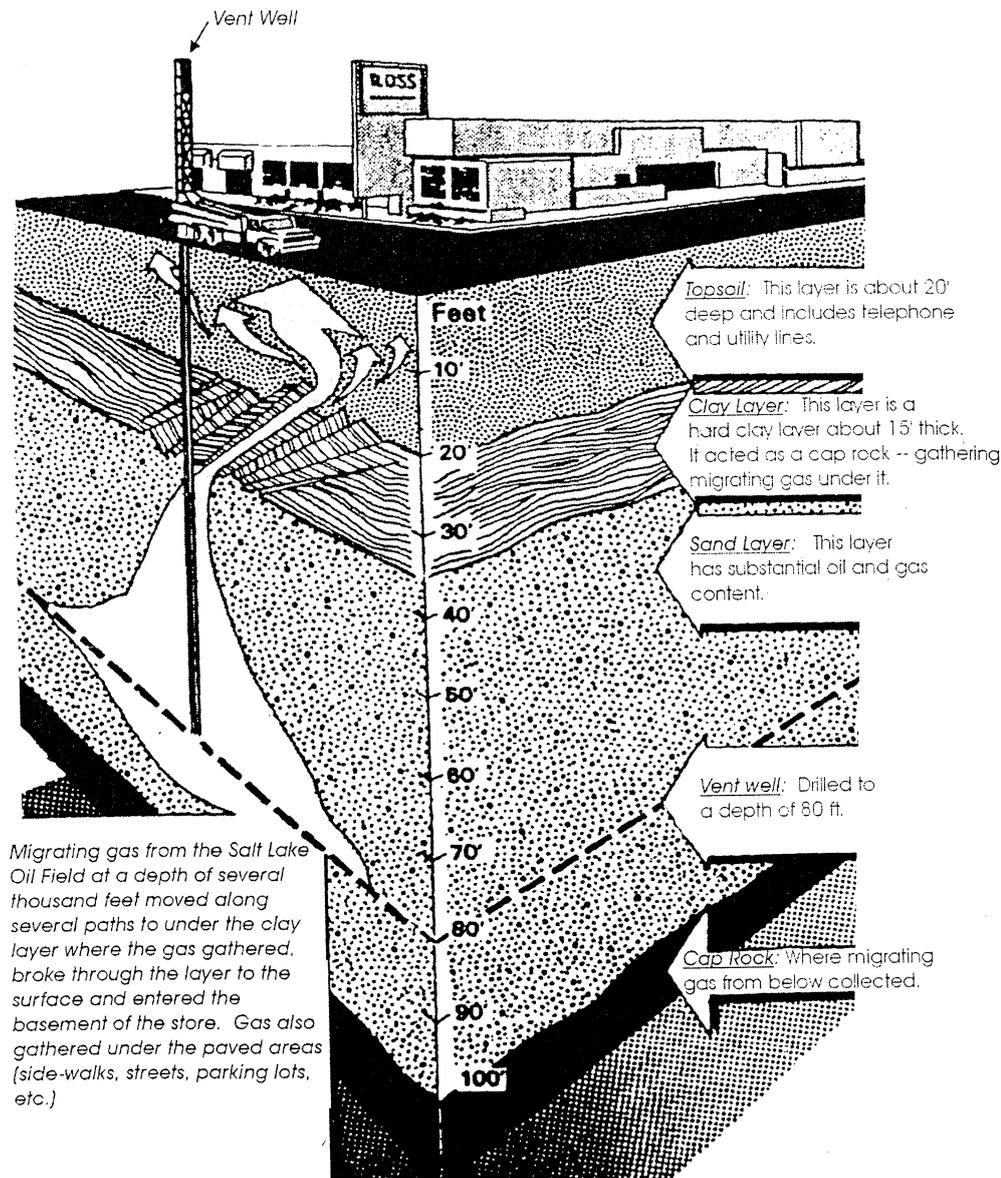

Fig. 1

Schematic showing how gas entered the basement of the department store and the surrounding area (modified after an article by George Ramos and Ted Thackery in the Los Angeles Times 1985; Illustration by Michael Hall)

buildings in the immediate vicinity of the Third Street and Ogden explosion site. Additionally, these commercial establishments were required to share the weekly monitoring expenses associated with the permanent soil gas probes that are depicted in Fig. 2. Unfortunately, the Anthony No. 1 gas well (see Figs. 1, 2), that was installed to vent gas from the underlying formation, became plugged in the 1989 time period. Namely, the weekly monitoring of the soil probes failed to provide advanced warning of a near-disaster on February 7, 1989.

The near disaster of February 7, 1989

On the morning of February 7, 1989, a pedestrian who was walking by the Gilmore Bank building, located on the

north side of Third Street and across the street from the 1985 explosion site, observed gas bubbling through the ground in a planter box. The fire department was called, which led to the discovery of area-wide gas seeps emerging from below the sidewalks and streets, a near repeat of the 1985 incident, but without an explosion.

It was discovered that the Anthony vent well had become plugged at the perforated intervals of the permeable sand zone depicted in Fig. 1. This condition was aggravated by the ground water movement existing at the depth of vent well.

The response team soon recognized similarities to the 1985 explosion and fires, and the area was immediately cordoned off to prevent ignition and explosion of the gas. In the wake of this near disaster, the City of Los Angeles undertook a second task force study. There is overwhelming scientific evidence that the gas accumulations were the direct result of ongoing oil and gas production, and leaking oil wells.

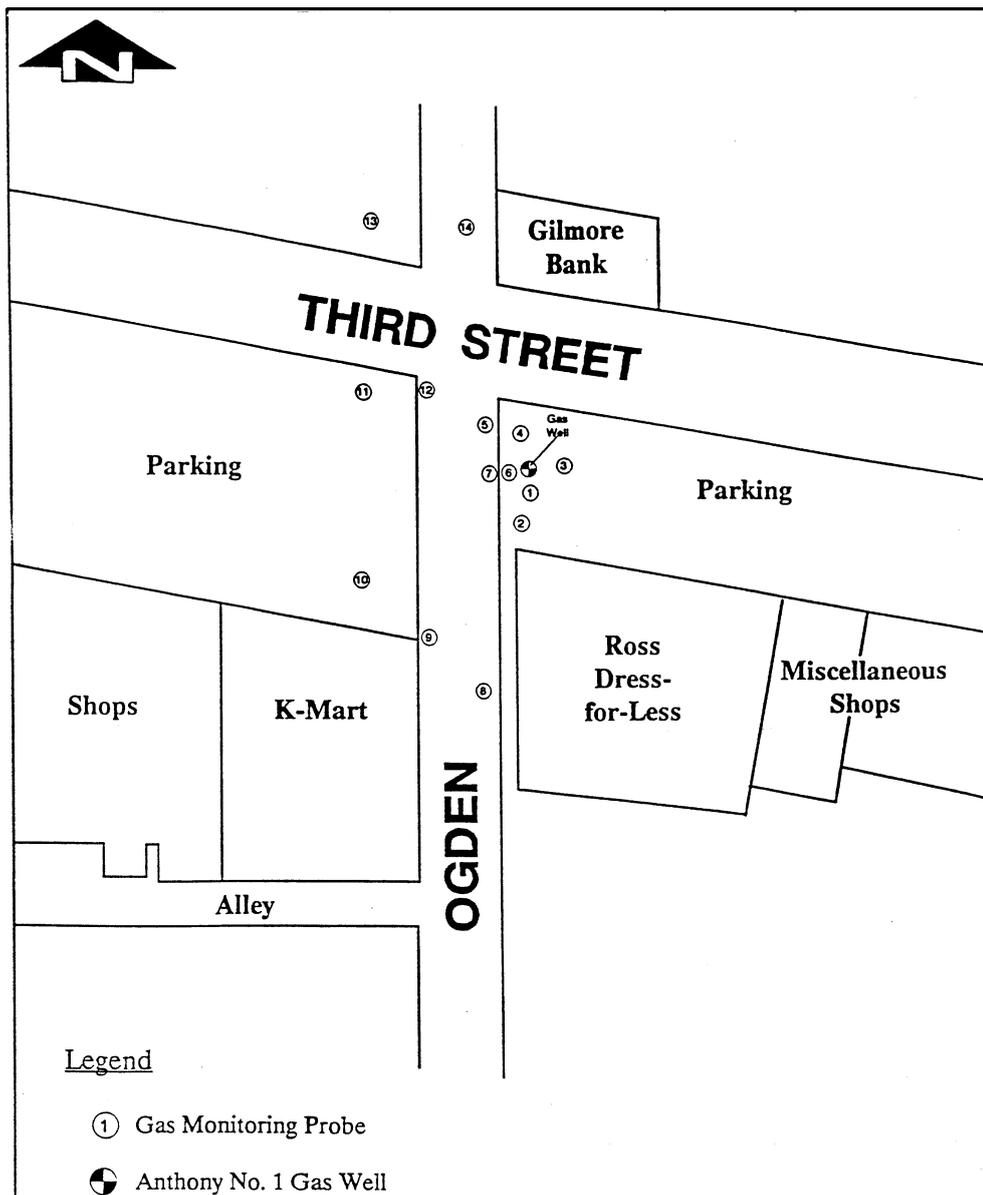

Fig. 2
Probe location map; 3rd St. and Ogden Drive, Los Angeles, California (courtesy of City of Los Angeles Fire Department)

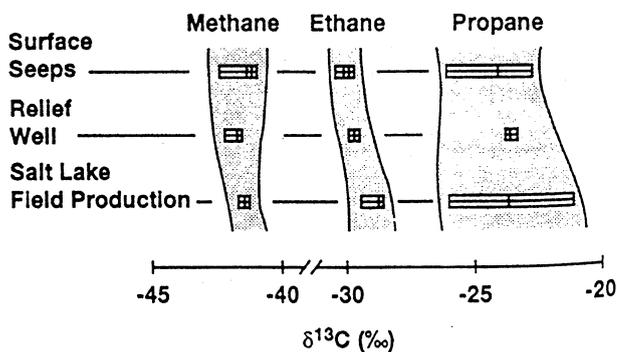

Fig. 3
Carbon isotopic fingerprinting of gas leaking from reservoir to the surface (after Schoell and others 1993, Fig. 8, p. 7)

Well records clearly demonstrate that the Metropolitan No. 5 well had developed serious corrosion leaks in the well casing. These leaks were ongoing, and caused large

quantities of oilfield gases to leak into secondary collector zones below both the explosion site and under the Hancock Park Elementary School.

The gas fingerprinting experts (Schoell and others 1993; Jenden 1985) showed the match between the field production gases and the gas from seeps at the surface (Fig. 3).

There is an increased risk of a similar incident occurring somewhere else within approximately 70 oilfields within the Los Angeles Basin. The most important lesson to be learned from the Fairfax explosion is the need to carefully evaluate the integrity of the many old oil wells in the Los Angeles Basin that can serve as the primary source and/or the pathways for the oilfield gases to migrate to the surface. The authors have confirmed this enormous hazard by evaluating hundreds of documented well leaks, and identifying the causes of the leaks. Virtually all well leaks can be traced to the poor

well completion and/or abandonment procedures (e.g., poor cementing practices).

Environmental hazards of oil well leaks

Wells that were drilled and completed many years ago are subject to ongoing corrosion and deterioration of both the steel casings and the cements.

Gas intrusion into cemented wellbores and the resultant leakage to the surface and porous formations below the wellhead have been persistent problems in the oil and gas industry for many years (Marlow 1989). Pressure and temperature cycling on the cement bonding characteristics, an acute problem in the gas storage industry, can give rise to shoe leaks and loss of bonding in the annular cement. To help quantify the annular leakage problem in gas storage wells, a survey was prepared and sent to the members of the American Gas Associations Pipeline Research and Storage Reservoir Supervisory Committees. The survey attempted to determine the magnitude of the annular leakage problem.

Tests showed that even when the most up-to-date cement types and techniques are used, leakage can and will occur in a significant number of cases (Marlow 1989 pp. 1147, 1148). For example, in a study of 250 casing jobs over a 15-month period with new cements, 15% of the wells leaked (Watters and Sabins 1980). Accordingly, the poor cementing and completion practices, typical of the many old wells located in the Los Angeles Basin, are giving rise to very serious environmental problems associated with gas leakage to the surface in the annular space, as discussed herein.

Numerous fields have accumulations of hydrogen sulfide that will eventually destroy the integrity of both the steel and cement relied upon to provide protection against gas migration, including abandonments performed to the current standards of the DOGGR. The corrosive conditions of hydrogen sulfide are well known, and have defied engineering solutions (Craig 1993).

Ongoing seismic activity in the Los Angeles Basin is also a major factor in contributing to a well integrity problem. For example, the 1971 Sylmar earthquake was responsible for causing well blowouts in the Fairfax (Salt Lake Oilfield) area (Khilyuk and others 2000).

Wilshire and Curson gas seep

A very serious gas seep at the intersection of Wilshire and Curson (directly across the street, and south of the La Brea Tar Pits) was discovered in 1999. This required the City of Los Angeles to install a vent pipe on the south-west corner of this intersection in order to direct the oilfield gases into the air above the adjoining three story commercial building. The odors from the gas emitted from the vent pipe are noticeable throughout the area.

The commercial office building to the immediate east of this seep location was experiencing gas migration through the foundation and into the building. A ventilation system is operating 24 h/day within the subterranean parking structure of that building in order to mitigate against the risk of an explosion.

Historical records of the area, reviewed by the writers, revealed that an old abandoned well had been drilled near the location of the seep. However, the high-density commercial development in the area has prevented finding the well.

South Salt Lake oilfield gas seeps from gas injection

In January 2003, serious gas leakage problems were discovered in the South Salt Lake Oilfield, located in a residential area near the Fairfax area (viz., in the vicinity of Allendale and Olympic Boulevard). The oilfield operator had been injecting natural gas into the South Salt Lake Oilfield for approximately two years, under elevated pressures to enhance recovery. However, gas began leaking to the surface along abandoned and poorly completed wellbores. In fact, the Division of Oil and Gas records reveal that numerous wells were drilled before the official records were maintained. Accordingly, the existence and abandonment status of some of these wells is unknown. High-density urban development, largely of apartment buildings has occurred directly over many of the old wells.

Montebello underground gas storage

The partially depleted Montebello Oilfield was converted into an underground gas storage operation. Natural gas was transported into the field through interstate pipelines and injected under high pressure (exceeding 105.6 kg/cm²) into the 8th Zone at a depth of approximately 2,286 m. This storage gas was discovered leaking to the surface along old wellbores that had been drilled in the 1930s era. In some instances, homes had to be abandoned and torn down to provide access to drilling rigs in an attempt to repair and/or reabandon old wells. Studies revealed that the cement plugs used in well abandonment and the integrity of the well casings and cements were not adequate to seal off the high-pressure storage gas from migrating along the wellbores to the surface. This facility had to be abandoned because of the gas leaks. However, it will take many years to deplete the gas to pre-storage conditions.

These examples indicate the importance of a systematic examination of how wells leak, and the dangers posed by allowing residential construction to occur directly over old wells. If each well leak is evaluated in isolation of the long history of problems in an area, the true dangers may not be recognized.

Playa Del Rey underground gas storage

The Playa del Rey Oilfield, located in the Marina del Rey area of the Los Angeles Basin, was converted to an underground gas storage operation in the 1942 time period, and has been operated in that manner ever since. The Venice Oilfield adjoins the area to the immediate north. The gas storage reservoir has been leaking into the adjoining Venice Oilfield since the early years of operation (Riegle 1953). There are over 200 old and abandoned wells throughout this area, including wells that had to be abandoned in order to accommodate the construction of the Marina del Rey Boat Harbor (Fig. 4). For example, some old wells are located directly below the main channel that connects to the Pacific Ocean. Numerous gas seeps have been observed by the authors of this paper within the boat harbor, and within the Ballona Flood Control Channel that bisects the area and extends eastward along the old Los Angeles Riverbed alignment.

The Los Angeles River was responsible for depositing a massive gravel layer that extends eastward providing a highly permeable zone for leaking oilfield gases to collect and migrate easterly, including under the influence of tidal forces. The gravel zone begins (viz., below surface sediments) at a depth of approximately 15 m (referred to as the "15-meter Gravel") and extends to a depth of several

hundred feet. This gravel zone interconnects many of the old wells in the area, and serves to conceal the identity of wells that are experiencing the worst leakage. Gas fingerprinting has established that the leaking well gases match the gases seeping to the surface along the flood control channel and into the surrounding residential areas.

This gravel zone is saturated with oilfield gases, which becomes additionally pressurized during the heavy rains as a result of the shallow aquifer being recharged. Surface gas seeps become very pronounced because of this pressurization, and can be observed bubbling through standing water during rains. Probes placed into the 15-meter Gravel Zone have measured gas flow rates as high as 20–30 l/min. Also, drilling rigs have experienced blowouts as a result of encountering the high-pressure gas zone when penetrating to 15 m.

These examples, including the Ross Department Store explosion and vent well histories, reveal the importance of understanding the underlying hydrology in the identification of hazardous oilfield gas seeps to the surface (also see Toth 1996). These studies have confirmed that the underlying permeable aquifers can act to conceal the true magnitude of the gas migration hazards. Accordingly, soil gas studies must include determination of the magnitude of dissolved oilfield gases contained in the near-surface aquifers. This may include multiple zones, requiring the use of deep soil probes.

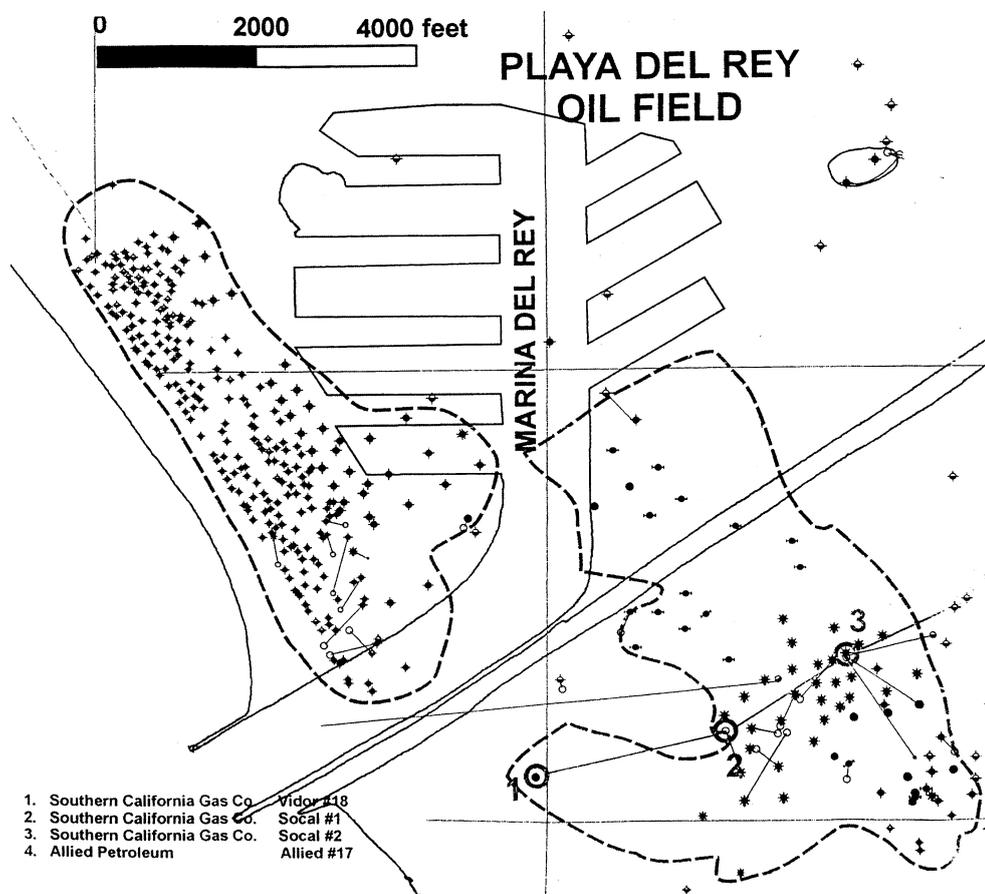

Fig. 4
Playa Del Rey oilfield (courtesy of Jack West, petroleum geologist, Fullerton, California)

A review of well abandonment records for the Playa del Rey and Venice oilfields has revealed very serious leakage problems. Leakage within the annular space between the casing and drillhole, because of poor cementing (see above), is a serious problem. Most of the wells depicted in Fig. 4 were drilled in the 1930s, before prudent cementing practices were used. For example, wells that had been abandoned as recently as 1993—to make way for housing developments—were found to be leaking when excavations were begun for the actual construction. In each case, homes were constructed directly over the old wells after minimal efforts were taken in an attempt to reseal the wells. Because of the small lots and high-density construction, there will be no room for reaccessing the wells using conventional drilling rigs.

Most of the construction in the Playa del Rey and Venice oilfield areas has failed to provide gas detection or other mitigation measures (e.g., as required by the Methane Ordinance) in order to deal with these gas migration hazards. For example, the underground gas storage operations at Playa del Rey involves injection of storage gas under high pressure (approximately 120 kg/cm²). Gas inventory studies (Tek 1987) have shown that leakage is directly proportional to the reservoir pressure maintained for gas storage (see Fig. 5). This raises serious questions about the appropriateness of locating gas storage fields in highly populated urban settings, especially where many homes have been built directly over poorly-abandoned wells. It is paramount that a fundamental understanding of how wells leak and proper procedures for monitoring are developed. Gas storage pressures are typically selected by

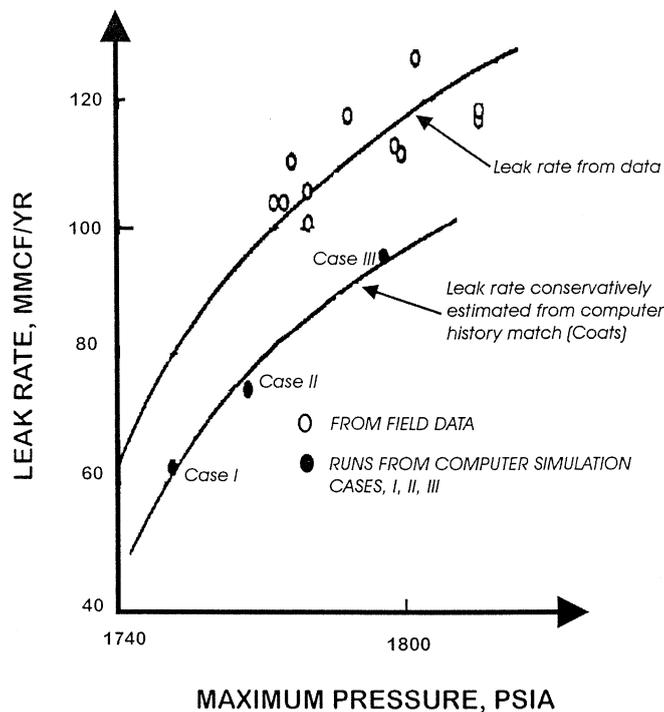

Fig. 5

Gas leak rate for various maximum reservoir pressures for Leroy Gas Storage project, Wyoming (modified after Tek 1987, Fig. 11–16)

Fig. 6

Los Angeles City oilfield (after California Division of Oil and Gas 1991)

the gas storage operator to maximize the storage volume, and to enhance retrievability of the gas when market demands dictate recovery (usually during cold spells when usage skyrockets). Also, cyclic operations associated with gas injection and withdrawal may create fractures.

Hutchinson, Kansas, gas storage leaks, explosions and fires of January 17–18, 2001

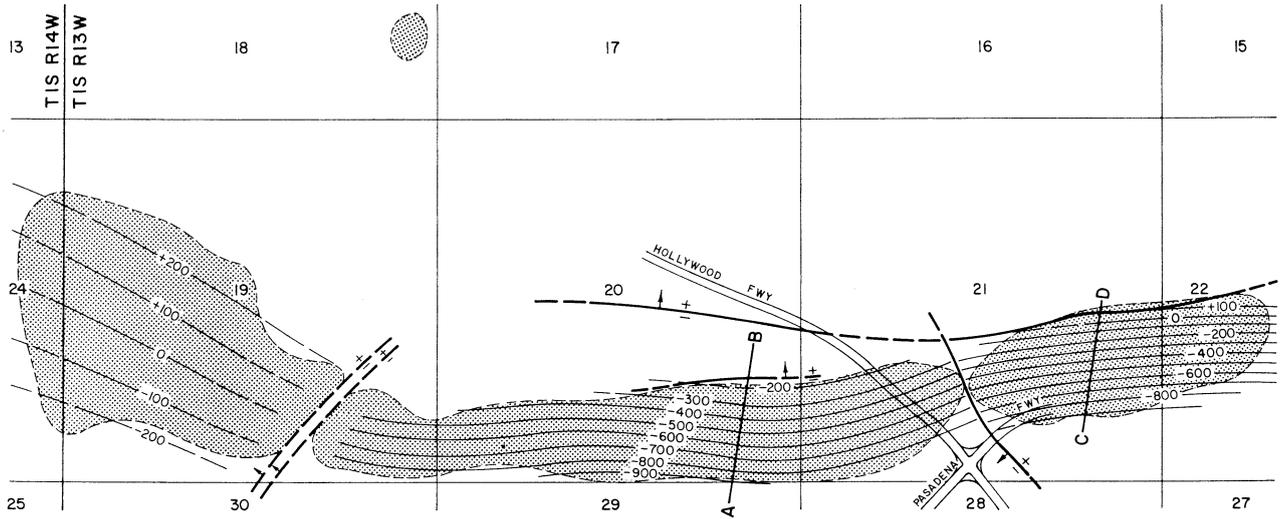

Underground gas storage leaks caused a devastating explosion and fires in the downtown area of Hutchinson, Kansas, on January 17, 2001 (Allison 2001). There was a release of natural gas from the ground water under several stores. Upon ignition, windows were blown out, and within minutes two businesses were ablaze. The fire department was unable to extinguish the flames because of the ongoing migration of gas into the area.

On the following day, leaking gas migrated into a trailer park on the outskirts of the town, causing a second explosion, and killing two people. The gas leakage was traced to a leaking storage gas reservoir about 7 miles from the town. Possibly, gas migrated along the fractures, formed as a result of subsidence, into the aquifer, and the water carried this gas to the sites of explosions.

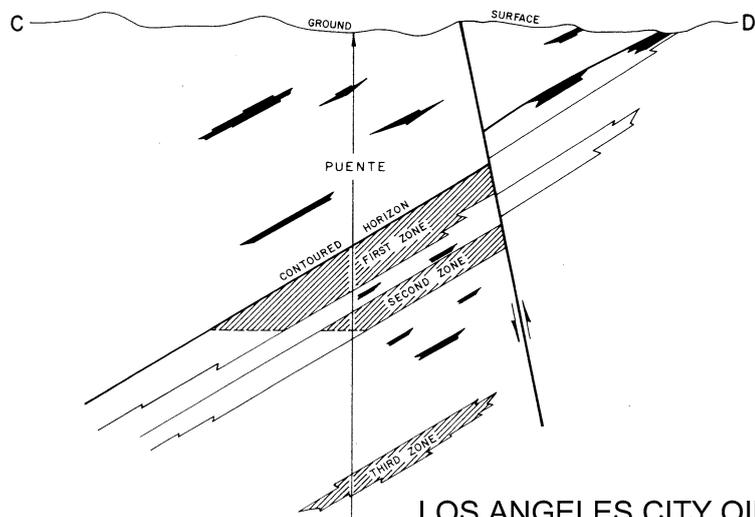

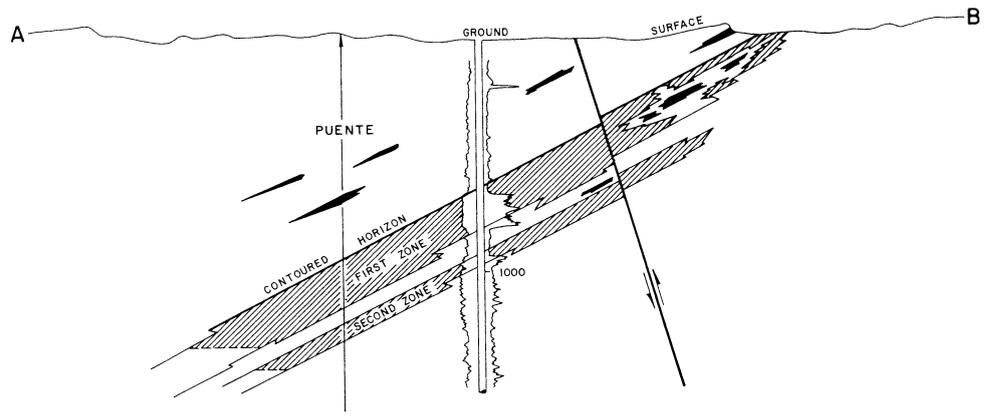

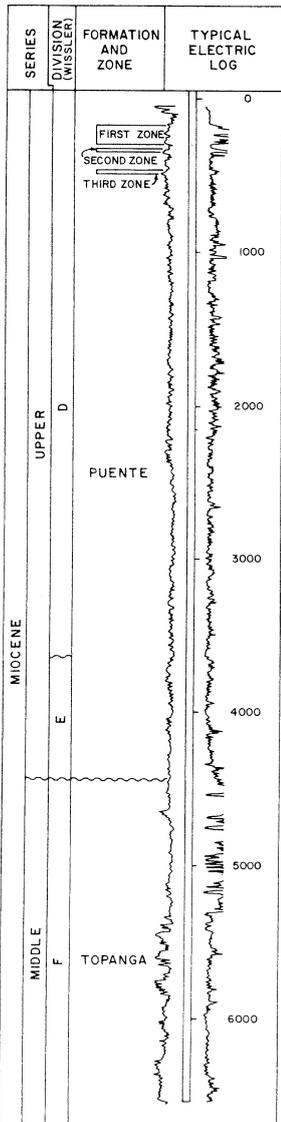

Santa Fe Springs oilfield

A study was undertaken by the authors to determine the integrity of operational oil wells in the Santa Fe Springs oilfield. To facilitate this review, a time period was selected after heavy rains in which the well cellars were partially filled with water. This allowed observation of gas bubbles seeping to the surface along well casings. Results were systematically recorded for more than 50 wells, some of which were used for waterflooding operations at pressures approaching 84.4 kg/cm². Approximately 75% of the wells were found to be leaking.

The waterflooding for enhanced oilfield recovery can be a dangerous practice due to hydraulic fracturing which could create avenues for the migration of gas to the surface creating an explosion hazard. Pressurization of an oilfield by way of water injection or gas injection requires careful attention to the integrity of the wells throughout the oilfield, and should not be undertaken until a soil gas monitoring program has been implemented in the vicinity of each well and fault to detect the potential leakage of gas to the surface. This is also necessary to determine the need for well repairs and/or well reabandonment.

CONTOURS ON TOP OF FIRST ZONE

LOS ANGELES CITY OIL FIELD

Belmont school construction on an oilfield

The Belmont Learning Center, a proposed high school in downtown Los Angeles, was in the process of being constructed over the Los Angeles City Oil Field before being abandoned. The site chosen was on a 0.14 km² parcel of land bounded by 1st Street to the south, Temple Street to the north, and Beaudry St. to the east. This location is over a shallow oilfield that has an outcrop to the surface just north of the building site. Furthermore, major faults criss-cross the area as illustrated in Fig. 6 (California Division of Oil and Gas 1991). The area is also part of the Elysian Park blind thrust fault system that has a generally east-west trend, which helps explain the uplifting and tilting of petroliferous formation depicted in Fig. 6.

Oil wells in the area continue to produce from shallow oil deposits at a depth no greater than 213 m. Most of the wells were drilled in the early 1900s, and continue to produce. All of the oilfield production gases are released to the atmosphere in the residential areas surrounding the wells. This includes four operational wells at the northwest corner of the school property.

Environmental studies, undertaken only after construction was undertaken, have revealed oilfield gas seepage to the surface over most of the 0.14 km² parcel, including the area directly under the school buildings. The project was abruptly halted when gas seepage was detected in the main electrical vault room of the project, just before the power was to be energized.

Soil gas studies revealed that methane (explosive levels) and other gases are migrating to the surface, including hydrogen sulfide. Measurements at the wellhead, and at other seep locations, revealed releases to the air of over 300 parts per million (ppm) of hydrogen sulfide. At depth, hydrogen sulfide was measured at over 3,000 ppm. These alarming results were extensively evaluated by the authors herein, and commented on during the many environmental reviews for the project (Endres 1999, 2002).

Over \$175 million has been spent on the project by the Los Angeles Unified School District. At least \$20 million has been spent on environmental site characterization alone. A double passive membrane has been proposed to be installed over the entire 0.14 km² site. One expert proposed drilling of a slant well to intercept the main avenue of gas migration (fault) and, thus, divert the direction of gas movement.

A recent discovery of surface faulting extending under several of the school buildings has placed a further halt on construction, and may doom the entire project.

This case history clearly identifies the extreme caution needed in evaluating the environmental suitability of sites located over oilfields, especially for school construction. The State of California has passed recent legislation that requires direct participation by the Department of Toxic Substances Control (DTSC) in the future school site selection process in order to avoid a repeat of the Belmont failure.

Subsidence problems caused by oilfield fluids production

One of the most serious environmental problems caused by oilfield operations within the Los Angeles Basin has been subsidence (Chilingarian and others 1995). Subsidence exists in virtually every oilfield within the Los Angeles Basin (Wentworth and others 1969). Subsidence is caused by the reduction of pore pressure within the reservoir resulting from fluids production. The resulting increase in the effective stress causes compaction which is propagated to the surface, typically causing a bowl-shaped subsidence at the surface, centered over the oilfield (see Fig. 7). The subsidence area is approximately twice the size of the oilfield itself (Khilyuk and others 2000). The enormity of the problem is well known for the Wilmington Oilfield that reached approximately 8.5 m before corrective action was taken by implementing a massive water injection program. This required legislative action in order to bring about a unitization of the oilfield to allow the flooding water program to be implemented. It has also become the public policy of the State of California to arrest subsidence, especially in coastal areas, through the use of water injection.

Minimizing the consequences of subsidence requires implementing a subsidence-monitoring program. The standard in use today in oilfields throughout the world (Endres and others 1991) is the Global Positioning Satellite System (GPS). The disasters of the past can be directly traced to the failure to perform adequate monitoring for subsidence. Conventional surveying and now satellite geodesy, permit determination of vertical and horizontal movements of the land surface above oilfields with great accuracy and at relatively minimal cost.

The Baldwin Hills reservoir failure of 1963

On December 14, 1963, at about 11:15 a.m., an unprecedented flow of water was heard in the spillway pipe at Baldwin Hills Dam in the Inglewood Oilfield area of Los Angeles. A short time later water broke violently through the downstream face of the dam, causing massive property damage to homes located below the dam and five deaths. The owner, the Los Angeles Department of Water and Power, had operated the dam continuously from July 1951 until its failure on December 14, 1963. Although an ongoing surveillance for leaks within spillways was carried out, no monitoring for oilfield subsidence was undertaken. The Inglewood Oilfield, discovered in September 1924, lies under the western half of the Baldwin Hills area. It covers about 4.9 km² and in 1963 had more than 600 producing wells (see Fig. 8). The field adjoins the reservoir site on the south and west, the nearest reported production at the time of the reservoir failure being from three wells within 213 m of the south rim.

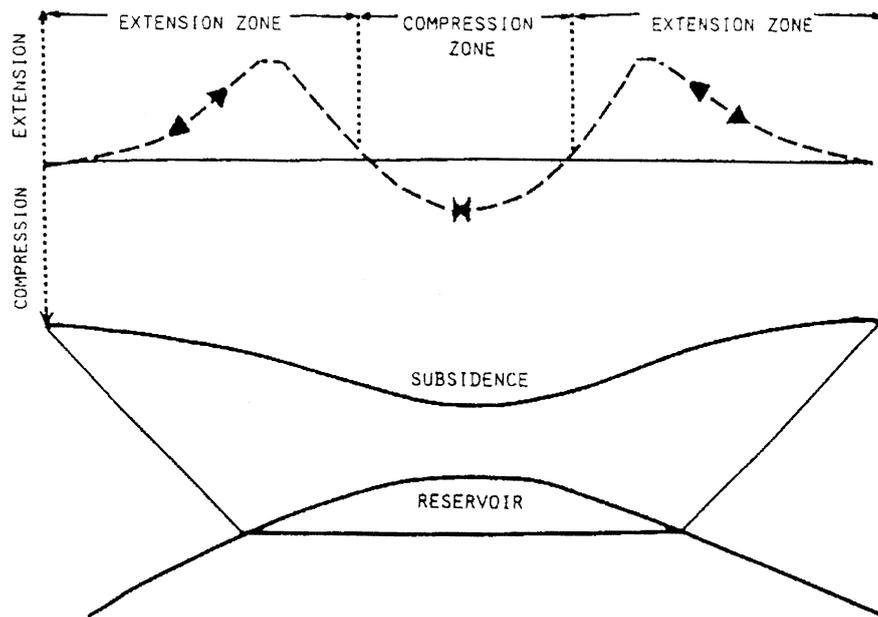

Fig. 7

Schematic diagram of compressive and tensile stress distribution in subsiding formation (modified after Gurevich and Chilingarian 1993, Fig. 1, p. 244)

Analysis of failure revealed ground movement that correlated directly with the Inglewood Oilfield fluids production (see Fig. 9). The total area of subsidence resembled an elliptical bowl with its center about 805 m west of the reservoir and centered over the oilfield. Subsidence at the reservoir site was about 0.9 m, compared to nearly 3.4 m at the subsidence bowl. Noteworthy was the fact that the southwest corner (viz., direction of maximum subsidence) had dropped more than the northeast corner, resulting in differential settlement across the dam of approximately 0.15 m. Furthermore, a review of survey data from 1934 to 1961 and 1963 showed lateral movement in the direction of subsidence depression.

The Inglewood-Newport Beach active strike-slip fault also bisects the area (see Fig. 8), with numerous faults branching off of the main fault in the area. Drilling records clearly reveal these many branching faults, indicating the enormous potential for differential movement along individual fault blocks. Indeed, a post-accident investigation revealed that differential fault block movement had caused rupturing of the asphaltic membrane used as a water seal over the floor of the dam.

Although fluid extraction and resultant subsidence were the prime contributors to the rupture of the reservoir, there is substantial evidence to indicate that water injection to stimulate oil production was also a contributing factor (Hamilton and Meehan 1971). Increased fluid pressures in the reservoir resulting from secondary recovery were sufficient to force brine water to the surface along faults. These forces, along with the lubricating influence of the water exacerbated differential movement along the individual fault blocks.

Recently, a large housing development was proposed for the Baldwin Hills area, virtually over the above described subsidence area. Large retaining walls (exceptionally high) were contemplated to enhance views (and presumably to add value to the individual lots). These retaining walls would have been extremely vulnerable to geologically

active and subsidence-prone area. When the developer became aware of the history of land movement in the area from ongoing oilfield production, the property was sold to the State for use as a public park.

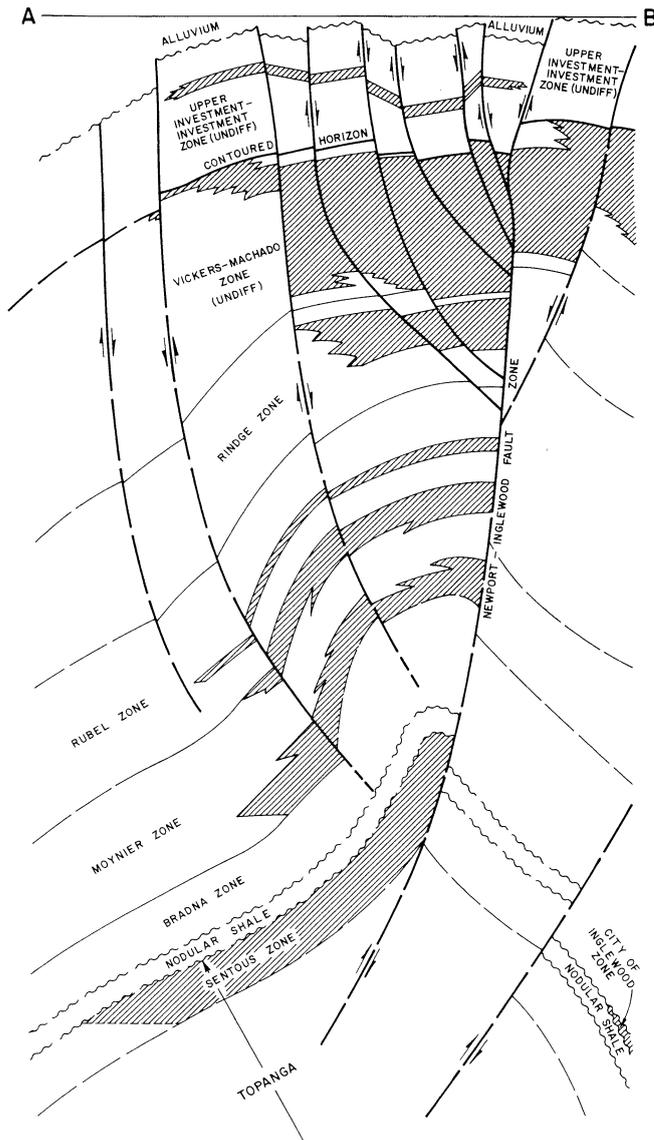

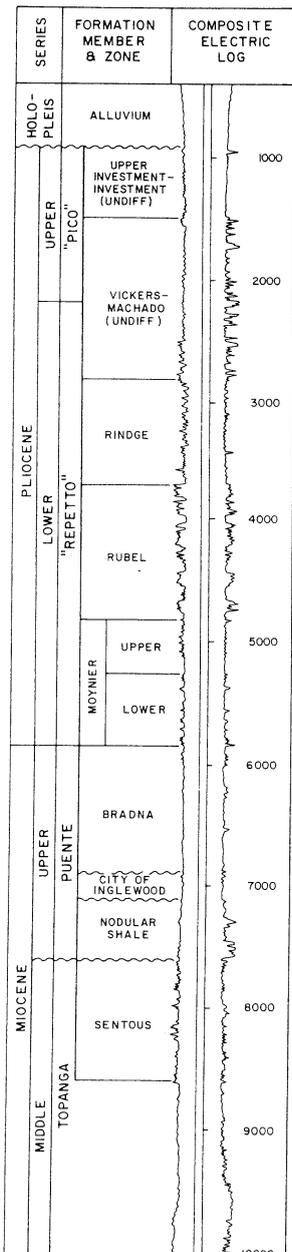

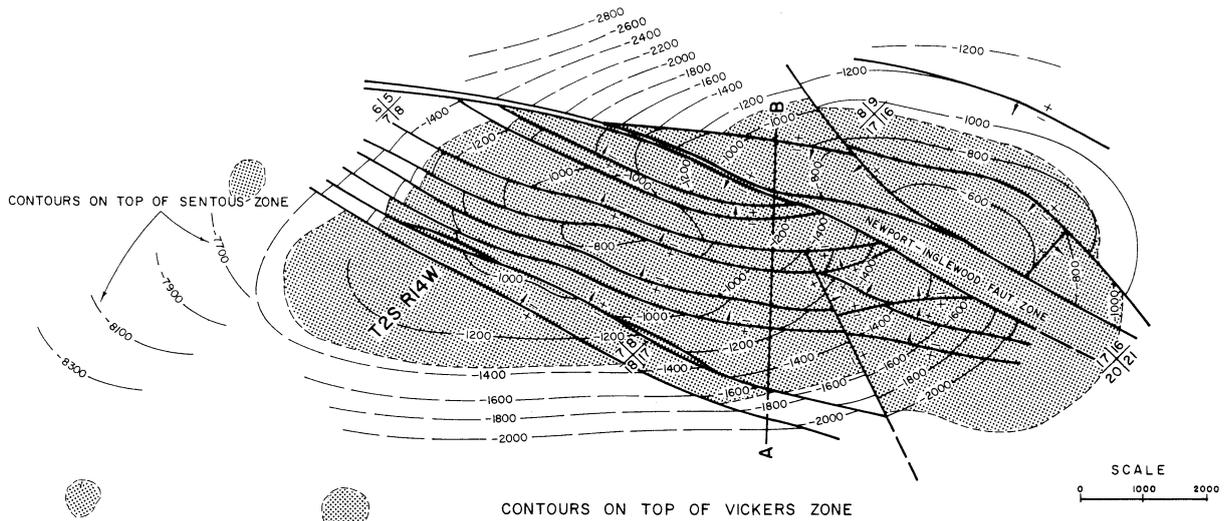

This case history highlights the importance of proper planning and monitoring of the land movement in an area that has been heavily impacted by major faulting, oilfield subsidence, and secondary recovery.

Redondo Beach, King Harbor subsidence

During a winter storm in January 1988, waves overtopped the breakwater constructed by the U.S. Army Corps of Engineers in order to protect the Redondo Beach King Harbor Boat Marina and surrounding commercial structures. Enormous damage resulted, including the destruction of the Portofino Inn. King Harbor is located at the northwest end of the Torrance Oil Field, directly over the Redondo Beach Oilfield (which is considered an extension of the Torrance Oilfield). The City of Redondo Beach had granted permission for offshore drilling from slant wells in that city.

The heights of benchmarks (used by the U.S. Army Corps of Engineers to construct the breakwater) were based on a U.S. Coast and Geodetic Survey of 1945. These benchmarks were assumed fixed, because the Corps of Engineers did not suspect subsidence until 1985, when surveys showed the breakwater crests to be as much as 0.6 to 0.9 m above the original design elevations. Apparently, nothing was done to protect the harbor, or to warn the commercial establishments prior to the storm of January 1988.

Investigation following the disaster revealed that nearly 0.6 m of subsidence had occurred under the breakwater as a result of oil production beginning in 1943, but with

INGLEWOOD OIL FIELD

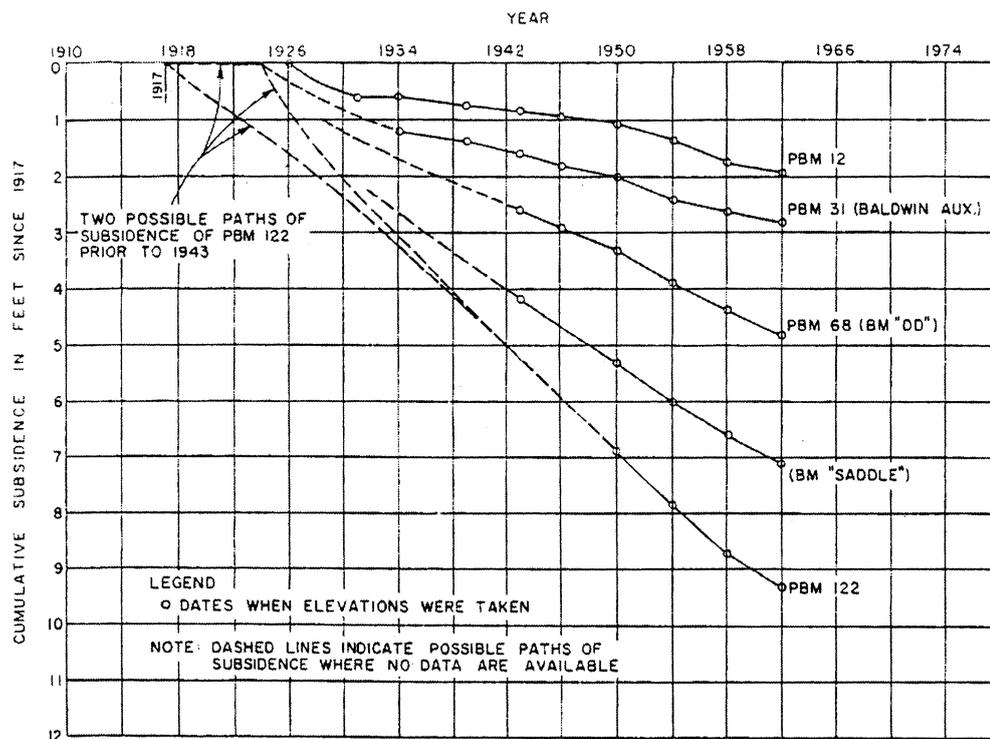

Fig. 9
Subsidence of benchmarks, Baldwin Hills area, Los Angeles, California (after California Department of Water Resources, Baldwin Hills Reservoir, Apr. 1964)

accelerated subsidence occurring after the approval of tideland oil production in 1956.

A jury trial in the Torrance Superior Court resulted in a multi-million dollar judgment against the U.S. Army Corps of Engineers and the City of Redondo Beach. Several oil companies involved in the oil production settled prior to the case going to trial.

The main lesson to be learned is that this disaster could have been averted if proper monitoring for subsidence had been undertaken. It is important to note that the judgment was upheld on appeal, in which the Appellate Court found that undertaking oilfield production in such an urban setting constituted an ultra hazardous activity, requiring the utmost standard of care. Virtually every oilfield in the Los Angeles Basin has experienced subsidence as a result of fluid production. Accordingly, an appropriate standard of care for all oilfield operators should be to undertake monitoring from the onset of production.

Playa Del Rey/Marina Del Rey subsidence

Historical measurement data regarding subsidence in the Playa del Rey/Venice oilfield areas reveal almost 0.6 m of subsidence from the time that oil production began in the 1920s and through 1970. However, no subsidence

Fig. 8

Structural contour map of the Inglewood Oilfield, Los Angeles, California. Contours are on top of the Vickers Zone (after California Division of Oil and Gas 1991)

monitoring has occurred since 1970, despite the fact that fluid production has continued to the present. The Marina del Rey breakwater is vulnerable to subsidence, as is the coastal area.

The most vulnerable are the old wells that were drilled and completed in the 1930s. Any damage to the oil wells (including cements) due to movement along faults present the potential for increased gas migration to the surface. This is especially critical because the oilfields underlying the area are being used to store high-pressure gas transported in from out of the State of California. Figure 10 is presented to illustrate the interrelationship among earthquakes, gas migration, and subsidence resulting from oilfield production (Chilingarian and others 1995; Gurevich and others 1993).

Clearly, these oilfield operations required the utmost degree of vigilance in order to protect the high-density urban development in the area. Monitoring for subsidence and gas migration is essential in order to meet this standard of care.

The release of air toxics from surface operations, wellheads and pipelines

The Federal Environmental Protection Agency (EPA) has determined that the primary hazardous air pollutants (HAP) emitted from oil and natural gas transmission and storage facilities are (see Federal Register, Volume 63, No.25/Feb.6, 1998):

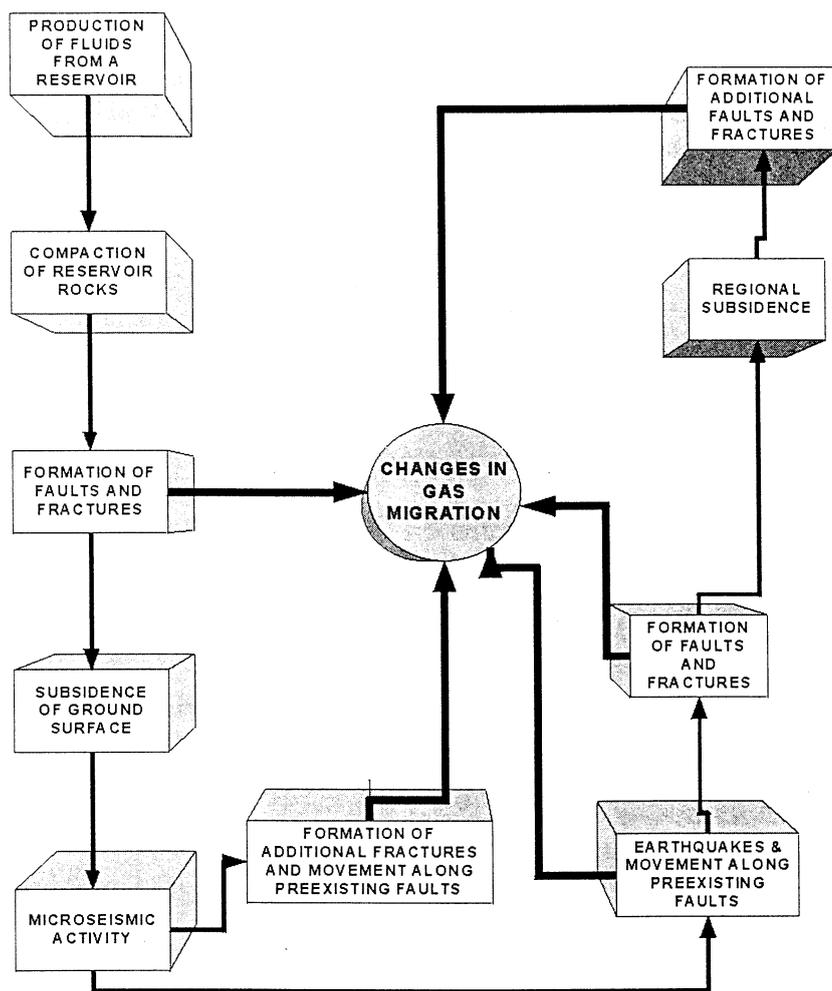

Fig. 10

Schematic diagram of system relationships among the production of fluids, compaction, subsidence, and seismic activity (Modified after Chilingarian and others 1995, Fig. 1, p. 41)

1. Benzene
2. Toluene
3. Ethylbenzene
4. Xylenes

These compounds are collectively referred to as the BTEX chemicals. The BTEX chemicals are the aromatic components of crude oil. For a further discussion of these hazardous components of crude oil see McMillen and others (2001). Although crude oil has variable contents of aromatic hydrocarbons, depending upon the origin, the API rating of the crude oil can be a good predictor of the content of aromatics, especially benzene (see Fig. 11). The higher the API gravity of the crude oil, the higher the percentage of aromatics in the crude oil.

Tissot and Welte (1978) found that 95% of the crude oils produced around the world fell into the distribution pattern shown in Fig. 12. As an example, the composition of a 35^o API-gravity crude oil is as follows (Hunt 1979):

| Molecular type | Weight percent |
|----------------|----------------|
| Paraffins | 25 |
| Naphthenes | 50 |
| Aromatics | 17 |
| Asphaltenes | 8 |
| Total | 100 |

The majority of crude oils have been reported to contain 15 to 40% aromatics. The aromatics are characterized by a double carbon bond, which has been directly linked to the health hazards posed by these chemicals. Benzene, a known human carcinogen, has been linked in the medical literature to leukemia, aplastic anemia, lymphomas and a variety of other cancer related ailments.

Oil and gas production facilities are required to provide warnings to the public regarding certain hazardous oilfield chemicals, including benzene and toluene, under California Health and Safety Code Section 25249.6 (otherwise known as Proposition 65).

Most facilities are not required to identify the amount or the specific types of chemicals being released to the atmosphere from their operations. The Federal EPA has identified dehydration equipment as a major source of benzene and toluene air toxics emissions, and has proposed legislation to curtail such emissions, especially in residential areas.

Venting of oilfield gases to the atmosphere must be viewed as a hazardous activity, because the oilfield gases can contain appreciable levels of benzene. Oilfield gases and condensates have the highest contents of benzene. A typical content of benzene in the oilfield gases can vary between 30 parts per million (ppm) to over 800 ppm. For this reason, the natural gas should be carefully tested for its benzene content before venting of large quantities of

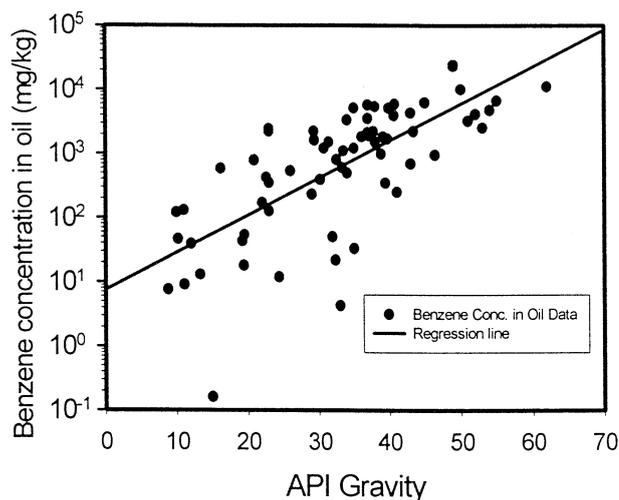

Fig. 11

Benzene concentrations versus API gravity for 61 crude oils and 14 condensates (API gravity data were unavailable for eight crude oils) (after Rixey 2001)

gas is undertaken. Also, vent stack emissions should be carefully monitored. Additional concerns and precautions must be taken in and around sour oilfield operations. Hydrogen sulfide, even in small quantities, can be hazardous to the health. The research conducted at the University of Southern California Medical Facility (Kilburn 1998, 1999) has established central nervous system damage from the neurotoxin effects of hydrogen sulfide even at concentration in air as low as 1 ppm. This is much lower than the workplace standards that have been considered safe in the past. This also highlights the importance of not relying upon workplace standards regarding air toxics emissions in the case of residential areas and school sites. Safety, health, and environmental considerations need to be made a top priority in the land use planning where urban development coexists with the oil- and gas-field operations.

Conclusions

The history of the Los Angeles Basin oilfields has demonstrated the need to exercise a high degree of vigilance regarding the environmental hazards posed by these operations. Land use planning and governmental entity decisions regarding allowing massive real estate development over and adjacent to these operations sometime ignored the health and safety risks posed by these operations. The primary purpose of this paper has been to show the importance of reviewing a long history of environmental problems created by this mixed land usage, and to identify what steps need to be taken to avert future disasters. This includes the necessity of taking the following steps:

Gas migration monitoring: Much closer attention must be given to the need to perform ongoing monitoring for gas migration into the near surface soils in areas heavily impacted by historical oil production, and where there are many old and abandoned wells. It is very important to monitor gas migration near the fault zones.

Subsidence monitoring: Monitoring for subsidence in the oil and gas producing areas is necessary in order to protect against the undermining of foundations and highly sensitive changes in elevation (especially in coastal areas), and to reduce the risk of gas migration hazards. Subsidence gives rise to faults and fractured zones, which are avenues for gas migration.

Air Toxics monitoring: The release of air toxics from surface operations, wellheads and pipelines must be carefully monitored in order to protect the public health, especially from the release of such chemicals as benzene, toluene, ethylbenzene, xylene (viz., the BTEX aromatic hydrocarbons) and hydrogen sulfide. Great caution is required in the operation of vapor recovery equipment and in the monitoring of toxic emissions in order to take corrective action.

Soil and groundwater monitoring: Soil and groundwater must be carefully evaluated for petroleum and drilling

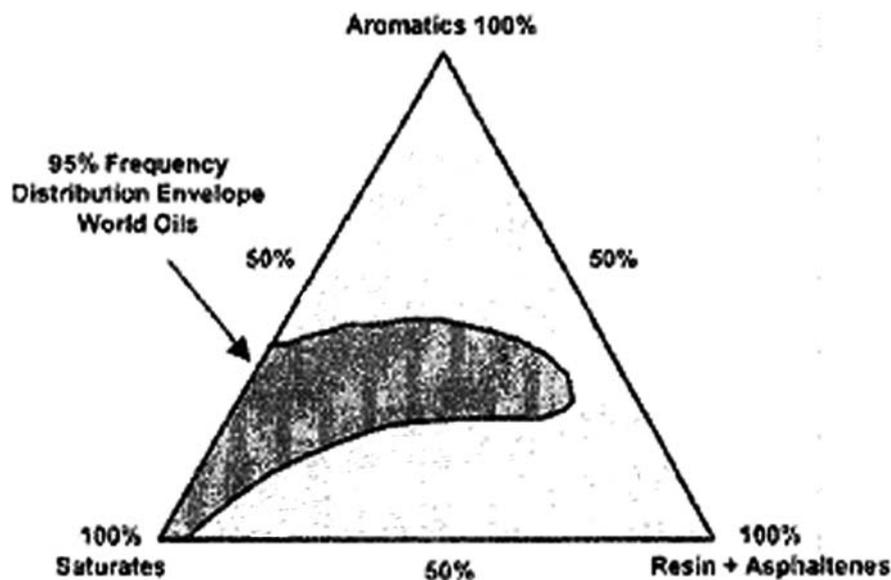

Fig. 12

Ternary diagram showing the class composition of crude oils (after Tissot and Welte 1978)

mud contamination, and appropriate steps must be taken to remediate the soil and water contamination before development is allowed to proceed. This requires an evaluation of the underlying aquifers, which become a ready target for the oil and gas migration hazards.

Soil gas monitoring: Soil gas monitoring is an essential step in the evaluation of soil and aquifer contamination by historic oil and gas field operations. It is also necessary to determine what mitigation measures may be necessary to protect against migration of explosive and toxic oilfield gases into residential and commercial structures. This will be an ongoing problem in many areas that must employ gas detectors, vent pipes, membrane barriers and ventilation systems in order to protect against the gas migration hazards.

Oil and gas well leaks and ongoing monitoring: Oil and gas wells must be carefully evaluated, and old wells must be abandoned to protect against the risk of oilfield gases migrating up the old wellbores and entering the near-surface environment. There has been a long history of this very serious problem, establishing that the prior well abandonment procedures have been often inadequate in dealing with this extremely dangerous problem.

Building over abandoned wells: Land planning and issuance of building permits should require adequate room to provide access for a drilling rig to reenter old wells, when they begin leaking.

As a final conclusion, the authors would like to quote the editorial of Professor George V. Chilingar, Founder of Journal of Petroleum Science and Engineering and Managing Editor (*J Petrol Sci Eng* 9:237): "... Underground gas storage and oil and gas production in urban areas can be conducted safely if proper procedures are followed." "After recognition of the existing problem, proper safe operating procedures can be easily developed."

REQUIREMENTS FOR CALIFORNIA UNDERGROUND GAS STORAGE PROJECTS

DISCUSSION DRAFT

CALIFORNIA CODE OF REGULATIONS, TITLE 14 CHAPTER 4. DEVELOPMENT, REGULATION, AND CONSERVATION OF OIL AND GAS RESOURCES

Subchapter 1. Onshore Well Regulations

[SECTION 1724.9 IS DELETED]

NEW ARTICLE ADDED:

Article 4. Requirements for Underground Gas Storage Projects

1726. Purpose, Scope, and Applicability.

The purpose of this article is to set forth regulations governing underground gas storage projects. Underground gas storage projects and gas storage wells are not subject to the requirements of Sections 1724.6 through 1724.10.

AUTHORITY:

Note: Authority cited: Sections 3013 and 3106, Public Resources Code. Reference: Section 3106, 3220 and 3403.5 Public Resources Code.

1726.1. Definitions.

(a) The following definitions are applicable to this article:

(1) "Area of review" means the volumetric vertical and horizontal extent of the reservoir used for underground gas storage and surrounding areas that may be subject to its influence. The area of review is delineated by the geologic extent of the reservoir such as impervious rock, structural closure, decrease or loss of porosity and permeability, or hydrodynamic forces in a three dimensional image.

(2) "Caprock" means the rock layer or layers at the upper boundary of the storage reservoir acting as the primary barrier preventing upward migration of fluids.

(3) "Fluid" means liquid or gas.

(4) "Gas storage well" means a well used to inject or withdraw gas from an underground storage project.

(5) "Reservoir" means the hydrocarbon reservoir that is being used to store natural gas in an underground gas storage project. The entire depth interval of a reservoir from the shallowest to the deepest depth can be subdivided into one or more depth intervals, which are referred to in this article as "zones".

(6) "Underground gas storage project" means a project for the injection and withdrawal of natural gas into an underground reservoir for the purpose of storage. An underground gas storage project includes the reservoir used for storage, the confining caprock, gas storage wells, observation wells, and any other wells approved for use in the project. A gas storage project also includes the wellheads and, to the extent that they are subject to regulation by the Division, attendant facilities, and other appurtenances.

AUTHORITY:

Note: Authority cited: Sections 3013 and 3106, Public Resources Code. Reference: Section 3106, 3220 and 3403.5 Public Resources Code.

1726.2. Approval of Underground Gas Storage Projects.

(a) A Project Approval Letter shall be obtained from the Division before any injection occurs as part of an underground gas storage project. The Project Approval Letter shall specify the location and nature of the underground gas storage project, as well as the conditions of the Division's approval. Changes to the operational parameters of an underground gas storage project are subject to approval by the Division and shall be noted in either an addendum to the Project Approval Letter or a revised Project Approval Letter. Underground gas storage project operations shall not occur or continue unless consistent with the terms and conditions of a current Project Approval Letter.

(b) The Division will review underground gas storage projects to verify adherence to the terms and conditions of the Project Approval Letter, and will periodically review the terms and conditions of the Project Approval Letter to ensure that they effectively prevent damage to life, health, property, and natural resources. Ongoing approval of an underground gas storage project is at the Division's discretion and a Project Approval Letter is subject to suspension, modification, or rescission by the Division.

(c) If the Division determines that operation of an underground gas storage project is inconsistent with the terms and conditions of a current Project Approval Letter, or otherwise poses a threat to life, health, property, or natural resources, then upon written notice from the Division specified operations shall cease immediately, or as soon as it is safe to do so.

AUTHORITY:

Note: Authority cited: Sections 3013 and 3106, Public Resources Code. Reference: Section 3106, 3220 and 3403.5 Public Resources Code.

1726.3. Risk Management Plans.

(a) For each underground gas storage project, the operator shall submit a Risk Management Plan to the Division for review and approval. The Risk Management Plan shall identify potential threats and hazards to well and reservoir integrity, as well as life, health, property, and natural resources; assess risks based on potential severity and estimated likelihood of occurrence of each threat; identify the preventive and monitoring processes employed to mitigate each risk identified as well as overall and integrated risks; and specify a process for periodic review and reassessment of the risk assessment and prevention protocols. Risk assessment and prevention protocols shall be consistent with and additional to any other existing requirement in statute or regulation. The operator shall state what method and guidance it has followed in preparing the risk assessment. The Risk Management Plan shall specify a schedule for submission of risk assessment results to the Division. All Risk Management Plans shall include at least the following risk assessment and prevention protocols:

(1) Well construction and design standards, consistent with the requirements of Section 1726.5. If the operator has gas storage wells that are not in conformance with the requirements of Section 1726.5, then the Risk Management Plan shall include a work plan for either bringing the wells into conformance or phasing the wells out of use.

(2) For each gas storage well, employment as appropriate of surface and/or subsurface automatic or remote-actuated safety valves based on the following:

(A) The well's distance from dwellings, other buildings intended for human occupancy, or other well-defined outside areas where people may assemble such as campgrounds, recreational areas, or playgrounds;

(B) Gas composition, total fluid flow, and maximum flow potential;

(C) The distance between wellheads or between a wellhead and other facilities, and access availability for drilling and service rigs and emergency services;

(D) The risks created by installation and servicing requirements of safety valves;

(E) The risks to and from the well related to roadways, rights of way, railways, airports, and industrial facilities;

(F) Proximity to environmentally or culturally sensitive areas;

(G) Alternative protection measures which could be afforded by barricades or distance or other measures;

(H) Age of well;

(I) The risks of well sabotage;

(J) The current and predicted development of the surrounding area, topography and regional drainage systems and environmental considerations; and

(K) Evaluation of geologic hazards such as seismicity, active faults, landslides, subsidence, and potential for tsunamis.

(3) Ongoing verification and demonstration of the mechanical integrity of each well used in the underground gas storage project and each well that intersects the reservoir used for gas storage. The mechanical integrity testing protocols for gas storage wells shall, at a minimum, adhere to the requirements of Section 1726.6.

- (4) Corrosion monitoring and evaluation including the following:
 - (A) Evaluation of tubular integrity and identification of defects caused by corrosion or other chemical or mechanical damage;
 - (B) Corrosion potential of wellbore produced fluids and solids, including the impact of operating pressure on the corrosion potential of wellbore fluids and analysis of partial pressures;
 - (C) Corrosion potential of annular and packer fluid;
 - (D) Corrosion potential of current flows associated with cathodic protection systems;
 - (E) Corrosion potential of all formation fluids, including fluids in formations above the storage zone; and
 - (F) Corrosion potential of uncemented casing.
 - (5) Ongoing evaluation of gas storage wells including monitoring of casing pressure changes at the wellhead, analysis of facility flow erosion, hydrate potential, individual facility component capacity and fluid disposal capability at intended gas and liquid rates and pressures, and analysis of the specific impacts that the intended operating pressure range could have on the corrosive potential of fluids in the system.
 - (6) Material balance monitoring in accordance with the requirements of Section 1726.7(b).
 - (7) Ongoing verification and demonstration of the integrity of the reservoir including demonstration that reservoir integrity will not be adversely impacted by operating conditions.
 - (8) Identification of potential threats and hazards associated with operation of the underground gas storage project including the following:
 - (A) Evaluation of likelihood of events and consequences related to the events;
 - (B) Determination of risk ranking to develop preventive and mitigating measures to monitor or reduce risk;
 - (C) Documentation of risk evaluation and description of the basis for selection of preventive and mitigating measures;
 - (D) Provision for data feedback and validation;
 - (E) Regular, periodic risk assessment reviews to update information and evaluate risk management effectiveness; and
 - (F) Analysis and risk assessment of geologic hazards including, and not limited to seismicity, faults, subsidence, inundation by tsunamis, sea level rise, and floods.
 - (G) Analysis and risk assessment of hazards associated with the potential for fire.
 - (9) If observation wells are employed, identification and documentation of baseline conditions such as wellbore pressure, pressure of monitored annuli, gas composition and liquid level.
 - (10) Consideration of potential for impacts to groundwater quality resulting from operations of the underground gas storage project.
 - (11) Prioritization of risk mitigation efforts based on potential severity and estimated likelihood of occurrence of each threat.
 - (12) An emergency response plan that accounts for the threats and hazards identified in the Risk Management Plan and that complies with the requirements of Section 1726.9.
- (b) The Division will make completed Risk Management Plans and significant updates to the Risk Management Plans available to the California Public Utilities Commission. If any part of a

Risk Management Plan is subject to confidential treatment, then the Division will segregate the confidential records and only provide them if the California Public Utilities Commission has agreed to treat the records as confidential.

1726.4. Underground Gas Storage Project Data Requirements.

(a) For all underground gas storage projects, the operator shall provide the Division with data, analysis, and interpretation that demonstrate to the Division's satisfaction that stored gas will be confined to the approved zone(s) of injection and that the underground gas storage project will not cause damage to life, health, property, or natural resources. The operator shall provide the data specified in this section and any data that, in the judgment of the Supervisor, are pertinent and necessary for the proper evaluation of the proposed project. The data provided by the operator shall be to a level of detail and certainty satisfactory to the Division, and the operator shall ensure that required data is complete and current, regardless of the date of approval of the gas storage project. The data submitted to the Division shall include the following:

(1) Oil and gas reserves of all proposed storage zones prior to start of injection, including calculations, to indicate the storage capacity of the reservoir being considered for gas storage.

(2) Description of existing or proposed surface and subsurface safety devices, tests, and precautions to be taken to ensure safety of the project.

(3) Proposed produced water disposal method.

(4) Maximum and minimum reservoir pressure for the underground gas storage project and the data and calculations supporting the bases for the pressure limits. The pressure limits shall account for the following:

(A) The pressure required to inject fluids, particularly at total inventory, shall not exceed the design pressure limits of the reservoir, caprock, wells, well heads, piping or associated facilities.

(B) The minimum reservoir pressure shall take into account the historic minimum operating pressure and reservoir geomechanical competency. The impacts of intended minimum reservoir pressure shall be accounted for as it relates to geomechanical stress and liquid influx.

(5) An engineering and geological study demonstrating that injected gas will not migrate out of the approved zone or zones, such as through another well, geologic structure, faults, fractures or fissures, or holes in casing. The study shall include, but is not limited to:

(A) Statement of primary purpose of the project.

(B) Reservoir characteristics of each injection zone, such as porosity, permeability, average thickness, areal extent, fracture gradient, original and present temperature and pressure, and original and residual oil, gas, and water saturations.

(C) A comprehensive geologic characterization of the gas storage project including lithology of the storage zone or zones and sealing mechanisms as well as all formations encountered from surface to the deepest well in the project. The geologic characterization shall include any

information that may be required to ensure injected or withdrawn gas does not have an adverse effect on the project or pose a threat to life, health, property or natural resources. The geologic characterization shall include potential pathways for gas migration and areas or formations where potential entrapment of migrated gas could occur. Information to accompany the geologic study shall include but is not limited to:

- (i) Structure contour maps drawn on a geologic marker at or near the top of each gas storage zone in the project area, indicating faults and other lateral containment features.
- (ii) Isopach map of each gas storage reservoir or subzone in the project area.
- (iii) At least two geologic cross sections through at least four gas storage wells in the project area and the areas immediately adjacent.
- (iv) Representative electric log to a depth below the deepest producing zone identifying all geologic units, formations, aquifers with groundwater that has 10,000 or less milligrams per liter of total dissolved solids content, aquifers with groundwater that has 3,000 or less milligrams per liter of total dissolved solids content, oil or gas zones, and gas storage reservoirs.
- (v) Additional information including, but not limited to: isopach, isoGOR, isoBAR, structure-contour, 3-D, water-oil, or gas-oil ratio maps of the project and other information which will delineate all known features such as faults and fractures within the area of influence of the gas storage project.

(D) Reservoir fluid data for each gas storage zone, such as oil gravity and viscosity, water quality, presence and concentrations of non-hydrocarbon components in the associated gas (e.g. hydrogen sulfide, helium, etc.), and specific gravity of gas.

(E) A map of the area of review showing the location and status of all wells within and adjacent to the boundary of the area of review. The wellbore path of directionally drilled wells shall be shown, with indication of the interval penetrating the gas storage zone(s) of the underground gas storage project.

(F) Casing diagrams, including all data specified in Section 1726.4.1, of all wells that are within the area of review and that are in the same or a deeper zone as the gas storage project, including directionally drilled wells that intersect the area of review in the same or deeper zone. The casing diagrams must demonstrate that the wells in the area will not be a potential conduit for gas to migrate outside of the approved zone of gas storage or otherwise have an adverse effect on the project or cause damage to life, health, property, or natural resources. At a minimum, the casing diagrams must demonstrate that:

- (i) Plugged and abandoned wells have cement across all perforations and extending at least 100 feet above the highest of the top of a landed liner, the uppermost perforations, the casing cementing point, the water shutoff holes, or the intended zone of injection; and
- (ii) Wells that are not plugged and abandoned and that have been inactive for more than two years have cement plugs across all hydrocarbon zones, the base of groundwater that has 10,000 or less milligrams per liter of total dissolved solids content, and groundwater that has 3,000 or less milligrams per liter of total dissolved solids content.

(G) Identification of all wells within the area of review that are not in the same or a deeper zone as the underground gas storage project, including description of the total depth of the well and the estimated top of the gas storage reservoir below the well.

(H) Wells completed in or penetrating through the intended gas storage reservoir shall be identified and evaluated for containment assurance for the design of gas storage operation volumes, pressure, and flow rates. The operator should identify, and the Division confirm, wells which may require integrity testing or well logging in order to meet the integrity demonstration. The Division may select plugged and abandoned wells to be re-entered, examined, re-plugged and abandoned, or monitored to manage identified containment assurance issues prior to approval of gas storage operations.

(I) The planned or estimated well drilling and plugging and abandonment program to complete the project, showing all gas storage wells, plugged and abandoned wells, other wells related to the project, and unit boundaries.

(J) Maps of the locations of underground disposal horizons, mining, and other subsurface industrial activities not associated with oil and gas production or gas storage operations within the area of review, to the extent it is publicly available.

(6) A gas storage injection and withdrawal plan that includes all of the following:

(A) Maximum anticipated surface injection pressure and maximum anticipated daily rate of injection, by well.

(B) Monitoring system or method acceptable to the Division to be utilized to ensure the gas injected is confined to the intended approved zone(s) of injection.

(C) A wellhead monitoring system acceptable to the Division for the detection of leaks.

(D) A list of proposed cathodic protection measures for plant, lines, and wells, where employed.

(E) A summary of the source and analysis of the gas injected, submitted to the Division on an annual basis.

(7) The name and API number of all gas storage wells and other wells that are part of the underground gas storage project.

(8) Any data that, in the judgment of the Supervisor, are pertinent and necessary for the proper evaluation of the underground gas storage project.

(b) Updated data shall be provided to the Division if conditions change or if more accurate data become available.

(c) All data filed with the Division under this section shall be submitted electronically, in a format acceptable to the Division. All maps, diagrams and exhibits shall be clearly labeled as to scale, north arrow, coordinate system, and purpose, and shall clearly identify wells, boundaries, zones, contacts, and other relevant data.

(d) Where it is infeasible to supply the data specified in subdivision (a), the Division may accept alternative data, provided that the alternative data demonstrate to the Division's satisfaction that injected gas will be confined to the approved reservoir or reservoirs of injection and that the underground gas storage project will not cause damage to life, health, property, or natural resources.

(e) The operator shall consult with the Division if the operator believes that there is a basis under state or federal law for confidential treatment of any data submitted to the Division. If the Division agrees that there is a basis for confidential treatment of data submitted, then the Division will take appropriate steps to maintain the confidentiality of that data.

(f) The Division will make all data received under this section available to the California Public Utilities Commission upon request. If the requested records are subject to confidential treatment, then the Division will only provide the records if the California Public Utilities Commission has agreed to treat the records as confidential.

AUTHORITY:

Note: Authority cited: Sections 3013 and 3106, Public Resources Code. Reference: Section 3106, 3220 and 3403.5 Public Resources Code.

1726.4.1. Casing Diagrams.

(a) Casing diagrams submitted under Section 1726.4 shall adhere to the following requirements:

(1) Casing diagrams shall include all of the following data:

(A) Operator, lease name, well number, and API number of the well;

(B) Ground elevation from sea level;

(C) Reference elevation (i.e. rig floor or Kelly Bushing);

(D) Base of groundwater that has 3,000 or less milligrams per liter of total dissolved solids content;

(E) Base of groundwater that has 10,000 or less milligrams per liter of total dissolved solids content;

(F) Sizes, weights, grades, and connection types of casing and tubing;

(G) Details on associated equipment such as subsurface safety valves, packers, gas lift mandrels;

(H) Depths of shoes, stubs, and liner tops;

(I) Depths of perforation intervals, water shutoff holes, cement port, cavity shots, cuts, patches, casing damage, top of junk or fish left in well, and any other feature that influences flow in the well or may compromise the mechanical integrity of the well;

(J) Drill bit size diameter and depth of drilled hole;

(K) Cement plugs inside casings, including top and bottom of cement plug, with method of determination;

(L) All cement fill behind casings, including top and bottom of cemented interval, with method of determination;

(M) Type and weight (density) of fluid between cement plugs;

(N) Depths and names of the formation(s), zone(s), and geologic markers penetrated by the well, including the top and bottom of the gas storage zone(s);

(O) All information used to calculate the cement slurry (volume, density, yield), including but not limited to, cement type and additives, for each cement job; and

(P) All of the information listed in this paragraph for all previous drilled or sidetracked well bores.

(2) Measured depth and true vertical depth shall be provided for all measurements required under subdivision (a)(1).

(3) For directionally drilled wells, a directional survey shall be provided with inclination, azimuth measurements, and surface location.

(4) Casing diagrams shall be submitted in an electronic format acceptable to the Division.

(5) For all wells to be used for gas injection and/or withdrawal, the casing diagram shall include the mechanical well barrier elements that comprise the primary and secondary barriers as specified in section 1726.5.

AUTHORITY:

Note: Authority cited: Sections 3013 and 3106, Public Resources Code. Reference: Section 3106, 3220 and 3403.5 Public Resources Code.

1726.5. Well Construction Requirements.

(a) Operators shall design, construct, and maintain gas storage wells to effectively ensure mechanical integrity under anticipated operating conditions for the underground gas storage project. The operator shall ensure that a single point of failure does not pose an immediate threat of loss of control of fluids and make certain that integrity concerns with a gas storage well are identified and addressed before they can become a threat to life, health, property, or natural resources.

(b) Operators can demonstrate that a gas storage well adheres to the performance standard in subdivision (a) by demonstrating all of the following:

(1) The well has been completed with both primary and secondary mechanical well barriers to isolate the storage gas within the storage reservoir and transfer storage gas from the surface into and out of the storage reservoir.

(A) At minimum, the primary mechanical barrier shall be comprised of the following elements:

(i) Production casing to surface with the required integrity to contain reservoir pressure;

(ii) Tubing with packer and production tree with the required integrity to contain reservoir pressure; and

(iii) Surface Controlled Subsurface Safety Valve (SCSSV) or Christmas tree valve with the required integrity to contain reservoir pressure that halts flow through the well.

(B) At minimum, the secondary mechanical barrier shall be comprised of the following elements:

(i) Casing cement that overlaps at least 100 feet between two concentric casings, with good quality cement bond;

(ii) Wellhead with annular valves and seals and the required integrity to contain reservoir pressure;

(iii) Casing with hanger and seal assembly;

(iv) Tubing hanger with seals; and

(v) Christmas tree master valve.

(2) Each string of casing is designed to safely contain the expected internal and external pressures and tensile loads.

(3) The surface casing is of sufficient size, weight, grade, competency, and depth to support subsequent drilling operations.

(4) The production casing is of sufficient size, weight, grade, competency, and depth to maintain the well integrity, and is compatible with fluid chemical composition. The production casing is designed to accommodate fluids on injection and withdrawal at the maximum expected pressures and velocities. The production casing is free of open perforations or holes other than the planned completion interval(s). Perforations created for investigative or remedial work are sealed to establish hydraulic isolation.

(5) Casing connections are appropriate for use in the well design and exceed the expected mechanical loads.

(6) The gas storage well is cemented so as to maintain the integrity of the storage zone(s) by providing isolation of the reservoir from communication with other sources of permeability or porosity through the wellbore. Isolation is accomplished by filling the annular space between the casing and formation with competent cement to create a seal so that communication of fluids from the storage zone or other zones of interest is prevented.

(7) The cementing operations used a cement slurry designed for the anticipated wellbore conditions. All casing was cemented in a manner that ensures proper distribution and bonding of cement in the annular spaces. Additionally, cementing operations meet or exceed the following requirements:

(A) Surface casing is cemented with sufficient cement to fill the annular space from the shoe to the surface to protect ground water.

(B) Intermediate and production casings, if not cemented to the surface, are cemented with sufficient cement to fill the annular space to at least 500 feet above the gas storage reservoir, oil and gas zones or anomalous pressure intervals and to at least 100 feet above the base of groundwater that has 3,000 or less milligrams per liter of total dissolved solids content.

(8) Cement plugs provide for effective zonal isolation.

(9) Any remedial cement slurry and placement techniques are designed for the specific wellbore conditions, formations, and type of repairs.

(10) Cement bond log or evaluation acceptable to the Division is on file that indicates an adequate cement bond between the casing, cement and geologic formations. A competent cement bond extends across the caprock, and at least 100 feet above the gas storage reservoir.

(11) For wells equipped with tubing and packer, packer is set in cemented casing within caprock or at a location acceptable to the Division.

(c) If the operator does not demonstrate that a gas storage well meets the criteria of subdivision (b), then the operator shall demonstrate to the Division's satisfaction that an alternative method of well design and construction has been employed that effectively adheres to the performance standard of subdivision (a). The Division will determine on a case-by-case

basis whether the operator has effectively demonstrated that a gas storage well that does not conform to the criteria in subdivision (b) meets the performance standard in subdivision (a).

AUTHORITY:

Note: Authority cited: Sections 3013 and 3106, Public Resources Code. Reference: Section 3106, 3220 and 3403.5 Public Resources Code.

1726.6. Mechanical Integrity Testing.

(a) The operator shall, at a minimum, conduct the following mechanical integrity testing on each gas storage well:

(1) A temperature and noise log shall be conducted at least annually to ensure integrity. All anomalies identified shall be immediately reported to the appropriate district office and explained to the Division's satisfaction.

(2) A casing wall thickness inspection, employing such methods as magnetic flux and ultrasonic technologies, shall be performed at least every two years to determine if there are possible issues with casing integrity. The results shall be compared against prior results and any other available data to determine the corrosion rate. If the casing wall thickness inspection indicate that within the next 24 months thinning of the casing will diminish the casing's ability to contain the well's maximum allowable operating pressure utilizing Barlow's equation or another method acceptable to the Division, then the well shall be remediated and shall not be used for injection or withdrawal without subsequent approval from the Division. The Division may approve a less frequent casing wall thickness inspection schedule for a well if the operator demonstrates to the Division's satisfaction that the well's corrosion rate is low enough that biennial inspection is not necessary.

(3) A pressure test of the production casing shall be conducted at least every two years. If injection in the gas storage well is through tubing and packer, then the pressure test shall be of the casing-tubing annulus of the well. Pressure tests shall be conducted at a pressure at least as high as 115 percent of the maximum operating pressure. A lower testing pressure may be approved by the Division if necessary to ensure that testing does not compromise the mechanical integrity of the well. Pressure testing shall be conducted with liquid unless the Division approves pressure testing with gas. If a pressure test does not indicate a final stabilized pressure and less than 10 percent pressure loss over a minimum 30 minute test, then the well shall not be used for injection or withdrawal without subsequent approval from the Division. The Division may require a longer duration of up to 60 minutes pressure testing based on individual circumstances. The Division may approve a less frequent pressure testing schedule for a well if the operator demonstrates to the Division's satisfaction that other measures to ensure the integrity of the well warrant less frequent pressure testing.

(b) A newly constructed gas storage well, or a reworked gas storage well that has had its existing production casing modified from its previous condition during rework activities, shall be tested as per subdivision (a).

(c) The Division may require additional testing as needed to demonstrate the integrity of the well.

(d) The appropriate district office shall be notified at least 48 hours before performing mechanical integrity testing so that Division staff may have an opportunity to witness the testing. All mechanical integrity testing shall be documented and copies of test results shall be submitted to the Division in an electronic format within 30 days.

AUTHORITY:

Note: Authority cited: Sections 3013 and 3106, Public Resources Code. Reference: Section 3106, 3220 and 3403.5 Public Resources Code.

1726.7. Monitoring Requirements.

(a) In addition to the mechanical integrity testing requirements under Section 1726.6, the operator shall monitor for the presence of annular gas by measuring and recording annular pressure at least once a day. The operator shall evaluate any anomalous annular gas occurrence and report it to the Division. This requirement may be met by employment of a real-time data gathering system, such as Supervisory Control and Data Acquisition.

(b) The material balance behavior of an underground gas storage project's storage reservoir shall be monitored relative to the original design and expected reservoir behavior. Unexpected conditions detected during monitoring shall be evaluated and corrected in order to avoid an incident or loss. Monitoring frequency should be based on factors such as reservoir and well fluid loss potential and flow potential, as outlined in the Risk Management Plan. Material balance support data will be submitted to the Division at least once a year, or upon request. Acceptable reservoir integrity monitoring and analysis methods include any of the following, or an equally effective method approved by the Division:

(1) Monitoring average reservoir pressure versus inventory and comparing that to expected conditions in order to allow for the discovery and correction of any anomalies or unexpected conditions. Liquid level shall be taken into account when utilizing observation wells. Semiannual field shut-in tests, usually conducted at the point of seasonally high and low inventories, shall be conducted for inventory verification.

(2) Installation and monitoring of strategically located observation wells in the vicinity of spill points, within an aquifer, and above the caprock in potential collector formations to detect the presence or movement of gas using methods which can include review of fluid level records, well pressures, geophysical logging, gas composition or other tools and methods deemed appropriate.

(3) Monitoring offset hydrocarbon production or disposal operations for unexplained flow or pressure changes. The monitoring shall include operations in zones above and below the storage reservoir as well as laterally offset locations.

(4) Conducting subsurface correlation and gas identification logs such as gamma ray-neutron logs to confirm the location of gas being injected into the intended storage reservoir, as needed.

(c) The operator of an underground gas storage project shall employ a real-time data gathering system, such as Supervisory Control and Data Acquisition, by January 1, 2020.

(d) The operator shall continually track all wells that are within the area of review and that are in the same or a deeper zone as the gas storage project and ensure that all such wells that are not plugged and abandoned and that have been inactive for more than two years have cement plugs across all hydrocarbon zones, the base of groundwater that has 10,000 or less milligrams per liter of total dissolved solids content, and groundwater that has 3,000 or less milligrams per liter of total dissolved solids content.

(e) The operator of an underground gas storage project shall adhere to an inspection and leak detection protocol that has been approved by the Division. The protocol shall include inspection of the wellhead assembly and attached pipelines for each of the gas storage wells used in association with the underground gas storage project, and the surrounding area within a 100-foot radius of the wellhead of each of the wells used in an underground gas storage project. The inspection protocol shall provide for inspection at least once a day, employing effective gas leak detection technology such as infrared imaging. The operator's selection and usage of gas leak detection technology shall take into consideration detection limits, remote detection of difficult to access locations, response time, reproducibility, accuracy, data transfer capabilities, distance from source, background lighting conditions, geography, and meteorology. The Division will consult with the California Air Resources Board when reviewing an inspection and leak detection protocol submitted under this subdivision. The requirements of this subdivision shall cease to apply if the California Air Resources Board adopt and implement regulations with the same or stricter requirements.

AUTHORITY:

Note: Authority cited: Sections 3013 and 3106, Public Resources Code. Reference: Section 3106, 3220 and 3403.5 Public Resources Code.

1726.8. Inspection, Testing, and Maintenance of Wellheads and Valves.

(a) Where installed, the operator of an underground gas storage project shall test all surface and subsurface safety valve systems to ensure ability to hold anticipated pressure at least every six months. The tests shall be conducted in accordance with American Petroleum Institute Recommended Practice 14B (6th Edition, September 2015), or equivalent, to confirm operational integrity. The appropriate district office shall be notified at least 48 hours before performing testing so that Division staff may witness the operations, and documentation of the testing shall be maintained and available for Division review. A closed storage well safety valve system shall be re-opened with operator staff at the site of the valve to ensure the absence of any unforeseen issues. Within 90 days of finding that a surface or subsurface safety valve is inoperable, the operator shall either repair the safety valve or temporarily plug the well. An appropriate alternative timeframe for testing a valve or addressing an inoperable surface or subsurface safety valve may be approved by the Division.

(b) At least annually, the operator of an underground gas storage project shall test the master valve and wellhead pipeline isolation valve for proper function and verify ability to isolate the well.

(c) The operator shall equip gas storage wells with valves to provide isolation of the wells from the pipeline system and to allow for entry into the wells.

(d) The operator shall equip all ports on the wellhead assembly above the casing bowl of gas storage wells with valves, blind flanges, or similar equipment.

AUTHORITY:

Note: Authority cited: Sections 3013 and 3106, Public Resources Code. Reference: Section 3106, 3220 and 3403.5 Public Resources Code.

1726.9. Emergency Response Plan.

(a) The operator of an underground gas storage project shall have an emergency response plan approved by the Division and ready for immediate implementation. The emergency response plan shall specify a schedule for carrying out drills to validate the plan. The drills shall address the readiness of personnel and their interaction with equipment including required third party service providers and their current contact information.

(b) The emergency response shall at a minimum address the following scenarios:

- (1) Collisions involving well heads;
- (2) Well fires and blowouts;
- (3) Hazardous material spills;
- (4) Equipment failures;
- (5) Natural disasters/emergencies;
- (6) Leaks and well failures;
- (7) Medical emergencies; and
- (8) Explosions.

(c) The emergency response plan shall at a minimum include all of the following:

- (1) Written actions plans establishing assigned authority to the appropriate qualified person(s) at a facility for initiating effective emergency response and control;
- (2) Accident-response measures that outline response activities, leakage mitigation approaches, and well control processes for well failure and full blowout scenarios;
- (3) Protocols for emergency reporting and response to appropriate government agencies
- (4) Specification of personnel roles and responsibilities;
- (5) Internal and external communication protocol;
- (6) Emergency contact information including area codes; and
- (7) Procedures for notification.

REQUIREMENTS FOR UNDERGROUND GAS STORAGE PROJECTS

FINAL TEXT OF EMERGENCY REGULATIONS

Added text is shown in underline.

Deleted text is shown in ~~strikethrough~~.

CHAPTER 4. DEVELOPMENT, REGULATION, AND CONSERVATION OF OIL AND GAS RESOURCES

Subchapter 1. Onshore Well Regulations

Article 3. Requirements

1724.9. Underground Gas Storage Projects

~~The data required by the Division prior to approval of a gas storage project include all applicable items listed in Section 1724.7(a) through (e), and the following, where applicable:~~

(a) For all underground gas storage projects, the operator shall provide the data required under Section 1724.7 and the operator shall comply with the requirements of Section 1724.10, unless the requirement is clearly not applicable to a gas storage project or the Division otherwise advises that the requirement is not applicable to a gas storage project. The operator shall ensure that required project data is complete and current, regardless of the date of approval of the gas storage project. If project data for an existing project is incomplete, then the operator shall submit the required data to the Division as soon as is practicable. In addition to the data required under Section 1724.7, the operator of an underground gas storage project shall provide the Division with the following:

(1) ~~(a)~~ Characteristics, petrophysical properties, mechanical properties, and maps of the cap rock, such as including areal extent, average isopach thickness, structure contour, formation fracture gradient, primary and secondary permeability, lithology and lithologic variation, and threshold pressure, and locations and characteristics of faults and fractures.

~~(2) (b)~~ Oil and gas reserves of storage zones prior to start of injection, including calculations.

~~(3) (c)~~ List of proposed surface and subsurface safety devices, tests, and precautions to be taken to ensure safety of the project.

~~(4) (d)~~ Proposed waste water disposal method.

(b) The Project Approval Letter for an underground gas storage project shall state the maximum and minimum reservoir pressure and include data and calculations supporting the bases for the pressure limits. The pressure limits shall account for the following:

(1) The pressure required to inject intended gas volumes, particularly at total inventory, and the pressure limit shall not exceed the design pressure limits of the reservoir, wells, wellheads, piping or associated facilities.

(2) The minimum reservoir pressure shall not be designed less than historic minimum operated pressure unless reservoir geo-mechanical competency can be demonstrated to the Division's satisfaction. The impacts of intended minimum reservoir pressure shall be accounted for in the data required under subdivision (a)(1) as it relates to geo-mechanical stress, reservoir liquid influx, surface facility gas cleaning and liquid handling, and liquid disposal, all of which affect the maximum reservoir cycling capacity of the storage field and can impact mechanical integrity of the facilities.

(c) In addition to the mechanical integrity testing requirements under 1724.10(j), the operator shall monitor the tubing-casing annulus, if there is one, of each well that is part of an underground gas storage project. The operator shall monitor for presence of annular gas by measuring and recording annular pressure and annular gas flow. Such monitoring shall be done at least once a day when the well is not being used for withdrawal. The operator shall evaluate any anomalous annular gas occurrence and immediately report it to the Division. The operator shall begin complying with this requirement within one month of the effective date of this section.

(d) Where installed, the operator of an underground gas storage project shall function test all surface and subsurface safety valve systems within three months of the effective date of this section, and every six months after that. The tests shall be conducted in accordance with manufacturer's recommendations to confirm operational integrity and mitigate any integrity isolation findings. The appropriate district office shall be notified at least 48 hours before performing testing so that Division staff may witness the operations, and documentation of the testing shall be maintained and available for Division review. A closed storage well safety valve system shall be manually re-opened at the site of the valve after an inspection and not opened from a remote location.

Within 90 days of finding that a surface or subsurface safety valve is inoperable, the operator shall either repair or remove the safety valve or temporarily plug the well. A longer timeframe for addressing an inoperable surface or subsurface safety valve may be approved by the Division.

(e) Within 21 days of the effective date of this section, the operator of an underground gas storage project shall submit an inspection and leak detection protocol to the Division for review and approval. The protocol shall include inspection of the wellhead assembly and attached pipelines for each of the wells used in an underground gas storage project, and the surrounding area within a 100' radius of the wellhead of each of the wells used in an underground gas storage project, unless the operator can demonstrate that some part of that area is obstructed. The inspection protocol shall provide for inspection at least once a day, employing effective gas leak detection technology such as infrared imaging, and shall provide for immediately reporting detected leaks to the Division. The operator's selection and usage of gas leak detection technology shall take into consideration detection limits, remote detection of difficult to access locations, response time, reproducibility, accuracy, data transfer capabilities, distance from source, background lighting conditions, geography, and meteorology. The Division will consult with the California Air Resources Board when reviewing an inspection and leak detection protocol submitted under this subdivision.

(f) Within three months of the effective date of this section, and annually thereafter, the operator of an underground gas storage project shall test the operation of the master valve and wellhead pipeline isolation valve for proper function and verify ability to isolate the well. The operator shall submit documentation of the results of testing done under this subdivision within 10 days of completing the testing, but shall immediately notify the Division if testing indicates a lack of function.

(g) Within six months of the effective date of this section, the operator of an underground gas storage project shall submit a Risk Management Plan to the Division for review and approval. The Risk Management Plan shall identify potential threats and hazards to well and reservoir integrity; assess risks based on potential severity and estimated likelihood of occurrence of each threat; identify the preventive and monitoring processes employed to mitigate the risk associated with each threat; and specify a process for periodic review and reassessment of the risk assessment and prevention protocols. Risk assessment and prevention protocols shall be consistent with and additional to any other existing requirement in statute or regulation. The Risk Management Plan shall specify a schedule for submission of risk assessment results to

the Division. All Risk Management Plans shall include at least the following risk assessment and prevention protocols:

(1) Ongoing verification and demonstration of the mechanical integrity of each well used in the underground gas storage project and each well that intersects the reservoir used for gas storage. The protocols for verifying and demonstrating well integrity shall not be limited to compliance with the mechanical integrity testing requirements under Section 1724.10(j), and shall include consideration of the age, construction, and operation of each well.

(2) Corrosion monitoring and evaluation including consideration of the following:

(A) Evaluation of tubular integrity and identification of defects caused by corrosion or other chemical or mechanical damage;

(B) Corrosion potential of wellbore produced fluids and solids, including the impact of operating pressure on the corrosion potential of wellbore fluids and analysis of partial pressures;

(C) Corrosion potential of annular and packer fluid;

(D) Corrosion potential of current flows associated with cathodic protection systems;

(E) Corrosion potential of all formation fluids, including fluids in formations above the storage zone;

(F) Corrosion potential of uncemented casing annuli; and

(G) Corrosion potential of pipelines and other production facilities attendant to the underground gas storage project.

(3) Protocols for evaluation of wells and attendant production facilities that include monitoring of casing pressure changes at the wellhead, analysis of facility flow erosion, hydrate potential, individual facility component capacity and fluid disposal capability at intended gas and liquid rates and pressures, and analysis of the specific impacts that the intended operating pressure range could have on the corrosive potential of fluids in the system.

(4) Ongoing verification and demonstration of the integrity of the reservoir including demonstration that reservoir integrity will not be adversely impacted by operating conditions.

(5) Identification of potential threats and hazards associated with operation of the underground gas storage project including the following:

(A) Evaluation of likelihood of events and consequences related to the threats and hazards;

___ (B) Determination of risk ranking to develop preventive and mitigating measures to monitor or reduce risk;

___ (C) Documentation of risk evaluation and description of the basis for selection of preventive and mitigating measures;

___ (D) Provision for data feedback and validation; and

___ (E) Regular, periodic risk assessment reviews to update information and evaluate risk management effectiveness.

___ (6) Prioritization of risk mitigation efforts based on potential severity and estimated likelihood of occurrence of each threat.

___ (h) The requirements of this section shall not be construed to replace or restrict an operator's compliance with any specific requirements applicable to pipelines and associated facilities pursuant to Parts 190-199 of Title 49 of the United States Code of Federal Regulations.

DEPARTMENT OF ENVIRONMENTAL PROTECTION
Air Quality

DOCUMENT NUMBER: 275-2101-003

TITLE: Air Quality Permit Exemptions

EFFECTIVE DATES: July 26, 2003,
August 10, 2013 for Category No. 33 and Category No. 38
Exemptions

AUTHORITY: Act of January 8, 1960, P.L. (1959) 2119, No 787, as amended,
known as The Air Pollution Control Act, (35 P.S. § 4001 et seq.)

POLICY: Plan Approval and Operating Permit Exemptions

PURPOSE: The document provides criteria for sources and physical changes to
sources determined to be eligible for permitting exemptions as
sources of minor significance.

APPLICABILITY: Staff/Regulated Public

DISCLAIMER: The policies and procedures outlined in this guidance document
are intended to supplement existing requirements. Nothing in the
policies or procedures shall affect applicable statutory or
regulatory requirements.

The policies and procedures herein are not an adjudication or a
regulation. There is no intent on the part of the Department to give
these rules that weight or deference. This document establishes the
framework for the exercise of DEP's administration discretion in
the future. DEP reserves the discretion to deviate from this policy
statement if circumstances warrant.

**COMMONWEALTH OF PENNSYLVANIA
DEPARTMENT OF ENVIRONMENTAL PROTECTION
BUREAU OF AIR QUALITY**

**NOTICE
Plan Approval and Operating Permit Exemptions**

Consistent with the applicable provisions of the Pennsylvania Air Pollution Control Act (APCA), 35 P.S. §4001 *et seq.* and 25 Pa. Code § 127.14 (relating to exemptions), the Department of Environmental Protection (Department) may determine sources or classes of sources to be exempt from the plan approval and permitting requirements of 25 Pa. Code Chapter 127 (relating to construction, modification, reactivation and operation of sources). This guidance document identifies the following: exemptions under Section 127.14(a); exemptions under Section 127.14(a)(8) that do not require submission of a Request for Determination (RFD) form; exemption criteria that the Department may use when an owner or operator of a source or a facility is seeking an exemption from plan approval; further qualifications regarding plan approval exempted sources; exemptions under Section 127.14(a)(9) related to physical changes; and exemption criteria for operating permits. This amended guidance document is applicable to sources that will be constructed as new or modified sources after the effective date of this document. It does not apply to sources that were constructed or modified prior to the effective date of this guidance document and operating lawfully without a permit. Sources exempted from plan approvals are not automatically exempted from operating permit requirements.

Words and terms that are not defined in this document have the meaning set forth in 25 Pa. Code §121.1 (relating to definitions) or the APCA (35 P.S. § 4003), 25 Pa. Code, Chapters 121 - 145 and applicable definitions codified in the Code of Federal Regulations including 40 CFR Parts 60 and 63.

Listing of Plan Approval Exemptions

Section 127.14(a) Exemptions

In accordance with § 127.14(a), approval is not required for the construction, modification, reactivation or installation of the following:

1. Air conditioning or ventilation systems not designed to remove pollutants generated by or released from other sources.
2. Combustion units rated at 2.5 million or less Btus per hour of heat input.
3. Combustion units with a rated capacity of less than 10 million Btus per hour of heat input fueled by natural gas supplied by a public utility or by commercial fuel oils which are No. 2 or lighter-viscosity less than or equal to 5.82 C St--and which meet the sulfur content requirements of § 123.22 (relating to combustion units). Combustion units converting to fuel oils which are No. 3 or heavier-viscosity greater than 5.82 C St or contain sulfur in excess of the requirements of § 123.22 require approval. For the purpose of this section, commercial fuel oil shall be virgin oil which contains no reprocessed, recycled, or waste material added.

4. Sources used in residential premises designed to house four or less families.
5. Space heaters which heat by direct heat transfer.
6. Mobile sources.
7. Laboratory equipment used exclusively for chemical or physical analyses.
8. Other sources and classes of sources determined to be of minor significance by the Department.

Section 127.14(a)(8) Exemptions

The following is a list of those sources and classes of sources determined, in accordance with § 127.14(a)(8), to be exempt from the Plan Approval requirements of §§ 127.11 and 127.12. The commencement of construction of sources is exempted from the plan approval requirements provided the exemption criteria are met. Unless labeled otherwise, emission rates are to be considered actual tons per year (tpy). Note that certain exceptions and qualifications regarding this list are contained in the discussion that follows the list.

1. Incinerators with rated capacities less than 75 lb per hour burning a municipal or residual waste as defined by the Bureau of Land Recycling and Waste Management.
2. Shot blast and sandblasting units with appropriately designed fabric collectors, cartridge collectors or scrubbers manufactured as an integral part of the design and which have exhaust volumes equal to or smaller than 5,000 scfm.
3. Combustion turbines rated at less than 1,000 horsepower or 10.7 gigajoules per hour.
4. Internal combustion engines rated at less than 100 brake horsepower. Note Category 38 addresses oil and gas facilities.
5. Portable, temporary internal combustion engines used for 14 days or less at special events (such as county fairs, circuses and concerts).
6. Internal combustion engines regardless of size, with combined NO_x emissions less than 100 lbs/hr, 1000 lbs/day, 2.75 tons per ozone season and 6.6 tons per year on a 12-month rolling basis for all exempt engines at the site.
7. Natural gas-fired heat-treating furnaces with less than 10 million Btus per hour heat input (fuel burning emissions only).
8. Steam aspirated vacuum degassing of molten steel.
9. Coal handling facilities processing less than 200 tons per day. (Thermal coal dryers and pneumatic coal cleaners remain subject to the requirements of § 127.11). This exemption includes internal combustion engines meeting the criteria for plan approval exemption described in category 6 above.

10. Wet sand and gravel operations (screening only) and dry sand and gravel operations (including crushers) processing unconsolidated materials with a rated capacity of less than 150 tons per hour.
11. Coal and non-metallic mineral handling activities directly associated with either deep or surface mines that consist only of conveyors and non-vibratory screens (aka. grizzlies). This exemption includes internal combustion engines meeting the criteria for plan approval exemption described in category 6 above.
12. Portable crushers that are controlled with properly located water sprays or with fabric filters, have a rated capacity less than 150 tons per hour, operated during daylight, and located on a site for less than 60 days; provided, however, that the crushers do not process materials containing asbestos. This exemption includes; associated screens and drop points; tub grinders used to mulch grubbing waste; and, internal combustion engines meeting the criteria for plan approval exemption described in category 6 above.
13. Concrete batch plants and associated storage vessels that are equipped with appropriately designed fabric collectors.
14. Bulk material storage bins, except those associated with a production facility with total actual facility particulate emissions greater than 10 tpy.
15. Storage vessels for volatile organic compounds [which do not contain hazardous air pollutants (HAPs)] which have capacities less than 40 m³ (10,000 gallons) based on vessel dimensions, unless subject to § 129.59 (bulk gasoline terminals) or § 129.60(b) and (c) (bulk gasoline plants).
16. Storage vessels containing non-VOC, non-malodorous, or nonhazardous air pollutant materials.
17. Diesel fuel, Nos. 2, 4 and 6 fuel oils, or kerosene and jet fuel storage and dispensing facilities as long as the stored or dispensed product has a vapor pressure less than 1.5 psia.
18. Covered wastewater transfer systems such as covered junction boxes, sumps, and tanks at industrial sites.
19. Plastic bead or pellet milling, screening, and storage operations (does not include handling and storage of resin powders).
20. Plastic parts casting ovens and injection molding processes.
21. Tire buffing.
22. Paper trimmers/binders.
23. Vocational education shops. Chemistry laboratories at schools and colleges.
24. Bench-scale laboratory equipment used for kinetic studies, mass/energy transport studies, chemical synthesis and physical or chemical analysis.
25. Research and development activities with annual emission rates:

- i. less than or equal to 20 tpy of CO;
 - ii. less than or equal to 0.12 tpy of lead;
 - iii. less than or equal to 3 tpy of PM₁₀;
 - iv. less than or equal to 8 tpy of SO₂ or VOC;
 - v. less than or equal to 10 tpy of NO_x;
 - vi. less than or equal to one tpy of a single HAP or 2.5 tpy of a combination of HAPs.
26. Woodworking facilities including sawmills and pallet mills which process green wood; or, small woodworking facilities processing kiln-dried wood or wood products (flakeboard, particleboard, etc.) associated with pattern shops, retail lumber yards, shipping and packing departments, etc. This category also includes woodworking facilities of any size processing kiln-dried wood or wood products equipped with appropriately designed fabric collectors designed to have emission rates that are less than 0.01 gr/dscf.
- This exemption does not apply to woodworking facilities processing wood that has been treated with a wood preservative of any kind. The term "woodworking facilities" refers only to operations in which wood or a wood product is sawed, sanded, planed, or similarly shaped or reshaped. The term does not include such activities as painting, finishing, hardboard manufacturing, plywood manufacturing, and the like.
27. Smokehouses.
28. Slaughterhouses (rendering cookers remain subject to the requirements of § 127.11).
29. Restaurant operations.
30. Degreasing operations using solvents containing no more than 5% VOC by weight, except those emitting more than 2.7 tons of VOCs or those subject to the Federal NESHAP for halogenated solvent cleaners under 40 CFR Part 63.
31. Sources of uncontrolled VOC emissions not addressed elsewhere in this exemption listing modified or newly added, such that emission increases are less than 2.7 tpy. Facilities' claiming this exemption must provide a 15-day prior written notification to the Department and limit VOC emission increases to less than 2.7 tpy.
32. Dry-cleaning facilities that are not subject to § 129.70, NSPS, MACT (area MACT sources are currently deferred from plan approval and operating permit requirements), PSD or NSR requirements.
33. a. Retail gasoline dispensing facilities and similar vehicle-fueling operations at industrial facilities.
- b. Compressed natural gas dispensing facilities meeting the following requirements:

- i. Combined NO_x emissions from the stationary internal combustion engines at a facility less than 100 lbs/hr, 1000 lbs/day, 2.75 tons per ozone season (the period beginning May 1 of each year and ending on September 30 of the same year) and 6.6 tons per year on a 12-month rolling basis. The emissions criteria do not include emissions from sources which are approved by the Department in plan approvals, general plan approval/general operating permits or emissions from sources at the facility approved under Category No. 33(a).
- ii. Combined VOC emissions from all the sources at the facility less than 2.7 tons on a 12-month rolling basis. If the VOCs include HAPs, the HAP exemption criteria in this paragraph must be met. Compliance with this criterion will be determined using any generally accepted model or calculation methodology. Combined HAP emissions [not including Polychlorinated Biphenyls (PCBs), Chromium (Cr), Mercury (Hg), Lead (Pb), Polycyclic Organic Matter (POM), Dioxins and Furans] at the facility less than 1000 lbs. of a single HAP or one ton of a combination of HAPs in any consecutive 12-month period. The emissions criteria do not include emissions from sources which are approved by the Department in plan approvals, general plan approval/general operating permits, or emissions from sources approved under Category No. 33(a) at the facility.
- iii. The owner or operator of the compressed natural gas fueling station will annually perform a leak detection and repair (LDAR) program that includes either the use of an optical gas imaging camera such as a FLIR camera or a gas leak detector capable of reading methane concentrations in air of 0% to 5% with an accuracy of +/- 0.2% or other leak detection monitoring devices approved by the Department. The LDAR program will be conducted on valves, flanges, connectors, storage vessels/storage tanks, and compressor seals in natural gas or hydrocarbon liquids service. Leaks are to be repaired no later than 15 days after leak detections unless facility shutdowns or ordering of replacement parts are necessary for repair of the leaks. For the storage vessel, any leak detection and repair are to be performed in accordance with 40 CFR Part 60, Subpart OOOO.
 - A. A leak is considered repaired if one of the following can be demonstrated:
 1. No detectable emissions consistent with Method 21 specified in 40 CFR Part 60, Appendix A;

2. A concentration of 2.5% methane or less using a gas leak detector;
3. No visible leak image when using an optical gas imaging camera;
4. No bubbling at leak interface using a soap solution bubble test specified in Method 21. A procedure based on the formation of bubbles in a soap solution that is sprayed on a potential leak source may be used for those sources that do not have continuously moving parts and that do not have a surface temperature greater than the boiling point or less than the freezing point of the soap solution; or
5. Any other method approved by the Department.

B. Leaks, repair methods and repair delays are to be recorded and maintained for five years. If a gas leak detector is used, a leak is to be detected by placing the probe inlet at the surface of a component. The Department may grant an extension for leak detection deadlines or repairs upon written request from the owner or operator of the facility documenting the justification for the requested extension.

34. Sources of particulate matter (not subject to NESHAPs, NSPS, PSD, or major source requirements) that are controlled by a baghouse, have an emission rate which meets the limits of Chapter 123, and are exhausted indoors and cannot be bypassed to exhaust to the outdoor atmosphere. These sources should not emit more than 0.12 tpy of lead, one tpy of a single HAP or 2.5 tpy of a combination of HAPs. Multiple sources within this category may be exempt from plan approval requirements.
35. Sources emitting inert gases only, such as argon, helium, krypton, neon, and xenon; pure constituents of air such as nitrogen, oxygen, or carbon dioxide; or, methane or ethane.
36. Source(s) qualifying under § 127.449 as de minimis emission increases.
37. Sources that exhaust to a filter/baghouse and have particulate loading (before control) below limits specified in Chapter 123.
38. Oil and gas exploration, development, and production facilities and associated equipment and operations meeting the following provisions:
 - a. Conventional wells, wellheads and all other associated equipment. A conventional well is any well that does not meet the definition of unconventional gas well in 58 PA.C.S § 3203.

- b. Well drilling, completion and work-over activities.
- c. Non-road engines as defined in 40 CFR § 89.2.
- d. Unconventional wells, wellheads, and associated equipment, provided the applicable exemption criteria specified in subparagraphs i, ii, iii, iv and v are met.
 - i. Within 60 days after the well is put into production, and annually thereafter, the owner/operator will perform a leak detection and repair (LDAR) program that includes either the use of an optical gas imaging camera such as a FLIR camera or a gas leak detector capable of reading methane concentrations in air of 0% to 5% with an accuracy of +/- 0.2% or other leak detection monitoring devices approved by the Department. LDAR is to be conducted on valves, flanges, connectors, storage vessels/storage tanks, and compressor seals in natural gas or hydrocarbon liquids service. Leaks are to be repaired no later than 15 days after leak detections unless facility shutdowns or ordering of replacement parts are necessary for repair of the leaks. The optical gas imaging camera or other Department-approved gas leak detection equipment are to be operated in accordance with manufacturer-recommended procedures. For the storage vessel, any leak detection and repair will be performed in accordance with 40 CFR Part 60, Subpart OOOO.
 - A. A leak is considered repaired if one of the following can be demonstrated:
 - 1. No detectable emissions consistent with Method 21 specified in 40 CFR Part 60, Appendix A;
 - 2. A concentration of 2.5% methane or less using a gas leak detector and a VOC concentration of 500 ppm or less;
 - 3. No visible leak image when using an optical gas imaging camera;
 - 4. No bubbling at leak interface using a soap solution bubble test specified in Method 21; or a procedure based on the formation of bubbles in a soap solution that is sprayed on a potential leak source may be used for those sources that do not have continuously moving parts and that do not have a surface temperature greater than the boiling point or less than the freezing point of the soap solution; or

5. Any other method approved by the Department.
- B. Leaks, repair methods and repair delays will be recorded and maintained for five years. If a gas leak detector is used, a leak is to be detected by placing the probe inlet at the surface of a component. The Department may grant an extension for leak detection deadlines or repairs upon the receipt of a written request from the owner or operator of the facility documenting the justification for the requested extension.
- ii. Storage vessels/storage tanks or other equipment equipped with VOC emission controls achieving emissions reduction of 95% or greater. Compliance will be demonstrated consistent with 40 CFR Part 60, Subpart OOOO or an alternative test method approved by the Department.
 - iii. Combined VOC emissions from all the sources at the facility less than 2.7 tons on a 12-month rolling basis. If the VOCs include HAPs, the HAP exemption criteria in this paragraph will be met. Compliance with this criterion is to be determined using any generally accepted model or calculation methodology. Combined HAP emissions [not including Polychlorinated Biphenyls (PCBs), Chromium (Cr), Mercury (Hg), Lead (Pb), Polycyclic Organic Matter (POM), Dioxins and Furans] at the facility less than 1000 lbs of a single HAP or one ton of a combination of HAPs in any consecutive 12-month period. The emission criteria do not include emissions from sources which are approved by the Department in plan approvals, or the general plan approvals/general operating permits at the facility and the emissions from sources meeting the exemption criteria in subparagraphs i, ii, and iv.
 - iv. Flaring activities as outlined below:
 - A. Flaring used at exploration wells to determine whether oil and/or gas exists in geological formations or to appraise the physical extent, reserves and likely production rate of an oil or gas field.
 - B. Flaring used for repair, maintenance, emergency or safety purposes.
 - C. Flaring used for other operations at a wellhead or facility to comply with 40 CFR Part 60, Subpart OOOO requirements.
 - D. Enclosed combustion device including enclosed flare will be used for all permanent flaring operations at a wellhead or facility. These flaring

operations will be designed and operated in accordance with the requirements of 40 CFR § 60.18.

- v. Combined NO_x emissions from the stationary internal combustion engines at wells, and wellheads less than 100 lbs./hr., 1000 lbs./day, 2.75 tons per ozone season (the period beginning May 1 of each year and ending on September 30 the same year), and 6.6 tons per year on a 12-month rolling basis. The emission criteria do not include emissions from sources which are approved by plan approvals or the general plan approvals/general operating permits at the facility.

The owner or operator will comply with all applicable state and federal requirements including notification, record keeping, and reporting requirements as specified in 40 CFR Part 60 Subpart OOOO. The owner or operator will also demonstrate compliance with the exemption criteria using any generally accepted model or calculation methodology within 180 days after the well completion or installation of a source. The owners and operators of sources not meeting the provisions of subsections a-d of this category may submit an RFD form to the Department. If the RFD is not approved by the Department, an application for authorization to use a general permit or a plan approval application is to be submitted to the Department, as appropriate.

- 39. Combustion units with a rated capacity of less than 10 million Btus per hour of heat input fueled by natural gas supplied by an independent gas producer. Sources firing natural gas supplied by an independent producer shall be given the same consideration given sources that fire natural gas provided by a public utility.
- 40. Any source qualifying for exemption based on criteria contained in a general permit developed in accordance with the procedures described in §§ 127.601 through 127.642.
- 41. Powdered metal sintering furnaces using only organic lubricants equal to or less than 0.75% organic lubricant by weight. The furnace atmosphere must contain hydrogen (H₂) at 3% or greater. The furnace must also maintain an operating flame curtain between the part entry and pre-heat zone. In the absence of an operating flame curtain, the furnace must operate an afterburner.

A sintering furnace using only metal containing lubricants may be exempted if the furnace emits particulate matter not exceeding 0.15 lb./hr. (determined by mass balance or stack tests). Note, for mass balance purposes, the following conversion factors are to be used:

Zinc Stearate to Zinc Oxide particulate matter = 0.129,

Lithium Stearate to Lithium Carbonate particulate matter = 0.15.

The Department may approve alternate conversion factors provided a satisfactory written justification is submitted to the Department.

A sintering furnace using organic lubricants and operating outside the limitations specified above, may be exempted under a case-by-case determination through the execution of a Request for Determination of Requirement for Plan Approval Application form. The owner/operator of a sintering furnace exempt from permitting requirements must notify the Department within 30 days of the furnace installation. For sintering furnaces using metal containing lubricants, records must be maintained to demonstrate compliance with the particulate matter emission limit of 0.15 lb/hour for each product.

Facilities that use both organic and metal-containing lubricants are exempted if the lubricants are less than 0.75% organic lubricant by weight; and, the furnace is designed and operated as described in the preceding paragraph and emits particulate matter at rates less than 0.15 lb./hr (determined by mass balance or stack tests).

The previous exemption does not apply to sintering furnaces used to sinter parts that are treated with oil.

42. Facilities engaged primarily in collision repair and refinishing of automobiles and light duty trucks.
43. Remediation of gasoline or fuel oil contaminated soil, groundwater or surface water by equipment installed, maintained and operated as provided herein. All air exhaust points are controlled by dual, activated carbon beds operating in series or a thermal/catalytic oxidizer. For activated carbon beds, monitoring (e.g. intrinsically safe ionization detector) at an appropriate frequency (e.g., one-fourth the predicted time to breakthrough of the first bed) must be performed at the inlet, between the first and second beds and after the second bed. If breakthrough of the first bed is detected, the first bed is removed, the second bed is shifted to the first position and the new bed is placed in the second position. Monitoring, operating, and maintenance records are maintained and available to the Department upon request. Equipment installed and operated as described above must be designed to achieve a minimum VOC control efficiency of 90%. As long as actual annual emissions after control are less than one TPY VOC or HAPs, the remediation project is determined to be of minor significance in accordance with 127.14 (8), no Air Quality Plan Approval is required and no Request for a Determination (RFD) needs to be filed. Other remediation projects may be considered for exemption via a Request For Determination and may be required to obtain Plan Approval at the discretion of the Department on a case-by-case basis.
44. Any source granted an exemption by the Department through the execution of a Request for Determination of Requirement for Plan Approval/Operating Permit (RFD) form.

Further Qualifications Regarding Plan Approval Exempted Sources:

1. This notice shall not be construed to exempt facilities that include multiple sources of air contaminants, unless specifically stated in the source category.
2. The addition of any source that would subject the facility to major source New Source Review or Prevention of Significant Deterioration, Title V or Reasonably Available Control Technology (RACT) requirements shall comply with plan approval requirements, even if such sources are within a category in the above list.

3. Sources exempt from plan approval may be required to be included in the operating permit if the source is not included in the trivial activity listing.
4. Sources located in Allegheny and Philadelphia Counties may be subject to different permitting requirements. Please contact the Allegheny County Air Quality Program at 412-567-8115 or the Philadelphia Air Management Services at 215-823-7580 for information applicable to sources located in those counties.
5. Any sources claiming an exemption based on emission thresholds must keep adequate records to clearly demonstrate to the Department that the applicable thresholds are not exceeded.

These determinations do not exempt the above-listed sources from compliance with the emission limitations, work practice, and other applicable requirements contained in Chapters 121, 122, 123, 124, 127, 129, and 135. Although a source may be exempt from the plan approval and operating permit requirements of Chapter 127, the source is subject to all other applicable air quality regulations. For example, combustion units exempt from the requirements of Chapter 127 are not exempt from the opacity limitations of § 123.41 or the emission limitations of § 123.22. Storage vessels for organic compounds with capacities between 2,000 gallons to 40,000 gallons, not subject to the requirements of Chapter 127, must install pressure relief valves in accordance with the requirements of § 129.57. (Note: Storage vessels in this size range would also not be subject to the requirements of §§ 129.59 and 129.60.)

If the Department determines that any exempted source is causing air pollution in violation of Section 8 of the Air Pollution Control Act, 35 P. S. § 4008, or 25 Pa. Code 121.7, the Department may order the installation of additional air cleaning devices. In those cases, plan approvals and operating permits may be required.

Requests for exemptions from the plan approval requirements of Chapter 127 for multiple source facilities must be considered on a case-by-case basis.

As noted in Category 44 of the list, additional exemptions, when appropriate, may be obtained through the submission of a completed Request for Determination of Requirement for Plan Approval Application form. These forms are available from any of the Department's Air Quality offices and on the DEP website [www. dep.state.pa.us](http://www.dep.state.pa.us) under the Air Quality page.

Physical Changes Qualifying for Exemption Under Section 127.14(a)(9)

In accordance with § 127.14(a)(9), the Department has determined that the following physical changes qualify for plan approval exemption if the change: a) would not violate the terms of an operating permit, the Air Pollution Control Act, the Clean Air Act or the regulations adopted under the acts; b) would not result in emission increases above the allowable in the operating permit; and, c) would not result in an increased ambient air quality impact for an air contaminant. These changes may be made without notification to the Department.

Caution: Do not make determinations regarding the following list without consideration of the preceding criteria.

1. Changes in the supplier or formulation of similar raw materials, fuels, paints and other coatings which do not affect emissions and which meet all applicable standards and limitations.
2. Changes in product formulations that do not affect air emissions.
3. Changes that result in different speciation of pollutants but fall within permit limitations.
4. Changes in the method of raw material addition.
5. Changes in the method of product packaging.
6. Changes in temperature, pressure, or other operating parameters that do not adversely affect air cleaning device performance or air emissions.
7. Additions of or changes to sampling connections used exclusively to withdraw materials for testing and analysis including air contaminant detection and vent lines.
8. Changes to paint drying oven length designed to alter curing time, so long as capture efficiencies of control equipment are not altered.
9. Routine maintenance, inspection and cleaning of storage tanks and process vessels or the closure or dismantling of a storage tank or process.
10. Changing water sources to air cleaning devices when there is no effect on air cleaning device performance or air emissions.
11. Moving a source from one location to another at the same facility with no change in operation or controls.
12. Installation of an air-cleaning device that is not installed to comply with regulatory requirements and will not be used to generate emission reduction credits.
13. Repairing, replacing, upgrading, maintaining, or installing pollution control device instrumentation or component equipment including pumps, blowers, burners, filters, filter bags, devices for measuring pressure drop across an air cleaning device or a filter breakage detector for a baghouse, provided such changes would not violate an operating permit term or condition.
14. Installing a fume hood or vent system for industrial hygiene purposes or in a laboratory.
15. The temporary (no longer than six months) replacement of a source with a source of equal or less emission potential.
16. Repairing, replacing, upgrading, maintaining, or installing equipment and processes at oil and gas extraction and production facilities and operations. The category includes equipment or processes used either to drill or alter oil and natural gas to the point of lease custody transfer, to plug abandoned wells and restore well sites, or treat and dispose of associated wastes.

In accordance with § 127.14(c), additional physical changes may be determined to be of minor significance and not subject to plan approval requirements through the following procedure:

1. If the changes do not involve the installation of equipment, the changes may be made within 7 calendar days of the Department's receipt of a written request provided the Department does not request additional information or objects to the change within the 7-day period.
2. If the changes involve the installation of equipment, the changes may be made within 15 calendar days of the Department's receipt of a written request provided the Department does not request additional information or objects to the change within the 15-day period.
3. If the change would violate the terms of an operating permit the plan approval exemption may be processed contemporaneously with the minor operating permit modification under the procedures described in § 127.462.

Exemption Criteria for Operating Permits

A Title V operating permit is needed by all facilities that have the potential to emit (PTE) exceeding the levels described in the definition of "Title V facility." A state-only operating permit is needed for facilities that do not have a PTE which exceeds the Title V facility thresholds, but which has actual emissions equal to or exceeding the facility levels summarized below. An existing facility which does not have a PTE exceeding the Title V facility thresholds and which does not have actual emissions exceeding the levels shown below is exempt from the requirement to obtain an operating permit.

State-Only Operating Permit Facility Exemptions*

| Pollutant | PTE< | Actual Emission Rate< |
|------------------|----------------|---------------------------------|
| CO | 100 TPY | 20 TPY |
| NO _x | 100 TPY** | 10 TPY |
| SO _x | 100 TPY | 8 TPY |
| PM ₁₀ | 100 TPY | 3 TPY |
| VOCs | 50 TPY** | 8 TPY |
| Single HAP | 10 TPY | 1 TPY |
| Multiple HAPs | 25 TPY | 2.5 TPY |

- * Sources located in Allegheny and Philadelphia Counties may be subject to different permitting requirements. Please contact the Allegheny County Air Quality Program at 412-567-8115 or the Philadelphia Air Management Services at 215-823-7580 for information applicable to sources located in those counties.
- * 25 TPY for Severe Ozone NA areas including Bucks, Chester, Delaware, and Montgomery counties.

Sources listed in the plan approval exemption list should be included in an operating permit application unless it is also included in the listing of trivial activities. When a RFD is issued for a source not included on the list of trivial activities the source need not be brought onto the operating permit until the renewal of the operating permit. So long as all applicable requirements are met there is no need to revise an operating permit to include a source installed under an RFD or the de minimis provisions of an operating permit. Only in the case where a physical change of minor significance would violate the terms of an operating permit should a plan approval exemption and a minor permit modification under § 127.462 be processed contemporaneously. A facility that currently has or should have a plan approval or an operating permit is not exempted from the operating permit requirements. However, if the facility would now be eligible for exemption, the owner/operator may submit a RFD in accordance with § 127.14(c).

Exempted Facility and Source Categories for Operating Permits

Unless preclude by the Clean Air Act, or the regulations there under, the following facilities and source categories are exempted from the operating permit requirements of § 127.402.

1. Residential wood stoves.
2. Asbestos demolition/renovation sites.
3. Facilities engaged primarily in collision repair and refinishing of automobiles and light duty trucks.
4. Retail gasoline stations.

Deferral of Operating Permit Requirements for Area Sources

Sources subject to MACT standards are not exempted from operating permit requirements. However, the permitting of MACT area sources will be deferred at this time. Area MACT sources emit or have the PTE less than 10 tpy of any hazardous air pollutant or 25 tpy of any combination of hazardous air pollutants. These non-major sources include: perchloroethylene dry cleaning, halogenated solvent cleaning, ethylene oxide commercial sterilization and fumigation operations, hard and decorative chromium electroplating, chromium anodizing tanks and secondary lead smelters. These MACT area sources are still required to meet all applicable emission control requirements established by the respective MACT requirement. The owner or operator of a MACT area source need not submit an operating permit application until December 9, 2004.

Trivial Activities

Trivial activities are those located within a facility, which do not create air pollution in significant amounts. These insignificant activities need not be described in a Title V or state-only operating permit application. Also, these activities do not require a plan approval. Sources listed in the plan approval exemption list should be included in an operating permit application unless it is also listed in the following list. Certain of these listed activities include qualifying statements intended to exclude many similar activities.

1. Combustion emissions from propulsion of mobile air contamination sources. The term "mobile air contamination source" means an air contamination source, including, but not limited to, automobiles, trucks, tractors, buses and other motor vehicles; railroad locomotives; ships, boats and other waterborne craft. The term does not include a source mounted on a vehicle, whether the mounting is permanent or temporary, which source is not used to supply power to the vehicle. Examples might include lawn mowers, tow and lift vehicles, and the like.
2. Air-conditioning units used for human comfort that do not have applicable requirements under Title VI of the Act.
3. Ventilating units used for human comfort that do not exhaust air pollutants into the ambient air from any manufacturing, industrial or commercial process.
4. Electric space heaters. Propane and gas fired space heaters with a plant-wide capacity less than 2.5 million Btus per hour heat input and which have not been subject to RACT requirements.
5. Electrically heated furnaces, ovens and heaters, and other electrically operated equipment from which no emissions of air contaminants occur.
6. Non-commercial food preparation.
7. Use of office equipment and products, not including printers or businesses primarily involved in photographic reproduction.
8. Any equipment, machine or device from which emission of air contaminant does not occur.
9. Janitorial services and consumer use of janitorial products.
10. Internal combustion engines used for landscaping purposes.
11. Garbage compactors and waste barrels.
12. Laundry activities, except for dry-cleaning and steam boilers.
13. Bathroom/toilet vent emissions.
14. Emergency (backup) electrical generators at residential locations.

15. Tobacco smoking rooms and areas.
16. Blacksmith forges.
17. Plant maintenance and upkeep activities (such as, grounds-keeping, general repairs, cleaning, painting, welding, plumbing, re-tarring roofs, installing insulation, and paving parking lots) provided these activities are not conducted as part of a manufacturing process, are not related to the source's primary business activity, and not otherwise triggering a permit modification.¹
18. Repair or maintenance shop activities not related to the source's primary business activity, not including emissions from surface coating or de-greasing (solvent metal cleaning) activities, and not otherwise triggering a permit modification.
19. Portable electrical generators that can be moved by hand from one location to another.²
20. Hand-held equipment for buffing, polishing, cutting, drilling, sawing, grinding, turning or machining wood, metal or plastic.
21. Brazing, soldering and welding equipment, and cutting torches related to maintenance and construction activities that do not result in emission of HAP metals.³
22. Air compressors and pneumatically operated equipment, including hand tools.
23. Batteries and battery charging stations, except at battery manufacturing plants.
24. Storage tanks, vessels, and containers holding or storing liquid substances that will not emit any VOC or HAP.
25. Propane or natural gas tanks and containers.
26. Storage tanks, reservoirs, and pumping and handling equipment of any size containing soaps, vegetable oil, grease, animal fat, and nonvolatile aqueous salt solutions, provided appropriate lids and covers are utilized.
27. Equipment used to mix and package, soaps, vegetable oil, grease, animal fat, and nonvolatile aqueous salt solutions, provided appropriate lids and covers are utilized.
28. Drop hammers or hydraulic presses for forging or metalworking.
29. Equipment used exclusively to slaughter animals, but not including other equipment at slaughterhouses, such as rendering cookers, boilers, heating plants, incinerators, and electrical power generating equipment.
30. Vents from continuous emissions monitors and other analyzers.
31. Natural gas pressure regulator vents.
32. Hand-held applicator equipment for hot melt adhesives with no VOC in the adhesive formulation.

33. Equipment used for surface coating, painting, dipping or spraying operations, except those that will emit VOC or HAP.
34. CO₂ lasers used only on metals and other materials that do not emit HAP in the process.
35. Consumer use of paper trimmers/binders.
36. Electric or steam-heated drying ovens and autoclaves, but not the emissions from the articles or substances being processed in the ovens or autoclaves or the boilers delivering the steam.
37. Salt baths using nonvolatile salts that do not result in emissions of any regulated air pollutants.
38. Laser trimmers using dust collection to prevent fugitive emissions.
39. Bench-scale laboratory equipment used for kinetic studies, mass/energy transport studies, chemical synthesis and physical or chemical analysis.
40. Sources emitting inert gases only, such as argon, helium, krypton, neon, and xenon; pure constituents of air such as nitrogen, oxygen, or carbon dioxide; or the organic aliphatic hydrocarbon gases methane and ethane.
41. Routine calibration and maintenance of laboratory equipment or other analytical instruments.
42. Equipment used for quality control/assurance or inspection purposes, including sampling equipment used to withdraw materials for analysis.
43. Hydraulic and hydrostatic testing equipment.
44. Environmental chambers not using hazardous air pollutant (HAP) gasses.
45. Shock chambers.
46. Humidity chambers.
47. Solar simulators.
48. Fugitive emissions related to movement of passenger vehicles, provided the emissions are not counted for applicability purposes and any required fugitive dust control plan or its equivalent is submitted.
49. Process water filtration systems and demineralizers, but not including air strippers.
50. Demineralized water tanks and demineralizer vents.
51. Boiler water treatment operations, not including cooling towers.
52. Oxygen scavenging (de-aeration) of water.
53. Potable water treatment systems.

54. Ozone generators.
55. Fire suppression systems and activities involved in fire protection training, first aid or emergency medical training.
56. Emergency road flares.
57. Steam vents and safety relief valves.
58. Steam leaks.
59. Steam cleaning operations.
60. Steam sterilizers.
61. Reserved.
62. Typesetting, image setting, and plate making equipment used in the preparatory phase of printing.

If an applicant conducts an activity that is believed trivial but not covered by this listing, the applicant may list the activity in an operating permit application and provide a written justification for listing the activity as trivial. If the Department accepts the applicant's justification, no further information will be required on the activity. If the Department rejects the justification, additional information must be included in an operating permit application submitted to the Department.

¹Cleaning and painting activities qualify if they are not subject to VOC or HAP control requirements. Asphalt batch plant owners/operators must still get a permit.

²"Moved by hand" means that it can be moved without the assistance of any motorized or non-motorized vehicle, conveyance, or device.

³Brazing, soldering and welding equipment, and cutting torches related to manufacturing and construction activities that emit HAP metals are more appropriate for treatment as insignificant activities based on size or production level thresholds. Brazing, soldering, welding and cutting torches directly related to plant maintenance and upkeep and repair or maintenance shop activities that emit HAP metals are treated as trivial and listed separately in this appendix.

**WPX ENERGY ROCKY MOUNTAIN, LLC'S AND WPX ENERGY PRODUCTION, LLC'S
PRE-HEARING STATEMENT**

IN THE MATTER OF OIL & GAS RULEMAKING EFFORTS REGARDING PROPOSED
REVISIONS TO:

REGULATION NUMBER 3, PARTS A, B, AND C;

REGULATION NUMBER 6, PART A;

REGULATION NUMBER 7

WPX ENERGY ROCKY MOUNTAIN, LLC and WPX ENERGY PRODUCTION, LLC (collectively "WPX"), by and through undersigned counsel, respectfully submits to the Colorado Air Quality Control Commission ("Commission") its Prehearing Statement ("PHS") in the above-referenced rulemaking.

I. Executive Summary.

Pursuant to 5 CCR 1001-1 ("Procedural Rules"), Section V.E.6.c.(i), WPX provides the following executive summary in support of its PHS.

In general, WPX supports the Division's proposed regulations, recognizing that the regulations require stringent and broad-based requirements in excess of federal requirements, particularly for certain owners and operators, like WPX, who operate in the Piceance attainment areas. The proposed regulations implement a "one size fits all" approach, even though operations and potential fugitive emissions vary between basins state-wide. WPX operates in the Piceance basin, where, as even the state recognizes, potential fugitives are lower than other areas of the state. As such, WPX is supportive of the proposed regulations except where the requirements impose significant cost expenditures without corresponding increased environmental benefits. WPX thus has proposed minimal targeted revisions to the proposed regulatory language relating to the LDAR requirements to address these issues, without impacting the environmental benefit proposed by the regulations.

In general, WPX requests three changes to the proposed language of Regulation 7: (1) An "off-ramp" to decreasing frequency of instrument-based monitoring under the Leak Detection and Repair ("LDAR") requirements (or "skip monitoring") as a demonstration of reduced leaks is made (with the corresponding requirement of going back to the initial frequency if more than a limited number of leaks are detected in subsequent monitoring events) (5 CCR 1001-9, § XVII.F.5e); (2) clarification of what constitutes "unsafe to monitor" scenarios (5 CCR 1001-9, § XVII.F.5.g.(ii)); and (3) extending the date on which existing and new well production facilities must meet the proposed 500 ppm leak detection rate to January 1, 2016 (5 CCR 1001-9, § XVIII.F.6). In addition, WPX is proposing several clarifications to correct obvious typographical, grammatical, and formatting errors

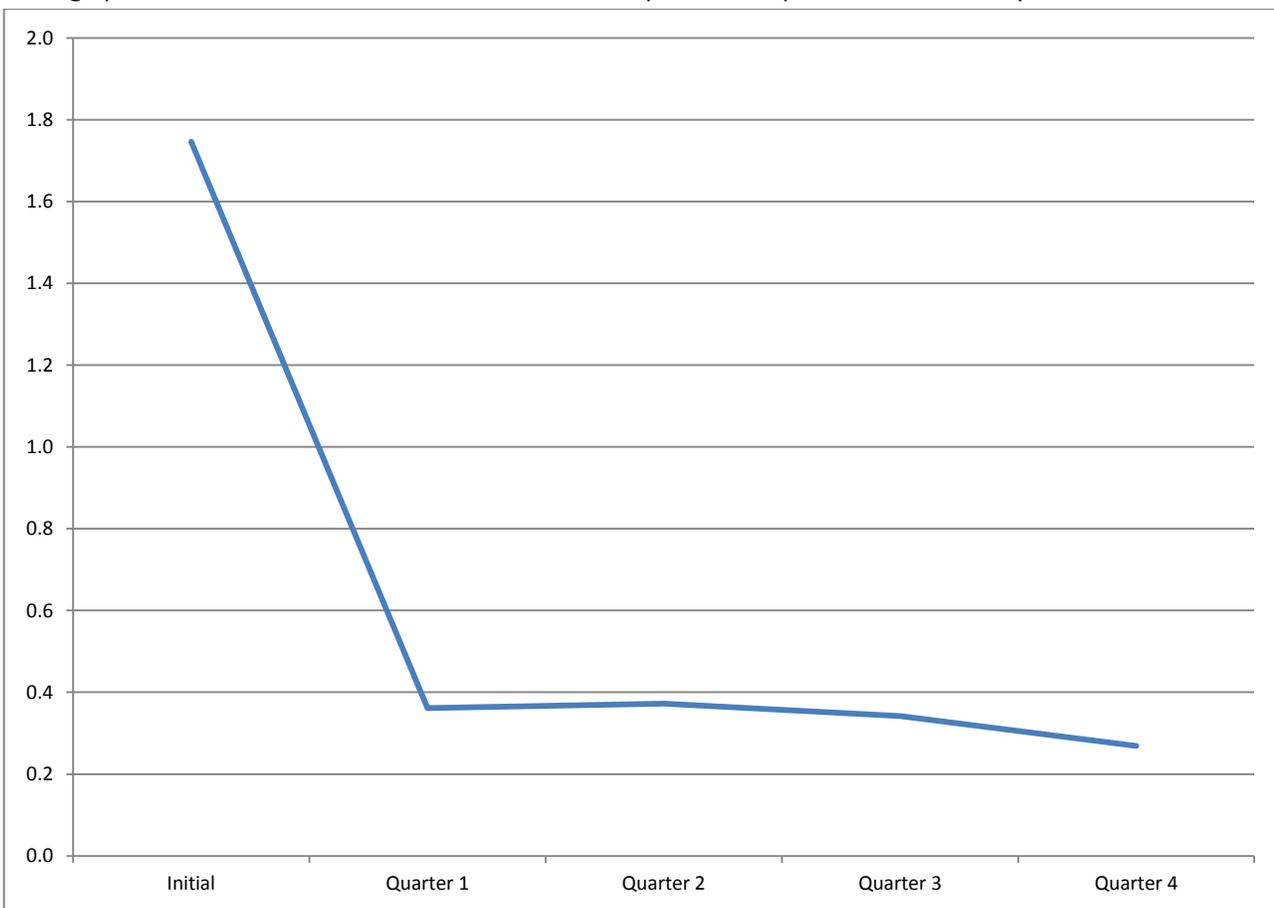

in the Division’s proposed regulations, and to create consistency in how the regulations address the same issues and incorporate clarifications by the Division discussed during the stakeholder process.

Based on case-specific studies of ongoing LDAR programs across a number of states and time periods, WPX includes documentation in its PHS that, following implementation of an LDAR program, the leak rate frequency found upon initial monitoring drops significantly during subsequent regular monitoring, to less than a one percent leak rate of components. Such reduced leak rates have been demonstrated to be sustainable in the long term. This data, summarized in the attached technical report by a recognized long-term LDAR consultant, Trihydro, supports the concept of allowing “skip monitoring” (or the practice of allowing for reduced monitoring frequency based on demonstrated good performance) as a valid concept in LDAR programs. The key points included in Trihydro’s analysis, *see* PHS EX A, demonstrate the following:

- Following implementation of an LDAR program, the leak rate frequency found upon initial monitoring can be expected to drop significantly during subsequent monitoring throughout the first year, to less than a one percent leak rate as observed in the analysis.

See PHS EX A, Figure 4:

Average percent new leaks found over number of components inspected in Case Study 1.

- This lower leak rate frequency is sustainable in the longer-term.
- Caution must be used when comparing leak rate data from other facilities or locations that may have significant differences from the facilities regulated under the proposed regulation.
- The specified fugitive emission factors will result in over estimating uncontrolled actual emissions. This is due to the manner in which the factors were developed, EPA's assumed 10,000 ppm leak rate, and the outdated data used to develop those emission factors (the data is approximately 20 years old).
- By not incorporating the concept of "skip period monitoring" into the proposed regulation, companies that implement high performance LDAR programs will be penalized.
- Facility LDAR monitoring is time consuming.

See attached PHS EX A.

WPX's targeted proposal therefore allows owners and operators who consistently demonstrate low leak rates to be rewarded for consistent low emissions. Comparison of longstanding LDAR programs for gas plant components that are similar to well production facility components demonstrates that, after the initial leak detection monitoring period, ongoing periodic monitoring events do not increase the frequency of leak detection. In fact, after the initial leak detection, discovery of leaks declines dramatically and continues at the low levels during the ongoing quarterly monitoring events.

In addition, some of the Division's proposed regulations require compliance with leak detection concentrations that are far below the current requirements. Manufacturers and suppliers need time to demonstrate and construct equipment and components that meet the more stringent levels; owners and operators need time to, if necessary, replace or retrofit equipment and components that do not meet the more stringent proposed requirements. Again, WPX is not challenging the proposed regulation standards, but simply for practicality and to ensure proper implementation, is requesting a slight modification as to when such stringent leak detection concentrations are applicable. Note that WPX acknowledges the immediate requirement for leak detection to 2000 ppm (much more stringent than the current 10,000 ppm standard), and is only requesting a slight delay in implementing the 500 ppm leak detection concentration for existing well production facilities and for any new facilities.

Finally, as noted above, operations and facility layouts vary throughout the state. Many of WPX's production facility locations are remote, and spread over larger areas with significant distances between locations. Many of the facilities are also subject to seasonal access issues, poor road conditions, and harsher weather at elevations. WPX is concerned about the safety of its operators and therefore proposes clarifying the language on what constitutes unsafe conditions for monitoring to ensure the safety of its employees and contractors.

WPX believes that its expert's testimony would be valuable to the Commission. WPX also believes it important to convey to the Commission the differences within the state, particularly with respect to its Piceance operations. As such, WPX requests forty-five minutes to present its direct

case (expert and factual testimony) and fifteen minutes for rebuttal and any additional time that may be required to cross-examine adverse witnesses.

II. Specific Factual and Legal Issues.

A. Not All Operators Are Similarly Situated.

WPX is in a unique position with all our Colorado exploration and production operations located in the Piceance Basin. We acknowledge that reducing VOCs emissions is important but would also like the Commission to recognize that potential emissions from our operations are different than emissions from other Basins in the state and that the economics for controlling these emissions are also different. All of WPX's operations in the Piceance Basin are located in an attainment area in Garfield and Rio Blanco Counties. A number of factors associated with the Piceance Basin are anticipated to make implementing a rigorous LDAR program even more challenging than at other production facilities within the state.

WPX production facilities are primarily natural gas operations with limited condensate production. The potential fugitive emissions from our production facilities are very low. These fugitive emissions have been estimated to be less than APEN thresholds (two tons per year) and in many cases are less than 0.5 tons per year. Our total VOC/hydrocarbon emissions from our production facilities are also considerably smaller than from other basins due to a number of factors. The natural gas wells in this area produce much lower volumes of condensate and the condensate is not as volatile as condensate produced from other areas. The operating/production pressures are also different compared to the DJ Basin. The division has assigned the Piceance Basin attainment area VOC emission factors of 10 lb/bbl for condensate tanks based on the lower production rates, operational differences, and the nature of the condensate. The State emission factor for condensate tanks in the DJ Basin is 13.7 lb/bbl. WPX's actual site-specific emission factors based on analytical data collected from WPX site condensate are only a fraction (10 to 50 percent) of the state emission factors – or 1 to 5 lbs/bbl – significantly lower than the State factors.

In addition to the factors described above, many of WPX's production facility locations are remote, spread over larger areas with significant distances between locations. Many of the facilities are also subject to seasonal access issues, poor road conditions, and harsher weather at elevations. WPX utilizes SCADA systems, site visits, and other remote tools to actively manage and ensure that operation and production activities are performed in an environmentally responsible manner. All of these factors identified above will contribute significant challenges to implement a rigorous LDAR program; however we recognize the value of a LDAR program that focuses on achieving effective environmental benefit/emission reductions and minimizes administrative burdens and eliminates unnecessary activities that do not contribute to finding and fixing leaks.

B. Proposed Justifications for Targeted Revisions to the Proposed Rules.

For above reasons, as well as the justifications set forth below, WPX identifies the following factual issues and provides justification for its proposed changes as follows.

1. Proposed revisions to Section XVII.F.5.e.

XVII.F.5.e. **The largest estimated uncontrolled actual emissions from a single storage tank battery determines** the frequency at which inspections must be performed. If no storage tanks are located at the well production facility or multi-well site, operators will rely on the potential to emit of VOC for all of the emissions sources, including emissions from components located at the facility. All components at a well production facility or storage tank must be inspected **either in accordance with Table 3 or Alternative Table 3A.**¹

Descriptors were added to language in paragraph XVII.F.5.e to clarify how inspection frequencies are to be determined based on the largest “uncontrolled actual emissions” from a single storage tank battery. Without these clarifications this paragraph may not be interpreted consistently and it may not be clear which LDAR inspection frequency is applicable to a particular production facility. During the rule making Work Group meetings, this clarification was provided by the Division as its interpretation of how storage tank “uncontrolled actual emissions” would apply in determining which threshold to which a production facility would be subject.

2. Proposed revisions to Section XVII.F.5.e.

XVII.F.5.e.² **The largest estimated uncontrolled actual emissions from a single storage tank battery determines** the frequency at which inspections must be performed. If no storage tanks are located at the well production facility or multi-well site, operators will rely on the potential to emit of VOC for all of the emissions sources, including emissions from components located at the facility. All components at a well production facility or storage tank must be inspected **either in accordance with Table 3 or Alternative Table 3A.**

| Threshold (per XVII.F.5.e.) VOC Emissions (tpy, uncontrolled actual for sites with tanks or PTE for sites without tanks) | Inspection Frequency |
|--|---|
| > 0 and ≤ 6 | One time using Approved Instrument Based Monitoring Method and thereafter using monthly AVO |
| > 6 and ≤ 12 | Annually with monthly AVO |
| > 12 and ≤ 50 | Quarterly with monthly AVO |
| > 50 | Monthly |
| Multi-well sites without storage tanks after April 15, 2014, that have a PTE > 20 tpy VOC | Monthly |

An alternative inspection frequency schedule pursuant to Alternative Table 3A may be implemented once a reduced LDAR demonstration is made. A reduced LDAR

¹ Note that the text set forth here contains WPX’s proposed language, with highlighting to illustrate where WPX proposes changes to the Division’s proposed regulation. For the actual redlined version of the proposed language, *see* ALT EX D at p. 11.

² Note that the text set forth here contains WPX’s proposed language, with highlighting to illustrate where WPX proposes changes to the Division’s proposed regulation. For the actual redlined version of the proposed language, *see* ALT EX D at p. 11-13.

demonstration requires that an owner or operator identify fewer than either (1) the specified number of leaking components listed in “Demonstration of Reduced LDAR – Monitoring History” in Alternative Table 3A or (2) two percent of the total components for that facility during a single monitoring event, for at least two consecutive monitoring events.

Once the reduced LDAR demonstration is made pursuant to this Section, the alternative inspection frequency pursuant to Alternative Table 3A may remain in place until, during any monitoring event under the alternative inspection frequency, more leaks are identified than allowed under Alternative Table 3A’s “Demonstration of Reduced LDAR – Monitoring History.” Using the alternative inspection frequency identified in Alternative Table 3A, during any monitoring event, if more leaks are identified than listed in the “Demonstration of Reduced LDAR – Monitoring History,” then the original monitoring frequency identified in Table 3 shall become applicable until or if the operator can make another reduced LDAR demonstration for that facility.

| Alternative Table 3A | | |
|--|---|---|
| Threshold (per XVII.F.5.e.) VOC Emissions (tpy, uncontrolled actual for sites with tanks or PTE for sites without tanks) | Demonstration of Reduced LDAR - Monitoring History | Alternative Inspection Frequency |
| > 0 and ≤ 6 | | One time using Approved Instrument Based Monitoring Method and thereafter using monthly AVO |
| > 6 and < 12 | | Annually with monthly AVO |
| > 12 and ≤ 50 | 5 or less component leaks (or 2% of total components) identified in each of two consecutive monitoring events. | Annually with monthly AVO |
| > 50 | 10 or less component leaks (or 2% of total components) identified in each of two consecutive monitoring events. | Quarterly with monthly AVO |
| Multi-well sites without storage tanks after April 15, 2014, that have a PTE > 20 tpy VOC | 10 or less component leaks (or 2% of total components) identified in each of two consecutive monitoring events. | Quarterly with monthly AVO |

WPX believes that if a rigorous LDAR program is applied to well production facilities it should be implemented to ensure the environmental benefit/fugitive VOC emission reductions are achieved and that the program minimizes administrative burdens and does not utilize unnecessary resources. The proposed LDAR inspection frequencies are extremely intense and would be the most resource intensive program applied to any production facility in the county. The proposed monthly inspection frequencies are more intense than dictated by federal requirements for new gas plants and refineries (which only require quarterly monitoring). Given that the potential fugitive emissions from

gas plants are significantly higher than production facilities, more frequent inspections may not achieve any added environmental benefit for production facilities.

In WPX's proposal, an alternative inspection frequency may be applied if a company is able to demonstrate a specified low number of leaks in their monitoring history (two consecutive monitoring events). The reduced inspection frequencies are applied only to the Instrument Based Monitoring as the monthly AVO remains in place and constant. WPX used representative component counts within the various production threshold categories as a basis of how many components would represent two percent of the total components at a facility recognizing that it is unlikely and infeasible that site-specific component counts for each production facility could be obtained and maintained for many operators given the number and nature of production facilities and activities. However, WPX has proposed allowing the flexibility to use the representative number or a percentage of the total components at a facility if an owner or operator so chooses. The requested changes are performance based and the inspection frequencies revert back to the original frequencies if the number of leaks identified rise above the identified thresholds; ensuring production facilities maintain a low number of new component leaks.

WPX believes that reduced Instrument Based Monitoring inspection frequencies are justified by the following facts:

- Information provided by Trihydro, provided in PHS EX A, indicates that, by implementing a LDAR program, a facility can expect to find more leaks initially and then the percent of leaks found over time decreases to a very consistent low percent over time. Performing Instrument Based Monitoring on a monthly or quarterly basis in addition to monthly AVO LDAR monitoring does not make economic sense. Crucially, based on the data, there would not be any added environmental benefit for the additional resources expended.
- Implementing a LDAR program will be more resource intense for production facilities than for gas plants as an equal number of components for a gas plant would be spread over a greater distance for production facilities. Implementation of LDAR at production facilities located in the Piceance Basin may be even more difficult due to the remoteness of the facilities, distance between facilities, higher elevations, and road conditions. WPX's production facilities are located over a vast area in remote locations with significant distance between locations. On a fair weather day, the driving time between some facilities can take thirty (30) minutes to three (3) hours and travel time increases due to poor weather and road conditions. *See* PHS EX B and PHS EX C.
- WPX's estimated potential fugitive VOC emissions from all of its production sites are below APEN thresholds (2 tons/year) and the majority of facilities are below 0.5 tons per year. Therefore the potential environmental benefit of continuing frequent monitoring for each of these sites is very small when monitoring has already demonstrated consistent compliance with low leak levels.
- As indicated in information provided by an LDAR expert, reduced frequency LDAR monitoring or "Skip Monitoring" is an accepted practice that encourages implementation of effective LDAR programs with good performance. PHS EX A.

- Based on the information provided by Trihydro, *see* PHS EX A, the estimated fugitive emissions are being overestimated because the emission factors currently being applied to calculate fugitives are inflated. Using a 500 ppm leak definition will further make the estimated fugitive emissions based on these EPA emission factors more inflated. Therefore the environmental benefit or emission reductions are also being over estimated making the cost per ton of fugitive emission reductions much higher than estimated by the Division.

Note that for consistency and to match the revised language in XVII.F.5.e., WPX has also proposed clarifying language referring to both Table 3 (already included) and Alternative Table 3A (new) in Sections XVII.F.5.c and d. *See* ALT EX D at 11.

3. Proposed revisions to Section XVII.F.5.f.

XVII.F.5.f. Phase-in of Approved Instrument Based Monitoring Methods: Owners and operators of existing well production facilities and/or storage tanks shall identify and repair leaks from components using an Approved Instrument Based Monitoring Method, in accordance with the following schedule:

XVII.F.5.f.(i) Beginning January 1, 2015, facilities with uncontrolled actual VOC emissions greater than 50 tpy or multi-well sites.

XVII.F.5.f.(ii) Beginning July 1, 2015, facilities with uncontrolled actual VOC emissions greater than ~~20~~12 tpy but less than or equal to 50 tpy.

XVII.F.5.f.(iii) Beginning January 1, 2016, facilities with uncontrolled actual VOC emissions greater than 6 tpy but less than or equal to ~~20~~12 tpy.

XVII.F.5.g.(iv) By July 1, 2016, facilities with uncontrolled actual VOC emissions less than or equal to 6 tpy.

Corrections were made to the language in Section XVII.F.5.f to make the numbers consistent with Table 3 (12 instead of 20). WPX believes this was a typographical error. If not, then the numbers in Table 3 in Section XVII.F.5.e. need to be revised to replace 12 with 20. *See* ALT EX D at 13.

4. Revisions to Section XVII.F.5.g.(ii)

XVII.F.5.g.(ii) Unsafe to monitor components are those that cannot be monitored without exposing monitoring personnel to an immediate danger as a consequence of completing the monitoring, which includes weather conditions preventing access to the site, or that endanger monitoring personnel or equipment, or prevent use of Approved Instrument Based Monitoring Methods (such as reflection due to precipitation).³

Additions were made to language in Section XVII.F.5.g.(ii) to specifically include scenarios that may prevent monitoring due to conditions that endanger personnel or equipment. WPX recognizes that there are a number of conditions, events, or situations that could prevent safe

³ Note that the text set forth here contains WPX's proposed language, with highlighting to illustrate where WPX proposes changes to the Division's proposed regulation. For the actual redlined version of the proposed language, *see* ALT EX D at p. 13-14.

monitoring. It was the intention of these additions to identify some of these scenarios to ensure monitoring is done safely and for enforcement clarification. *See also* PHS EX C.

5. Revisions to Section XVII.F.6.

- XVII.F.6.a. For Method 21 monitoring at existing facilities, a leak is any concentration of hydrocarbon above 2,000 parts per million (ppm), except for existing well production facilities where leak is defined as any concentration of hydrocarbon above 500 ppm after January 1, 2016.
- XVII.F.6.b. For Method 21 monitoring at facilities constructed after ~~May 1, 2014~~ January 1, 2016, a leak is any concentration of hydrocarbon above 500 ppm.⁴

Clarifications were made to the language in Section XVII.F.6.a and b. These changes were made for consistency to better match other implementation dates included in the regulation, including facilities with uncontrolled actual VOC emissions between zero and 12 tons per year.

In addition, implementation of the 500 ppm leak definition after January 1, 2016 allows time for companies and equipment suppliers to ensure that equipment purchased for new production or existing facilities can meet the 500 ppm leak definition requirements. WPX contacted a number of our equipment suppliers to gage potential impacts of incorporating a 500 ppm leak definition. We have received a mixed response from our vendors. While some vendors are prepared to provide equipment that meets these standards, others vendors need time to evaluate their equipment to determine if they can meet these new standards with their existing equipment or need to re-design/re-engineer their equipment. As such, pushing out the time frame to require the 500 ppm leak definition standards allows both vendors and owners and operators time to ensure compliance with the proposed standard at both existing and new facilities.

To ensure consistency with these proposed changes, the language at Section XVII.F.7.d. was similarly revised to include the clarification that the 500 ppm standard for existing well production facilities does not go into effect until January 1, 2016 (although the 2000 ppm standard will go into effect for existing well production facilities immediately), and to ensure that the 500 ppm standard does not go into effect for any new facility until January 1, 2016. *See* ALT EX D at 15. The referenced language is set forth below:

- XVII.F.7.d. For leaks identified using an Approved Instrument Based Monitoring Method, owners and operators have the option of either repairing the leak in accordance with the repair schedule set forth in Section XVII.F.7. or conducting follow-up monitoring using Method 21 within five (5) working days of the leak detected. If the follow-up Method 21 monitoring shows that the leak concentration is less than or equal to 2,000 ppm hydrocarbon for existing facilities (other than existing well production facilities after January 1, 2016), or 500 ppm for new facilities or existing well production facilities after January 1, 2016, then the emission shall not be considered a leak for purposes of this Section.

⁴ Note that the text set forth here contains WPX's proposed language, with highlighting to illustrate where WPX proposes changes to the Division's proposed regulation. For the actual redlined version of the proposed language, *see* ALT EX D at p. 14.

6. Proposed revisions to Section XVII.C.3.a.

- XVII.C.3.a. In addition to any applicable Approved Instrument Based Monitoring Methods, audio, visual, olfactory (“AVO”) inspection of the storage tank and any associated equipment (i.e. separator, air pollution control equipment, or other pressure reducing equipment), must be completed as often as liquids are loaded out from the storage tank. However, AVO inspection is required no more frequently than every seven (7) days or less frequently than every thirty (30) days. AVO monitoring is not required for components and tanks that are difficult, unsafe, or inaccessible to monitor pursuant to Section XVII.F.5.g.⁵

WPX proposes this revision for clarification and consistency with the LDAR definition of what is difficult, unsafe, or inaccessible to monitor. As currently drafted, the proposed STEM regulations only included that AVO monitoring is not required for components and tanks that are “unsafe to monitor.” WPX proposes the clarification with reference to Section XVII.F.5.g, which defines what is difficult, unsafe, or inaccessible to monitor and provides consistency in the proposed regulations.

7. Proposed revisions to Section XVII.F.4.

- XVII.F.4. Inspection schedules for natural gas compressor stations: Beginning January 1, 2015, owners and operators of natural gas compressor stations shall inspect components for leaks using an Approved Instrument Based Monitoring Method, in accordance with the following Table 2, except for components subject to XVII.F.5.g. For purposes of this Section XVII.F.4., fugitive emissions shall be calculated using the emission factors of Table 2-4 of the 1995 EPA Protocol for Equipment Leak Emission Estimates (Document EPA-453/R-95-017), or other Division approved method.

WPX proposed the above typographical correction, to change the “of other Division approved method” to the intended “or other Division approved method.”

III. List of Issues for Commission to Resolve.

As addressed above, the issues WPX requests the Commission to resolve are limited in nature, and can be summarized into three main points.

The primary issue is whether it is appropriate to implement skip period monitoring, a recognized practice in LDAR programs, where an owner or operator consistently demonstrates a reduction in leaks below a specified threshold. If continued decreased leaks are not demonstrated, then WPX agrees that the original monitoring frequency should be reestablished until the reduced leak threshold is again demonstrated.

A secondary issue is whether the proposed regulations, in light of their stringent requirements and first-time enforcement of such requirements for the regulated facilities, provide sufficient time to suppliers of component parts to assure owners and operators that the equipment that is in place, or that will be installed in new facilities, is adequate to meet the new requirements. Based on

⁵ Note that the text set forth here contains WPX’s proposed language, with highlighting to illustrate where WPX proposes changes to the Division’s proposed regulation. For the actual redlined version of the proposed language, see ALT EX D at p. 6.

discussions with suppliers, additional time is needed to ensure that companies and suppliers can be assured of the 500 ppm leak detection rate. At issue here is whether a slight delay in implementing the 500 ppm leak detection rate, recognizing that the 2000 ppm leak detection rate will go into effect immediately, is therefore warranted.

A final issue for the Commission's consideration is clarifying what constitutes "unsafe" conditions for monitoring, particularly since owners and operators across the state are not similarly situated with respect to the location and conditions of access to their facilities.

IV. Exhibits.

The following Exhibits are proposed for submission in support of WPX's position on the Division's proposed rulemaking:

1. Trihydro Corporation Report, including its accompanying figures and tables. *See* PHS EX A.
2. Map of WPX's Piceance operating locations. *See* PHS EX B.
3. Photographs illustrating the location of and types of facilities WPX has within the State, including documentation of remoteness and challenges in inclement weather. *See* PHS EX C.
4. Any exhibits identified by any other person or party.

V. List of Witnesses.

1. Brad Moss, District Production Manager, WPX Piceance Operations.

Mr. Moss may testify regarding the operations of WPX in the Piceance, including a description of why its operations differ from other areas in the state.

2. Jay Christopher, Business Unit Manager, Air and Process Services, Trihydro Corporation.

Mr. Christopher may testify regarding the report submitted by Trihydro Corporation, including the basis for, and conclusions of that report.

3. JoDell Mizoue, Environmental Supervisor, Air Compliance, WPX.

Ms. Mizoue may testify regarding the operations of WPX in the Piceance, including information about costs and time associated with monitoring, recordkeeping and documentation associated with the proposed regulations.

4. Any witness identified or called by any other person or party.
5. Impeachment and rebuttal witnesses.

6. Any witness identified in any exhibit submitted by any other person or party.

VI. Written Testimony.

WPX submits the report by Trihydro Corporation as written testimony to be incorporated into the record. WPX reserves the right to call its witnesses to explain and present the data and conclusions reached in the report.

WPX has not submitted written testimony of other potential witnesses as it has not been ordered by the Commission, but if so required, reserves its right to submit such testimony with its rebuttal to the Prehearing Statements, or by other such time frame ordered by the Commission.

VII. Text of Alternative Proposed Rule.

WPX refers the Commission to its ALT EX D, attached to WPX's simultaneously filed Alternative Proposal, which sets forth in redlined and highlighted text WPX's alternative proposed rule. Note that the revisions suggested by WPX are found at p. 6 and pgs. 10 -15 of the ALT EX D. As noted, WPX does not believe that its targeted comments rise to the level of an alternate proposal, but out of an abundance of caution has presented them as such, along with the accompanying required documents set forth in Procedural Rules Section V.C.3.a through k. *See* WPX's Alternate Proposal ("ALT") submitted simultaneously with WPX's Prehearing Statement.

VIII. Narrative Pursuant to Section 25-7-105.1, 110.5(1)(d) and 133(3).

WPX notes that its alternate proposal does not introduce new or different requirements than the regulations proposed by the Division. As noted by the Division, the proposed rules are more stringent than the federal regulations. WPX's alternate proposal is no more stringent than the Division's proposed regulatory language. As such, WPX relies on and incorporates here the statements made by the Division in its Agenda Item Control Sheet Issue Statement (submitted November 18, 2013), as well as the Draft Statement of Basis, Specific Statutory Authority, and Purpose (submitted by the Division on November 18, 2013) as part of this rulemaking, which address the issues required by Procedural Rule Section V.E.6.c.(viii).

IX. Final Economic Impact Analysis.

Pursuant to the Commission's Order dated December 18, 2013 ("Order"), any alternate proposal submitted to the Commission does not need to include a Final Economic Impact Analysis. *See* Order, Subpart B. The Commission has ordered that the Final Economic Impact Analysis be filed on or before January 30, 2014. As such, WPX does not include a final economic impact analysis at this point.

However, as requested by the Division, WPX points out that the initial economic analysis submitted by the Division on November 18, 2013 as it relates to LDAR issues, Section C, pages 14 to 20, underestimates the costs associated with LDAR implementation (the only section addressed in WPX's alternate proposal). WPX believes that the costs set forth by the Division are underestimated for several reasons, including that the Division only estimates one additional FTE will be necessary to conduct the inspections, and that the Division did not calculate any costs associated with the

additional documentation required by the increased monitoring requirements (including the AVO monitoring), nor did the Division calculate any costs associated with the time to repair and document the inspections or any leaks that are found. In addition, the Division's estimate of times necessary to conduct inspections does not take into account the location and time to travel from one facility to another, which in some areas of the state, particularly where WPX operates, can take up to three hours in good weather just to get to a site.

WPX also notes that its alternate proposal will in any event potentially save some costs for owners and operators if they can demonstrate reduced leak detection rates on a regular basis and therefore the costs associated with WPX's alternate proposal, at a minimum, would be less than costs associated with the Division's proposal.

WPX reserves its right to submit a final economic analysis on or before January 30, 2014 as allowed by the Commission's Order.

X. Reservation of Rights.

WPX expressly reserves its right to amend, delete, modify, add to, and/or supplement the materials and issues, including additional legal argument or witnesses and exhibits identified in this Prehearing Statement and provided to the Commission along with this document, and including WPX's Alternate Proposal, based on the Division's presentation in its case-in-chief, as well as in consideration of alternate rule proposals and prehearing statements (including direct testimony or lists of witnesses) that may be submitted by other parties to this matter.

Respectfully submitted this 6th day of January, 2014.

WPX ENERGY ROCKY MOUNTAIN, LLC and WPX
ENERGY PRODUCTION, LLC

BEFORE THE COLORADO AIR QUALITY CONTROL COMMISSION

**REGARDING REVISIONS TO REGULATION NUMBERS 3, 6 AND 7
February 12-21, 2014 Hearing**

**REBUTTAL STATEMENT OF
ENCANA OIL AND GAS (USA) INC.**

Encana Oil & Gas (USA) Inc. (Encana) filed for and was granted party status in the above-captioned matter. Encana duly and timely filed its prehearing statement. Pursuant to the 25 November 2013 Notice of Public Rulemaking in the above-captioned matter, and the Air Quality Control Commission's (Commission) procedural rule V.E.6.d, Encana now respectfully submits this rebuttal statement and accompanying materials.

I. EXECUTIVE SUMMARY

In December 2012, the Air Pollution Control Division (Division) notified the oil and gas industry, other stakeholders, and the public that the Division was “considering revisions related, but not limited, to the full adoption of 40 CFR Part 60, Subpart OOOO (“NSPS OOOO”) and to air pollutant emission notice reporting and construction permit thresholds, as well as additional control measures for oil and gas operations and equipment.”¹ Almost a year later, the Commission formally initiated a rulemaking proceeding to consider revisions to Regulations 3, 6, and 7 to fully incorporate by reference NSPS OOOO and to “establish state-only volatile organic compound (VOC) and other hydrocarbon emission control requirements for oil and natural gas operations.”² In the intervening months, the Division convened numerous large stakeholder meetings, as well as smaller subcommittee meetings to explore a wide range of issues related to the instant proceeding. Numerous stakeholders participated and, in many

² <http://www.colorado.gov/cs/Satellite?blobcol=urldata&blobheadname1=Content-Disposition&blobheadname2=Content-Type&blobheadvalue1=inline%3B+filename%3D%22Notice+Of+Rulemaking+Hearing.pdf%22&blobheadvalue2=application%2Fpdf&blobkey=id&blobtable=MungoBlobs&blobwhere=1251913358003&ssbinary=true> (last visited Jan. 24, 2014)

instances, submitted written materials outlining the issues they asserted should be addressed in a rulemaking. The agendas and some of the materials exchanged can be found on the Division's web site.³

Encana agrees with the argument expressed by many parties that fair notice and process is integral to the development of regulatory proposals that satisfy Colorado's procedural requirements for rulemaking, as well as fundamental fairness. But while some of the more than thirty parties to this rulemaking assert that the Commission's process fails one or more particulars of Colorado's Administrative Procedure Act (APA), Colo. Rev. Stat. § 24-4-101, *et seq.* (2013), the record of stakeholder consultation prior to the notice of rulemaking and the materials filed in this matter by the Division and other stakeholders, including Encana, suggest the procedural requirements of the Colorado APA have been more than met.

Every interested party has been given abundant opportunity to raise issues and propose alternative approaches for management and control of atmospheric emissions from the oil and gas industry. The materials posted on the Division's web site provide a picture of the robust back-and-forth that was had among diverse parties. Many of the concerns expressed during that process are reflected in the Division's proposal. For example, many industry parties expressed concerns about how visible emissions are monitored and enforced; the Division's proposal includes language to accomplish that goal.

Encana believes that more than adequate process has been provided. Moreover, by the time all parties, including the Division, have had full opportunity to present their arguments and evidence at hearing, it will be clear that the more granular admonitions of the APA also have been satisfied. *See, e.g.*, Colo. Rev. Stat. § 24-4-103(4)(b).

Encana believes the Division has also met the requirements of the Colorado Air Pollution Prevention and Control Act (Colorado Air Act), Colo. Rev. Stat. § 25-7-101, *et seq.* (2013). Colorado has a long and proud tradition as a leading-edge innovator in managing and controlling air pollution, owing in large part to the Act's commitment to proactive action to prevent air pollution problems as well as to manage existing air pollution. The proposal from the Division is in keeping with that tradition.

The proposal from the Division will measurably reduce emissions of volatile organic compounds and hydrocarbons across the state from the oil and gas sector, including in the Denver Metro/North Front Range Ozone Nonattainment Area. The Division's proposal will accomplish that goal, in substantial part, by establishing a requirement for instrument-based monitoring of wellhead facilities and compressor stations to ensure that leaks are timely repaired, and by establishing a Storage Tank Emissions Management program that will reduce emissions and

³ <http://www.colorado.gov/cs/Satellite/CDPHE-AQCC/CBON/1251647985820> (last visited Jan. 24, 2014).

increase capture efficiency from storage tanks in the oil and gas sector. By requiring these control measures on a statewide basis, the Commission would be making a permissible policy decision, within its scope of authority, to proactively address air pollution in some parts of the state that currently are designated as attainment while working to reduce air pollution in the ozone nonattainment area.

As noted already, the Colorado Air Act anticipates that the Commission will act in response to existing problems and in anticipation of potential future air quality problems. Nothing requires the Commission to limit the scope of its regulations to a specific region; indeed, the Act contemplates that in appropriate circumstances, the Commission may establish statewide control measures, as the Division proposes here. While the Act creates an expectation of reasoned decision-making, a goal no doubt shared by all parties, the Act permits the Commission to set priorities and to attack problems seriatim. The Colorado Air Act does not require the Commission to resolve large and complex problems at one rulemaking.

Based on its experience in Wyoming's Jonah Field (see section V, *infra*) Encana believes that the Division's proposal reflects a common-sense approach that appropriately balances environmental benefits and costs. As such, the Division's proposal falls within the scope of the Colorado Air Act.

It is worthy of mention that some parties seek even more stringent requirements for monitoring, repair, and certain control measures than those proposed by the Division. Other parties seek less frequent monitoring, less demanding repair requirements, and less stringent control measures. The Division has plotted a thoughtful, comprehensive, but balanced middle ground in addressing air pollution, relying upon technologically feasible and cost-effective strategies. Encana stated at the outset its support for the Division's proposal, and reiterates that support in this rebuttal statement.

II. NARROWING ISSUES:

PROPOSED LANGUAGE FROM DCP MIDSTREAM PREHEARING STATEMENT

In its prehearing statement, DCP Midstream stated that it supports the Division's proposal as an appropriate policy step but urged the Commission to consider five discrete, targeted clarifications that would ease and clarify compliance with Section XVII by natural gas compressor stations without diminishing the environmental benefits to be gained by adoption of these revisions. Those targeted clarifications consisted of the following changes:

1. A minor revision to the proposed definition of Natural Gas Compressor Station to make clear that these regulations do not extend to natural gas processing stations, which already are subject to significant federal emissions control requirements;

2. A minor revision to the glycol dehydrator control requirements to ensure that operators are not required to replace existing, permitted and effective emissions controls;
3. Revision of the definition of component, along with accompanying additions to ensure that compressor seals and open ended lines and valves are appropriately managed;
4. Minor revisions to the Statement of Basis and Purpose regarding the definition of Well Production Facility to make clear the demarcation between a natural gas producer's well facilities and those facilities operated by a midstream company; and
5. Minor revisions to the Storage Tank inspection and monitoring requirements to clarify the operation of those requirements with respect to midstream facilities as opposed to those at well production facilities.

Encana carefully considered these proposed revisions, and concluded that they clarify the proposed revisions to Section XVII and ease compliance burdens and cost without lessening the proposed revisions' effectiveness. Consequently, Encana endorses these revisions *in toto*.

III. THE COMMISSION HAS THE STATUTORY AUTHORITY TO REGULATE VOCs AND HYDROCARBONS

The Commission's authority to regulate emissions of volatile organic compounds and nitrogen oxides, both of which are ozone precursors, from the oil and gas sector (and other source categories) is clear. However, the Division's proposal in this instance would expand Regulation 7's reach to include hydrocarbon emissions from the oil and gas sector. Several parties have challenged the Commission's authority to do so.

Certainly, "state agencies are creatures of statute and have 'only those powers expressly conferred by the legislature.'" *Pawnee Well Users, Inc. v. Wolfe*, 2013 WL 6172292 (Colo S.Ct. Nov. 25, 2013)(citations omitted). It is equally true that in construing a statutory provision, the courts will look first to the express language of the statute itself, and will resort to alternative tools of statutory construction only if the statutory language is ambiguous. *Jefferson County Bd. of Equalization v. Gerganoff*, 241 P.3d 932, 935 (2010);⁴ *Dept. of Revenue v. Woodmen of the World*, 919 P.2d 806, 809-810 (1996).

The Colorado Air Act specifically provides that the Commission shall promulgate emissions controls, and that such controls may include regulations pertaining to "sulfur oxides, sulfuric

⁴ Even were the statute ambiguous, a reviewing court would give great weight to an agency's interpretation of its own organic statute. *Smith v. Farmers Insurance Exchange*, 9 P.3d 335, 340 (2000).

acids, hydrogen sulfide, nitrogen oxides, carbon oxides, hydrocarbons, fluorides, and any other chemical substance.” Colo. Rev. Stat. § 25-7-109(2)(c)(2013)(emphasis added).

The plain language of this enabling legislation provides the Commission with the authority to adopt the regulation at issue here. Encana offers no opinion on whether the Commission has the authority to regulate any other pollutant. That question is not presented in this instance, and it is not necessary for the Commission to address it in a hypothetical context. It is sufficient to note that the General Assembly has given the Commission the authority to regulate emissions of hydrocarbons.

IV. THIS RULEMAKING COMPORTS WITH THE PROCEDURAL REQUIREMENTS OF THE ADMINISTRATIVE PROCEDURE ACT AND THE COLORADO AIR ACT

A. Administrative Procedure Act

The Administrative Procedure Act (APA), Colo. Rev. Stat. § 24-4-101, *et seq* (2013), creates a roadmap for adoption of rules by administrative agencies. While some parties disagree, Encana believes that a fair reading of the process and the record show that the Division has adhered to the statutory mileposts along the way, assuring compliance with the spirit as well as the legal requirements of the APA.

The Division formally notified stakeholders more than a year ago that the Division was contemplating revisions to Regulations 3, 6 and 7 with respect to the oil and gas sector.⁵ The Division convened a stakeholder process that involved numerous meetings as well as the exchange of ideas, both in writing and orally. The Division and stakeholders engaged in a robust discussion of alternatives. Along the way, some issues were raised but left unresolved. In other instances, the parties moved toward agreement. For example, the notion of a Storage Tank Emission Management (STEM) program emerged as an alternative to the initial idea of adopting a presumptive-BACT control requirement. Along the way, different groups of stakeholders offered their individual recommendations for what a rulemaking proposal should embrace. The proposal that the Division ultimately settled on relied in many respects upon a joint proposal that had been developed in a collaborative effort by Encana, Anadarko Petroleum Corporation, Noble Energy, and Environmental Defense Fund. Even that proposal incorporated numerous elements developed by other stakeholders throughout the process.

⁵ <http://www.colorado.gov/cs/Satellite?blobcol=urldata&blobheadername1=Content-Disposition&blobheadername2=Content-Type&blobheadervalue1=inline%3B+filename%3D%22Notice+of+2013+Rulemaking+Stakeholder+Meetings.pdf%22&blobheadervalue2=application%2Fpdf&blobkey=id&blobtable=MungoBlobs&blobwhere=1251844864207&ssbinary=true> (last visited Jan. 24, 2014).

Consistent with the provisions of the APA, the Division then submitted to the Commission Memoranda of Notice requesting that the Commission consider revisions to Regulations 3, 6, and 7.⁶ The Division's proposal included draft language of the proposal accompanied by draft Statements of Basis and Purpose and plain language explanations of the proposed action. The Division's proposal was accompanied by a draft Economic Impact Analysis.⁷ At its regular meeting on November 21, 2013, the Commission formally noticed its intent to initiate a rulemaking proceeding to consider revisions to Regulations 3, 6, and 7.

The APA permits affected interest to request the preparation of a cost-benefit analysis, a regulatory impact analysis, or both, for inclusion in the rulemaking process. Colo. Rev. Stat. § 24-4-103(2.5)(a). Several parties made just such a request.⁸ The Division has agreed to prepare these documents, and the Hearing Officer directed that the cost-benefit statement be made available by the Division no later than February 7, and that the regulatory impact analysis be made available no later than February 14.⁹

In Encana's view, the Division has adhered to the procedural requirements for rulemaking established by the General Assembly. The Division has compiled substantial information in the record to demonstrate the basis and purpose of the proposed regulation, Colo. Rev. Stat. § 24-4-103(4)(b)(I), and Encana believes that record is sufficient to justify adoption of the proposed rules in this case.

⁶ The memoranda of notice can be found at <http://www.colorado.gov/cs/Satellite/CDPHE-AQCC/CBON/1251647985820>.

⁷ All of these materials can be found at the Commission's web site, *id.*

⁸ A list of the requesters, and copies of their requests can be found at the Commission's web site:

<http://www.colorado.gov/cs/Satellite?blobcol=urldata&blobheadername1=Content-Disposition&blobheadername2=Content-Type&blobheadervalue1=inline%3B+filename%3D%22Combined+List+of+Requests+for+Cost+Benefit+and+Regulatory+Analysis+%2846+pages+-+revised+12%2F20%2F13%29%29.pdf%22&blobheadervalue2=application%2Fpdf&blobkey=id&blobtable=MungoBlobs&blobwhere=1251929901749&ssbinary=true>.

⁹ <http://www.colorado.gov/cs/Satellite?blobcol=urldata&blobheadername1=Content-Disposition&blobheadername2=Content-Type&blobheadervalue1=inline%3B+filename%3D%22Order+by+the+Commission.pdf%22&blobheadervalue2=application%2Fpdf&blobkey=id&blobtable=MungoBlobs&blobwhere=1251929901605&ssbinary=true>. It is important to note that “[f]f the agency has made a good faith effort” to comply with the requirement for preparation of a cost-benefit analysis, the rule :shall not be invalidated in the basis that the contents of the cost-benefit analysis are insufficient or inaccurate.” Colo. Rev. Stat. § 24-4-103(2.5)(d)(2013).

B. Colorado Air Act

Several parties contend that the proposal falls short of the requirements set by the Colorado Air Act. However, an examination of the Act's requirements and their application in this proceeding demonstrates that the core requirements of the Air Act have been met.

In adopting Colorado's Air Act, the General Assembly declared that

... it is the policy of the state to maintain the national ambient air quality standards, and to prevent the significant deterioration of air quality in those portions of the state where air quality is better than the national ambient air quality standards. To that end, it is the purpose of this article to require the use of all available practical methods which are technologically feasible and economically reasonable so as to reduce, prevent, and control air pollution throughout the state of Colorado.

Colo. Rev. Stat. § 25-7-102 (2013). The same section requires that control measures "bear a reasonable relationship to the economic, environmental, and energy impacts and others costs of such measures." In its prehearing statement and Economic Impact Analysis, the Division, along with other parties, provided substantial information on the economic reasonableness and feasibility of the LDAR, STEM and control measures called for in this proposal. Encana will provide additional support for that proposition in their testimony. Encana also believes the proposed rule reasonably balances costs and environmental benefits. Accordingly, Encana believes the record will more than adequately support adoption of the instant proposal.

Section 25-7-102 also requires the Division to develop and maintain an inventory of emissions to facilitate the Division's and the Commission's manifold responsibilities. The Division and the Regional Air Quality Council have been developing such inventories for some years. The Regional Air Quality Council's prehearing statement refers both to emissions inventories and trends, and ongoing modeling efforts with respect to the Denver Metro/North Front Range Ozone Nonattainment Area. The Division has provided substantial information on the relative emissions and emission trends of different source categories. Some parties argue that the inventories overstate emissions and emissions trends from the oil and gas sector and other parties argue those inventories significantly understate emissions and emission trends. While the Division and other entities will continually revise and update inventories as new science becomes available, the record reflects that the Division has submitted extensive information on this issue. Therefore, Encana believes this requirement of the Air Act has been satisfied.

Notably, the Air Act grants the Commission "maximum flexibility in developing an effective air quality control program," permits the Commission to divide the state into "such control regions or areas as may be necessary or desirable for effective administration of this article," and specifically notes that the Commission may adopt regulations that are applicable to the whole

state or to specified areas of the state. Colo. Rev. Stat. § 25-7-106(1)(a)-(c) (2013). This section of the Colorado Air Act acknowledges the inherent complexity involved in understanding the generation, transport, and chemistry of air pollution, and provides the Commission with the necessary flexibility to adapt its regulations as science develops and situations change.

Some parties argue that the Commission erred in making its proposed regulations applicable statewide, even though the Commission's organic statute expressly permits such action. Some also argue, in addition, that by applying these regulations statewide, the Commission proposes to effectively designate the entire state as a nonattainment area under the federal Clean Air Act. Encana does not believe that is the case here. The Division has expressly and emphatically stated that the proposed amendments to Regulation 7 would be state-only and will not be proposed for inclusion in Colorado's state implementation plan; the proposed rules include specific notations to that effect. Such action is explicitly contemplated by Colo. Rev. Stat. § 25-7-105.1. The mere act of applying a targeted, discrete, common sense set of regulations to the oil and gas sector statewide does not convert this to a SIP action, to a re-designation of areas as nonattainment, or to creation of a statewide nonattainment area. Rather, it speaks to the Division's desire to reduce complexity in its regulations, and to address air pollution issues proactively, which Encana supports.

Adopting these rules as state-only requirements fits well with the Division's stated goal of addressing existing and potential air pollution issues within the state's legal authority, without adding the extra burden of making these provisions federally enforceable. This will permit the state and the industry to work together to implement these measures, assess their effectiveness, and to consider technical adjustments as new data are collected. The Division has explained why, in its view, these measures are needed, even if they may exceed current federal requirements. *See* Colo. Rev. Stat. § 110.5(5)(2013).

C. Conclusion.

The Colorado General Assembly has chosen to vest part-time citizen bodies, such as the Air Quality Control Commission, with rulemaking authority, bounded by the APA. *Colorado Ground Water Comm'n v. Eagle Peak Farms, Ltd.*, 919 P.2d 212, 216 (1996). The instant rulemaking is quasi-legislative in nature, and necessarily calls upon the Commission to make policy as well as factual determinations, though policy determinations may predominate. *Id. See also, Citizens for Free Enterprise v. Dept. of Revenue*, 649 P.2d 1054, 1063-1064 (1982). Of course, the Commission's decision must be based on the administrative record, Colo. Rev. Stat. § 24-4-106, and if the agency's decision is reasonable it will be affirmed. *Brighton Pharmacy, Inc. v. Colorado State Pharmacy Bd.*, 160 P. 3d 412 (Colo. App. 2007)

The Division has compiled a record demonstrating the basis and purpose for regulation in this matter, as well as substantial evidence that the control measures being proposed are

economically reasonable and technically feasible. Other parties have provided and will provide additional support for the Division's proposal. The Division calculates that the proposed regulations will yield significant reductions in emissions of volatile organic compounds and hydrocarbons across the state, including in the ozone nonattainment area. The Division also has provided information on the reasonableness of the phase-in schedule for instrument-based monitoring, the effective dates for installation of controls on glycol dehydrators, and replacement of high-bleed pneumatics with low-bleed pneumatics. The Division reasonably concluded that application of these measures statewide would provide additional environmental benefits at a reasonable cost while reducing confusion for the regulated industry and the general public. While some parties argue for more frequent instrument-based monitoring and others argue for less frequent instrument-based monitoring of components at wellhead facilities and compressor stations, the Division's proposal can be tied to evidence in the record showing that its policy choice reflects a careful balancing of the proposal for additional regulation with a due regard for the cost and feasibility of the proposed control measures.

V. THE PROPOSED LEAK DETECTION AND REPAIR REQUIREMENTS ARE ECONOMICALLY REASONABLE AND TECHNICALLY FEASIBLE

A. Auditory, Visual, and Olfactory Inspections.

The proposal will require Auditory, Visual, and Olfactory (AVO) inspections of tanks and other equipment as an adjunct in many cases to instrument-based monitoring. Encana currently has operational practices and procedures in place that can support this requirement with limited cost. In Encana's operations, lease operators visit well production facilities on a regular basis, typically daily or every other day, and complete monitoring tasks supporting the current Regulation 7 requirements such as monitoring pilot lights, checking for the presence or absence of smoke, etc. Additionally, Encana already has data tracking systems in place to track and record these compliance monitoring tasks. As such, adding AVO inspections to the lease operators' duties will result in little additional cost to Encana. However, Encana will need to train the lease operators to conduct and record their AVO inspections as part of their regular duties. Encana estimates that the lease operators will be able to visit 10-30 sites per day in the DJ Basin, and 10-20 sites per day in the Piceance Basin. For facilities with emissions controls, the results of those AVO inspections could then be captured in the company's tracking database, which currently exists. Encana will need to expand this database to capture the results of AVO inspections at sites without emissions controls and estimates these costs will be minimal.

B. Encana's Experience with Leak Detection and Repair Supports the Economically Reasonable Approach Reflected in the Division's Proposal.

Driven by the desire for regulatory certainty and other business considerations, Encana has gained significant experience with LDAR programs at its operations in the Jonah Field in Wyoming. In total, Encana conducts approximately 2,040 instrument-based inspections per year at its Jonah facilities and carefully records the results. Encana uses a comprehensive database to track inspections and corresponding leaks. With these data Encana is able to calculate the annual non-amortized cost of the program. While Encana can speak only to its experiences, Encana has a unique perspective on the utility and cost-reasonableness of LDAR programs.

The Division's proposal requires owners and operators of well production facilities to use instrument-based technologies to inspect their facilities for leaks, and repair leaks that exceed a certain defined threshold. The Division's proposal establishes different inspection frequencies for Leak Detection and Repair (LDAR) for facilities based on uncontrolled actual emissions. Some parties have argued that the inspection frequencies should be made more rigorous, even for the smallest sources, and that the value of the natural gas recovered offsets the program costs. As noted below, it has been Encana's experience that the value of the gas recovered does not offset the program costs of an instrument-based monitoring program for well production facilities. Other parties also have suggested that an instrument-based system loses its efficacy after an initial set of inspections. However, Encana's experience with an instrument-based monitoring program for well production facilities show that leaks continued to be detected well into the established LDAR program.

Notably, under the Division's proposal, the smallest sources, with uncontrolled actual emissions less than 6 tons per year, will require a single instrument-based inspection. Encana calculates that these one-time inspections will yield significant environmental benefits, because the monitoring data from the company's experience in Wyoming shows the greatest number of leaks was discovered within the first monitoring event. Larger facilities will be required to conduct more frequent instrument-based inspections, and the largest facilities will be required to conduct inspections on a monthly basis. Data from Encana's Wyoming program suggest that while emissions decrease after an initial set of inspections, a number of small leaks continue to be discovered as the program progresses. This supports the utility of more frequent inspections at larger facilities because these facilities have greater potential for higher total emissions volumes and numbers of leaks.¹⁰

Viewed somewhat differently, Encana's data also suggest that while the largest reductions in VOC emissions occur in the first year of an LDAR program, regardless of whether the program entails monthly, quarterly, or annual inspections, emissions reductions are still being realized in subsequent years of the LDAR program. Encana also examined its Wyoming data for monthly

¹⁰ In graphing the decline in emissions and numbers of leaks detected, Encana used actual data combining all facilities. Encana expects that the shape of the curve showing the decline in emissions would be less steep if the frequency of inspections also declined. These data suggest that while tiering is essential, building in an option to reduce inspection frequencies may lead to both higher volumes of emissions and higher numbers of leaks.

monitoring over a four-year period, and extrapolated those data to other monitoring frequencies. These data suggest that monthly inspections result in the lowest emissions but significant reductions are still achieved at the other monitoring frequencies. However, as noted above, an LDAR program is likely to produce the greatest reductions in VOC emissions from large facilities and that the potential for diminishing returns is reduced by the use of tiered monitoring frequencies. Encana believes that the tiered monitoring is the best approach for balancing costs with benefits.

Encana's experience shows that at no time, under any monitoring frequency, does the value of the gas recovered equal or exceed the costs of the monitoring program. In fact, the delta between costs and savings, measured solely by the value of natural gas captured, is significant at all inspection frequencies. This is directly contrary to the claims made by a witness for the Conservation Organizations and an exhibit offered by the Local Government Coalition.

At the same time, it has been Encana's experience that building into the regulation a tiered approach, in which larger facilities are subject to progressively more frequent instrument-based monitoring, is significant in examining the costs and benefits of an LDAR program. By applying its Wyoming experience to its Colorado assets, Encana estimates that total costs of the proposed rule (non-amortized) will decline significantly after the initial year (in which capital costs are incurred). As noted elsewhere, this tiered approach is likely to yield the greatest environmental benefit: while small facilities' leaks likely will be captured after an initial inspection, larger facilities likely will have more components and higher pressures and, therefore, higher potential emissions. Accordingly, more frequent inspections are useful at those large facilities.

Finally, Encana emphasizes that while it supports the rule at issue here, as a common sense, achievable set of control measures, Encana's data show that these measures will impose significant costs and that the value of recovered gas will not offset those costs. Implementation of the leak detection requirements, for example, will require at least an initial inspection at more than 1,100 facilities, as well as quarterly or monthly inspections at more than another 300 facilities. A requirement to conduct annual inspections at those 1,100 facilities, each with tank emissions of less than 6 tons/year, would dramatically increase the program's total costs and logistical challenges of an LDAR program, yet likely would yield a very modest incremental environmental benefit, at most. Encana strongly cautions the Commission about the additional costs that would be imposed by an inspection regime more stringent than contemplated by the proposed rule.

VI. CONCLUSION

Encana believes that the legal and procedural requirements for rulemaking in this case have been satisfied and urges adoption of the Division proposal, with appropriate technical and clarifying changes as the hearing may reveal are necessary.

VII. REBUTTAL WITNESSES

Witnesses who may testify at the hearing, on both in support of the proposed regulations and on rebuttal on behalf of Encana include:

1. James Martin
Beatty & Wozniak, P.C.
Attorney for Encana Oil & Gas (USA) Inc.

Mr. Martin may testify to the legal and policy issues raised in Encana's Prehearing Statement, Rebuttal Statement, and accompanying materials.

2. Cindy Allen
Team Lead – Environmental and Regulatory Compliance
Encana Oil & Gas (USA) Inc., acting by and through its authorized agent,
Encana Services Company Ltd.

Ms. Allen may testify to Encana's experience with leak detection and repair.

VII. WRITTEN TESTIMONY

At this time, Encana does not intend to submit written witness statements. However, Encana reserves its right to file written testimony in advance of the hearing if doing so would assist in achieving a more efficient hearing.

VIII. ATTACHMENTS

A. Encana submits the attached legal memorandum to aid the Commission in its evaluation of claims and arguments that Encana believes are outside the scope of the Commission's Notice: **LEGAL MEMORANDUM ASSERTING CERTAIN CLAIMS ARE OUTSIDE THE SCOPE OF THE NOTICE OF RULEMAKING**

B. RESUME OF CINDY ALLEN

IX. REQUEST FOR TIME

Absent intervening events, Encana foresees no need for time in addition to the time allocation as provided by the Hearing Officer's Prehearing Order.

Respectfully submitted this 30th day of January 2014.

PREFACE

On March 28, 2014 the Obama Administration released a key element called for in the President's Climate Action Plan: a Strategy to Reduce Methane Emissions. The strategy summarizes the sources of methane emissions, commits to new steps to cut emissions of this potent greenhouse gas, and outlines the Administration's efforts to improve the measurement of these emissions. The strategy builds on progress to date and takes steps to further cut methane emissions from several sectors, including the oil and natural gas sector.

This technical white paper is one of those steps. The paper, along with four others, focuses on potentially significant sources of methane and volatile organic compounds (VOCs) in the oil and gas sector, covering emissions and mitigation techniques for both pollutants. The Agency is seeking input from independent experts, along with data and technical information from the public. The EPA will use these technical documents to solidify our understanding of these potentially significant sources, which will allow us to fully evaluate the range of options for cost-effectively cutting VOC and methane waste and emissions.

The white papers are available at:

www.epa.gov/airquality/oilandgas/whitepapers.html

1.0 INTRODUCTION

The oil and natural gas exploration and production industry in the U.S. is highly dynamic and growing rapidly. Consequently, the number of wells in service and the potential for greater air emissions from oil and natural gas sources is also growing. There were an estimated 504,000 producing gas wells in the U.S. in 2011 (U.S. EIA, 2012a), and an estimated 536,000 producing oil wells in the U.S. in 2011 (U.S. EIA, 2012b). It is anticipated that the number of gas and oil wells will continue to increase substantially in the future because of the continued and expanding use of horizontal drilling combined with hydraulic fracturing (referred to here as simply hydraulic fracturing).

Due to the growth of this sector and the potential for increased air emissions, it is important that the U.S. Environmental Protection Agency (EPA) obtain a clear and accurate understanding of emerging data on air emissions and available mitigation techniques. This paper presents the Agency's understanding of emissions and available emissions mitigation techniques from a potentially significant source of emissions in the oil and natural gas sector.

Oil and gas production from unconventional formations such as shale deposits or plays has grown rapidly over the last decade. Oil and natural gas production is projected to steadily increase over the next two decades. Specifically, natural gas development is expected to increase by 44% from 2011 through 2040 (U.S. EIA, 2013b) and crude oil and natural gas liquids are projected to increase by approximately 25% through 2019 (U.S. EIA, 2013b). According to the U.S. Energy Information Administration (EIA), over half of new oil wells drilled co-produce natural gas (U.S. EIA, 2013a). The projected growth is primarily led by the increased development of shale gas, tight gas, and coalbed methane resources utilizing new production technology and techniques such as horizontal drilling and hydraulic fracturing.

Along with the increase in number of wells, the amount of related equipment that has the potential to leak will increase as well. The emissions that occur from leaks are in the form of gasses or evaporated liquids that escape to the atmosphere. Some of the potential leak emissions from these sources include methane and VOCs. The proportion of the different types of air

emissions is affected by the composition of the gas in the formation. For example, there tends to be a higher concentration of VOCs in wet gas plays than in dry gas plays.

The emissions data and the mitigation techniques in this paper are based on the onshore natural gas leak emissions that occur from natural gas production, processing, transmission, and storage. However, some of these emissions estimates and mitigation techniques are also applicable to oil wells that co-produce natural gas.

For the purposes of this paper, leaks are defined as VOC and methane emissions that occur at onshore facilities upstream of the natural gas distribution system (i.e., upstream of the city gate). This includes leak emissions from natural gas well pads, oil wells that co-produce natural gas, gathering and boosting stations, gas processing plants, and transmission and storage infrastructure. Potential sources of leak emissions from these sites include agitator seals, compressors seals, connectors, pump diaphragms, flanges, hatches, instruments, meters, open-ended lines, pressure relief devices, pump seals, valves, and improperly controlled liquids storage.¹ For the purposes of this paper, emissions from equipment intended to vent as part of normal operations, such as gas driven pneumatic controllers, are not considered leaks. The definition of leak emissions in this paper was derived by reviewing the various approaches taken in the available literature. Many studies and data sources define leak emissions differently, therefore, in the discussion of these various sources in Section 2 the definition each study uses is compared to the definition presented here.

Leak emissions occur through many types of connection points (e.g., flanges, seals, threaded fittings) or through moving parts of valves, pumps, compressors, and other types of process equipment. Changes in pressure, temperature and mechanical stresses on equipment may eventually cause them to leak. Leak emissions can also occur when connection points are not fitted properly, which causes leaks from points that are not in good contact. Other leaks can occur due to normal operation of equipment, which over time can cause seals and gaskets to

¹ Emissions from storage vessels are often required to be controlled by state or federal regulations (e.g., reduced by 95%). Emissions beyond the required level of control from control equipment that is not operating properly, such as leaking vapor recovery units or improperly sized combustors, are considered leaks for the purposes of this white paper.

wear. Weather conditions can also affect the performance of seals and gaskets that are intended to prevent leaks. Lastly, leak emissions can occur from equipment that is not operating correctly, such as storage vessel thief hatches that are left open or separator dump valves that are stuck open.

This document provides a summary of the EPA's understanding of VOC and methane leak emissions at onshore oil and natural gas production, processing, and transmission facilities. This includes available emission data, estimates of VOC and methane emissions and available mitigation techniques. Section 2 of this document describes the EPA's understanding of emissions from leaks at onshore oil and natural gas production, processing, and transmission facilities, and Section 3 discusses available mitigation techniques to reduce emissions from leaks at these facilities. Section 4 summarizes the EPA's understanding based on the information presented in Sections 2 and 3, and Section 5 presents a list of charge questions for reviewers to assist the EPA with obtaining a more comprehensive picture of VOC and methane emissions from leaks and available mitigation techniques.

2.0 OIL AND NATURAL GAS SECTOR LEAKS EMISSIONS DATA AND EMISSIONS ESTIMATES

There are a number of published studies that have estimated leak emissions from the natural gas production and petroleum, processing and transmission sector. These studies have used different methodologies to estimate these emissions, including the use of equipment counts and emission factors, extrapolation of emissions from equipment, and measurement and analysis of leaks. In some cases the studies focus on different portions of the natural gas production and petroleum, processing and transmission and storage sector (e.g., well sites), while others try to account for all leak emissions across the oil and gas sectors. Some of these studies are listed in Table 2-1, along with an indication of the type of information contained in the study (i.e., activity level).

Although methane emissions from oil and natural gas production operations have been measured, analyzed and reported in studies spanning the past few decades, VOC emissions from these operations are not as well represented.

2.1 Protocol for Equipment Leak Emission Estimates (U.S. EPA, 1995)

The EPA protocol provides standard procedures for estimating the total organic compound mass emissions from leaks at oil and natural gas production facilities. The protocol provides four different approaches for estimating leak mass emissions at oil and natural gas production sites. The correlation equations and emission factors were developed from leak data collected from refineries, marketing terminals, oil and gas production operations and synthetic organic chemical manufacturing industry (SOCMI) facilities.

Emission factors and correlations have been developed for the following equipment types: valves, pumps, compressors, pressure relief valves, connectors, flanges, and open-ended lines. An "others" category has also been developed for the petroleum industry. Development of emission factor and correlation equations for the oil and natural gas production facilities were derived from data from six gas plants that were screened by the EPA and the American Petroleum Institute² and from leak emission measurement data from 24 oil and natural gas

² DuBose, D.A., J.I. Steinmetz, and G.E. Harris (Radian Corporation). Frequency of Leak Occurrence and Emission

production facilities collected by the American Petroleum Institute.^{3,4} The emissions calculated from these emission factors and correlation equations are leak emissions that occur at onshore oil and natural gas production and natural gas processing facilities.

Protocol Leak Estimation Approaches

The protocol document provides four approaches that can be used to estimate mass emissions from leaks.

Average Emission Factor Approach

The first approach involves counting the components by type (e.g., valves, pump seals, connectors, flanges, and open-ended lines) and service (e.g., gas, heavy oil, light oil, and water/oil) at the facility and applying the appropriate average oil and gas production operations emission factors to these counts (see Table 2-4 in U.S. EPA, 1995) to calculate the total organic compound emissions from leaking equipment. There is also an “other” equipment type emission factor that was derived for compressors, diaphragms, drains, dump arms, hatches, instruments, meters, pressure relief valves, polished rods, relief valves, and vents.

Although the average emission factors are in units of kilogram per hour per individual source, it is important to note that these factors are most valid for estimating emissions from a population of equipment (U.S. EPA, 1995). The average factors are not intended to be used for estimating emissions from an individual piece of equipment over a short time period (e.g., 1 hour).

Factors for Natural Gas Liquid Plants. Final Report. Prepared for U.S. Environmental Protection Agency. Research Triangle Park, NC. EMB Report No. 80-FOL-1. July 1982.

³ Fugitive Hydrocarbon Emissions from Oil and Gas Production Operations, API 4589, Star Environmental, Prepared for American Petroleum Institute, 1993.

⁴ Emission Factors for Oil and Gas Production Operations, API 4615, Star Environmental, Prepared for American Petroleum Institute, 1995.

Screening Ranges Approach

The second approach to estimating leak emissions is the screening range approach. This approach is intended primarily to aid in the analysis of old datasets that were collected for older regulations that used 10,000 parts per million by volume (ppmv) as the leak definition. This approach uses the results from EPA Method 21 measurement of leak concentration of components to determine the number of components with a leak greater than or equal to 10,000 parts per million (ppm) and the number of components with a leak less than 10,000 ppm. The estimated emissions are then calculated using the count of components by type, service, and screening value ($\geq 10,000$ ppm or $< 10,000$ ppm) at the facility and applying the appropriate average oil and gas production operations emission factors to these counts (see Table 2-8 in U.S. EPA, 1995).

This screening range approach is a better indication of the actual leak rate from individual equipment than the average emission factor approach (U.S. EPA, 1995). However, available data indicate that measured mass emission rates can vary considerably from the rates predicted by use of these screening range emission factors.

EPA Correlation Approach

The third approach is a correlation approach that uses the measured Method 21 screening value (in ppm) for each component and inputs that screening value into correlation equations that calculate the emission rate (see Table 2-10 in U.S. EPA, 1995). This approach offers an additional refinement to estimating emissions from leaks by providing an equation to predict mass emission rate as a function of concentration determined by EPA Method 21 screening for a particular equipment type. Correlations for the petroleum industry apply to refineries, marketing terminals and oil and gas production operations. The petroleum industry correlation equations estimate total organic compound (TOC) emission rates.

The EPA Correlation Approach is preferred when actual screening values (in ppm) are available. Correlations can be used to estimate emissions for the entire range of non-zero screening values, from the highest potential screening value to the screening value that represents the minimum detection limit of the monitoring device. This approach involves entering the non-

zero, non-pegged screening value into the correlation equation, which predicts the TOC mass emission rate based on the screening value. Default zero emission rates are used for screening values of zero ppmv and pegged emission rates are used for pegged screening values, where the screening value is beyond the upper limit measured by the portable screening device.

The "default-zero" leak rate is the mass emission rate associated with a screening value of zero. (Note that any screening value that is less than or equal to ambient background concentration is considered a screening value of zero.) The correlations mathematically predict zero emissions for zero screening values. However, data collected by the EPA show this prediction to be incorrect (U.S. EPA, 1995), because mass emissions have been measured from equipment having a screening value of zero. A specific goal when revising the petroleum industry correlations was to collect mass emissions data from equipment that had a screening value of zero. These data were used to determine a default-zero leak rate associated with equipment with zero screening values.

Unit Specific Correlation Approach

The fourth approach calls for developing unit-specific correlations and corresponding mass emission rates. This is done by measuring the screening value in ppm and measuring the mass emission rate by “bagging” the component. A component is bagged by enclosing the component to collect leaking vapors. Measured emission rates from bagged equipment coupled with screening values can be used to develop unit-specific screening value/mass emission rate correlation equations. Unit-specific correlations can provide precise estimates of mass emissions from leaks at the process unit. However, it is recommended that unit-specific correlations are only developed in cases where the existing EPA correlations do not give reasonable mass emission estimates for the process unit (U.S. EPA, 1995).

2.2 GRI/EPA Methane Emissions from the Natural Gas Industry, Volume 8: Equipment Leaks (GRI/U.S. EPA, 1996)

This report provides an estimate of annual methane emissions from leaks from the natural gas production sector using the component method. The component method uses average emission factors for components and the average number of components per facility to estimate

the average facility emissions. The average facility emissions were then extrapolated to a national estimate using the number of natural gas production facilities.

The study used two approaches to estimate component emissions for the onshore natural gas production, offshore natural gas production, natural gas processing, natural gas transmission and natural gas storage sectors. The first approach involved screening components using a portable hydrocarbon analyzer and using EPA correlation equations (U.S. EPA, 1995) to estimate the leaking emissions. The EPA correlation equations provide an average leak rate per source using the equipment type (e.g., connectors, flanges, open-ended lines, pumps, valves, other), type of material (e.g., gas, heavy oil, light oil, water/light oil), the leak definition used, and the leak fraction determined by the screening. This approach was used to determine component emission factors for some onshore production sources, natural gas processing and the offshore production sector.

The screening of components involved using a portable instrument to detect leaks around, flanges, valves, and other components by traversing the instrument probe over the entire surface of the component. The components were divided into the following categories:

- Valves (gas/vapor, light liquid, heavy liquid)
- Pump Seals (light liquid, heavy liquid)
- Compressor Seals (gas/vapor)
- Pressure Relief Valves (gas/vapor)
- Connectors, which include flanges and threaded unions (all services)
- Open-Ended Lines (all services)
- Sampling Connections (all services)

All components associated with an equipment source or facility were screened using the procedures specified in EPA Method 21. The maximum measured concentration was recorded using a portable instrument that met the specifications and performance criteria in EPA Method 21. In general, an organic vapor analyzer (OVA) that used a flame ionization detector (FID) was

used for conducting the screening measurements. A dilution probe was used to extend the upper range of the instrument from 10,000 to 100,000 ppmv.

The second approach used the GRI Hi-FlowTM (trademark of the Gas Research Institute) sampler or a direct flow measurement to replace data measured using the enclosure method. This method was used to determine emission factors for some of the offshore production sources. The sampler has a high flow rate and generates a flow field around the component that captures the entire leak. As the sample stream passes through the instrument, both the flow rate and the total hydrocarbon (THC) concentration are measured. The mass emission rate can then be determined using these measurements. Offshore leak emissions are not covered in this paper; therefore, the estimates derived from this method will not be discussed further.

For onshore natural gas production, the facilities were broken up into two categories; eastern natural gas production and western gas production to account for regional differences in the methane content of the natural gas. The sources of these leak emissions include gas wells, separators, heaters, dehydrators, metering runs and gathering compressors.

A summary of the average equipment emissions, activity factor, and annual methane emissions for the onshore production sector is presented in Table 2-2. These factors have been used in other reports and studies of methane emissions from the oil and gas sector, including the Inventory of U.S. Greenhouse Gas Emissions and Sinks, which will be discussed in more detail in Section 2.1.4.

As shown in the tables, the study estimated that 15,512 million standard cubic feet per year (MMscf/yr) of methane are emitted as leaks from 271,928 onshore natural gas production wells in the U.S. for the 1992 base year. This converts to approximately 292,930 metric tons (MT) of methane emitted to the atmosphere in the base year.

Table 2-2. GRI/EPA National Annual Emission Estimate for Onshore Natural Gas Production in the United States (1992 Base Year)^a

| Equipment | Average Equipment Methane Emissions (scf/yr) | Activity Factor, Equipment Count | Annual Methane Emissions (MMscf) | Annual Methane Emissions (MT)^b | 90% Confidence Interval |

| Western U.S. Total | | | 14,886 | 281,103 | 45% |
| Total | | | 15,512 | 292,930 | - |

a - Derived from Tables 5-2 and 5-3 (GRI/U.S. EPA, 1996).

b - Annual methane emissions calculated assuming methane density of 41.63 lb/Mscf.

c - Sm. gathering compressor emission factor does not include compressor seal emissions.

d - Lg. gathering compressor emission factor does not include compressor seal or compressor blowdown emissions.

e - Gathering station emission factor does not include site blowdown line emissions.

The national annual methane emissions from natural gas processing were calculated using published statistics from the Oil and Gas Journal. The 1992 data from the journal listed the total number of natural gas processing plants to be 726. The national methane emissions were calculated using this activity factor and the average facility methane emissions for a natural gas processing plant. The plant methane emissions were calculated using average component counts for gas processing equipment (e.g., valves, connectors, open-ended lines, pressure relief valves, blowdown open-ended lines, compressor seals and miscellaneous). For natural gas processing plants, the average emissions from equipment was estimated to be 2.89 MMscf/yr (18.9 MT). The annual methane emissions from the equipment associated with reciprocating compressors and the equipment associated with centrifugal compressors located at natural gas processing plants were estimated to be 0.538 MMscf/yr (10.2 MT) and 0.031 MMscf/yr (0.585 MT), respectively, in 1992. These methane emissions from the gas processing plant and compressors do not include emissions from starter lines, blowdown lines or compressor seals, which are considered to be vented emissions and not leaks for the purposes of this paper. The ratio of reciprocating and centrifugal compressors located at these plants was based on site visit data from 11 natural gas processing plants. The ratio determined from this data was calculated to be 85% reciprocating and 15% centrifugal. Table 2-3 summarizes the national annual methane emissions from natural gas processing plants, which was estimated to be 3,968 MMscf or 74,921 MT.

Table 2-3. GRI/EPA National Annual Emission Estimate for Natural Gas Processing Plants in the United States (1992 Base Year)^a

| Equipment | Average Facility Methane Emissions (MMscf/yr) | Activity Factor, Number of Plants/Compressors | Annual Methane Emissions (MMscf) | Annual Methane Emissions (MT)^b | 90% Confidence Interval |
|--|--|--|---|--|--------------------------------|
| Gas Processing Plant ^c | 2.40 | 726 | 1,744 | 32,925 | 27% |
| Reciprocating Compressors ^d | 0.538 | 4,092 | 2,201 | 41,571 | 36% |
| Centrifugal Compressors ^e | 0.031 | 726 | 22.5 | 425 | 218% |
| Total | | | 3,968 | 74,921 | 46% |

a - Derived from Table 5-5 (GRI/U.S. EPA, 1996).

b - Annual methane emissions calculated assuming methane density of 41.63 lb/Mscf.

c - Gas processing plant emission factor does not include site blowdown emissions.

d - Reciprocating compressor emission factor does not include rod packing, blowdown or starter emissions.

e - Centrifugal compressor emission factor does not include compressor seal, blowdown or starter emissions.

The annual methane emission from transmission compressor stations was calculated using activity data based on statistics by the Federal Energy Regulatory Commission (FERC). The data reported to FERC account for 70% of the total transmission pipeline mileage. The split between reciprocating and turbine compressors was estimated using data from the GRI TRANSDAT database. The average methane emissions from compressor station equipment were estimated to be 3.01 MMscf/yr (56.8 MT) in 1992. The annual methane emissions from the equipment associated with reciprocating compressors and the equipment associated with centrifugal compressors located at transmission stations were estimated to 0.552 MMscf/yr (10.4 MT) and 0.018 MMscf/yr (0.34 MT), respectively. Table 2-4 summarizes the national annual methane leak emissions from natural gas transmission stations, which was estimated to be 50,733 MMscf or 957,999 MT. These methane emissions from the compressor station and compressors do not include emissions from starter lines, blowdown lines or compressor seals, which are considered to be vented emissions and not equipment leaks for the purposes of this paper.

Table 2-4. GRI/EPA National Annual Emission Estimate for Natural Gas Transmission Compressor Stations in the United States (1992 Base Year)^a

| Equipment | Average Facility Methane Emissions (MMscf/yr) | Activity Factor, Number of Stations/Compressors | Annual Methane Emissions (MMscf) | Annual Methane Emissions (MT)^b | 90% Confidence Interval |

| Total | | | 50,733 | 957,999 | 52% |

a - Derived from Table 5-6 (GRI/U.S. EPA, 1996).

b - Annual methane emissions calculated assuming methane density of 41.63 lb/Mscf.

c - Compressor station emission factor does not include site blowdown emissions.

d - Reciprocating compressor emission factor does not include rod packing, blowdown or starter emissions.

e - Centrifugal compressor emission factor does not include compressor seal, blowdown or starter emissions.

For natural gas storage facilities, the annual methane emissions were calculated using activity data based on published data in Gas Facts. The number of compressors and injection/withdrawal wells located at natural gas storage facilities were estimated using data collected from site visits to eight facilities. The average methane emissions from natural gas storage facilities were estimated to be 6.80 MMscf/yr (128 MT). The annual average methane emissions from an injection/withdrawal well were estimated to be 0.042 MMscf/yr (0.79 MT). The annual methane emissions from equipment for reciprocating and centrifugal compressors were estimated to be 0.47 MMscf/yr (8.9 MT) and 0.017 MMscf/yr (0.32 MT), respectively, in 1992. The national methane emissions from storage facilities were estimated to be 4,644 MMscf or 87,713 MT and are provided in Table 2-5. These methane emissions from the storage facility and compressors do not include emissions from starter lines, blowdown lines or compressor seals, which are considered to be vented emissions and not leaks for the purposes of this paper.

Table 2-5. GRI/EPA National Annual Emission Estimate for Natural Gas Storage Facilities in the United States (1992 Base Year)^a

| Equipment | Average Facility Emissions (MMscf/yr) | Activity Factor, Number of Facilities/ Compressors | Annual Methane Emissions (MMscf) | Annual Methane Emissions (MT) ^b | 90% Confidence Interval |
|--|---------------------------------------|--|----------------------------------|--|-------------------------|
| Storage Facilities ^c | 6.80 | 475 | 3,230 | 61,004 | 100 |
| Injection/Withdrawal Wells | 0.042 | 17,999 | 756 | 14,275 | 76 |
| Reciprocating Compressors ^d | 0.47 | 1,396 | 656 | 12,390 | 80 |
| Centrifugal Compressors ^e | 0.017 | 136 | 2.3 | 43.7 | 130 |
| Total | | | 4,644 | 87,713 | 57 |

a - Derived from Table 5-7 (GRI/U.S. EPA, 1996).

b - Annual methane emissions calculated assuming methane density of 41.63 lb/Mscf.

c - Storage facility emission factor does not include site blowdown emissions.

d - Reciprocating compressor emission factor does not include rod packing, blowdown or starter emissions.

e - Centrifugal compressor emission factor does not include compressor seal, blowdown or starter emissions.

2.3 Greenhouse Gas Reporting Program (U.S. EPA, 2013)

In October 2013, the EPA released the 2012 greenhouse gas (GHG) data for Petroleum and Natural Gas Systems⁵ collected under the Greenhouse Gas Reporting Program (GHGRP). The GHGRP, which was required by Congress in the FY2008 Consolidated Appropriations Act, requires facilities to report data from large emission sources across a range of industry sectors, as well as suppliers of certain GHGs and products that would emit GHGs if released or combusted.

The GHGRP covers a subset of national emissions, as facilities are required to submit annual reports only if total GHG emissions are 25,000 metric tons carbon dioxide equivalent (CO₂e) or more. Facilities use uniform methods prescribed by the EPA to calculate GHG emissions, such as direct measurement, engineering calculations, or emission factors. In some cases, facilities have a choice of using one of the multiple available calculation methods for an emission source provided.

⁵ The implementing regulations of the Petroleum and Natural Gas Systems source category of the GHGRP are located at 40 CFR Part 98, subpart W.

Methods for calculating emissions from leaks depend on the industry segment. Facilities in the onshore petroleum and natural gas production segment use population counts and population emission factors for calculating emissions from leaks. Population counts are determined based on either (1) a count of all major equipment (wellheads, separators, meters/piping, compressors, in-line heaters, dehydrators, heater-treaters, and headers) multiplied by average component counts specified in the subpart W regulations, or (2) a count of each component individually for the facility. Emissions are then calculated by multiplying population count by the appropriate population emission factor specified in the subpart W regulations.

Facilities in the onshore gas processing and gas transmission segments use counts of leaking components and leak emission factors for calculating emissions from leaks. The counts of leaking components are identified during an annual leak survey using an optical gas imaging (OGI) instrument, EPA Method 21, infrared (IR) laser beam illuminated instrument, or an acoustic leak detection device. Once the leaking components have been identified and counted, the emissions are calculated by multiplying the count of a specific type of leaking component by the appropriate leak emission factor specified in the subpart W regulations.

For the 2012 reporting year, reported methane emissions from leaks from onshore petroleum and natural gas production were 364,453 MT, onshore natural gas processing were 13,527 MT, and onshore natural gas transmission compression were 15,868 MT.

2.4 Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2012 (U.S. EPA, 2014)

The EPA leads the development of the annual Inventory of U.S. Greenhouse Gas Emissions and Sinks (GHG Inventory). This report tracks total U.S. GHG emissions and removals by source and by economic sector over a time series, beginning with 1990. The U.S. submits the GHG Inventory to the United Nations Framework Convention on Climate Change (UNFCCC) as an annual reporting requirement. The GHG Inventory includes estimates of methane and carbon dioxide for natural gas systems (production through distribution) and petroleum systems (production through refining).

The natural gas production system covers all equipment that process or transport natural gas from oil and gas production sites. (All equipment that process or transport hydrocarbon

liquids are covered in the oil systems section of the GHG Inventory.) The natural gas production segment is broken into six regions (North East, Midcontinent, Rocky Mountain, South West, West Coast, and Gulf Coast) and includes estimates for gas wells, separation equipment, gathering compressors, gathering pipelines, drilling and well completions, normal operations, condensate tank vents, well workovers, liquids unloading, vessel blowdowns, and process upsets.

For the natural gas production segment, only methane emissions from gas wells, field separation equipment, and gathering compressor systems will be discussed from the GHG Inventory. Leaks from gas wells include emissions from various components, such as connectors and valves, on a wellhead. Field separation equipment includes heaters, separators, dehydrators, meters and piping. Gathering compressor systems include reciprocating compressors, equipment such as scrubbers and coolers associated with the compressors, and the piping. Leaks from field separation equipment and gathering compressor systems include emissions from components in these equipment and systems. The only exception is the gathering compressors source that includes both leak emissions and vented emissions from compressor seals in the GHG Inventory. (Note: Vented emissions from compressors are not defined as leaks in this paper, but are discussed in the white paper on compressors.) The 2014 GHG Inventory (published in 2014; containing emissions data for 1990-2012) calculates potential⁶ methane leak emissions from gas wells and field separation equipment using emission factors from the GRI/EPA study (GRI/U.S. EPA, 1996). The emission factors from the GRI/EPA study are split regionally into Eastern and Western factors. These emission factors are adapted in the 2014 GHG Inventory for each of the NEMS regions by adjusting the GRI/EPA emission factors for the NEMS region-specific methane content in produced natural gas. All of the emission factors from the GRI/EPA study assume methane content of 78.8% in the produced natural gas. However, the 2014 GHG

⁶ The calculation of emissions for each source of in the GHG Inventory generally involves first the calculation of potential emissions (methane that would be emitted in the absence of controls), then the compilation of emissions reductions data, and finally the calculation of net emissions by deducting the reductions data from the calculated potential emissions. This approach was developed to ensure an accurate time series that reflects real emission trends. Key data on emissions from many sources are from GRI/U.S. EPA 1996, and since the time of this study practices and technologies have changed. While the study still represents best available data for some emission sources, using these emission factors alone to represent actual emissions without adjusting for emissions controls would in many cases overestimate emissions. As updated emission factors reflecting changing practices are not available for most sources, the GRI/U.S. EPA 1996 emission factors continue to be used for many sources for all years of the GHG Inventory, but they are considered to be potential emissions factors, representing what emissions would be if practices and technologies had not changed over time.

Inventory uses regional methane contents obtained from a 2001 study by the Gas Technology Institute (GTI) on unconventional gas and gas composition⁷ to adjust the GRI/EPA emission factors to account for the regional methane content differences. The GHG Inventory emissions are then calculated by applying the modified GRI/EPA emission factors to component counts for each year of the GHG Inventory. Because component counts are not available for each year of the GHG Inventory, a set of industry activity data drivers was developed and used to update activity data.⁸ The 2014 GHG Inventory, emission factors, and methane emissions are presented by region in Table 2-6. The 2014 GHG Inventory estimated 332,662 MT of potential methane leak emissions from gas wells and field separation equipment from natural gas production activities in 2012.

Table 2-6. 2011 Data and Calculated Methane Potential Leak Emissions for the Natural Gas Production Segment by Region^a

| Region | Activity | Activity Data | Emission Factor | Calculated Potential Emissions (MT) |
|------------|-------------------------------------|---------------|-----------------------|-------------------------------------|
| North East | Associated Gas Wells | 38,770 | NA | NA |
| | Non-associated Gas Wells | 112,607 | 7.67 scfd/well | 6,071 |
| | Gas Wells with Hydraulic Fracturing | 46,367 | 7.54 scfd/well | 2,457 |
| | Heaters | 318 | 15.38 scfd/heater | 34 |
| | Separators | 112,872 | 0.97 scfd/separator | 771 |
| | Dehydrators | 22,164 | 23.53 scfd dehydrator | 3,665 |
| | Meters/Piping | 7,910 | 9.75 scfd/meter | 542 |

⁷ GRI-01/0136 GTI's Gas Resource Database: Unconventional Natural Gas and Gas Composition Databases. Second Edition. August, 2001.

⁸ For example, recent data on various types of field separation equipment in the production stage (i.e., heaters, separators, and dehydrators) are unavailable. Each of these types of field separation equipment was determined to relate to the number of gas wells. Using the number of each type of field separation equipment estimated by GRI/EPA in 1992, and the number of gas wells in 1992, a factor was developed that is used to estimate the number of each type of field separation equipment throughout the time series. The annual well count data used for these sources were obtained from a production database maintained by DrillingInfo, Inc. (DrillingInfo, 2012).

| Region | Activity | Activity Data | Emission Factor | Calculated Potential Emissions (MT) |
|----------------|-------------------------------------|----------------------|------------------------|--|
| Midcontinent | Associated Gas Wells | 27,470 | NA | NA |
| | Non-associated Gas Wells | 77,896 | 7.45 scfd/well | 4,080 |
| | Gas Wells with Hydraulic Fracturing | 30,156 | 8.35 scfd/well | 1,771 |
| | Heaters | 43,869 | 14.9 scfd/heater | 4,596 |
| | Separators | 47,003 | 0.94 scfd/separator | 311 |
| | Dehydrators | 15,064 | 95.54 scfd dehydrator | 10,118 |
| | Meters/Piping | 143,186 | 9.45 scfd/meter | 9,509 |
| Rocky Mountain | Associated Gas Wells | 32,598 | NA | NA |
| | Non-associated Gas Wells | 9,665 | 35.05 scfd/well | 2,381 |
| | Gas Wells with Hydraulic Fracturing | 73,755 | 40.72 scfd/well | 21,115 |
| | Heaters | 38,040 | 56.73 scfd/heater | 15,172 |
| | Separators | 41,627 | 120 scfd/separator | 35,099 |
| | Dehydrators | 11,630 | 89.58 scfd dehydrator | 7,324 |
| | Meters/Piping | 97,399 | 52.01 scfd/meter | 35,609 |
| South West | Associated Gas Wells | 155,119 | NA | NA |
| | Non-associated Gas Wells | 13,860 | 37.24 scfd/well | 3,628 |
| | Gas Wells with Hydraulic Fracturing | 27,627 | 37.24 scfd/well | 7,232 |
| | Heaters | 11,243 | 58.97 scfd/heater | 4,661 |
| | Separators | 23,316 | 125 scfd/separator | 20,435 |
| | Dehydrators | 5,784 | 93.11 scfd dehydrator | 3,786 |
| | Meters/Piping | 55,885 | 54.06 scfd/meter | 21,237 |

| Region | Activity | Activity Data | Emission Factor | Calculated Potential Emissions (MT) |
|---------------|-------------------------------------|----------------------|------------------------|--|
| West Coast | Associated Gas Wells | 29,726 | NA | NA |
| | Non-associated Gas Wells | 1,999 | 42.49 scfd/well | 597 |

^a Derived from ANNEX 3 Methodological Descriptions for Additional Source or Sink Categories (U.S. EPA, 2014).

The gas processing and gas transmission segments are not broken into regions like the gas production segment in the 2014 GHG Inventory. Instead, these segments provide national level emission estimates for their individual emission sources. For both segments, leak emissions include emissions from all components in the gas plants and on compression systems. The transmission segment leaks include leaks from transmission pipelines. The 2014 GHG Inventory calculates potential methane emissions from these sources using emission factors from the GRI/EPA study (GRI/U.S. EPA, 1996) and a 2010 ICF International (ICF) memo to the EPA on centrifugal compressors (ICF, 2010). The GHG Inventory emissions are calculated by applying

the emission factors to activity counts (in this case, gas plants, compressor station counts, compressor counts, and pipeline miles) for each year of the inventory. Because some component counts are not available for each year of the GHG Inventory, a set of industry activity data drivers was developed and used to update activity data.⁹ The 2014 GHG Inventory gas processing and gas transmission sources, emission factors, and methane emissions are presented in Table 2-7. For 2012, the 2014 GHG Inventory estimated 33,681 MT of potential methane emissions from gas processing leak emissions and 114,348 MT of potential methane emissions from gas transmission leak emissions.

Table 2-7. 2011 Data and Calculated Methane Potential Leak Emissions for the Natural Gas Processing and Natural Gas Transmissions Segments^a

| Segment | Activity | Activity Data | Emission Factor | Calculated Potential Emissions (MT) |
|------------------|----------------|---------------|--------------------|-------------------------------------|
| Gas Processing | Plants | 606 | 7,906 scfd/plant | 33,681 |
| Gas Transmission | Pipeline Leaks | 303,126 | 1.55 scfd/mile | 3,311 |
| | Station | 1,799 | 8,778 scfd/station | 111,037 |

^a Derived from ANNEX 3 Methodological Descriptions for Additional Source or Sink Categories, pg. A-177 (U.S. EPA, 2014).

For 2012, the 2014 GHG Inventory data estimates that potential emissions from leaks in production, processing and transmission are approximately 480,691 million MT of methane or about 8% of overall potential methane emissions from oil and gas.

2.5 Measurements of Methane Emissions at Natural Gas Production Sites in the United States (Allen et al., 2013)

A study completed by multiple academic institutions and consulting firms was conducted to gather methane emissions data at onshore natural gas sites in the U.S. This study used direct

⁹ For example, individual compressor counts and compressor station counts are not available. Instead, these are obtained using a ratio of compressors to gas plants (for processing) and ratios of stations to pipeline miles and compressors to pipeline miles (for transmission) in the base year 1992. The 1992 ratios are then multiplied by the activity drivers, i.e., gas plant count or miles of pipeline, in the current year to estimate activity in current year.

measurements of methane emissions at 190 onshore natural gas sites in the U.S. (150 production sites, 27 well completion flowbacks, 9 well unloadings, and 4 workovers). The study covered the natural gas production segment.

For leak emissions, the study collected emissions data from 150 sites, 146 sites with wells and 4 sites with separators and other equipment on site. Leak emissions data from piping, valves, separators, wellheads, and connectors are provided in Table 2-8. The first step used to identify leaks from natural gas production sites was to scan the site using an OGI camera. The threshold for detection of a leak with the camera was 30 g/hr (Allen et al., 2013). After leaks were identified by the camera, the flow rate and the concentration of the leaks were measured using a Hi-Flow Sampler™ and the mass emission rate calculated. The instrument was calibrated using samples consisting of pure methane in ambient air. To account for the effect of ethane, propane, butane and higher alkanes on the leak measurements, gas composition data were collected for each natural gas production site that was visited. Based on the gas composition, the percentage of carbon accounted for by methane in the sample stream was determined. This percentage, multiplied by the total gas flow rate reported by the instrument, was the methane flow.

Table 2-8. Summary of Emissions from Leaks

| | Emissions Per Well ^a | | | | |
|--|---------------------------------|---------------|---------------|----------------|----------------|
| | Appalachian | Gulf Coast | Midcontinent | Rocky Mountain | All Facilities |
| Number of Sites with Wells Visited (number of wells with leaks detected) | 47 (30) | 54 (31) | 26 (19) | 19 (17) | 146 (97) |
| Methane Emission Rate (scf/min/well) | 0.098 ± 0.059 | 0.052 ± 0.030 | 0.046 ± 0.024 | 0.035 ± 0.026 | 0.064 ± 0.023 |
| Whole Gas Emissions Rate (based on site specific gas composition) (scf/min/well) | 0.100 ± 0.060 | 0.058 ± 0.033 | 0.055 ± 0.034 | 0.047 ± 0.034 | 0.070 ± 0.024 |

^a All leaks detected with the OGI camera, and does not include emissions from pneumatic pumps and controllers.

The study authors concluded the average values of leak emissions per well reported in Table 2-8 are comparable to the average values of potential emissions per well for gas wells, separators, heaters, piping and dehydrator leaks (0.072 scf methane/min/well) from the 2013 GHG Inventory, calculated by dividing the potential emissions in these categories in the 2013 GHG Inventory by the number of wells (Allen et al., 2013).

2.6 City of Fort Worth Natural Gas Air Quality Study (ERG, 2011)

The city of Fort Worth solicited a study that reviewed air quality issues associated with natural gas exploration and production. The goals of the study were to answer the following four questions:

- How much air pollution is being released by natural gas exploration in Fort Worth?
- Do sites comply with environmental regulations?
- How do releases from these sites affect off-site air pollution levels?
- Are the city's required setbacks for these sites adequate to protect public health?

To answer these questions, the study collected ambient air monitoring and direct leak and vented emissions measurements and performed air dispersion modeling. The study collected data from 375 well pads, 8 compressor stations, a gas processing plant, a saltwater treatment facility, a drilling operation, a hydraulic fracturing operation, and a completion operation. The point source test data was collected using an OGI camera, a toxic vapor analyzer (TVA), a Hi-Flow Sampler™ and stainless steel canisters. Each site was surveyed with an OGI camera and, if a leak was observed by the camera, the concentration of the leak was measured using the TVA. In addition, 10% of the total valves and connectors and the other components were surveyed using the TVA to determine leaks at or above 500 ppmv. The emission rates of the leaks identified by the OGI camera and the TVA survey were determined using a Hi-Flow Sampler™ to measure the volumetric flow rate of the leak. Gas samples from selected leaks were collected in stainless steel canisters for VOC and HAP analysis by a gas chromatograph/mass spectrometer (GC/MS).

Based on the results of the point source leak survey, the study estimated the total organic emissions to be 20,818 tons per year or 18,819 megagrams per year (Mg/yr), with well pads

accounting for more than 75% of the total emissions. Hydrocarbons with low toxicities (methane, ethane, propane, and butane) accounted for approximately 98% of the emissions from this study. A summary of the average and maximum emissions from each of the site types is provided in Table 2-9. Table 2-10 provides a summary of the measured emissions by equipment type (e.g., connector, valve, other). Valves include manual valves, automatic actuation valves, and pressure relief valves. Connectors include flanges, threaded unions, tees, plugs, caps and open-ended lines where the plug or cap was missing. The category “Other” consists of all remaining components such as tank thief hatches, pneumatic valve controllers, instrumentation, regulators, gauges, and vents.

Table 2-9. Average and Maximum Point Source Emission Rates by Site Type^a

| Site Type | TOC (tons/yr) | | VOC (Tons/yr) | |
|-----------------------------|---------------|---------|---------------|---------|
| | Average | Maximum | Average | Maximum |
| Well Pad | 16 | 445 | 0.07 | 8.6 |
| Well Pad with Compressor(s) | 68 | 4,433 | 2 | 22 |
| Compressor Station | 99 | 276 | 17 | 43 |
| Processing Facility | 1,293 | 1,293 | 80 | 80 |

a - Derived from Table 3.5-1 (ERG, 2011).

Table 2-10. Average and Maximum Point Source Emission Rates by Equipment Type^a

| Equipment Type | Methane (lb/yr) | | VOC (lb/yr) | |
|----------------|-----------------|---------|-------------|---------|
| | Average | Maximum | Average | Maximum |
| Connectors | 8,918 | 169,626 | 27.6 | 171 |
| Other | 20,914 | 497,430 | 142 | 4,161 |
| Valves | 27,585 | 570,083 | 29.7 | 123 |

a - Derived from Emissions Calculation Workbook spreadsheet.

Some general observations of the well pad data provided in the Fort Worth report are:

- At least one leak was detected at 283 out of the 375 well pads monitored with an OGI technology with an average of 3.2 leaks detected per well pad;
- The TVA detected at least one leak greater than 500 ppm at 270 of the 375 well pads that were monitored with an average of 2.0 leaks detected per well pad;
- The number of wells located on well pads ranged from 0 to 13 with the average number of wells being 2.98 with a 99% confidence level of 0.31;
- The average number of components at each well site was 212 valves, 1596 connectors, 3 storage tanks, and 0.4 compressors;
- 124 out of the 375 well pads had at least one compressor onsite;
- There were 17 different owners of the 375 well sites in the Fort Worth area with the average number of well sites per owner being 22;
- Of the 1,330 leaks that were detected using either OGI technology or the TVA, 200 (15%) were classified as connector type leaks, 90 (7%) were classified as valve type leaks, and 1,040 (78%) were classified as other type leaks.
- Of these 1,330 leaks that were detected using OGI technology or the TVA, 1,018 (77%) were classified as non-tank leaks and the remaining 312 (23%) were classified as tank leaks.

2.7 Measurements of Well Pad Emissions in Greeley, CO (Modrak, 2012)

An onsite direct measurement study of emissions from 23 well pads in areas near

Greeley, CO (Weld County) was performed over a one-week period in July 2011. This study used the same source testing contractor and non-invasive leak detection and measurement procedures (OGI and Hi-Flow Sampler™) as in the City of Fort Worth Natural Gas Air Quality Study (ERG, 2011). Other than the number of production pads investigated (375 vs. 23), there were three major differences in the studies.

- The City of Fort Worth Air Quality Study was conducted in a predominately dry gas area of the Barnett shale whereas the Greeley study was conducted in an area with much higher relative condensate/oil production rates (wet gas). A typical leak or vented emission in a dry gas area is likely to have a higher methane to VOC ratio compared to an emission in a wet gas area.
- The State of Colorado requires emissions from condensate/oil tanks to be collected and controlled (e.g. routed to an enclosed combustors). In the City of Fort Worth Air Quality Study, most storage tanks contained produced water and were not controlled.
- The City of Fort Worth Air Quality Study used the EPA Compendium Method TO-15 and ASTM 1945 (for methane) for source canister analysis, whereas the Greeley study used the Ozone Precursor method (EPA/600-R-98/161) coupled with ASTM 1946/D1945 analysis of methane, ethane and propane. The canister analysis set used in the Greeley study had significantly more overlap for oil and gas product-related compounds (i.e. ethane, propane, other alkanes), whereas the TO-15 method provided more coverage for HAP compounds.

The objectives of the limited scope Greeley well pad study were to improve understanding of methane and speciated VOC emissions and investigate the use of commercially available non-invasive measurement approaches for application to wet gas production operations (including tank emissions).

The average production pad in the Greeley study consisted of 5 wells, 258 valves, 2,583 connectors, 3 condensate tanks, 1 produced water tank, 4 thief hatches, 5 pressure relief devices, 3 separators and 1 enclosed combustor control device. A total of 93 emission points were found with OGI technology at the 23 production sites and the emission rates were measured using a high volume sampler with a subset of 33 additionally sampled using evacuated canisters. A

disproportionate number of detected emissions were found to be associated with storage tanks (72%). For the purposes of this white paper, a tank-related air emission is considered a leak if it exceeds the state or local emission limits. The study authors concluded condensate tank-related emissions observed in the Greeley study were not effectively collected and controlled. However, due to single point and instantaneous nature of the measurements, it is not known if these uncollected emissions exceed the state allowance.

Considering only emissions measurements with canister analysis, the average methane emissions from all storage tanks, excluding samples of known flash emissions, were much lower in the Greeley study compared to the City of Fort Worth Air Quality Study, 0.77 tons/year (n=21) and 21.9 tons/year (n=54), respectively. In contrast, the average VOC tank related emissions were much higher in the Greeley study compared to the City of Fort Worth Air Quality Study, 5.38 tons/year and 0.48 tons/year, respectively. Non-tank emissions followed similar trends: emissions of methane were higher in the City of Fort Worth Air Quality Study (7.73 tons/year (n=92) and 1.01 tons/year in the Greeley study (n=5)), while VOC emissions were higher in the Greeley study (0.46 tons/year in the Greeley study and 0.02 tons/year in the City of Fort Worth Air Quality Study). The authors noted that these emission estimates are based on instantaneous measurements. Because tank-related emissions vary diurnally and by season and may contain a residual flash emissions component, the extrapolation to yearly values (i.e., tons/year) is for informational purposes only and should not be used for comparison to permit or control limits. A journal article with additional analysis of these studies is in preparation (Modrak, 2012; Brantley et al., 2014a).

2.8 Quantifying Cost-Effectiveness of Systematic Leak Detection and Repair Programs Using Infrared Cameras (CL, 2013)

The study presented a summary of 4,293 surveys from two private sector firms that provide gas emission detection and measurement services to oil and gas facilities in the U.S. and Canada. These surveys only covered certain regions of the U.S. and Canada. The surveys included three categories of facilities: gas processing plants (614 surveys), compressor stations (1,915 surveys; includes both gas transmission and gas gathering systems), and well sites (1,764 surveys; includes single well heads and sites with up to 15 well heads). The surveys were

conducted using OGI technology to locate leaking components and the leak rates were measured using a high-volume sampler. In some cases, where the facility owners did not need a precise volume measurement or where the leaking component was difficult to access for measurement, an estimate (evaluated visually using OGI technology based on the extensive experience of the operators) was used to make the decision to repair.

The study found that of the 58,421 components that were identified in the surveys, 39,505 (68%) were either leaking or venting gas. A summary of the leak rates for each of the categories is provided in Table 2-11. As the table shows, the study found that gas processing plants had the highest leak rate, followed by compressor stations and then well sites. The study noted that vents are the most common source of gas emissions from the identified emission sources, and about 40% of the vent emissions come from instrument controllers and compressor rod packing. Other vent sources come from production/storage tanks, lube oil vents, compressors, pumps, and engines. (Note: vented emissions are not considered leaks for the purposes of this paper).

Table 2-11. Distribution of Facilities Within Each Category by Leak Rate (in Mcf of gas per facility per year)^a

| Category | No leaks | ≤ 99 | 100-499 | 500-1499 | ≥ 1500 |
|-----------------------------|-----------------|-------------|----------------|-----------------|---------------|
| Gas processing plants | 3% | 17% | 32% | 25% | 23% |
| Compressor stations | 11% | 30% | 36% | 15% | 9% |
| Well sites & well batteries | 36% | 38% | 18% | 5% | 2% |

a - Derived from Table 3 (CL, 2013).

The study results show that, for the facilities in the study, gas processing plants are the most likely to have leaks and the most likely to have large leaks, followed by compressor stations, and, lastly, well sites.

2.9 Mobile Measurement Studies in Colorado, Texas, and Wyoming (Thoma, 2012)

As will be described in detail in Section 3.4, emerging mobile measurement technologies are providing new capability for detection and measurement of emissions from upstream oil

and gas production and other sectors. The EPA developed and applied one such mobile inspection technique as part of its Geospatial Measurement of Air Pollution (GMAP) program. (Thoma, 2012; Brantley et al., 2014b). Designed to be a rapidly-deployed inspection approach that can cover large areas, OTM 33A can locate unknown emissions (e.g., pipeline leaks or malfunctions) and can provide an emission rate assessment for upstream oil and gas sources, such as well pads located in relatively open areas. With measurements executed from stand-off observation distances of 20 m to 200 m, the mobile approach is not as accurate as onsite direct measurements but can provide source strength assessments with an accuracy of +/- 30% under favorable conditions with repeat measurements. OTM 33A relies on statistically representative downwind plume sampling, relatively obstruction-free line of sight observation, and a knowledge of the distance to the source (Thoma, 2012; Brantley et al., 2014b).

The EPA used OTM 33A to conduct several survey field campaigns in Weld County, CO in July 2010 and July 2011; areas near Fort Worth, TX (Wise, Parker, Tarrant, and Denton Counties) in September 2010 and 2011; in Sublette County, WY in June 2011, July 2012 and June 2013; and in the Eagle Ford, TX area (Maverick, Dimmit, La Salle, Webb, and Duval Counties) in September 2011. A total of 84 methane emission assessments were conducted in the Fort Worth area, 216 in WY, 93 in CO, and 22 in the Eagle Ford with offsite canister acquisition. Additionally, VOC emission estimates were executed at approximately 46% of these measurements. A subset of these field studies are described in (Thoma, 2012) with an expanded discussion, and slight revision of results to be published in (Brantley et al., 2014b). These data are primarily from well pads and represent an integration of all emissions (leak and vented) on the site. (Note: Vented emissions are not defined as “leaks” in this paper, therefore, the emission rates presented below include emissions that are not considered leaks in this paper). The study authors note, as with all instantaneous measurement approaches, the OTM 33A assessment may capture emissions that are short-term in nature (i.e., flash emissions) so extrapolation to annual emissions is difficult.

The preliminary results from the study (Thoma, 2012) show median methane emission rates of 0.21 grams per second (g/s), 0.43 g/s and 0.79 g/s and VOC emission rates of 0.16 g/s, 0.04 g/s and 0.30 g/s for the CO, TX, and WY studies, respectively (excluding Eagle Ford).

The study authors note that using improved analysis procedures, the above median rates will likely be revised slightly lower in a future publication. Offsite OGI was used in many cases to positively identify the origin of emissions. The study authors concluded that many of the high emission values were attributed to maintenance-related issues such as open thief hatches, failed pressure relief valves, or stuck dump valves. The difference in VOC emissions between the TX studies and the CO and WY studies is a result of the natural gas from the TX well sites being a dry natural gas. Additional analysis of the emission measurements including comparisons to natural gas, condensate/oil, and produced water production will be contained in a forthcoming article (Brantley et al., 2014b).

2.10 Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries (ICF International, 2014)

The Environmental Defense Fund (EDF) commissioned ICF to conduct an economic analysis of methane emission reduction opportunities from the oil and natural gas industry to identify the most cost-effective approach to reduce methane emissions from the industry. The study projects the estimated growth of methane emissions through 2018 and focuses its analysis on 22 methane emission sources in the oil and natural gas industry (referred to as the targeted emission sources). These targeted emission sources represent 80% of their projected 2018 methane emissions from onshore oil and gas industry sources. Well site leaks (includes heaters, separators, dehydrators and meters/piping) and pipeline leaks are two of the 22 emission sources that are included in the study.

The study relied on the 2013 GHG Inventory for methane emissions data for the oil and natural gas sector. The emissions data were revised to include updated information from the GHGRP (U.S. EPA, 2013) and the *Measurements of Methane Emissions at Natural Gas Production Sites in the United States* study (Allen et al., 2013). The revised 2011 baseline methane emissions estimate was used as the basis for projecting onshore methane emissions to 2018. One of the major differences in the revised 2011 baseline methane emissions estimate developed by ICF is the inclusion of a separate category for gathering and boosting operations. The 2013 GHG Inventory includes gathering and boosting operations in the onshore production segment and is based on the GRI/EPA measurement study (GRI/U.S. EPA, 1996).

The 2011 baseline methane inventory developed by ICF used the wellhead emission factor developed from the University of Texas study (Allen et al., 2013) to estimate leak emissions from well sites, which was reported as 97.6 scf/day. This emissions factor was applied to the natural gas well counts obtained from World Oil magazine to estimate the total methane leak emissions from well sites. These changes resulted in an estimated 14 billion cubic feet (264,000 MT) of methane emissions from wellheads in comparison.

Leak emissions from heater, separators, dehydrators, and meters/piping in the natural gas production sector were calculated using the GRI/EPA emissions factors for each of these emission sources. The study estimated methane emissions were 15 billion cubic feet (283,000 MT) from these sources.

Natural gas processing plant leak emissions were determined by ICF using data from the GHGRP (U.S. EPA, 2013) and a list of processing plants maintained by the EIA. The study by ICF determined that there are 909 gas processing and treatment facilities in the U.S. The study estimated methane emissions from processing facilities to be 3 billion cubic feet (56,600 MT).

The study did not provide specific equipment leak information for the natural gas transmission and storage sectors. However, the report did provide information on pipeline leaks from transmission of natural gas. The report estimated methane emissions of 0.2 billion cubic feet (3,800 MT).

The estimate of total national emissions from leaks in the natural gas production, processing, transmission and storage segments for 2011 was 604,000 MT of methane.

2.11 Identification and Evaluation of Opportunities to Reduce Methane Losses at Four Gas Processing Plants (Clearstone, 2002)

This study, referred to as “Clearstone I,”¹⁰ presented the results of the implementation of a comprehensive directed inspection and maintenance (DI&M) program at four gas processing

¹⁰ “Identification and Evaluation of Opportunities to Reduce Methane Losses at Four Gas Processing Plants.” Prepared for GTI and the U.S. EPA under grant 827754-01-0, by Clearstone Engineering. June 20, 2002. Also, note that a follow-up study, referred to as Clearstone II, was released in 2006, which studied five processing plants, one being a repeat from the plants studied in Clearstone I.

plants in the western U.S. in 2000. The work done during this study involved a survey of all gas service equipment components, as well as the measurement or engineering calculation of gas flows into the vent and flare systems. This study did not focus on hydrocarbon liquid services. In total, 101,193 individual gas service components were screened, along with 5 process vents, 28 engines, 7 process heaters, and 6 flare/vent systems.

The leak survey was conducted using bubble tests with soap solution, portable hydrocarbon gas detectors, and ultrasonic leak detectors. A screening value of 10,000 ppm or greater was used as the leak definition. The majority of components were screened using soap solution, but if a component was determined to be emitting gas, a hydrocarbon gas analyzer was used to determine if the component would be classified as a leaker per the above definition. Most leak rates were measured using a Hi-Flow™ Sampler, unless the leak was above the upper limit of the unit’s design (14 m³/hour). If the Hi-Flow™ Sampler could not be used, bagging or other direct measurement techniques were used, as appropriate.

From the survey, approximately 2,630 of the 101,193 screened components (2.6%) were determined to be leaking. The study states that “components in vibrational, high-use or heat-cycle gas service were the most leak prone.” The majority of the leaks were attributed to a relatively small number of leaking components. Table 2-12 presents the breakdown of leak emissions by component type.

Table 2-12. Distribution of Natural Gas Emissions from Leaking Component Types

| Component Type | Percent of Leak Emissions |
|--|----------------------------------|
| Valves | 30.0% |
| Connectors | 24.4% |
| Compressor Seals ^a | 23.4% |
| Open-Ended Lines | 11.1% |
| Crankcase Vents (on Compressors) | 4.2% |
| Pressure Relief Valves | 3.5% |
| Other (Pump Seals, Meters, Regulators) | 3.4% |

^a For the purposes of this paper, compressor seal emissions are not considered leaks.

The study also provided an analysis of the payback periods for fixing the identified leaks. That analysis is discussed in Section 3.2 of this paper.

2.12 Cost-Effective Directed Inspection and Maintenance Control Opportunities at Five Gas Processing Plants and Upstream Gathering Compressor Stations and Well Sites (Clearstone, 2006)

This study, referred to as “Clearstone II,”¹¹ presented the results of a comprehensive emissions measurement program at 5 gas processing plants, 12 well sites, and 7 gathering stations in the U.S. in 2004 and 2005. This work was done as follow up on a study done in 2000, referred to as Clearstone I, in which four gas processing plants were surveyed. (Note: one of the gas processing plants surveyed in the Clearstone I study was also surveyed in the Clearstone II study.) The work done involved a survey of all gas service equipment components at these 24 sites. The goal was to identify cost-effective opportunities for reducing natural gas losses and process inefficiencies. In total, 74,438 individual components were screened.

The leak survey was conducted using bubble tests with soap solution, portable hydrocarbon gas detectors, and ultrasonic leak detectors. A screening value of 10,000 ppm or greater was used as the leak definition. The majority of components were screened using soap solution, but if a component was determined to be emitting gas, a hydrocarbon gas analyzer was used to determine if the component would be classified as a leaker per the above definition. Most leak rates were measured using a Hi-Flow™ Sampler, unless the leak was above the upper limit of the unit’s design (14 m³/hour). For consistency, both the Clearstone I and Clearstone II surveys used the same Hi-Flow™ Sampler. If the Hi-Flow™ Sampler could not be used, bagging or other direct measurement techniques were used, as appropriate.

¹¹ “Cost-Effective Directed Inspection and Maintenance Control Opportunities at Five Gas Processing Plants and Upstream Gathering Compressor Stations and Well Sites.” Prepared for the U.S. EPA under grant XA-83046001-1, by National Gas Machinery Laboratory, Clearstone Engineering, and Innovative Environmental Solutions, Inc. March 2006. Note: This study, referred to as “Clearstone II”, was a follow up to a study released in 2002, referred to as “Clearstone I,” which surveyed four processing plants, one of which was resurveyed in Clearstone II.

Secondarily to the above leak detection methodology, for all five surveys of gas processing plants in the study, OGI cameras were also used in order to compare the performance of the OGI cameras with conventional leak detection methods. Although no quantitative comparison was done, the study concluded that the cameras are able to screen components about three times as quickly as the other methods, find leaks that are inaccessible to the other methods, and allow for rapid leak source identification.

From the survey, approximately 1,629 of the 74,438 screened components (2.2%) were determined to be leaking. The study states, similarly to Clearstone I, that “components in vibrational, high-use, and heat-cycle gas service were the most leak prone.” Further, the majority of the leak emissions could be attributed to a relatively small number of the leaking components. Table 2-13 presents the breakdown of natural gas leak emissions by component type.

Table 2-13. Distribution of Natural Gas Emissions from Leaking Component Types

| Component Type | Percent of Leak Emissions |
|--|---------------------------|
| Open-Ended Lines | 32% |
| Connectors | 30% |
| Compressor Seals | 20% |
| Block Valves | 15% |
| Other (PRVs, Meters, Regulators, etc.) | 3% |

The study also provides a comparison for the one gas plant that was surveyed in both studies. This plant was resurveyed in order to investigate changes in its leak characteristics. It was noted that about 30% of the equipment components in the plant had been decommissioned between the surveys due to the replacement of old process units with newer ones. Generally, the replacement process units and equipment components had substantially reduced emission rates compared to the decommissioned units. The overall reduction for the new units was an 80% decrease in total hydrocarbon (THC) emissions compared to the old units. However, the THC emissions for the plant as a whole increased about 50% between the two surveys. The study

gives several possible reasons for this, including the fact that the five-year timeframe between surveys exceeded the mean repair life for most of the components. The study also states that there may have been inadequate follow-up to maintenance recommendations provided during the first survey, as the documentation of repairs indicated it was “unclear what maintenance activities were undertaken in response to the Phase I survey.”

3.0 AVAILABLE EMISSIONS MITIGATION TECHNIQUES

There are a number of technologies available that can be used to identify leaks and a number of approaches to repairing those leaks. The technologies for identifying leaks and the approaches to repairing leaks are discussed in separate sections below.

3.1 Leak Detection

A variety of approaches are used for leak detection. For many regulations with leak detection provisions, the primary method for monitoring to detect leaking components is EPA Reference Method 21 (40 CFR Part 60, Appendix A). Method 21 is a procedure used to detect VOC leaks from process equipment using an analyzer, such as a TVA or an OVA. In addition, other monitoring tools such as OGI cameras, soap solution, acoustic leak detection, ambient monitors and electronic screening devices can be used to monitor process components. A summary of these technologies is presented below.

3.1.1 Portable Analyzers

Description

A portable monitoring instrument is used to detect hydrocarbon leaks from individual pieces of equipment. These instruments are intended to locate and classify leaks based on the leak definition of the equipment as specified in a specific regulation, and are not used as a direct measure of mass emission rate from individual sources. The instruments provide a reading of the concentration of the leak in either ppm, parts per billion (ppb), or percent concentration. For portable analyzers, EPA Reference Method 21 requires the analyzer to respond to the compounds being processed, be capable of measuring the leak definition concentration specified in the

regulation, be readable to $\pm 2.5\%$ of the specified leak definition concentration and be equipped with an electrically driven pump to ensure that a sample is provided to the detector at a constant flow rate.

The portable analyzers can be used to estimate the mass emissions leak rate by converting the screening concentration in ppm to a mass emissions rate by using the EPA correlation equations from the Protocol for Equipment Leak Emission Estimates (U.S. EPA, 1995). The correlation equations in the Protocol can be used to estimate emissions rates for the entire range of screening concentrations, from the detection limit of the instrument to the “pegged” screening concentration, which represents the upper limit of the portable analyzers (U.S. EPA, 2003a).

The portable analyzers must be calibrated using a reference gas containing a known compound at a known concentration. Methane in air is a frequently used reference compound. The calibration process also determines a response factor for the instrument, which is used to correct the observed screening concentration to match the actual concentration of the leaking compound. For example, a response factor of “one” means that the screening concentration read by the portable analyzer equals the actual concentration at the leak (U.S. EPA, 2003a). Screening concentrations detected for individual components are corrected using the response factor (if necessary) and are entered into the EPA correlation equations to extrapolate a leak rate measurement for the component (U.S. EPA, 2003a).

Applications

The portable monitoring instruments operate on a variety of detection principles, with the three most common being ionization, IR absorption and combustion (U.S. EPA, 1995). The ionization detectors operate by ionizing the sample and then measuring the charge (i.e., number of ions) produced. Two methods of ionization currently used are flame ionization and photoionization. A standard flame ionization detector (FID) measures the total carbon content of the organic vapor sampled. Certain portable FID instruments are equipped with gas chromatograph (GC) options making them capable of measuring total gaseous non-methane organics or individual organic components (U.S. EPA, 1995). The photoionization detector (PID) uses ultraviolet light (instead of a flame) to ionize organic vapors. As with FIDs, the detector response varies with the functional group in the organic compounds. Photoionization

detectors have been used to detect leaks in process units in the Synthetic Organic Chemical Manufacturing Industry (SOCMI), especially for certain compounds, such as formaldehyde, aldehydes, and other oxygenated compounds, which may not give a satisfactory response on a FID or combustion-type detector (U.S. EPA, 1995).

Nondispersive infrared (NDIR) instruments operate on the principle of light absorption characteristics of certain gases. These instruments are usually subject to interference because other gases, such as water vapor and CO₂, may also absorb light at the same wavelength as the compound of interest (U.S. EPA, 1995). These detectors are generally used only for the detection and measurement of single components. For this type of detection, the wavelength at which a certain compound absorbs IR radiation is predetermined and the device is preset for that specific wavelength through the use of optical filters (U.S. EPA, 1995).

Combustion analyzers are designed either to measure the thermal conductivity of a gas or to measure the heat produced by combustion of the gas. The most common method in which portable VOC detection devices are used involves the measurement of the heat of combustion. These detection devices are referred to as hot wire detectors or catalytic oxidizers. Combustion analyzers, like most other detectors, are nonspecific for gas mixtures (U.S. EPA, 1995). In addition, combustion analyzers exhibit reduced response (and, in some cases, no response) to gases that are not readily combusted, such as formaldehyde and carbon tetrachloride (U.S. EPA, 1995).

The typical types of portable analyzers used for detecting leaks from components are OVAs and TVAs. An OVA is an FID, which measures the concentration of organic vapors over a range of 9 to 10,000 ppm (U.S. EPA, 2003a). A TVA combines both a FID and a PID and can measure organic vapors at concentrations exceeding 10,000 ppm. Toxic vapor analyzers and OVAs measure the concentration of methane in the area around a leak (U.S. EPA, 2003a).

Screening is accomplished by placing a probe inlet at an opening where leakage can occur. Concentration measurements are observed as the probe is slowly moved along the interface or opening, until a maximum concentration reading is obtained. The maximum concentration is recorded as the leak screening value. Screening with TVAs and OVAs can be a

slow process, requiring approximately one hour for every 40 components, and the instruments require frequent calibration.

Costs

The costs of the portable analyzers vary based on the type of analyzer used to measure leak concentrations. The documentation for the EPA National Uniform Emission Standards for Equipment Leaks (40 CFR part 65, subpart J) provides a cost of \$10,800 for a portable monitoring analyzer (RTI, 2011). Additional costs would also include labor costs associated with performing the screening and would depend on the number of components screened.

3.1.2 Optical Gas Imaging (IR Camera)

Description

Optical gas imaging (OGI) is a technology that operates much like a consumer video-camcorder and provides a real-time visual image of gas emissions or leaks to the atmosphere. The OGI camera works by using spectral wavelength filtering and an array of IR detectors to visualize the IR absorption of hydrocarbons and other gaseous compounds. As the gas absorbs radiant energy at the same waveband that the filter transmits to the detector, the gas and motion of the gas is imaged. The OGI instrument can be used for monitoring a large array of equipment and components at a facility, and is an effective means of detecting leaks when the technology is used appropriately. The EPA has worked extensively with OGI technology and is in the process of further evaluating its capabilities. Information presented below, unless otherwise cited, is based on that evaluation work.

Applications

The detection capability of the OGI camera is based on a variety of factors such as detector capability, gas characteristics of the leak, optical depth of the plume and temperature differential between the gas and background. The EPA is currently studying OGI technology in order to determine its capabilities and limitations.

The OGI system provides a technology that can potentially reduce the time, labor and

costs of monitoring components. The capital cost of purchasing an OGI system is estimated to be \$85,000 (Meister, 2009). The ICF economic analysis estimated the capital cost of the OGI system to be \$124,000 (ICF International, 2014). The EPA estimated that the OGI can monitor 1,875 pieces of equipment per hour at a petroleum refinery (RTI, 2012). This study assumes for every hour of video footage, the operator would spend an additional 1.4 hours conducting activities for calibration, OGI adjustments, tagging leaks and other activities. Another estimate, (ICF Consulting, 2003) stated that OGI can monitor 35 components per minute (2,100 components per hour). In comparison, the average screening rate using a handheld TVA or OVA is roughly 700 components per day (ICF Consulting, 2003). However, the EPA's recent work with OGI systems suggests these studies underestimate the amount of time necessary to thoroughly monitor components for leaks using OGI technology. Additionally, the number of pieces of equipment that could be monitored per hour at an upstream oil and gas facility would likely be less than at a refinery given that equipment tends to be farther apart at these facilities than at a refinery.

By increasing the number of pieces of equipment that can be viewed per hour, the OGI system could potentially reduce the cost of identifying leaks in upstream oil and gas facilities when compared to using a handheld TVA or OVA. A recent study (CL, 2013) analyzed 4,293 leak detection surveys completed for the oil and gas industry using OGI systems. These surveys were completed by external contractors hired by the owner or operator of the oil and gas facility. This study estimated the average abatement cost to be approximately \$0 per ton of VOC and approximately -\$375 per ton of VOC for well sites and compressor stations, respectively. These estimates assume all leaks that are found are repaired and the recovered methane can be sold for \$4/Mcf. The average costs of performing the OGI surveys in the study are \$2,300 for a compressor station, \$1,200 for multi-well batteries, \$600 for single well batteries and \$400 for well sites (CL, 2013). (Note: Only a prepublication draft was available of this report when the EPA was completing this white paper.)

Another advantage of OGI for detecting leaks is finding leaks not directly related to components while in the process of surveying the overall site. Leaks such as degradation in the exterior of tanks or leaks in lines buried underground would be seen with OGI but very hard to locate with a handheld TVA or OVA.

For the application of this technology to this sector, the gas characteristics are well suited for the typical OGI camera technology because the leaks tend to be almost all methane, alkane or aromatics. Methane, alkanes and aromatics are all detectable due to having carbon-hydrogen bonds.

OGI Operational Considerations

While the operator or inspector using OGI technology can see leaking emissions from equipment, quantifying the emissions is difficult. To quantify emissions with an OGI camera, extensive metadata, such as apparent background temperature, gas leak temperature, leak size and wind speed must also be taken. These parameters would then be used with a developed and evaluated algorithm to quantify emissions. The EPA is not aware of the existence or evaluation of such an algorithm at this time. However, in addition to algorithms, operators can use quantification equipment such as a Hi-Flow™ Sampler.

The OGI system is also sensitive to the ambient conditions around the equipment that is being inspected. The larger the temperature differential between the leaking gas and the contrasting background (e.g., sky, ground or equipment), the easier the leaking gas is to see. The apparent temperature of the sky, a commonly used background, is also highly dependent on weather conditions such as cloud cover, ambient temperature and relative humidity. Additionally, high or variable wind conditions can reduce the optical depth and make it difficult for gas leaks to be identified, because the gas plume is quickly carried away from the source of the leak. Both these characteristics could result in operators being unable to identify leaks if the ambient conditions are not optimal.

Lastly, the effectiveness of an OGI instrument is dependent on the training and expertise of the operator. Well-trained and experienced operators are able to detect leaks with the OGI system that lesser experienced operators do not detect.

Current OGI Usage in the Oil and Gas Industry

The EPA is not aware of any studies that estimate the extent of the usage of OGI systems in the oil and natural gas production sector. However, certain proposed and existing regulations allow OGI systems as an option for fulfilling leak detection requirements, and some companies

are using the technology voluntarily such as through the Natural Gas STAR program. Additionally, the GHGRP subpart W allows for the use of OGI technology in some circumstances and the Alternative Work Practice regulation (40 CFR Part 60, subpart A) allow the use of OGI technology along with an annual Method 21 survey as an alternative to a traditional leak detection and repair (LDAR) program using Method 21.

The State of Colorado recently proposed regulations that would require leak inspections at all well sites, compressor stations upstream of the processing plant and storage vessels. These proposed regulations allow OGI inspections, Method 21 or other “[d]ivision approved instrument based monitoring device or method” to detect leaks (CO Department of Public Health and Environment, Air Quality Control Commission, Regulation Number 7, Proposed November 18, 2013).

The State of Wyoming, as part of its permitting guidance, requires facilities with emissions greater than 4 tpy of VOCs in the Upper Green River Basin, the Jonah-Pinedale Anticline Development Area and Normally Pressured Lance to conduct quarterly leak emissions inspections, and OGI inspections are allowed in addition to Method 21 inspections or audio-visual-olfactory inspections (Wyoming Department of Environmental Quality, Oil and Gas Production Facilities, Chapter 6, Section 2 Permitting Guidance, September 2013).

The Alberta Energy Regulator requires that a “licensee of a facility must develop and implement a program to detect and repair leaks.” These programs must “meet or exceed” the Canadian Association of Petroleum Producer’s (CAPP) best management practice (BMP) for leak emissions management (CAPP, 2011). The CAPP BMP allows OGI technology for performing these leak inspections (CAPP, 2007).

Lastly, the EPA has found that owners and operators are voluntarily using OGI systems to detect leaks. However, the EPA does not know the extent of these voluntary efforts within the industry on a national level.

3.1.3 Acoustic Leak Detector

Description

Acoustic leak detectors are used to detect the acoustic signal that results when pressurized gas leaks from a component. This acoustic signal occurs due to turbulent flow when pressurized gas moves from a high-pressure to a low-pressure environment across a leak opening (U.S. EPA, 2003a). The acoustic signal is detected by the analyzer, which provides an intensity reading on the meter. Acoustic detectors do not measure leak rates, but do provide a relative indication of leak size measured by the intensity of the signal (or how loud the sound is) (U.S. EPA, 2003a).

Applications

Generally, two types of acoustic leak detection methods are used; high frequency acoustic leak detection and ultrasound leak detection. High frequency acoustic detection is best applied in noisy environments where the leaking components are accessible to a handheld sensor (U.S. EPA, 2003a). Ultrasound leak detection is an acoustic screening method that detects airborne ultrasonic signals in the frequency range of 20 kHz to 100 kHz and can be aimed at a potential leak source from a distance of up to 100 feet (U.S. EPA, 2003a). Ultrasound detectors can be sensitive to background noise, although most detectors typically provide frequency tuning capabilities so that the probe can be tuned to a specific leak in a noisy environment (U.S. EPA, 2003a).

A URS Corporation/University of Texas at Austin (URS/UT) study described a “through-valve acoustic leak detection device” or VPAC that was used to measure leaks at six sites (four gathering/boosting stations and two natural gas processing plants) (URS/UT, 2011). Leak measurements were made using the VPAC device and high volume sample to compare the readings from the two devices. The study authors found that there was no statistically significant correlation between the VPAC and the direct flow measurements, and the study authors determined that the VPAC method was not considered to be an accurate alternative to direct measurement for the sources tested (URS/UT, 2011).

Costs

No cost data for acoustic leak detectors were available in the studies or research

documents.

3.1.4 Ambient/Mobile Monitoring

Description

A growing number of research and industry groups are using mobile measurement approaches to investigate a variety of source emissions and air quality topics. For oil and natural gas applications, a vehicle can be equipped with at minimum a methane measurement instrument and GPS to facilitate discovery of previously unknown sources and in more advanced forms, provide information on source emission rates.

Applications

Mobile leak detection techniques sample emission plumes from stand-off (sometimes offsite) observing locations and are, therefore, generally less accurate than direct (onsite) source measurements. Mobile leak detection techniques can cover large survey areas and can be particularly useful in identifying anomalous operating conditions (e.g., pipeline leaks and well pad malfunctions) in support of onsite OGI and safety programs. All mobile techniques require downwind vehicle access and favorable wind conditions for plume transport to the observing location. The presence of trees or other obstructions can limit the efficacy of mobile leak detection techniques and in some cases prevent the application of remote source emission rate assessment.

Mobile leak detection instrument packages require some expertise for operation, especially in source emission rate measurement applications. Additionally, while mobile leak detection techniques can detect emissions around a site, such as a well site or gathering station, it cannot necessarily pinpoint the equipment that is the source of those emissions. Mobile leak detection techniques might be best used in conjunction with OGI technology; an OGI inspection would be triggered by the detection of above normal emissions by the mobile leak detection technique. In conversations with operators of upstream oil and natural gas facilities, the EPA has discovered that some companies are voluntarily using this two-phase approach to detect and then pinpoint VOC and methane leaks. It is believed that future forms of mobile leak detection

techniques for the oil and gas sector may include lower cost, work truck-mounted systems that provide fully autonomous detection capability for anomalous emissions in support of such an onsite OGI inspection (Thoma, 2012).

An example of a mobile leak detection technique applicable to the upstream oil and gas sector is being developed under the EPA's Geospatial Measurement of Air Pollution (GMAP) program (Thoma, 2012). The near-field OTM 33A produces a 20-minute "snapshot" measure of emissions from near ground level point sources at observation distances of approximately 20 to 200 m. With strict application and favorable conditions, this type of point sensor-based remote measurement has source emission rate measurement accuracies in the $\pm 30\%$ range with ensemble averages achieving accuracies within $\pm 15\%$ by reducing random error effects. Although future, fixed deployment, low cost sensor systems may provide long-term emission level monitoring capability for oil and gas production sites,¹² current mobile assessment approaches can only provide a "snapshot" of emissions. Because some oil and gas upstream sources possess significant temporal and seasonal variability, the short-term nature of observation must be considered to avoid error in exportation of instantaneous emissions (e.g., to tons per year estimates). Results of well pad measurements from multiple oil and gas fields using mobile measurement are presented in Section 2.

Costs

Current mobile measurement instrument packages can range in cost from approximately \$20,000 - \$100,000 depending on the capability of the package.

3.2 Repair

After a leak is detected, the owner or operator of the facility must decide whether or not to fix the leak, unless they are required to fix the leak due to regulatory or permitting obligations.

¹² A collaborative request for proposal (RFP) was released in the spring of 2014 by Apache Corporation, BG Group, EDF, Hess Corporation, Noble Energy, and Southwestern Energy called the "Methane Detectors Challenge: Continuous Methane Leak Detection for the Oil and Gas Industry." The "Challenge" is "designed to spur the development of cutting-edge, new technologies that provide continuous detection of methane emissions." Available at: <http://www.edf.org/energy/natural-gas-policy/methane-detectors-challenge>

This decision can be based on several factors, including, the cost of fixing the leak and the size of the leak. A number of studies discuss costs and effectiveness of various leak repair options.

3.2.1 Quantifying Cost-Effectiveness of Systematic Leak Detection and Repair Programs Using Infrared Cameras (CL, 2013)

This study, discussed previously in Section 2, provided an analysis of the net present values (NPVs) of repairing all of the identified leaks in the surveys using the estimated repair cost and the value of the recovered gas. The study found that over 90% of gas emissions from leaks can be repaired with a payback period of less than one year, assuming a value of \$3 per thousand cubic feet (\$/Mcf) for the recovered gas. However, when compared with the cost of the monitoring (estimated to be \$600 to \$1,800 per facility), the economic benefits of repairing the leaks at most facilities are less than the total cost of the survey. For well sites and well batteries, the study estimated that 1,424 of the sites (81%) had a negative NPV, which averaged -\$1,160 per facility. However, when the all of the individual well sites and well batteries are aggregated into a group, the aggregated NPV is positive, which suggests that a minority of sites have high leak rates and, thus, a positive NPV for monitoring and fixing leaks. These sites skew the mean NPV to a positive value.

The study also analyzed two alternative repair strategies: only repair leaks that are economic to repair (e.g., NPV > 0 for the repair) or repair of leaks that exceeded a certain threshold (e.g., 20 thousand cubic feet per year (Mcf/yr)). A summary of the findings for each of the scenarios is provided in Table 3-1.

Table 3-1. Comparison of Three Hypothetical Repair Strategies for Multi-Well Batteries^a

| Category | Repair all leaks | Repair leaks with a NPV>0 | Repair leaks > 20 Mcf |
|---|------------------|---------------------------|-----------------------|
| Potential leak reductions after survey | 94.5% | 92.6% | 88.1% |
| Methane abatement cost (\$/ton CO ₂ e) | 1 | 0.8 | 1.7 |
| VOC abatement cost (\$/ton VOC) | 46 | 41 | 79 |
| Average number of leaks to repair | 3.8 | 3.5 | 2.9 |

a - Derived from Table 3 (CL, 2013).

The study concludes that the potential leak reductions after survey, methane abatement cost, VOC abatement cost, and average number of leaks to repair are similar under each of the three strategies. The study authors conclude that the results are similar because once a leak is found it is almost always economic to repair it.

The study also provided costs of repair and leak detection based on the survey data. The average cost of hiring an external service provider to perform a survey using OGI technology was determined to be \$1,200 for multi-well batteries, \$600 for single well batteries, and \$400 for a well site. The range of costs of repair for well sites is shown in Table 3-2.

Table 3-2. Total Average Leak Rate and Repair Costs by Components at Well Sites

| Component | Leak rate (cfm) | Repair Costs | | | |
|-----------------------|-----------------|------------------|------------------|------------------|------------------|
| | | Minimum | Average | Median | Maximum |
| Connector/Connection | 0.11 | \$15 | \$56 | \$50 | \$5,000 |
| Instrument Controller | 0.03 | \$20 | \$129 | \$50 | \$2,000 |
| Valve | 0.04 | \$20 | \$90 | \$50 | \$5,500 |
| Open-Ended Line | 0.02 | --- ^b | --- ^b | --- ^b | --- ^b |
| Regulator | 0.02 | \$20 | \$189 | \$125 | \$1,000 |

a - Derived from Tables 6 and 7 (CL, 2013).

b – Repair costs for open-ended lines were not provided in the document.

3.2.2 Identification and Evaluation of Opportunities to Reduce Methane Losses at Four Gas Processing Plants (Clearstone, 2002)

The Clearstone I study, discussed in Section 2, provided analysis of the payback periods for fixing the identified leaks, and what level of emission reductions could be achieved. Overall, the study estimated that up to 95% of total natural gas losses can be reduced cost-effectively (assumed gas price of \$4.50 per Mcf), which corresponds to methane reductions of nearly 80%. The study also presents scenarios where only those reduction opportunities having a certain payback period (e.g., 6 months or 1 year) are implemented. For those cases, the estimated

percent of total natural gas loss reduction and corresponding reductions in methane are presented in Table 3-3. One caveat from the study is that the payback periods do not take into account the cost of the leak detection survey, only factoring in cost of repair and benefit of the gas captured.

Table 3-3. Achievable Emission Reduction Percentages for Given Positive Payback Periods

| Emission Type Reduction | Payback Period | | | |
|-------------------------|----------------|----------|-----------|-----------|
| | < 6 months | < 1 year | < 2 years | < 4 years |
| Natural Gas | 78.8% | 92.3% | 93.1% | 94.9% |
| Methane | 71.9% | 78.1% | 79.2% | 79.5% |

The study estimated that implementing all of the cost-effective repair opportunities identified would result in gross annual cost savings of approximately \$1.1 million across the plants in the study (based on a gas value of \$4.50 per Mcf). This amounts to over 50% of total cost-effective loss reduction opportunities identified for all emission sources (leaks, flaring, combustion equipment, and storage tanks) at the plants, and results in an average annual net savings of approximately \$280,000 per site (the site-specific values range between \$180,000 and \$330,000).

3.2.3 Cost-Effective Directed Inspection and Maintenance Control Opportunities at Five Gas Processing Plants and Upstream Gathering Compressor Stations and Well Sites (Clearstone, 2006)

The Clearstone II study, discussed in Section 2, analyzed the cost-effectiveness of repairing the leaks identified in the surveys that were performed. The study estimated that up to 96.6% of total natural gas losses could be reduced cost-effectively (assuming a gas price of \$7.15 per Mcf), which corresponds to methane reductions of 61%. The study also estimated that the average annual lost gas values from the sites surveyed were \$536,270 per gas plant, \$49,018 per gathering station, and \$3,183 per well site.

This study also provided the base repair cost and mean repair life for 16 types of components. The values for several of the more common components reported in the study are summarized in Table 3-4.

Table 3-4. Basic Repair Costs and Mean Repair Life for Several Common Leaking Components

| Component Type | Basic Repair Costs | | Mean Repair Life (years) |
|-------------------------------|--------------------|---------|--------------------------|
| | Low | High | |
| Compressor Seals ^a | \$2,000 | \$2,000 | 1 |
| Flanges | \$25 | \$400 | 2 |
| Open-End Lines | \$60 | \$1,670 | 2 |
| Pressure Relief Valves | \$79 | \$725 | 2 |
| Threaded Connections | \$10 | \$300 | 2 |
| Tubing Connections | \$15 | \$25 | 4 |
| Valves | \$60 | \$2,229 | 2 - 4 |
| Vents | \$2,000 | \$5,000 | 1 |

^a For the purposes of this paper, compressor seal emissions are not considered leaks.

3.2.4 Natural Gas STAR Directed Inspection and Maintenance (U.S. EPA, 2003a, U.S. EPA, 2003b, and U.S. EPA, 2003c)

For detecting and repairing leaks, the Natural Gas STAR program recommends implementation of a DI&M program to economically reduce methane emissions from leaking components (U.S. EPA, 2003a, U.S. EPA, 2003b, and U.S. EPA, 2003c). A DI&M program, which can be implemented at any facility in the upstream or downstream sector of the industry, starts with a comprehensive baseline emissions survey. This survey involves screening all of the components at the facility to identify the leaking components, as well as measuring the identified leaks to determine emission rates. Determining an emissions rate is an important step that allows the economic evaluation of mitigation techniques. Natural Gas STAR partners have reported using OGI technology to effectively scan large numbers of components in a short span of time. The choice of leak detection equipment typically depends on the number of components to be scanned. Optical gas imaging technology is popular at facilities that have thousands of

components, such as at processing plants. From previous field studies conducted by the EPA and Natural Gas STAR partners, the EPA has observed that typically 20% of the top leaking components account for approximately 80% of the emissions from a facility. This provides a strong basis to conduct DI&M at facilities because fixing a small number of leaks can significantly reduce the total leak emissions from a facility.

Once the leaking sources have been identified, the next step recommended is the economic analysis of mitigation techniques. The estimated repair costs for the identified leaks can be compared to the potential savings from fixing the leaks based on the value of natural gas, and the leaks that are determined to be economical to fix by the owner can be repaired.

Not all leaks identified can be fixed immediately. For example, leaks on a flange on a transmission pipeline cannot be fixed without shutting down the system and purging the pipeline of all the natural gas. The identification of leaks before a shutdown through a DI&M program helps facilities focus on specific areas during a shutdown cycle. Shutdown cycles are usually short, lasting from a day up to a week.

The Natural Gas STAR program also lists average emission rates, repair cost ranges, and payback periods for fixing leaks at several different facilities. Tables 3-5 and 3-6 show the emission rates and repair costs for several common leaking components at gas processing plants, transmission compressor stations, and gate stations.

Table 3-5. Total Average Leak Rate and Repair Costs by Component at Processing Plants

| Component | Average Component Leak Rate by Location (Mcf/yr) | | | Average Repair Cost |
|------------------------------|---|--------------------------|------------------------|---------------------|
| | Non-Compressor | Reciprocating Compressor | Centrifugal Compressor | |
| Connections | 6.7 | - | - | \$25 |
| Flanges | 88.2 | 89.7 | 115 | \$150 |
| Pressure Relief Valves | 3.9 | 308 | - | \$150 |
| Other Valves | 25 | 127 | 63.4 | \$130 |
| Compressor Seal ^a | - | 1,440 | 485 | \$2,000 |
| Open-Ended Line (OEL) | 43 | - | - | \$65 |
| Compressor Blowdown OEL | - | 1,417 | 2,887 | \$5,000 |

Note: Adapted from exhibit 5 in “Directed Inspection and Maintenance at Gas Processing Plants and Booster Stations” Lessons Learned document. Available online: http://epa.gov/gasstar/documents/ll_dimgasproc.pdf

^a For the purposes of this paper, compressor seal emissions are not considered leaks.

Table 3-6. Total Average Leak Rate and Repair Costs by Component at Compressor Stations

| Component | Average Component Leak Rate by Location (Mcf/yr) | | Average Repair Costs | |
|-----------------------|--|----------------|----------------------|---------|
| | On Compressor | Off Compressor | Low | High |
| Ball/Plug Valves | 0.64 | 5.33 | \$40 | \$120 |
| Blowdown Valve | - | 207.5 | \$200 | \$600 |
| Compressor Valve | 4.1 | - | \$60 | \$60 |
| Unit Valve | - | 3,566 | \$70 | \$2,960 |
| Flange | 0.81 | 0.32 | \$300 | \$1,250 |
| Open-Ended Line | - | 81.8 | \$45 | \$45 |
| Pressure Relief Valve | - | 57.5 | \$1,000 | \$1,000 |
| Connection | 0.74 | 0.6 | \$10 | \$30 |

Note: Adapted from exhibits 4 and 5 in “Directed Inspection and Maintenance at Compressor Stations” Lessons Learned document. Available online: http://epa.gov/gasstar/documents/ll_dimcompstat.pdf.

3.2.5 Update of Fugitive Equipment Leak Emission Factors (CAPP, 2014)

In February of 2014, CAPP issued a report on emission factors for leaks at upstream oil and gas facilities in Alberta and British Columbia. This report served as an update to similar factors that were developed in 2005, prior to the implementation of DI&M BMPs in both these provinces. The report compares the 2005 leak emission factors to the 2014 leak emission factor in order to draw conclusions regarding the effectiveness of the DI&M BMPs in Alberta and British Columbia.

Leak survey results provided by eight industry participants in Alberta and British Columbia were the basis of the emission factors. The results came from 120 facilities and included approximately 276,947 components. All surveys were conducted after 2007. The study authors used this data to develop average emission factors for each type of component and then

compared those factors to the factors developed in 2005. Table 3-7 provides a comparison of the emission factors for each type of component from the 2005 study and the 2014 study.

Table 3-7. Comparison of Total Hydrocarbon Leak Emission Factors for Upstream Oil and Gas Facilities that have Implemented DI&M BMPs

| Sector | Component | Service^a | 2014 Emission Factor (kg/hour) | 2005 Emission Factor (kg/hour) | Ratio of 2014 to 2005 Emission Factors |
|---------------|------------------------------|----------------------------|---------------------------------------|---------------------------------------|---|
| Gas | Compressor Seal ^b | GV | 0.04669 | 0.71300 | 0.065 |
| Gas | Connector | GV | 0.00082 | 0.00082 | 1.000 |

^a GV = Gas/Vapor, LL = Light Liquid

^b For the purposes of this paper, compressor seal emissions are not considered leaks.

The study authors conclude that emissions from leaks have decreased 75% among the survey participants since the implementation of the DI&M programs in Alberta and British Columbia. The leak factors for almost all categories of equipment decreased. The authors did not use this data to develop national or regional estimates of total leak emissions.

4.0 SUMMARY

The EPA has used the information presented in this paper to inform its understanding of leak emissions and potential techniques that can be used to identify and mitigate leaks in the oil and natural gas production, processing, transmission and storage sectors. The following are characteristics the Agency believes are important to understanding this source of VOC and methane emissions:

- The 2014 GHG Inventory estimates there are approximately 332,662 MT of potential methane leak emissions from gas production, 33,681 MT of potential methane leak emissions from gas processing, and 114,348 MT of potential methane leak emissions gas transmission.
- Several studies suggest that the majority of methane and VOC emissions from leaks come from a minority of components (CL, 2013; Clearstone, 2002; and Clearstone, 2006). Furthermore, one study concludes that the majority of methane and VOC emissions from leaks come from a minority of sites (CL, 2013). One study found that the majority of leak emissions from these sites may be attributed to maintenance-related issues such as open thief hatches, failed pressure relief valves, or stuck dump valves (Thoma, 2012).
- The methane and VOC leak emissions from well sites depend on a number of different factors including: the number of wells located at the site, the number of compressors located at the well site and the number and type of processing equipment (separators, heaters, etc.) used at the site.
- Currently, portable analyzers provide an effective approach for both locating and measuring the concentration of leaks from oil and natural gas production sites.
- There are several other technologies being used to detect leaks for the oil and natural gas sectors. These technologies include OGI and ambient/mobile monitoring.

- OGI is being increasingly used to locate leaks in the oil and gas industry. The technology can potentially provide a more time and cost efficient method for locating leaks than traditional technologies, such as portable analyzers. However, there may be limitations to this technology.
 - The technology must be used methodically in order to address certain limitations, such as sensitivities to ambient conditions.
 - OGI technology does not quantify emissions. It may be possible to develop algorithms to quantify emissions with data from OGI, but, to the EPA's knowledge, such algorithms are not currently available.
- Ambient/mobile monitoring and OGI technology might be most effective when used in tandem. In such cases, an OGI inspection could be triggered by the detection of above normal emissions by the ambient/mobile monitoring equipment. This approach potentially could reduce or eliminate OGI inspections at facilities with minimal leak emissions.
- Available information suggests that once a leak is found it is almost always economical to repair the leak. According to the studies reviewed, the cost of detecting the leak is generally far larger than the cost of fixing the leak.
- The CAPP 2014 study and experience through the Natural Gas STAR program suggest DI&M programs can effectively decrease leak emissions.

5.0 CHARGE QUESTIONS FOR REVIEWERS

1. Did this paper appropriately characterize the different studies and data sources that quantify VOC and methane emissions from leaks in the oil and natural gas sector?
2. Please comment on the approaches for quantifying emissions and on the emission factors used in the data sources discussed. Please comment on the national estimates of emissions and emission factors for equipment leaks presented in this paper. Please comment on the activity data used to calculate these emissions, both on the total national and regional equipment counts.
3. Are the emission estimating procedures and leak detection methods presented here equally applicable to both oil and gas production, processing, and transmission and storage sectors?

4. Are there ongoing or planned studies that will substantially improve the current understanding of VOC and methane emissions from leaks and available techniques for detecting those leaks? Please list the additional studies you are aware of.
5. Are there types of wells sites, gathering and boosting stations, processing plants, and transmission and storage stations that are more prone to leaks than others? Some factors that could affect the potential for leaks are the number and types of equipment, the maintenance of that equipment, and the age of the equipment, as well as factors that relate to the local geology. Please discuss these factors and others that you believe to be important.
6. Did this paper capture the full range of technologies available to identify leaks at oil and natural gas facilities?
7. Please comment on the pros and cons of the different leak detection technologies. Please discuss efficacy, cost and feasibility for various applications.
8. Please comment on the prevalence of the use of the different leak detection technologies at oil and gas facilities. Which technologies are the most commonly used? Does the type of facility (e.g., well site versus gathering and boosting station) affect which leak detection technology is used?
9. Please provide information on current frequencies of revisit of existing voluntary leak detection programs in industry and how the costs and emission reductions achieved vary with different frequencies of revisit.
10. Please comment on the potential for using ambient/mobile monitoring technologies in conjunction with OGI technology. This would be a two-phase approach where the ambient/mobile monitoring technology is used to detect the presence of a leak and the OGI technology is used to identify the leaking component. Please discuss efficacy, cost and feasibility.
11. Please comment on the cost of detecting a leak when compared to the cost to repair a leak. Multiple studies described in this paper suggest that detecting leaks is far more costly than repairing leaks and, due to generally low costs of repair and the subsequent product recovery, it is almost always economical to repair leaks once they are found. Please comment on this overall conclusion.

12. If the conclusion is correct that it is almost always economical to repair leaks once they are found, then how important is the quantification of emissions from leaks when implementing a program to detect and repair leaks?
13. Please comment on the state of innovation in leak detection technologies. Are there new technologies under development that are not discussed in this paper? Are there significant advancements being made in the technologies that are not described in this paper?

Table of Contents

| | <u>Page</u> |
|---|-------------|
| Executive Summary | xii |
| 1.0 Introduction | 1-1 |
| 2.0 Ambient Air Monitoring..... | 2-1 |
| 2.1 Site Selection | 2-2 |
| 2.1.1 Site S-1 (Background Site)..... | 2-4 |
| 2.1.2 Site S-2 (Mobile Sources Site)..... | 2-6 |
| 2.1.3 Site S-3 (Pre-Production Site)..... | 2-6 |
| 2.1.4 Site S-4 (High-Level Activity Site, Collocated)..... | 2-8 |
| 2.1.5 Site S-5 (High-Level Activity Site, Collocated)..... | 2-9 |
| 2.1.6 Site S-6 (Moderate-Level Activity/Fence line Site) | 2-10 |
| 2.1.7 Site S-7 (Moderate-Level Activity/Fence line Site) | 2-11 |
| 2.2 Sampling Protocol..... | 2-12 |
| 2.3 Sample Analysis | 2-15 |
| 2.4 Quality Assurance/Quality Control..... | 2-18 |
| 2.4.1 Completeness | 2-19 |
| 2.4.2 Measurement Precision | 2-20 |
| 2.4.3 Measurement Accuracy | 2-22 |
| 2.5 Ambient Air Monitoring Results | 2-22 |
| 2.5.1 Summary Statistics..... | 2-22 |
| 2.5.2 Study Period Averaging | 2-28 |
| 2.5.3 Key Pollutants..... | 2-50 |
| 2.5.4 Integration with Meteorology | 2-51 |
| 2.6 Ambient Air Monitoring Conclusions | 2-73 |
| 3.0 Point Source Testing | 3-1 |
| 3.1 Introduction | 3-1 |
| 3.2 Point Source Emissions Survey Sampling Equipment | 3-3 |
| 3.2.1 The FLIR™ Infrared Camera | 3-6 |
| 3.2.2 The Toxic Vapor Analyzer (TVA)..... | 3-7 |
| 3.2.3 The Hi Flow Sampler | 3-8 |
| 3.2.4 Summa Canisters..... | 3-9 |
| 3.2.5 Miscellaneous Equipment | 3-10 |
| 3.3 Point Source Survey and Sampling Procedures..... | 3-10 |
| 3.3.1 Pre-Test Equipment Preparation | 3-11 |
| 3.3.2 Final Preparations | 3-12 |
| 3.3.3 Site Arrival | 3-12 |
| 3.3.4 IR Camera Survey | 3-14 |
| 3.3.5 Method 21 Site Survey with the Toxic Vapor Analyzer | 3-15 |
| 3.3.6 Hi Flow Sampler Emissions Testing..... | 3-17 |
| 3.3.7 Canister Sampling | 3-17 |
| 3.3.8 Completion of the Site Survey..... | 3-20 |
| 3.4 Emissions Calculation Procedures..... | 3-23 |

| | | |
|------------|---|------------|
| 3.4.1 | Well Pad, Compressor Station, Gas Plant, and Salt Water Disposal Facility Emissions | 3-23 |
| 3.4.2 | Direct Emission Calculations | 3-24 |
| 3.4.3 | Indirect Emission Calculations -- Correlation Equation Development..... | 3-26 |
| 3.4.4 | Applying Canister Results to Non-Canister Emission Points | 3-27 |
| 3.4.5 | Surrogate Canister Profiles | 3-29 |
| 3.4.6 | Calculation of Non-Sampled Low Level Emission Points..... | 3-30 |
| 3.4.7 | Compressor Engine Emissions | 3-32 |
| 3.4.8 | Well Drilling and Fracking Engine Emissions | 3-32 |
| 3.4.9 | Calculation of Method 21 TOC Screening Emission Factors | 3-32 |
| 3.5 | Point Source Emissions Results..... | 3-33 |
| 3.5.1 | Well Activity Emissions..... | 3-62 |
| 3.5.2 | Method 21 TOC Screening Emission Factors | 3-64 |
| 3.6 | Quality Control Results..... | 3-64 |
| 3.6.1 | IR Camera Daily Demo Results..... | 3-65 |
| 3.6.2 | Hi Flow Sampler Calibration Verification | 3-65 |
| 3.6.3 | TVA Calibration Procedures | 3-79 |
| 3.6.4 | Field Data Review..... | 3-89 |
| 3.6.5 | Canister Sample Collection QC..... | 3-89 |
| 3.6.6 | Analytical QC Results | 3-97 |
| 3.7 | Point Source Testing Conclusions | 3-98 |
| 4.0 | Air Dispersion Modeling..... | 4-1 |
| 4.1 | Modeling Scenarios and Source Parameters | 4-1 |
| 4.1.1 | Scenario 1 (Typical Well Pad)..... | 4-4 |
| 4.1.2 | Scenario 2 (Worst-Case Well Pad) | 4-7 |
| 4.1.3 | Scenario 3 (Worst-Case Compressor Station) | 4-11 |
| 4.1.4 | Scenario 4 (Co-located Worst-Case Well Pad and Worst-Case Compressor Station)..... | 4-14 |
| 4.2 | Model Setup and Options | 4-15 |
| 4.2.1 | Receptor Grids | 4-15 |
| 4.2.2 | Meteorological Data and Surface Parameters..... | 4-16 |
| 4.3 | Model Output..... | 4-16 |
| 4.4 | Electronic Modeling Files | 4-28 |
| 4.5 | Air Dispersion Modeling Conclusions..... | 4-31 |
| 5.0 | Public Health Evaluation..... | 5-1 |
| 5.1 | Methodology..... | 5-1 |
| 5.2 | Interpretation of Ambient Air Monitoring Data | 5-3 |
| 5.2.1 | Sensitivity of Monitoring Methods | 5-3 |
| 5.2.2 | Health Evaluation for Measured 24-Hour Average Concentrations..... | 5-9 |
| 5.2.3 | Health Evaluation for Program-Average Concentrations | 5-17 |
| 5.2.4 | Measured Concentrations: Main Findings, Limitations, and Uncertainties | 5-23 |
| 5.3 | Interpretation of Dispersion Modeling Data..... | 5-23 |
| 5.3.1 | Comparison of Modeled and Measured Air Pollution Levels | 5-24 |

| | | |
|------------|---|------------|
| 5.3.2 | Health Evaluation for Modeled 1-Hour Average Concentrations | 5-25 |
| 5.3.3 | Health Evaluation for Modeled Annual Average Concentrations | 5-32 |
| 5.3.4 | Adequacy of Setback Limits..... | 5-36 |
| 5.3.5 | Modeled Concentrations: Main Findings, Limitations, and Uncertainties | 5-41 |
| 5.4 | Additional Context for Selected Pollutants | 5-41 |
| 5.5 | Public Health Evaluation Conclusions..... | 5-51 |
| 6.0 | Regulatory Assessment | 6-1 |
| 6.1 | Federal Air Quality Rules..... | 6-1 |
| 6.1.1 | Operating Permits | 6-1 |
| 6.1.2 | Construction Permits | 6-2 |
| 6.1.3 | New Source Performance Standards | 6-2 |
| 6.1.4 | National Emission Standards for Hazardous Air Pollutants..... | 6-4 |
| 6.1.5 | Greenhouse Gas Reporting Program..... | 6-6 |
| 6.2 | Texas Commission on Environmental Quality Air Quality Rules | 6-6 |
| 6.2.1 | Permit-by-Rules | 6-7 |
| 6.2.2 | Standard Permit..... | 6-8 |
| 6.2.3 | New Source Review Permits | 6-9 |
| 6.2.4 | Control of Air Pollution from Visible Emissions and Particulate Matter | 6-9 |
| 6.2.5 | Control of Air Pollution from Sulfur Compounds..... | 6-9 |
| 6.2.6 | Standards of Performance for Hazardous Air Pollutants and for Designated Facilities and Pollutants | 6-10 |
| 6.2.7 | Control of Air Pollution from Volatile Organic Compounds..... | 6-10 |
| 6.2.8 | Control of Air Pollution from Nitrogen Compounds..... | 6-10 |
| 6.2.9 | Federal Operating Permits | 6-11 |
| 6.3 | City of Fort Worth Air Quality Rules | 6-11 |
| 6.4 | Regulatory Assessment Conclusions | 6-11 |
| 7.0 | Full Build-Out Estimates | 7-1 |
| 7.1 | Factors Affecting Natural Gas Production | 7-2 |
| 7.2 | Methodology for Forecasting Natural Gas Production | 7-5 |
| 7.3 | 2010 Base Year Emissions Inventory | 7-6 |
| 7.4 | 2010 through 2018 Projected Emissions Inventories..... | 7-16 |
| 7.5 | Full Build-Out Estimates Conclusions..... | 7-21 |
| 8.0 | Conclusions and Recommendations..... | 8-1 |
| 8.1 | Task Level Conclusions | 8-1 |
| 8.2 | Study Question Answers | 8-3 |
| 8.3 | Recommendations..... | 8-6 |
| 9.0 | References | 9-1 |

Appendix 2-A—COC Forms for Sites S-1 and S-5

Appendix 2-B—Analytical Results for SNMOC at Sites S-1 through S-5

Appendix 2-C—Analytical Results for EPA Compendium Method TO-15 at Sites S-1 through S-5

Appendix 2-D—Analytical Results for EPA Compendium Method TO-11A at Sites S-4 and S-5

Appendix 2-E—COC Forms and Analytical Results for Sites S-6 and S-7

Appendix 2-F—Final Concentration Data

Appendix 2-G—NATA Lowest Comparison Levels

Appendix 2-H—Final Meteorological Data

Appendix 3-A—Site Emissions Summary

Appendix 3-B—Emissions Workbook and Field Data

Appendix 3-C—Canister Data (Electronic)

Appendix 4-A—Electronic Modeling Files

Appendix 5-A—Additional Information on Health-Based Screening Values

Abbreviations

| | |
|-------------------|--|
| % CH ₄ | Leak expressed as percent methane |
| µg/m ³ | Micrograms per cubic meter |
| AQS | Air Quality Subsystem |
| ATSDR | Agency for Toxic Substances and Disease Registry |
| BACT | Best available control technology |
| BP | Barometric Pressure |
| Btu | British thermal unit |
| CCV | Continuing Calibration Verification |
| CFM | Cubic feet per minute |
| CH ₄ | Methane |
| CO | Carbon monoxide |
| CO ₂ | Carbon dioxide |
| COC | Chain of custody |
| CV | Coefficient of variation |
| DNPB | 2,4-dinitrophenylhydrazine |
| DQO | Data Quality Objective |
| EPA | U.S. Environmental Protection Agency |
| ERG | Eastern Research Group, Inc. |
| FID | Flame ionization detector |
| GC | Gas chromatograph |
| GC/MS | Gas chromatograph/Mass spectrometer |
| GIS | Geographic information system |
| GPS | Global Positioning System |
| H ₂ S | Hydrogen sulfide |
| HAP | Hazardous Air Pollutants |
| Hg | Mercury |
| HI | Hi |
| hp | Horsepower |
| ID | Identification |
| IR | Infrared |
| IRIS | Integrated Risk Information System |
| kPa | Kilopascals |
| lb | Pound |
| lbs/yr | Pounds per year |
| LCL | Lowest Comparison Level |
| LCS | Laboratory Control Standard |
| MDL | Method Detection Limit |
| mm | Millimeter |
| NA | Not available/not applicable |
| NATA | National-Scale Air Toxics Assessment |
| NESHAP | National Emissions Standard for Hazardous Air Pollutants |
| NM | Not monitored |
| NO _x | Oxides of nitrogen |
| NSPS | New Source Performance Standards |

| | |
|-------------------|---|
| NSR | New Source Review |
| NWS | National Weather Service |
| °F | Degrees Fahrenheit |
| PBR | Permit-by-Rule |
| PM | Particulate matter |
| PM _{2.5} | Particulate matter with a diameter of 2.5 micrometers or less |
| PM ₁₀ | Particulate matter with a diameter of 10 micrometers or less |
| ppbC | Parts per billion by carbon |
| ppbv | Parts per billion by volume |
| ppmv | Parts per million by volume |
| PRV | Pressure Relief Valve |

Executive Summary

The city of Fort Worth is home to extensive natural gas production and exploration as it lies on top of the Barnett Shale, a highly productive natural gas shale formation in north-central Texas. The Barnett Shale underlies 23 counties, including four (Tarrant, Denton, Wise, and Parker) that lie partly within the Fort Worth city boundaries. Over the last several years, natural gas production in the Barnett Shale has increased dramatically. This increase in activity has been brought about by advancements in drilling technologies, most notably hydraulic fracturing (fracking) and horizontal drilling.

As the Barnett Shale formation is located beneath a highly populated urban environment, extraction of natural gas from it has involved exploration and production operations in residential areas, near public roads and schools, and close to where the citizens of Fort Worth live and work. Due to the highly visible nature of natural gas drilling, fracturing, compression, and collection activities, many individual citizens and community groups in the Fort Worth area have become concerned that these activities could have an adverse effect on their quality of life.

In response to these concerns, on March 9, 2010, the Fort Worth City Council adopted Resolution 3866-03-2010 appointing a committee to review air quality issues associated with natural gas exploration and production. This committee was composed of private citizens, members of local community groups, members of environmental advocacy groups, and representatives from industry. The committee was charged to make recommendations to the City Council on a scope of work for a comprehensive air quality assessment to evaluate the impacts of natural gas exploration and production, to evaluate proposals submitted in response to a solicitation for conducting this study, and to ultimately choose a qualified organization to conduct the study.

Following an open bidding process, Eastern Research Group, Inc. (ERG) was selected to perform the Fort Worth Natural Gas Air Quality Study (FWNGAQS). ERG was asked to design a study that answered four key questions, originally established by the air quality committee. Since that time, ERG has completed extensive sampling activity throughout Fort Worth, and the sampling results support the following main conclusions:

- *How much air pollution is being released by natural gas exploration in Fort Worth?* ERG estimated emissions for 375 well pads, 8 compressor stations, one gas processing plant, a saltwater treatment facility, a drilling operation, a fracking operation, and a completion operation. Summed across all these sites, the total estimated emissions of organic compounds was 20,818 tons per year, with well pads accounting for more than three-fourths of those total emissions. The emissions contained dozens of pollutants with varying toxicities. Pollutants with relatively low toxicities (e.g., methane, ethane, propane, and butane) accounted for the overwhelming majority—approximately 98%—of the city-wide emissions. However, several pollutants with relatively high toxicities (e.g., benzene) were also emitted from these sites, though in considerably lower quantities. At a small subset of sites, the point source testing team noted signs of malfunctioning equipment that likely caused increased emissions. For example, some hatches atop tanks were ajar and not closed, and corrosion had apparently caused a hole to form on the roof of at least

one tank. Enhanced inspection and maintenance of equipment at the sites can help ensure that these preventable emissions are greatly reduced or eliminated. ERG also projected future emission rates based on an analysis of market forces, natural gas reserves, and other factors. This analysis found that city-wide emissions from the production of natural gas are projected to peak in 2012 and 2013 at 9% above 2010 levels. More detailed and technical information on emissions from natural gas sites is found in Sections 3 and 7 of this report.

- *Do sites comply with environmental regulation?* Numerous state and federal regulations could apply to natural gas production sites, but applicability of all regulations depends on site-specific nuances. The primary environmental regulation that would apply to natural gas extraction sites is TCEQ's oil and gas "permit-by-rule". This regulation is in the Texas Administrative Code and sets criteria for air permitting, based on the amount and type of emissions from a given facility. Based on the emission rates that ERG calculated for this project, five sites—a processing facility, three compressor stations, and one well pad—had overall emission rates that exceed regulatory thresholds that are supposed to trigger certain permitting requirements. Section 6 of this report identifies these five sites and presents their estimated emission rates.
- *How do releases from these sites affect off-site air pollution levels?* Scientists typically use two different methods when trying to understand how a given air pollution source affects local air quality. One approach is to conduct ambient air monitoring, which is directly measuring air pollution levels that people breathe. Another approach is to use dispersion modeling, which is estimating air pollution levels using models that predict how pollutants move through the air from the point where they are released. ERG used both approaches in the FWNGAQS. The ambient air monitoring program identified actual air pollution levels of nearly 140 pollutants at eight locations throughout the city, and the dispersion modeling study estimated air pollution levels at times when, and locations where, ambient monitoring did not take place.

A health-screening analysis of the measured and estimated air pollution levels identified three pollutants—acrolein, benzene, and formaldehyde—as the most important from a risk perspective. While Fort Worth residents are exposed to these and other pollutants released from natural gas sites, the measured and estimated air pollution levels did not reach levels that have been observed to cause adverse health effects. Further, the measured benzene and formaldehyde levels in Fort Worth were not unusually elevated when compared to levels currently measured by TCEQ elsewhere in Texas. There was insufficient data available to do a similar comparison for acrolein. ERG recommended focused additional study to ensure that these pollutants do not reach unhealthy levels in the future. Sections 2, 4, and 5 describe the monitoring, modeling, and health-screening analysis in greater technical detail.

- *Are the city's required setbacks for these sites adequate to protect public health?* For the overwhelming majority of sites considered in this study, the modeling analysis indicates that Fort Worth's 600-foot setback distance is adequate. For the relatively few sites with multiple, large line compressor engines, the modeling analysis found some areas beyond

the setbacks to have estimated acrolein and formaldehyde concentrations greater than protective health-based screening levels published by TCEQ. However, the estimated air pollution levels did not reach levels that have actually been found to cause symptoms or illness among exposed populations. Because the findings for these two pollutants are based entirely on estimated emission rates and modeled air quality impacts (as opposed to measured values), ERG recommends further evaluations of acrolein and formaldehyde at sites with multiple, large line engines to provide greater confidence in the adequacy and protectiveness of the city's setbacks. Some recent, short-term studies of limited scope have monitored for these pollutants, but a longer-term monitoring program is better suited for confirming this study's findings for acrolein and formaldehyde. Section 5 describes how ERG reached its conclusions regarding the adequacy of the city's setback distances.

Although this study did not reveal any significant health threats beyond setback distances, it is important to remember that the sources of concern for this project—natural gas exploration and production activity—are located in residential settings throughout a metropolitan area. Though the most toxic pollutants these sources emit are released in relatively low quantities, ERG fully supports implementing all reasonable precautions to reduce emissions from the well pads and compressor stations. Our recommendations in Section 8 of this report identify several specific opportunities for reducing emissions from natural gas production sites in Fort Worth.

1.0 Introduction

The city of Fort Worth is home to extensive natural gas production and exploration as it lies on top of the Barnett Shale, a highly productive natural gas shale formation in north-central Texas. The Barnett Shale underlies 23 counties, including four (Tarrant, Denton, Wise, and Parker) that lie partly within the Fort Worth city boundaries. Over the last several years, natural gas production in the Barnett Shale has increased dramatically. This increase in activity has been brought about by advancements in drilling technologies, most notably hydraulic fracturing and horizontal drilling.

As the Barnett Shale formation is located beneath a highly populated urban environment, extraction of natural gas from it has involved exploration and production operations in residential areas, near public roads and schools, and close to where the citizens of Fort Worth live and work. Due to the highly visible nature of natural gas drilling, fracturing, compression, and collection activities, many individual citizens and community groups in the Fort Worth area have become concerned that these activities could have an adverse effect on their quality of life.

In response to these concerns, on March 9, 2010, the Fort Worth City Council adopted Resolution 3866-03-2010 appointing a committee to review air quality issues associated with natural gas exploration and production. This committee was composed of private citizens, members of local community groups, members of environmental advocacy groups, and representatives from industry. The committee was charged to make recommendations to the City Council on a scope of work for a comprehensive air quality assessment to evaluate the impacts of natural gas exploration and production, to evaluate proposals submitted in response to a solicitation for conducting this study, and to ultimately choose a qualified organization to conduct the study.

The goals of the air quality study, as established by the air quality committee, are to help city officials answer the following four questions:

- How much air pollution is being released by natural gas exploration in Fort Worth?
- Do sites comply with environmental regulation?
- How do releases from these sites affect off-site air pollution levels?
- Are the city's required setbacks for these sites adequate to protect public health?

In order to answer these questions, the air quality committee identified several key tasks that should be included in this study: ambient air monitoring, point source testing, and air dispersion modeling.

Ambient air monitoring was conducted to measure outdoor pollution levels. Ambient air monitoring was included in the Fort Worth Natural Gas Air Quality Study to measure air pollution levels near selected natural gas facilities.

Point source testing was conducted to determine how much air pollution is being released by natural gas production in Fort Worth, and if natural gas extraction and processing sites

comply with environmental regulations. Under this task, various types of air testing equipment were used to detect, identify, and quantify the type and amount of air pollutants being emitted.

Air dispersion modeling was used to estimate the incremental air quality impacts caused by emissions from natural gas facilities. The modeling results provide perspective on air pollution levels at locations where, and at times when, ambient air samples were not collected. The results were used to assess whether the city's required setbacks (as published in City Ordinance No. 18449-02-2009) are adequately protective of public health.

Finally, a health evaluation compared the results of the ambient air monitoring program and air dispersion modeling to protective health-based screening levels. For selected pollutants, additional context was provided on toxicity and pollution levels typically observed at other locations in Texas.

This report presents the results of each of these tasks and activities, and is organized into eight sections as follows:

- Section 1 – Introduction. This section provides background information on the study.
- Section 2 – Ambient Air Monitoring. This section describes how the ambient air monitoring network was designed and implemented, and presents the ambient air monitoring results.
- Section 3 – Point Source Testing. This section describes how the point source testing task was conducted, what equipment was used, and how the data obtained was used to estimate emissions. The section also summarizes point source testing results.
- Section 4 – Air Dispersion Modeling. This section describes the air dispersion modeling task. It documents the major inputs, assumptions, site configurations, and results.
- Section 5 – Public Health Evaluation. This section interprets the ambient air monitoring data and the air dispersion modeling data from a public health perspective. It also comments on whether the setbacks are adequately protective of public health.
- Section 6 – Regulatory Assessment. This section provides details on the types of air quality regulations that may apply to natural gas exploration and production activities, and draws conclusions (where appropriate) on whether the sites visited under the point source task comply with applicable regulatory thresholds.
- Section 7 – Full Build-Out Estimates. This section discusses the factors expected to affect the growth of natural gas exploration and production in Fort Worth in the coming years and estimates future peak air emissions in Fort Worth.
- Section 8 – Conclusions and Recommendations. This section draws upon the results of each of the project activities to answer the four questions that defined the overall scope of this study. Several recommendations are also provided.

2.0 Ambient Air Monitoring

This section presents the findings of the ambient air monitoring component of this study, and contains six sub-sections.

- 2.1 Site Selection – Describes how the monitoring sites were identified.
- 2.2 Sampling Protocol – Describes how the ambient air monitoring samples were obtained.
- 2.3 Sample Analysis – Describes how the ambient air monitoring samples were analyzed at the laboratory.
- 2.4 Quality Assurance/Quality Control – This section describes the quality assurance and quality control (QA/QC) procedures employed during collection and analysis of the ambient air samples.
- 2.5 Ambient Air Monitoring Results – The results of the ambient air monitoring program are discussed in this section, including site-by-site study results.
- 2.6 Ambient Air Monitoring Conclusions – This section presents the conclusions of the ambient air monitoring program.

Ambient air is the air that people might expect to be exposed to at a road, school, or park near an air pollution emission source, such as a natural gas well pad or compressor station. Ambient air monitors are instruments that measure outdoor pollution levels in the ambient air. In this study, ambient air monitoring was conducted to assess the short-term prevalence and magnitude of concentrations of selected air toxics present in the air outside the property boundaries of air emissions sources such as a natural gas well pad or compressor station.

In this study, air pollution levels of nearly 140 pollutants (including over 40 Hazardous Air Pollutants (HAPs)) were measured over a two-month period with ambient air monitoring stations at eight different locations in Fort Worth. Sampling commenced on September 4, 2010, and concluded on October 31. Data obtained from this ambient air monitoring network can be used to:

- Assist in a better understanding of conclusions drawn from the point source sampling and analysis efforts.
- Characterize exposure to selected air toxics in ambient air at various locations in the city, as related to the proximity to certain natural gas activities (well pads, compressor stations, fracturing operations, etc.).
- Establish a representative determination of the concentration of air toxics, such as benzene, present in the ambient air in the area.
- Allow for a public health evaluation (See Section 5 for the full public health evaluation).

The ambient air monitoring network deployed in the field under this project was implemented in accordance with the *Ambient Air Monitoring Plan*, drafted in August 2010 and finalized on September 15, 2010. The *Ambient Air Monitoring Plan* identifies the goals and objectives of the ambient air monitoring network, provides technical background information (such as historical meteorological data) needed to identify candidate monitoring site locations, specifies the technical approach used to focus the list of candidate monitoring sites, and provides the final list of sites used in the study. Also, prior to implementation of the monitoring study, ERG prepared an approved Level 1 *Ambient Air Monitoring Quality Assurance Project Plan (QAPP)* which provided specific information on the sampling protocols, sampling analyses, and data reporting.

2.1 Site Selection

The final selection of eight monitoring sites occurred in two phases.

In Phase 1, geographic information system (GIS) data was obtained from the city of Fort Worth showing the locations of active and permitted natural gas activities, compressor stations, city property, nearby roadways, meteorological stations, and other features. These data and maps were overlaid to show natural gas activities in relation to residences, schools, businesses, existing (non-natural-gas) emission sources, and city-owned property. Monitoring on city-owned property was desirable for several reasons, including ensuring that the project team had site access seven days a week, maintaining the security of project staff and sampling equipment, and maintaining the integrity of the air sample by limiting the chance of vandalism or other tampering. During Phase 1, 20 potential monitoring site locations were identified.

In Phase 2, project staff visited each potential site to evaluate its suitability as a possible monitoring site location. During these visits, project staff interviewed site personnel and inspected the property, taking particular notice of potential obstructions (trees, buildings, etc.) or limitations (not enough land, no power, etc.) that would disqualify sites. At the end of Phase 2, and after consultation with city staff, eight locations were identified as suitable for inclusion in the ambient air monitoring network. These sites are listed below in Table 2.1-1.

Table 2.1-1. Final Ambient Air Network Monitoring Sites

| Site ID | Site Type | Coordinates |
|---------|---------------------|------------------------------|
| S-1 | Background | 32° 49.114'N 97° 02.953'W |
| S-2 | Mobile sources | 32° 33.379'N 97° 13.164'W |
| S-3A | Pre-production | 32° 45.897'N 97° 15.763'W |
| S-3B | Pre-production | 32° 46.569'N 97° 29.638'W |
| S-4 | High-level activity | 32° 47.249'N 97° 19.715'W |

Table 2.1-1. Final Ambient Air Network Monitoring Sites (Continued)

| Site ID | Site Type | Coordinates |
|---------|-------------------------------------|------------------------------|
| S-4C | High-level activity, collocated | 32° 47.249'N 97° 19.715'W |
| S-5 | High-level activity | 32° 59.044'N 97° 23.131'W |
| S-5C | High-level activity, collocated | 32° 59.044'N 97° 23.131'W |
| S-6 | Moderate-level activity, fence line | 32° 33.37'N 97° 18.820'W |
| S-7 | Moderate-level activity, fence line | 32° 34.223'N 97° 18.815'W |

The technical approach used to finalize the site selection process is described in detail in the *Ambient Air Monitoring Plan*. Figure 2.1-1 shows the ambient air monitoring site locations; each site is described below, along with a figure showing its location in more detail.

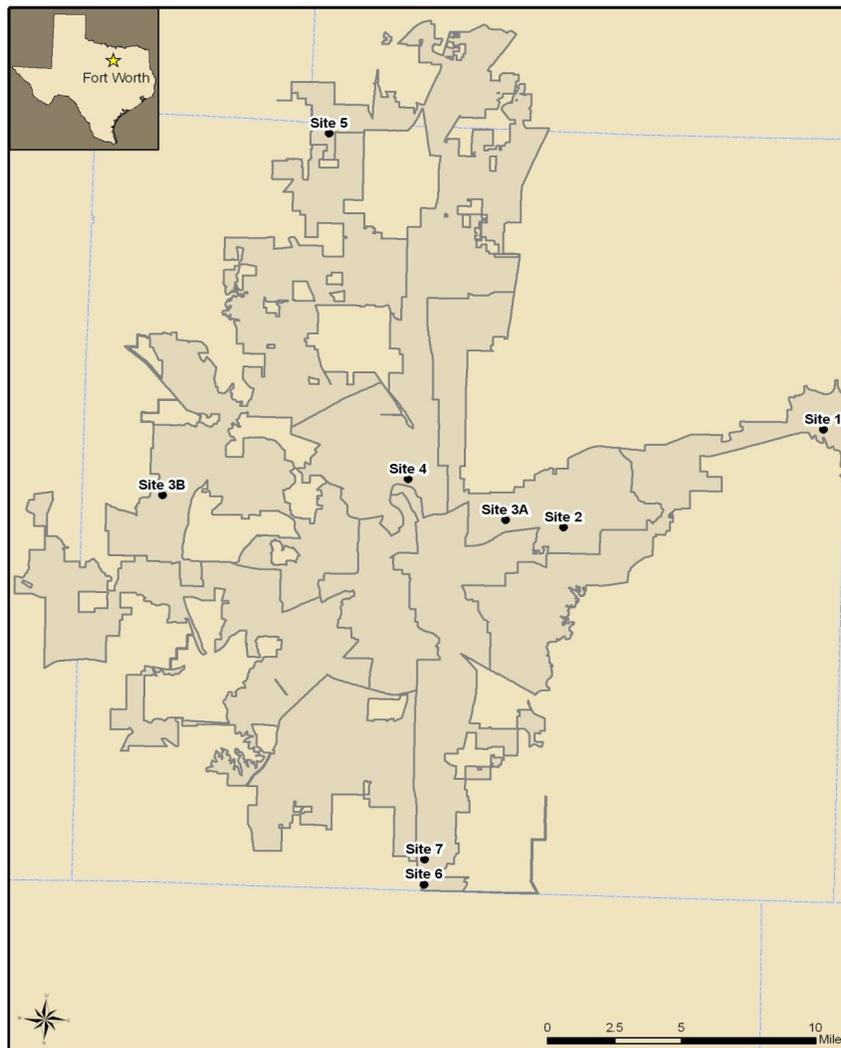

Figure 2.1-1. Ambient Air Monitoring Sites

2.1.1 Site S-1 (Background Site)

Site S-1 is located at Fort Worth Fire Station #33 (Figure 2.1-2), in the easternmost part of the city. Wind at this location predominantly blows from the south and southeast, meaning that there is expected to be minimal influence from natural gas exploration and production activities relative to areas further west (Figure 2.1-3). Therefore, this monitoring site is considered a “background” site, chosen to obtain background information on the air quality within the city of Fort Worth absent any impact from nearby natural gas sources. Speciated organic compounds were characterized at this site using the U.S. Environmental Protection Agency (EPA) Compendium Method TO-15 (see Section 2.3 for a description of EPA Compendium Method TO-15). Twenty samples were obtained from this location using a battery-operated system.

Figure 2.1-2. Aerial Map of Site S-1—Fire Station 33

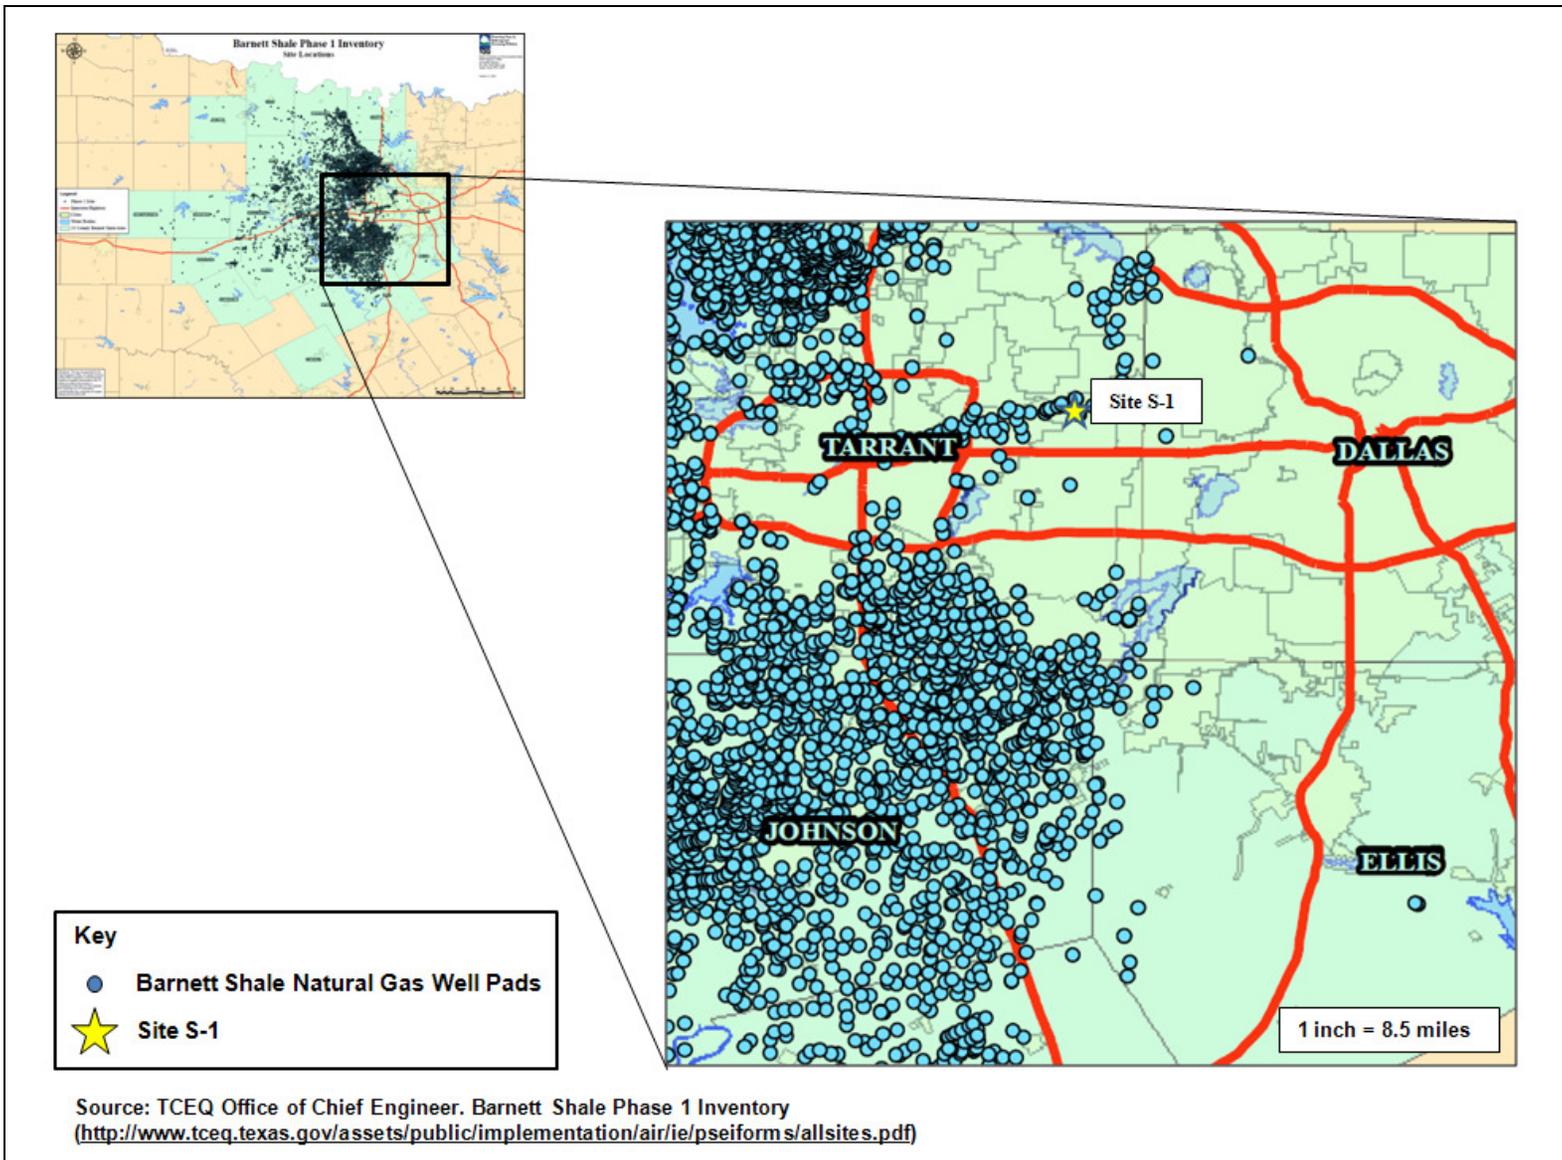

Figure 2.1-3. Overview of Barnett Shale Well Pads Near Site S-1

2.1.2 Site S-2 (Mobile Sources Site)

Site S-2 is located at the city's Environmental Collection Center (Figure 2.1-4), within a half-mile of the intersection of Interstate 820 and Interstate 30. The closest natural gas activity to this site is upwind, approximately 2 miles south of this intersection. Thus, this site was chosen to characterize pollutant concentrations from mobile sources along the two interstates, and to help determine how mobile sources (vehicles) affect ambient air within Fort Worth. Speciated organic compounds were characterized at this site using EPA Compendium Method TO-15. Eighteen samples were obtained from this location using a battery-operated system.

Figure 2.1-4. Aerial Map of Site S-2—Environmental Collection Center

2.1.3 Site S-3 (Pre-Production Site)

Site S-3 was chosen to characterize ambient air quality impacts of “pre-production” activities such as fracturing and flowback operations. The site was moved from one location to another, as described below; speciated organic compounds were characterized at these two locations using EPA Compendium Method TO-15.

Initially, this monitor was located at the Eastside Landfill (Figure 2.1-5), a capped landfill located just off of Interstate 30 to the east of downtown Fort Worth. Depending upon wind direction, this site enabled acquisition of air samples affected by either a fracturing operation (less than a quarter-mile to the south) or the Brentwood Saltwater Disposal Site (0.35 miles to the north). Eight samples were obtained from this location using a battery-operated system. Upon completion of the fracturing job, this site was re-located as described below.

On October 9, 2010, this monitoring site was moved to a Devon Energy lease site west of Fort Worth, approximately 1 mile west of Interstate 820, where fracturing and flowback operations were in process. This was the only site that was not located on city property, but there were no issues of site access from the field technician. Eight samples were obtained from this location using a battery-operated system. The location of this monitor is shown in Figure 2.1-6.

Figure 2.1-5. Aerial Map of Site S-3A—Eastside Landfill

Figure 2.1-6. Aerial Map of Site S-3B—Devon Energy Lease

2.1.4 Site S-4 (High-Level Activity Site, Collocated)

Site S-4, the Brennan Service Center (Figure 2.1-7), was located at a city-owned site north of downtown, less than one-half mile west of Interstate 35. This facility formerly served as a Fire Department Fleet Service Center and currently serves as a residential garbage drop-off station. This site is located within 0.4 miles northwest of one combined well pad and compressor station site, 0.8 miles north of another combined well pad and compressor station site, and 0.2 miles southwest of a well pad site. Concentrations from these natural gas operations, as well as from other sources, were characterized at this site. Speciated organic compounds were characterized at this site using EPA Compendium Method TO-15, and carbonyl compounds (including formaldehyde) were characterized using EPA Compendium Method TO-11A. Twenty volatile organic compound (VOC) and 20 carbonyl samples were obtained from this location using a powered system. This site was also designated as a collocated site, meaning that duplicate VOC and carbonyl samples would be taken at this site periodically. Indicators of sample system data quality are determined using the collocated data.

Figure 2.1-7. Aerial Map of Site S-4—Brennan Service Center

2.1.5 Site S-5 (High-Level Activity Site, Collocated)

Site S-5 was located at Fort Worth Fire Station #34 (Figure 2.1-8), in a residential area in the northern part of Fort Worth. This site's location has a high level of natural gas activity and is within a mile of dozens of natural gas wells upwind of this station. Speciated organic compounds were characterized at this site using EPA Compendium Method TO-15, and carbonyl compounds (including formaldehyde) were characterized using EPA Compendium Method TO-11A. Nineteen VOC and 20 carbonyl samples were obtained from this location using a powered system. This site was also designated as a collocated site.

Figure 2.1-8. Aerial Map of Site S-5—Fire Station 34

2.1.6 Site S-6 (Moderate-Level Activity/Fence line Site)

Site S-6 was located at the Spinks Airport (Figure 2.1-9), in the southern reaches of the city. This site was chosen because the monitor could be placed within 350 feet of an active well pad, making it a useful way to help evaluate the city's setback provisions. Speciated organic compounds were characterized at this site using EPA Compendium Method TO-15, and methane emissions were characterized at this site using EPA Compendium Method TO-14 (see Section 2.3 for a description of EPA Compendium Method TO-14). Nineteen samples were obtained from this location using a battery-operated system.

Figure 2.1-9. Aerial Map of Site S-6—Spinks Airport (South)

2.1.7 Site S-7 (Moderate-Level Activity/Fence line Site)

Site S-7 was also located at the Spinks Airport (Figure 2.1-10) in the southern reaches of the city. This site was also chosen to help evaluate the city's setback provisions, as this monitor was situated within 200 feet of an active well pad. Speciated organic compounds were characterized at this site using EPA Compendium Method TO-15, and methane emissions were characterized at this site using EPA Compendium Method TO-14. Eighteen samples were obtained from this location using a battery-operated system.

Figure 2.1-10. Aerial Map of Site S-7—Spinks Airport (North)

2.2 Sampling Protocol

At each of the eight sites, ambient air samples were collected once every three days. This schedule ensured that samples were collected on both weekdays and weekend days. The schedule provided some insights on how air quality varies by day of the week—an important consideration given that traffic patterns and other emission sources can vary from one day to the next.

The collection and analysis of ambient air monitoring samples for this study was performed in accordance with EPA Compendium Methods TO-15,¹ TO-11A,² and TO-14.³ As described in Section 2.1, each of the eight monitoring sites was chosen for a specific reason. Therefore, the sample collection procedure and analytical method used at each site varied. Table 2.2-1 identifies the original sample collection schedule and type of samples obtained at each site. Additional details on these can be found in the *Ambient Air Monitoring Plan*.

Table 2.2-1. Schedule of Collection Events

^a Volatile organic compound/speciated non-methane organic compound (VOC/SNMOC) samples analyzed using EPA Compendium Method TO-15.

^b Carbonyl samples analyzed using EPA Compendium Method TO-11A.

^c VOC/methane samples analyzed using EPA Compendium Method TO-15 (VOCs) and EPA Compendium Method TO-14 (methane).

Sampling at Sites S-1 through S-3, S-6, and S-7 was conducted using vacuum-regulated systems. These systems were battery-operated/passive and used pre-cleaned SUMMA[®] canisters to collect VOC and methane samples. Sampling at Sites S-4 and S-5 was conducted using two automated, mass-flow control systems. These systems are electrically powered and used pre-cleaned, evacuated SUMMA[®] canisters to collect VOC samples and 2,4-dinitrophenylhydrazine (DNPH) cartridges to collect carbonyl samples. All seven systems incorporated digital timers to ensure that 24-hour integrated samples were obtained (i.e., 00:01 to 23:50).

In order to obtain an integrated air sample for VOC analysis, air was drawn into a cleaned and pre-evacuated passivated SUMMA[®] canister through a calibrated flow limiting orifice

assembly that regulated the rate and duration of sampling. After the air sample was collected, the canister valve was closed automatically. The day following the sample collection, project staff visited each site; inspected the sample media for any errors, inconsistencies, or signs of tampering; and completed a chain-of-custody (COC) form for each of the samples. For each sample that was deemed viable for analysis, the sample and the COC form were shipped together to the laboratory for analysis. The information on the COC form included the following:

- Sample ID number
- Sampling equipment identification
- Sampling date
- Sampling start time
- Sampling end time
- Elapsed time
- Initial flowrate
- End flowrate
- Average flowrate
- Sample volume (total liters)
- Comments (field observations and/or anomalies during sampling)
- Name and signature of field operator releasing samples for shipment
- Condition of custody seal upon receipt by laboratory
- Condition of samples upon receipt by laboratory
- Signature of laboratory representative receiving shipment
- Date of sample receipt at laboratory

The samples obtained at Sites S-1 through S-5 were analyzed at Eastern Research Group's (ERG's) laboratory in Morrisville, North Carolina, while the samples obtained at Sites S-6 and S-7 were analyzed at TestAmerica's™ laboratory in Austin, Texas. Appendix 2-A contains the COC forms for Sites S-1 through S-5, Appendix 2-B contains the analytical results for SNMOCs at Sites S-1 through S-5, Appendix 2-C contains the analytical results for EPA Compendium Method TO-15 at Sites S-1 through S-5, Appendix 2-D contains the analytical results for EPA Compendium Method TO-11A at Sites S-4 and S-5, and Appendix 2-E contains the COC forms and analytical results for Sites S-6 and S-7.

Upon receipt, the canister information was recorded and the sample stored until analysis. Storage times of up to 45 days without compound concentration losses have been demonstrated for many of the VOCs (e.g., benzene, toluene, ethylbenzene, and xylenes) found in urban atmospheres. Although the required turnaround time under the method guidelines is 45 days, an actual turnaround time of approximately 30 days from sample receipt to sample analysis was typical.

2.3 Sample Analysis

Air toxics and SNMOC concentration data for each sample was obtained in accordance with the guidelines presented in EPA Compendium Method TO-15.¹ Method TO-15 provides guidance on sampling and analytical procedures for the measurement of a subset of the 97 VOCs that are included in the 1989 HAPs listed in Title III of the Clean Air Act Amendments of 1990.⁴ These VOCs are defined as organic compounds having a vapor pressure greater than 10^{-1} Torr at 25°C and 760 millimeter (mm) mercury (Hg), meaning that they are likely to exist in a gaseous phase under standard atmospheric conditions. Method TO-15 is used to analyze air samples for toxic compounds expected to be released from many air pollution sources, including natural gas production related activities.

Target air toxics species, and their corresponding method detection limits (MDLs) are presented in Table 2.3-1. Target SNMOC species and their corresponding MDLs are presented in Table 2.3-2.

Table 2.3-1. EPA Compendium Method TO-15 Target Compounds and Method Detection Limits

| Target Compounds | ppbv ^a | Target Compounds | ppbv |
|---------------------------|-------------------|------------------------------------|-------|
| 1,1,1-Trichloroethane | 0.020 | Dibromochloromethane | 0.011 |
| 1,1,2,2-Tetrachloroethane | 0.011 | Dichlorodifluoromethane | 0.012 |
| 1,1,2-Trichloroethane | 0.018 | Dichlorotetrafluoroethane | 0.012 |
| 1,1-Dichloroethane | 0.017 | Ethyl Acrylate | 0.011 |

The procedure used to analyze the sample under EPA Compendium Method TO-15 involves extracting a known volume of sample gas from the canister through a mass flow controller to a solid multi-sorbent concentrator. After the concentration step is completed, the VOCs are thermally desorbed, entrained in a carrier gas stream, and then focused in a small volume by trapping on a reduced temperature trap or small volume multi-sorbent trap. The sample is then released by thermal desorption and carried onto two gas chromatographic columns housed in a gas chromatograph (GC). This step separates the individual air toxics and SNMOC species. Air toxics are then measured using a mass spectrometer operated in the selected ion monitoring (SIM) mode. SNMOCs are measured concurrently using a flame ionization detector (FID).

Target carbonyl species from Method TO-11A² and their corresponding MDLs are presented in Table 2.3-3. Methane concentration data was obtained for Sites S-6 and S-7 using Method TO-14.³ The MDL for methane from Method TO-14 is presented in Table 2.3-4.

A detailed, technical description of the analytical procedures and sample handling procedures used for each sample can be found in the *Ambient Air Monitoring Plan* and in the *Ambient Air Monitoring Quality Assurance Project Plan*, which was originally submitted in August 2010 and revised in October 2010.

2.4 Quality Assurance/Quality Control

Throughout the process of ambient air network design, field implementation, sample collection, and sample analysis, QA/QC procedures were employed to ensure that the resultant data was of the highest quality and that the program would meet the Data Quality Objectives (DQOs) that were established at its onset. These procedures and steps are fully documented in the *Ambient Air Monitoring Plan* and the *Ambient Air Monitoring Quality Assurance Project Plan*. A summary of the QA/QC plan and results are provided below, including a discussion of DQOs, data completeness, measurement precision, and measurement accuracy.

The project DQOs answer the critical question of how good data must be in order to achieve the project goals. DQOs are used to develop the criteria that a data collection effort should satisfy, including where to conduct monitoring, how many sites to use, when to conduct

monitoring, what the measurement frequency should be, and acceptable measurement precision and accuracy. DQOs for this air quality study are presented in Table 2.4-1.

Table 2.4-1. Data Quality Objectives

| Element | Objective |
|--|--|
| Where to conduct monitoring | All sites must be located in close proximity to the potentially impacted populations, with the exception of the remote site (Site S-1). |
| Number of sites required | Eight fixed-location (including two collocated) sampling sites will be used to represent the entire city. Sites will be at city-owned and/or public use areas. They will be recommended by ERG as representative of the potentially impacted area. Final site selection will be accomplished through concurrence of ERG and Fort Worth Transportation and Public Works Department staff. |
| When to conduct monitoring | Sample collection will be conducted for a two-month duration. Samples will be collected from 00:01 to 23:50 hours (24 hours +/- 1 hour). |
| Frequency of monitoring | Sample collection episodes will be conducted once every three days. This schedule ensures that sampling is conducted multiple times on all days of the week, across the two-month duration of the program. |
| Overall completeness | Overall completeness must be 75% data capture at each monitoring site or greater. |
| Acceptable measurement precision for carbonyls | +/- 30% relative standard deviation (RSD) |
| Acceptable measurement accuracy for carbonyls | +/- 20% bias |
| Acceptable measurement precision for VOCs/SNMOCs | +/- 30% RSD |
| Acceptable measurement accuracy for VOCs | +/- 30% bias |

Prior to field deployment, all the measurement systems were certified to ensure that each system provided unbiased results.

2.4.1 Completeness

“Completeness” refers to the number of valid measurements collected compared to the number of scheduled sampling events. Data completeness requirements are included in the reference methods (see QAPP References, Section 21). Monitoring programs that consistently generate valid results have higher completeness than programs that consistently generate invalid samples. The completeness of an air monitoring program, therefore, is a qualitative measure of how effectively the program was managed.

During the two-month study period, the completeness of the monitoring network met or exceeded the DQO of 75% data capture at each site. Overall completeness was 96%. Table 2.4-2

summarizes the data completeness at each monitoring site by measurement system. As shown previously in Table 2.1-2, a total of 20 VOC/SNMOC samples were scheduled for each monitoring site and 20 carbonyl samples were scheduled for Sites S-4 and S-5.

Although the target number of valid samples was not obtained for Sites S-2, S-3, S-5, S-6, or S-7, the actual number of valid samples met or exceeded the DQO, thus providing sufficient data to calculate robust time-period averages. Invalid samples were due to a combination of equipment failure and human error, summarized below:

- On the first sample collection day (September 4), the sample collection program was incorrectly set, resulting in no sample collection at Sites S-2, S-5 (this affected the TO-15 sample only; the TO-11A carbonyl sample was collected successfully), and S-7.
- The sample collection systems at Sites S-6 and S-7 experienced gauge failure on September 7, so no samples were collected at those sites on that day.
- On September 10, the field operator did not fully open the canister valve at Site S-2, and no sample was collected.
- The October 31 sample collected at Site S-3 was never received at the laboratory, so no sample was analyzed for that site for that date.

A suitable location for Site S-3 (which targeted pre-production operations) was not identified until September 14. Therefore, this site only had 16 sample days. Additionally, due to the study duration (two months) and sampling frequency (1-in-3 days), it was not feasible to schedule make-up samples. Table 2.4-2 shows the final number of samples and completion percentage for each site.

Table 2.4-2. DQO: Overall Completeness

| Monitoring Site | Measurement System | Number of Samples Collected | Number of Samples Scheduled | Completion Percentage |
|-----------------|--------------------|-----------------------------|-----------------------------|-----------------------|
| S-1 | VOC/SNMOC | 20 | 20 | 100% |
| S-2 | VOC/SNMOC | 18 | 20 | 90% |
| S-3 | VOC/SNMOC | 15 | 16 | 94% |
| S-4 | VOC/SNMOC | 20 | 20 ^a | 100% |
| S-4 | Carbonyl | 20 | 20 ^a | 100% |
| S-5 | VOC/SNMOC | 19 | 20 ^a | 95% |
| S-5 | Carbonyl | 20 | 20 ^a | 100% |
| S-6 | VOC/SNMOC | 19 | 20 | 95% |
| S-7 | VOC/SNMOC | 18 | 20 | 90% |
| Total | | 169 | 176 | 96% |

^a Sites S-4 and S-5 had a total target of 40 samples each: 20 VOC samples and 20 carbonyl samples.

2.4.2 Measurement Precision

Measurement precision for this project is defined as the ability to acquire the same concentration from different instruments or samples while they are sampling the same gas stream,

with an acceptable level of uncertainty. It is a measure of mutual agreement among individual measurements of the same property, usually under prescribed similar conditions. For this monitoring program, measurement precision for the pollutants was assessed in two ways: system precision (across instrument samplers for collocated samples) and analytical precision (within instrument samplers for collocated and replicated samples).

Measurement precision is expressed as percent relative standard deviation (% RSD), which is calculated as follows:

$$\%RSD = \frac{\sigma}{\bar{X}} \times 100$$

Where:

σ is the standard deviation of the instrument-specific concentration determinations
 \bar{X} is the average of all instrument-specific concentration determinations

As summarized in Table 2.4-3, the *system precision* overall RSDs for VOCs, carbonyls, and SNMOCs easily met the DQO of 30% RSD.

Table 2.4-3. DQO: RSD Precision Calculation for Collocated VOC, Carbonyl, and SNMOC Instruments

| Method | Number of Collocated Data Sets | RSD Pollutant Ranges (%) | Overall RSD (%) |
|-----------|--------------------------------|--------------------------|-----------------|
| VOCs | 20 | 2.20–35.85 | 7.46 |
| Carbonyls | 20 | 6.15–44.43 | 23.99 |
| SNMOCs | 20 | 0.01–11.31 | 1.40 |

Analytical precision of the VOC and SNMOC methods was determined by collecting two sets of duplicate samples at Sites S-4 and S-5 and analyzing them in replicate. As summarized in Table 2.4-4, the analytical precision overall RSDs for VOCs, carbonyls, and SNMOCs easily met the DQO of 30% RSD.

Table 2.4-4. DQO: RSD Precision Calculation for Collocated and Replicate VOC and SNMOC Analyses

| Method | Number of Replicate Data Sets | RSD Pollutant Ranges (%) | Overall RSD (%) |
|-----------|-------------------------------|--------------------------|-----------------|
| VOCs | 20 | 0.01–21.32 | 4.57 |
| Carbonyls | 20 | 0.36–3.41 | 1.89 |
| SNMOCs | 20 | 1.07–34.11 | 9.21 |

2.4.3 Measurement Accuracy

Measurement accuracy for this project is defined as the ability to acquire the correct concentration data from an instrument or sample analysis with an acceptable level of uncertainty while measuring a reference gas stream of a known concentration. Bias is defined as the systematic or persistent distortion of a measurement process that causes error in one direction. Bias is determined by estimating the positive and negative deviation from the true value as a percentage of the true value.

Accuracy for the VOC and carbonyl analyses was established through audits that EPA prepared and submitted to ERG as a regular function of the EPA National Air Toxics Monitoring Program, which ERG manages and operates for EPA. The most recent audit for VOC HAPs was conducted in March 2010; the most recent audit for carbonyl HAPs was in May 2010. Table 2.4-5 summarizes the audit results for VOC and carbonyl HAPs. As the table shows, the overall percent differences are within 30% for VOC HAPs and 20% for carbonyl HAPs. This meets the DQOs presented in Table 2.4-1.

Table 2.4-5. VOC and Carbonyl HAP Audit Results

| Pollutant Group | Method | Proficiency Test Date | Overall % Difference |
|-----------------|--------|-----------------------|----------------------|
| VOC HAPs | TO-15 | March 2010 | -1.0 |
| Carbonyl HAPs | TO-11A | May 2010 | -11.4 |

2.5 Ambient Air Monitoring Results

This section presents ambient air concentrations, meteorological data, and spatial/temporal trends for the monitoring sites in this study. It first presents information for all the pollutants measured across the monitoring network, then by monitoring site. Finally, a more detailed analysis of a subset of key pollutants is presented by monitoring site. Nearly 140 different chemicals (including over 40 HAPs) were sampled for and analyzed in this study using EPA-approved sampling and analytical methodologies, as described in Section 2.3 of this report. It is important to note that, due to the configuration and purpose of each monitoring site, not all the same pollutants were sampled at each site. This is described in detail in Section 2.2.

2.5.1 Summary Statistics

This section reviews the monitoring data for the entire network. For each method type, it presents study-wide central tendency and variability statistics of the entire set of ambient air monitoring data collected. In total, over 15,000 data points were generated for this study. Individual measurements are presented in Appendix 2-F.

VOCs

A total of 59 VOCs were sampled, analyzed, and reported for in this study (Table 2.5-1). Eight VOCs had detection rates greater than 90%: benzene (94%), carbon tetrachloride (98%), chloromethane (100%), dichlorodifluoromethane (100%), methyl ethyl ketone (99%), propylene (98%), toluene (99%), and trichlorofluoromethane (100%). Acetone (2.807 ppbv), toluene (0.876 ppbv), and methyl ethyl ketone (0.827 ppbv) were the three VOCs with the highest average detected concentrations.

Table 2.5-1 also presents data distribution statistics, such as the minimum value, the maximum value, and the 25th, 50th, and 75th percentile values for the VOCs. As an indicator of variability of the VOC concentrations across the entire monitoring network, the coefficient of variation (CV) ratio is calculated. The CV ratio is the standard deviation divided by the mean, and is used to compare the relative dispersion in one set of data with the relative dispersion of another set of data. The lower the CV ratio, the less variability in the data measurements. The five VOCs with the lowest CV ratios and a minimum of 70% detects are trichlorofluoromethane (0.09), dichlorodifluoromethane (0.10), trichlorotrifluoroethane (0.10), dichlorotetrafluoroethane (0.13), and carbon tetrachloride (0.14). Conversely, the five VOCs with the highest CV ratios and a minimum of 70% detects are toluene (1.84), carbon disulfide (1.61), dichloromethane (1.39), *m,p*-xylene (1.24), and 1,2,4-trimethylbenzene (1.22).

Carbonyls

A total of 11 carbonyl pollutants were sampled, analyzed, and reported for in this study (Table 2.5-2). As described in Section 2.2, carbonyls were only sampled at Sites S-4 and S-5. Eight carbonyls had detection rates greater than 90%: acetaldehyde (100%), benzaldehyde (95%), butyraldehyde (100%), crotonaldehyde (100%), formaldehyde (100%), hexaldehyde (100%), propionaldehyde (100%), and valeraldehyde (93%). Acetaldehyde (2.81 ppbv), formaldehyde (0.931 ppbv), and butyraldehyde (0.110 ppbv) were the three carbonyls with the highest average detected concentrations.

Table 2.5-2 also presents data distribution statistics and CV ratios for the carbonyls. The four carbonyls with the lowest CV ratios and a minimum of 70% detects are crotonaldehyde (0.59), formaldehyde (0.71), acetaldehyde (0.73), and propionaldehyde (0.96). Conversely, the four carbonyls with the highest CV ratios and a minimum of 70% detects are hexaldehyde (1.98), butyraldehyde (1.29), valeraldehyde (1.20), and benzaldehyde (1.11).

Two carbonyls were not detected at either Site S-4 or Site S-5: 2,5-dimethylbenzaldehyde and isovaleraldehyde.

^a Summary statistics were only calculated for pollutants detected in at least six samples.

Methane and Speciated Non-Methane Organics

Methane was detected in each sample taken (100%)—37 samples at Sites S-6 and S-7 (Table 2.5-3). Methane had the highest concentrations of the study analytes (average of detects = 5,686 ppbv). Methane is not a HAP, and the overall CV ratio was 0.24.

A total of 67 SNMOCs were sampled, analyzed, and reported for in this study (Table 2.5-3). Seven speciated organics had detection rates greater than 90%: *n*-butane (93%), ethane (100%), ethylene (99%), isobutane (97%), isobutene/1-butene (97%), *n*-pentane (98%), and propane (100%). Ethane (16.028 ppbv), propane (5.325 ppbv), and isopentane (4.028 ppbv) were the three SNMOCs with the highest average detected concentrations.

Data distribution statistics and CV ratios for methane and the SNMOCs are also presented in Table 2.5-3. The five SNMOCs with the lowest CV ratios and a minimum of 70% detects are 1-hexene (0.48), isoprene (0.63), ethylene (0.69), 3-methylehexane (0.77), and 2-methylheptane (0.85). Conversely, the five VOCs with the highest CV ratios and a minimum of 70% detects are *n*-decane (1.92), *n*-nonane (1.90), isopentane (1.84), *trans*-2-butene (1.83), and *n*-Pentane (1.80).

All SNMOCs were detected at least once during the study period.

2.5.2 Study Period Averaging

This section presents information on the average pollutant concentrations, at each monitoring site, for the study period. Non-detect observations were replaced with zeroes when calculating these averages. This section focuses only on pollutants that were detected in at least 70% of the samples, because average concentrations for these pollutants have the least influence from non-detect observations. Thus, study period averages for pollutants that had more than 30% of their samples as non-detects were not calculated. This averaging technique is consistent with the study period averaging EPA uses in its Schools Air Toxics Monitoring Program (SATMP)⁵ and National-Scale Air Toxics Assessment (NATA) model-to-monitor comparison.⁶ In addition to the study period average, this section presents the confidence intervals for the study period average concentrations. The confidence interval is calculated using Student's *T*-test at the 95th percentile confidence level.

Table 2.5-3. Summary of Methane and Speciated Non-Methane Organic Compounds Across the Entire Monitoring Network

| Pollutant Name | Number of Detects | Average of Detects (ppbv) | Minimum Detected Value (ppbv) | Maximum Detected Value (ppbv) | 25 th Percentile Concentration (ppbv) | 50 th Percentile Concentration (ppbv) | 75 th Percentile Concentration (ppbv) | Coefficient of Variation |

NA = not available

^a Summary statistics were only calculated for pollutants detected in at least six samples.

The following observations were made:

- *Site S-1 (background site)*: A total of 71 out of 124 pollutants had at least 70% detects to compute study period averages (Table 2.5-4). The five pollutants with the highest average concentrations were ethane (6.474 ± 3.041 ppbv), propane (3.498 ± 1.207 ppbv), *n*-butane (2.262 ± 1.500 ppbv), isopentane (1.929 ± 1.172 ppbv), and isobutane (1.324 ± 0.727 ppbv). Site S-1 was located in an area with no natural gas wells typically upwind.
- *Site S-2 (mobile sources site)*: A total of 73 out of 124 pollutants had at least 70% detects to compute study period averages (Table 2.5-5). The five pollutants with the highest average concentrations were ethane (10.437 ± 4.571 ppbv), propane (4.812 ± 3.222 ppbv), *n*-butane (2.729 ± 1.574 ppbv), toluene (2.311 ± 1.803 ppbv), and isopentane (1.680 ± 0.615 ppbv). Site S-2 was located in an area next to major roadways.
- *Site S-3A (pre-production activity site)*: Note that this site conducted only nine samples over a three-week time frame. Thus, the average concentrations presented for this site may not be representative of the study period. Nevertheless, a total of 69 out of 124 pollutants had at least 70% detects to compute three-week averages (Table 2.5-6). The five pollutants with the highest average concentrations were ethane (16.133 ± 10.964 ppbv), propane (4.456 ± 3.073 ppbv), *n*-butane (1.408 ± 1.245 ppbv), ethylene (1.364 ± 0.528 ppbv), and isopentane (1.217 ± 0.627 ppbv). Site S-3A was located in an area downwind of fracturing fluid flowback operations.
- *Site S-3B (pre-production activity site)*: When pre-production operations were completed at Site S-3A, this monitoring site was moved to an area where additional pre-production activities were occurring. Thus, this site conducted only six samples over a two-week time frame, and the average concentrations presented for this site may not be representative of the study period. Nevertheless, a total of 63 out of 124 pollutants had at least 70% detects to compute two-week averages (Table 2.5-7). The five pollutants with the highest average concentrations were ethane (22.592 ± 11.170 ppbv), propane (8.844 ± 4.215 ppbv), *n*-butane (3.195 ± 1.526 ppbv), isobutane (1.588 ± 0.769 ppbv), and isopentane (1.087 ± 0.444 ppbv). Site S-3B was located in an area downwind of hydraulic fracturing activities.
- *Site S-4 (high-level activity site)*: A total of 82 out of 136 pollutants had at least 70% detects to compute study period averages (Table 2.5-8). The five pollutants with the highest average concentrations were ethane (18.229 ± 8.241 ppbv), isopentane (12.985 ± 5.511 ppbv), *n*-butane (10.993 ± 5.385 ppbv), propane (10.683 ± 4.918 ppbv), and *n*-pentane (5.491 ± 2.336 ppbv). Site S-4 was located in an area with high levels of well pad and compressor station activity.
- *Site S-5 (high-level activity site)*: A total of 75 out of 136 pollutants had at least 70% detects to compute study period averages (Table 2.5-9). The five pollutants with the highest average concentrations were ethane (14.077 ± 4.074 ppbv), propane (5.049 ± 1.773 ppbv), *n*-butane (2.072 ± 1.109 ppbv), acetaldehyde (1.824 ± 0.408 ppbv), and

Key Point: Pollutant Concentrations
Concentrations measured at Site S-4 were generally higher than at other sites. Concentrations measured at Sites S-6 and S-7 were generally lower relative to other sites.

isopentane (1.297 ± 1.262 ppbv). Site S-5 was located in an area with high levels of well pad activity.

- *Site S-6 (medium-level activity site):* A total of 15 out of 137 pollutants had at least 70% detects to compute study period averages (Table 2.5-10). The five pollutants with the highest average concentrations were methane ($5,758 \pm 796$ ppbv), ethane (21.412 ± 9.997 ppbv), propane (2.982 ± 1.154 ppbv), *n*-butane (1.015 ± 0.432 ppbv), and ethylene (0.632 ± 0.155 ppbv). Site S-6 was located in an area with moderate levels of well pad activity, including within 350 feet downwind of a well pad.
- *Site S-7 (medium-level activity site):* A total of 15 out of 137 pollutants had at least 70% detects to compute study period averages (Table 2.5-11). The five pollutants with the highest average concentrations were methane ($5,672 \pm 650$ ppbv), ethane (23.979 ± 11.236 ppbv), propane (3.967 ± 1.854 ppbv), *n*-butane (1.230 ± 0.604 ppbv), and ethylene (0.690 ± 0.173 ppbv). Site S-7 was located in an area with moderate levels of well pad activity, including within 200 feet downwind of a well pad.

2.5.3 Key Pollutants

At the conclusion of the ambient air monitoring data collection, ERG conducted an initial public health screening to determine whether selected pollutants were found at levels indicating an urgent health hazard. This screening was conducted using the same health screening values that EPA uses in its NATA (see Appendix 2-G), which are available for 40 pollutants in this study. In Section 5 of this report, ERG presents a broader health evaluation that considers health screening values for all 138 pollutants considered in the monitoring program, as well as the results of the air dispersion modeling effort discussed in Section 4.

Key Point: Key Pollutants

The key pollutants, based on the ambient monitoring data, were:

- Acetaldehyde
- Benzene
- 1,3-Butadiene
- Carbon tetrachloride
- *p*-Dichlorobenzene
- Formaldehyde
- Tetrachloroethylene

In reviewing this initial screening of key pollutants, note that:

- With one exception, ERG found no pollutant concentrations that exceeded any published short-term health benchmark published by the Texas Commission on Environmental Quality (TCEQ), EPA, or the Agency for Toxic Substances and Disease Registry (ATSDR). A single sample was found to have a hexachloro-1,3-butadiene concentration of 0.369 ppb, which is higher than TCEQ's short-term effects screening level (0.2 ppb). However, this particular sample was not analyzed within the method's required holding time, and the testing laboratory cautioned that the measurement is of limited reliability. Further discussion of this pollutant is found in Section 5.2.
- It is only appropriate to compare annual average concentrations, not individual measurements, to long-term health benchmark values such as the EPA NATA values.
- The study period was only for two months at eight sites; the study period averages at these eight sites are assumed to be an estimate of typical annual conditions. This approach is similar to EPA's SATMP study.
- The initial screening presented in this report only addresses 40 pollutants. The health evaluation in Section 5 presents interpretations for all pollutants considered in this monitoring program.

Tables 2.5-12 through 2.5-19 present average concentration summaries of the key pollutants of interest for each site. Key pollutants are ones whose average concentrations were greater than the Lowest Comparison Levels (LCLs) used in this study. Thus, these tables present a "factor of LCL" for each pollutant, and pollutants with a "factor of LCL" greater than 1 are identified as key. Additionally, Figures 2.5-1 through 2.5-7 present each key pollutant's study average confidence interval, which is useful in identifying statistically significant differences.

The following observations were made:

- Benzene and carbon tetrachloride were key HAPs at each site.
- The average acetaldehyde concentration at Site S-4 was considerably higher than the average acetaldehyde concentration at Site S-5 (Figure 2.5-1).
- The average benzene concentration at Site S-4 was considerably higher than all other average benzene concentrations at the other sites. The average benzene concentrations at Sites S-6 and S-7 were also considerably lower than those for Sites S-1, S-2, S-3A, and S-5 (Figure 2.5-2).
- The average 1,3-butadiene concentrations at Sites S-2 and S-4 were considerably higher than the average 1,3-butadiene concentration at Site S-5 (Figure 2.5-3).
- The average carbon tetrachloride concentration at Site S-1 was only considerably higher than the average carbon tetrachloride concentration at Site S-6 (Figure 2.5-4).
- There were no statistically significant differences in average *p*-dichlorobenzene concentrations across Sites S-1, S-2, S-3A, and S-4 (Figure 2.5-5).
- There were no statistically significant differences in average formaldehyde concentrations across Sites S-4 and S-5 (Figure 2.5-6).
- There were no statistically significant differences in average tetrachloroethylene concentrations across Sites S-1, S-2, S-3A, and S-4 (Figure 2.5-7).

2.5.4 Integration with Meteorology

Meteorological observations, such as wind speed and wind direction, can be useful in helping characterize the behavior of the ambient air monitoring data. For this study, no meteorological towers were placed at the monitoring locations, largely because more than 40 National Weather Service (NWS) and TCEQ meteorological stations in and around the city of Fort Worth operated during this monitoring program. Additionally, another dozen meteorological stations from the Weatherbug Network were available to be used.

Closest Meteorological Station

For each monitoring site, ERG identified the closest meteorological station that was operating during the monitoring timeframe. Table 2.5-20 identifies those stations. If observations were missing, or if a significant portion of a day's observations were identified as "calm" (less than 5 miles per hour), surrogate data was used to supplement the meteorological observations. Surrogate data sources include the NWS 1-minute data, TCEQ meteorological stations, and the Weatherbug Network. Table 2.5-20 also presents the surrogate data locations relative to the monitoring sites. All meteorological observations of wind speed, wind direction, temperature, and precipitation are presented in Appendix 2-H.

Table 2.5-12. Site S-1 Key Pollutant Averages

| Pollutant | Units | Mean of Measurements | 95% Confidence Interval on the Mean | Factor of EPA LCL ^a |
|---------------------------|-------|----------------------|-------------------------------------|--------------------------------|
| Benzene | ppbv | 0.245 ^b | 0.187–0.304 | 6.11 |
| 1,3-Butadiene | ppbv | 0.041 ^c | 0.022–0.059 | 2.69 |
| Carbon Tetrachloride | ppbv | 0.118 ^d | 0.112–0.123 | 4.38 |
| <i>p</i> -Dichlorobenzene | ppbv | 0.039 ^e | 0.025–0.053 | 2.58 |
| Tetrachloroethylene | ppbv | 0.038 ^f | 0.024–0.052 | 1.52 |

^a LCL refers to the Lowest Comparison Level of cancer and/or noncancer values, as used in EPA's NATA. LCLs for this study are presented in Appendix 2-G. "Factor of EPA LCL" is the pollutant study average (or mean of measurements) divided by its LCL.

^b The mean of measurements for benzene is the average of all sample results, which include 20 detections that ranged from 0.135 to 0.563 ppbv.

^c The mean of measurements for 1,3-butadiene is the average of all sample results, which include 18 detections that ranged from 0.01 to 0.137 ppbv, as well as two samples in which no chemical was registered by the laboratory analytical equipment.

^d The mean of measurements for carbon tetrachloride is the average of all sample results, which include 20 detections that ranged from 0.083 to 0.139 ppbv.

^e The mean of measurements for *p*-dichlorobenzene is the average of all sample results, which include 17 detections that ranged from 0.013 to 0.118 ppbv, as well as three samples in which no chemical was registered by the laboratory analytical equipment.

^f The mean of measurements for tetrachloroethylene is the average of all sample results, which include 17 detections that ranged from 0.015 to 0.109 ppbv, as well as three samples in which no chemical was registered by the laboratory analytical equipment.

Table 2.5-13. Site S-2 Key Pollutant Averages

| Pollutant | Units | Mean of Measurements | 95% Confidence Interval on the Mean | Factor of EPA LCL ^a |
|---------------------------|-------|----------------------|-------------------------------------|--------------------------------|
| Benzene | ppbv | 0.300 ^b | 0.257–0.343 | 7.48 |
| 1,3-Butadiene | ppbv | 0.057 ^c | 0.040–0.073 | 3.75 |
| Carbon Tetrachloride | ppbv | 0.117 ^d | 0.112–0.122 | 4.36 |
| <i>p</i> -Dichlorobenzene | ppbv | 0.051 ^f | 0.004–0.098 | 3.38 |
| Tetrachloroethylene | ppbv | 0.061 ^g | 0.032–0.090 | 2.44 |

^a LCL refers to the Lowest Comparison Level of cancer and/or noncancer values, as used in EPA's NATA.

LCLs for this study are presented in Appendix 2-G. "Factor of EPA LCL" is the pollutant study average (or mean of measurements) divided by its LCL.

^b The mean of measurements for benzene is the average of all sample results, which include 18 detections that ranged from 0.180 to 0.501 ppbv.

^c The mean of measurements for 1,3-butadiene is the average of all sample results, which include 18 detections that ranged from 0.024 to 0.147 ppbv.

^d The mean of measurements for carbon tetrachloride is the average of all sample results, which include 18 detections that ranged from 0.090 to 0.133 ppbv.

^e The mean of measurements for *p*-dichlorobenzene is the average of all sample results, which include 15 detections that ranged from 0.014 to 0.416 ppbv, as well as three samples in which no chemical was registered by the laboratory analytical equipment.

^f The mean of measurements for tetrachloroethylene is the average of all sample results, which include 18 detections that ranged from 0.012 to 0.218 ppbv.

Table 2.5-14. Site S-3A Key Pollutant Averages

| Pollutant | Units | Mean of Measurements | 95% Confidence Interval on the Mean | Factor of EPA LCL ^a |
|---------------------------|-------|----------------------|-------------------------------------|--------------------------------|
| Benzene | ppbv | 0.301 ^b | 0.173–0.428 | 7.50 |
| 1,3-Butadiene | ppbv | 0.049 ^c | 0.016–0.082 | 3.23 |
| Carbon Tetrachloride | ppbv | 0.118 ^d | 0.111–0.125 | 4.38 |
| <i>p</i> -Dichlorobenzene | ppbv | 0.030 ^e | 0.017–0.043 | 2.01 |
| Tetrachloroethylene | ppbv | 0.025 ^f | 0.011–0.039 | 1.00 |

^a LCL refers to the Lowest Comparison Level of cancer and/or noncancer values, as used in EPA's NATA.

LCLs for this study are presented in Appendix 2-G. "Factor of EPA LCL" is the pollutant study average (or mean of measurements) divided by its LCL.

^b The mean of measurements for benzene is the average of all sample results, which include nine detections that ranged from 0.157 to 0.636 ppbv.

^c The mean of measurements for 1,3-butadiene is the average of all sample results, which include eight detections that ranged from 0.023 to 0.123 ppbv, as well as one sample in which no chemical was registered by the laboratory analytical equipment.

^d The mean of measurements for carbon tetrachloride is the average of all sample results, which include nine detections that ranged from 0.104 to 0.134 ppbv.

^e The mean of measurements for *p*-dichlorobenzene is the average of all sample results, which include nine detections that ranged from 0.011 to 0.056 ppbv.

^f The mean of measurements for tetrachloroethylene is the average of all sample results, which include seven detections that ranged from 0.013 to 0.056 ppbv, as well as two samples in which no chemical was registered by the laboratory analytical equipment.

Table 2.5-15. Site S-3B Key Pollutant Averages

| Pollutant | Units | Mean of Measurements | 95% Confidence Interval on the Mean | Factor of EPA LCL ^a |
|----------------------|-------|----------------------|-------------------------------------|--------------------------------|
| Benzene | ppbv | 0.165 ^b | 0.137–0.193 | 4.11 |
| Carbon Tetrachloride | ppbv | 0.115 ^c | 0.107–0.122 | 4.26 |

^a LCL refers to the Lowest Comparison Level of cancer and/or noncancer values, as used in EPA's NATA. LCLs for this study are presented in Appendix 2-G. "Factor of EPA LCL" is the pollutant study average (or mean of measurements) divided by its LCL.

^b The mean of measurements for benzene is the average of all sample results, which include six detections that ranged from 0.132 to 0.214 ppbv.

^c The mean of measurements for carbon tetrachloride is the average of all sample results, which include six detections that ranged from 0.103 to 0.122 ppbv.

Table 2.5-16. Site S-4 Key Pollutant Averages

| Pollutant | Units | Mean of Measurements | 95% Confidence Interval on the Mean | Factor of EPA LCL ^a |
|---------------------------|-------|----------------------|-------------------------------------|--------------------------------|
| Acetaldehyde | ppbv | 3.802 ^b | 2.677–4.927 | 15.07 |
| Benzene | ppbv | 0.686 ^c | 0.465–0.906 | 17.08 |
| 1,3-Butadiene | ppbv | 0.092 ^d | 0.051–0.132 | 6.08 |
| Carbon Tetrachloride | ppbv | 0.113 ^e | 0.107–0.118 | 4.19 |
| <i>p</i> -Dichlorobenzene | ppbv | 0.060 ^f | 0.038–0.083 | 3.99 |
| Formaldehyde | ppbv | 1.140 ^g | 0.731–1.548 | 17.50 |
| Tetrachloroethylene | ppbv | 0.048 ^h | 0.034–0.061 | 1.90 |

^a LCL refers to the Lowest Comparison Level of cancer and/or noncancer values, as used in EPA's NATA. LCLs for this study are presented in Appendix 2-G. "Factor of EPA LCL" is the pollutant study average (or mean of measurements) divided by its LCL.

^b The mean of measurements for acetaldehyde is the average of all sample results, which include 20 detections that ranged from 1.35 to 9.06 ppbv.

^c The mean of measurements for benzene is the average of all sample results, which include 20 detections that ranged from 0.200 to 1.83 ppbv.

^d The mean of measurements for 1,3-butadiene is the average of all sample results, which include 18 detections that ranged from 0.015 to 0.304 ppbv.

^e The mean of measurements for carbon tetrachloride is the average of all sample results, which include 20 detections that ranged from 0.094 to 0.142 ppbv.

^f The mean of measurements for *p*-dichlorobenzene is the average of all sample results, which include 19 detections that ranged from 0.019 to 0.178 ppbv, as well as one sample in which no chemical was registered by the laboratory analytical equipment.

^g The mean of measurements for formaldehyde is the average of all sample results, which include 20 detections that ranged from 0.412 to 4.45 ppbv.

^h The mean of measurements for tetrachloroethylene is the average of all sample results, which include 20 detections that ranged from 0.015 to 0.116 ppbv.

Table 2.5-17. Site S-5 Key Pollutant Averages

| Pollutant | Units | Mean of Measurements | 95% Confidence Interval on the Mean | Factor of EPA LCL ^a |
|----------------------|-------|----------------------|-------------------------------------|--------------------------------|
| Acetaldehyde | ppbv | 1.824 ^b | 1.416–2.231 | 7.23 |
| Benzene | ppbv | 0.197 ^c | 0.162–0.232 | 4.90 |
| 1,3-Butadiene | ppbv | 0.018 ^d | 0.011–0.025 | 1.20 |
| Carbon Tetrachloride | ppbv | 0.108 ^e | 0.097–0.119 | 4.03 |
| Formaldehyde | ppbv | 0.723 ^f | 0.626–0.819 | 11.09 |

^a LCL refers to the Lowest Comparison Level of cancer and/or noncancer values, as used in EPA's NATA.

LCLs for this study are presented in Appendix 2-G. "Factor of LCL" is the pollutant study average (or mean of measurements) divided by its LCL.

^b The mean of measurements for acetaldehyde is the average of all sample results, which include 20 detections that ranged from 0.831 to 4.93 ppbv.

^c The mean of measurements for benzene is the average of all sample results, which include 19 detections that ranged from 0.104 to 0.359 ppbv.

^d The mean of measurements for 1,3-butadiene is the average of all sample results, which include 15 detections that ranged from 0.011 to 0.051 ppbv, as well as four samples in which no chemical was registered by the laboratory analytical equipment.

^e The mean of measurements for carbon tetrachloride is the average of all sample results, which include 19 detections that ranged from 0.053 to 0.140 ppbv.

^f The mean of measurements for formaldehyde is the average of all sample results, which include 20 detections that ranged from 0.474 to 1.32 ppbv.

Table 2.5-18. Site S-6 Key Pollutant Averages

| Pollutant | Units | Mean of Measurements | 95% Confidence Interval on the Mean | Factor of EPA LCL ^a |
|----------------------|-------|----------------------|-------------------------------------|--------------------------------|
| Benzene | ppbv | 0.097 ^b | 0.061–0.134 | 2.42 |
| Carbon Tetrachloride | ppbv | 0.097 ^c | 0.083–0.110 | 3.59 |

^a LCL refers to the Lowest Comparison Level of cancer and/or noncancer values, as used in EPA's NATA.

LCLs for this study are presented in Appendix 2-G. "Factor of EPA LCL" is the pollutant study average (or mean of measurements) divided by its LCL.

^b The mean of measurements for benzene is the average of all sample results, which include 15 detections that ranged from 0.070 to 0.263 ppbv, as well as four samples in which no chemical was registered by the laboratory analytical equipment.

^c The mean of measurements for carbon tetrachloride is the average of all sample results, which include 18 detections that ranged from 0.071 to 0.127 ppbv, as well as one sample in which no chemical was registered by the laboratory analytical equipment.

Table 2.5-19. Site S-7 Key Pollutant Averages

| Pollutant | Units | Mean of Measurements | 95% Confidence Interval on the Mean | Factor of EPA LCL ^a |
|----------------------|-------|----------------------|-------------------------------------|--------------------------------|
| Benzene | ppbv | 0.109 ^b | 0.066–0.152 | 2.71 |
| Carbon Tetrachloride | ppbv | 0.098 ^c | 0.079–0.117 | 3.65 |

^a LCL refers to the Lowest Comparison Level of cancer and/or noncancer values, as used in EPA's NATA. LCLs for this study are presented in Appendix 2-G. "Factor of EPA LCL" is the pollutant study average (or mean of measurements) divided by its LCL.

^b The mean of measurements for benzene is the average of all sample results, which include 14 detections that ranged from 0.064 to 0.282 ppbv, as well as four samples in which no chemical was registered by the laboratory analytical equipment.

^c The mean of measurements for carbon tetrachloride is the average of all sample results, which include 16 detections that ranged from 0.077 to 0.142 ppbv, as well as two samples in which no chemical was registered by the laboratory analytical equipment.

Figure 2.5-8 presents an overview of the monitoring sites and their nearest meteorological stations.

Windrose Analysis

In this set of analyses, ERG compared wind patterns on sample days to patterns for the whole sampling period, as well as comparing the sampling period's wind patterns to historical wind patterns. The purpose of these analyses was to confirm that sampling occurred under typical conditions. Finally, the historical two-month patterns were compared to the long-term annual patterns that were generated at onset of this study.

Key Point: Windrose Analysis
Based on the windrose profiles associated with each monitoring site during the sampling period, the locations of the monitoring sites were accurately sited relative to wind direction.

Windroses were created for several time periods (historical, annual for 2009, sample days, and sample period) for each sampling site. The data for the windroses came from the NWS stations, EPA's Air Quality System (AQS), and the Fort Worth Weatherbug Network; the windroses were created using Lakes Environmental's WRPlot[®] View (version 6.5.1) software.

The following observations are made for each site:

- *Site S-1:* As presented in Table 2.5-20, the closest meteorological station is located at Dallas–Fort Worth International Airport, approximately 5 miles north of Site S-1. As shown in Figure 2.5-9, all five time-period windroses appear similar, with winds predominantly from the south-southeast and south.
- *Site S-2:* As presented in Table 2.5-20, the closest meteorological station is located at Nolan High School, which is approximately 2 miles west of Site S-2. For historical comparisons, ERG used the meteorological data from Arlington Municipal Airport, a station approximately 10 miles to the southeast. As shown in Figure 2.5-10, the sample day and sample period windroses at Nolan High School are from the south, south-southeast, and southeast, while the windroses at Arlington Municipal Airport are predominantly southerly.
- *Site S-3A:* Similar to Site S-2, the closest meteorological station is located at Nolan High School, which is approximately one-half mile southwest of Site S-3A. For historical comparisons, ERG used the meteorological data from Arlington Municipal Airport, a station approximately 12 miles to the southeast. As shown in Figure 2.5-11, the sample day and sample period windroses at Nolan High School are from the south, south-southeast, and southeast, while the windroses at Arlington Municipal Airport are predominantly southerly.
- *Site S-3B:* As presented in Table 2.5-20, the closest meteorological station is located at Fort Worth Naval Air Station/Carswell Field, approximately 3 miles east of Site S-3B. As shown in Figure 2.5-12, all five time-period windroses appear similar, with winds predominantly from the south-southeast and south.
- *Site S-4:* As presented in Table 2.5-20, the closest meteorological station is located at Fort Worth Meacham Airport, approximately 3 miles northeast of Site S-4. As shown

- in Figure 2.5-13, all five time-period windroses appear similar, with winds predominantly from the south-southeast and south.
- *Site S-5*: As presented in Table 2.5-20, the closest meteorological station is located at Fort Worth Alliance Airport, approximately 4 miles east of Site S-5. As shown in Figure 2.5-14, all five time-period windroses appear similar, with winds predominantly from the south-southeast and south.
 - *Site S-6*: As presented in Table 2.5-20, the closest meteorological station is located at Spinks Airport, less than 0.75 miles north-northeast of Site S-6. As shown in Figure 2.5-15, all five time-period windroses appear similar, with winds predominantly from the south-southeast and south.
 - *Site S-7*: Similar to Site S-6, the closest meteorological station is located at Spinks Airport, less than half a mile southeast of Site S-7. As shown in Figure 2.5-16, all five time-period windroses appear similar, with winds predominantly from the south-southeast and south.

As described in the Ambient Air Monitoring Plan, the monitoring network was designed in part after understanding typical wind patterns in and around the City of Fort Worth through the use of historical windroses. Monitoring sites were placed to capture ambient air downwind of the target areas of interest. The general conclusion from the above windrose comparisons at each monitoring site during the study period is that wind patterns on sample days were generally typical of year-round and long-term historical wind patterns, indicating that the monitoring sites were able to collect samples from the target direction.

2.6 Ambient Air Monitoring Conclusions

Ambient air monitoring sampling at eight monitoring sites for nearly 140 pollutants yielded over 15,000 data points for this study. The ambient monitoring data presented in this report is based on air samples collected during a two-month timeframe at eight locations. The data should not be used to make inferences about air quality during times when, and locations where, samples were not collected. Insights from the dispersion modeling analysis have been used to help address this inherent limitation of the ambient air monitoring program, and a full discussion of the health implications of this study are presented in Section 5 of this report.

Key findings from the ambient monitoring study are as follows:

- 169 ambient air samples from 8 locations in Fort Worth were collected and analyzed, resulting in over 15,000 ambient air data points generated for this study.
- ERG found little variability across the sampling network for certain pollutants, such as carbon tetrachloride, chloroform, chloromethane, crotonaldehyde, dichlorodifluoromethane, dichlorotetrafluoroethane, ethylene, 1-hexene, isoprene, propylene, trichlorotrifluoromethane, and trichlorotrifluoroethane. The low variability across the entire network suggests that these pollutants are not affected by localized, anthropogenic sources, but rather exist as background pollutants.
- Benzene and carbon tetrachloride were identified as key VOCs at each site.
- Acetaldehyde and formaldehyde were identified as key carbonyls at Sites S-4 and S-5.
- No SNMOCs were identified as key pollutants.
- Concentrations measured at Site S-4 (located in a high-level activity area near compressor stations, well pads, and mobile sources) were generally higher than at other sites. For some of the key pollutants (acetaldehyde and benzene), concentrations at this site were considerably higher.
- Pollutant concentrations at Sites S-6 and S-7 (located in a medium-level activity area) were surprisingly low relative to other sites, especially given their close proximity to active well pad locations.
- Concentrations at Site S-1 (“background” site with no nearby natural gas well pads upwind) were generally similar to Site S-2 (“mobile sources” site). Concentrations at these two sites were slightly higher than Sites S-6 and S-7.
- Concentrations at the two “preproduction” sites did not display higher pollutant concentrations than the two monitoring stations designated as “background” and “mobile source” sites.
- Wind patterns observed during the sampling period were consistent with historical wind patterns, indicating proper placement of the ambient air monitors.

3.0 Point Source Testing

ERG subcontracted the point source testing task to Sage Environmental Consulting LP (Sage). This section discusses how the point source testing task was conducted and the results that were obtained.

This section has seven sub-sections:

- 3.1 Introduction – Provides a summary of the purpose of the point source study, the scope of work, and the project timeline.
- 3.2 Point Source Survey Sampling Equipment – This section describes the field instrumentation.
- 3.3 Point Source Survey and Sampling Procedures – This section discusses survey procedures, documentation of emission points, the collection of emission data, canister sampling, and data archival procedures.
- 3.4 Emissions Calculation Procedures – The development of canister-derived emissions, the application of correlation equations, the creation of surrogate tank and non-tank emissions profiles, the use of EPA default-zero emissions factors, the use of engine emissions tables, and the calculation of Screening Emissions Factors are discussed in this section.
- 3.5 Point Source Emissions Results – The results of the point source study are provided in the charts and tables of this section.
- 3.6 Quality Control (QC) Results – This section contains the results of the QC procedures specified in the Final Point Source Test Plan including instrument calibration checks, canister sample collection procedures, and laboratory analytical checks.
- 3.7 Point Source Testing Conclusions – This section presents conclusions of the point source testing task.
- Appendix 3-A: Emissions summary for each point source site surveyed.
- Appendix 3-B: Two DVD discs containing the emissions calculation workbook, “MASTER - Well Char Emission Data 2011-07-13_FINAL” together with the data collected for each point source site.
- Appendix 3-C: One DVD containing the canister sample logbooks and the canister analytical results, the laboratory quality control results and the canister chain-of-custody documentation.

3.1 Introduction

The purpose of the point source emissions study was to characterize emissions from natural gas-related point sources located within the Fort Worth city limits. These sources are categorized in seven groups:

- Well Pads – Comprising the largest group of sites visited, natural gas well pads typically contained several active wells, produced water storage tanks, separators, and

- metering runs (piping). Approximately one-third (123) of the well pads also had lift compressors used to increase a well's gas production rate. Emission sources typically related with well pads include equipment leaks, produced water and condensate storage and loading, and lift compressors. The amount of condensate production and related emissions are usually dependant on whether the produced gas is wet or dry gas.
- Compressor Stations – Compressor stations contain one or more large (generally 250 horsepower (hp) or greater) line compressors which provide the necessary pressure to move the natural gas through many miles of transmission lines. The most significant emissions from compressor stations are usually from combustion at the compressor engines or turbines. Other emissions sources may include equipment leaks, storage tanks, glycol dehydrators, flares, and condensate and/or wastewater loading. None of the compressor stations visited included turbines.
 - Processing Facilities – Processing facilities generally remove impurities from the natural gas, such as carbon dioxide, water, and hydrogen sulfide. These facilities may also be designed to remove ethane, propane, and butane fractions from the natural gas for downstream marketing. Processing facilities are usually the largest emitting natural gas-related point sources including multiple emission sources such as, but not limited to equipment leaks, storage tanks, separator vents, glycol dehydrators, flares, condensate and wastewater loading, compressors, amine treatment and sulfur recovery units. The Processing Plant visited included most of these sources except for sulfur recovery units.
 - Saltwater Treatment Facility – The single saltwater treatment facility permitted for operation within the City's boundaries uses underground injection to dispose of well production liquids such as oilfield brine, drilling mud, fracture materials, and well treatment fluids. Emission sources typically related with salt water treatment facilities include equipment leaks, storage tanks, and generators.
 - Drilling Operation – Drilling of a new well is typically a two to three week process from start to finish and involves several large diesel-fueled generators. Other emission sources related to drilling operations may include equipment leaks and waste storage.
 - Fracking Operation – Fracking is the high pressure injection of water mixed with sand and a variety of chemical additives into the well to fracture the shale and stimulate natural gas production from the well. Fracking operations can last for several weeks and involve many large diesel-fueled generators. Other emission sources related to fracking operations may include equipment leaks and waste storage.
 - Flowback – Flowback is a well completion activity that occurs following the conclusion of a fracking operation. Flowback thus entails the removal of fracking fluids from the well in preparation either for a subsequent phase of treatment or for cleanup and returning the well to production. Similar to fracking operations, other related emission sources may include equipment leaks and waste storage.

The point source teams surveyed a total of 388 sites (including repeat visits at two sites). The sites are identified by owner and type in Table 3.1-1. Figure 3.1-1 locates each site on an overlay map of Fort Worth. Figure 3.1-2 indicates which well pads were considered to be wet gas, and which were considered to be dry gas. For purposes of this study, a site was considered to be a wet gas site if it produced more than 1 barrel of condensate/day as indicated by the Texas Railroad Commission records.

Key Point: Sites Surveyed

This study included surveying a total of 388 sites comprised of well pads, compressor stations, processing facilities, a salt water treatment facility, drilling operations, fracking operations, and completion operations.

The point source emissions survey occurred in two phases. Phase I was completed in the fall of 2010 (August 30 – October 21, 2010). Phase II took place during the beginning months of 2011 (January 4 – February 16, 2011). There were no significant differences in methodology or scope between the two phases. Any slight differences between the methodologies are discussed below. During Phase I, 199 point source sites were surveyed and are identified using Point Source ID's PS-001 through PS-201. An additional 189 sites were completed in Phase II and are identified as Point Source ID's 6 through 487.

Quality Control results indicate that the field and the laboratory equipment were in a state of control during the point source survey and that project quality control checks were followed. Site-by-site emission summaries are provided in Appendix 3-A of this report. Appendix 3-B provides the field data and emission calculation workbook on two DVD discs. Appendix 3-C contains the canister analytical data on one DVD disc.

3.2 Point Source Emissions Survey Sampling Equipment

The point source surveys were carried out by two teams of two persons each. In Phase I each team was staffed by a Sage employee and an employee from Hicks & Co. Environmental (Hicks). This changed in Phase II to one team of two Sage employees while the other team remained a Sage and a Hicks employee. The point source teams were equipped with the following test equipment:

- FLIR™ Infrared (IR) Camera.
- Thermo Environmental™ Toxic Vapor Analyzer.
- Bacharach™ Hi Flow Sampler.
- Summa Passivated Stainless Steel Canisters from TestAmerica™.
- Miscellaneous Support Equipment (Global Positioning System (GPS) Finder, Laser Distance Finder, Weather meter, Digital Camera).

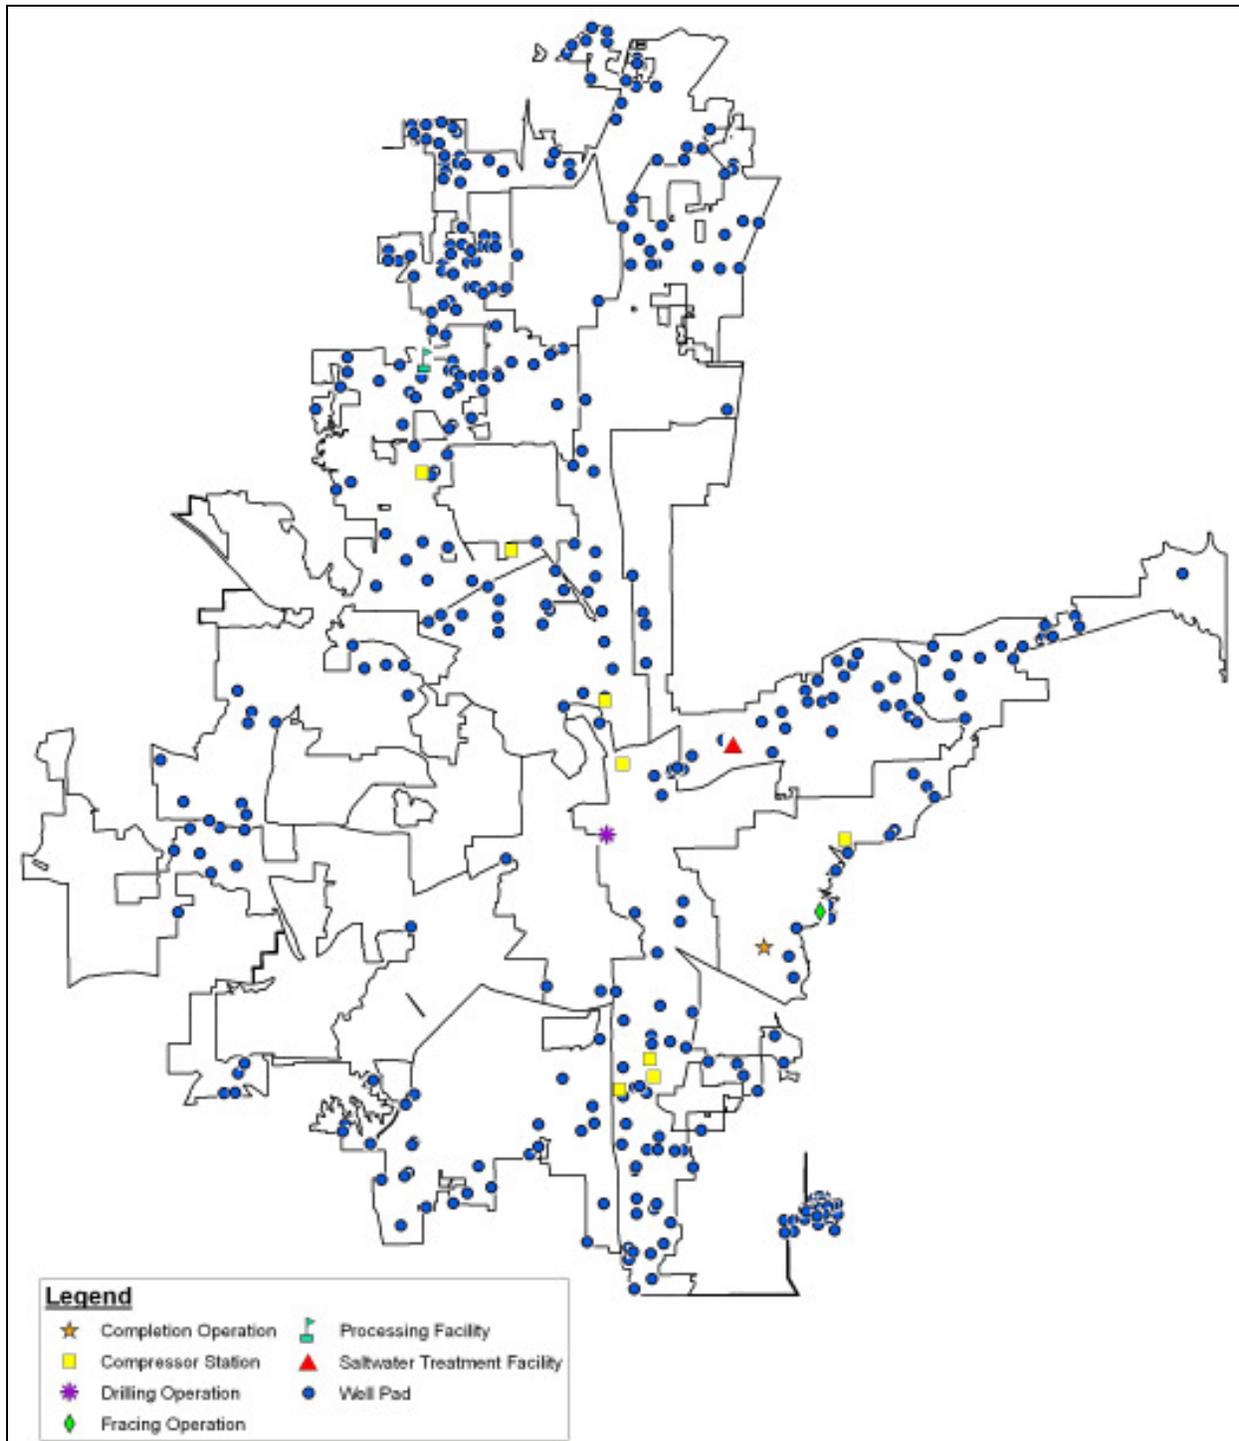

Figure 3.1-1. Point Source Survey Sites (August 2010 – February 2011)

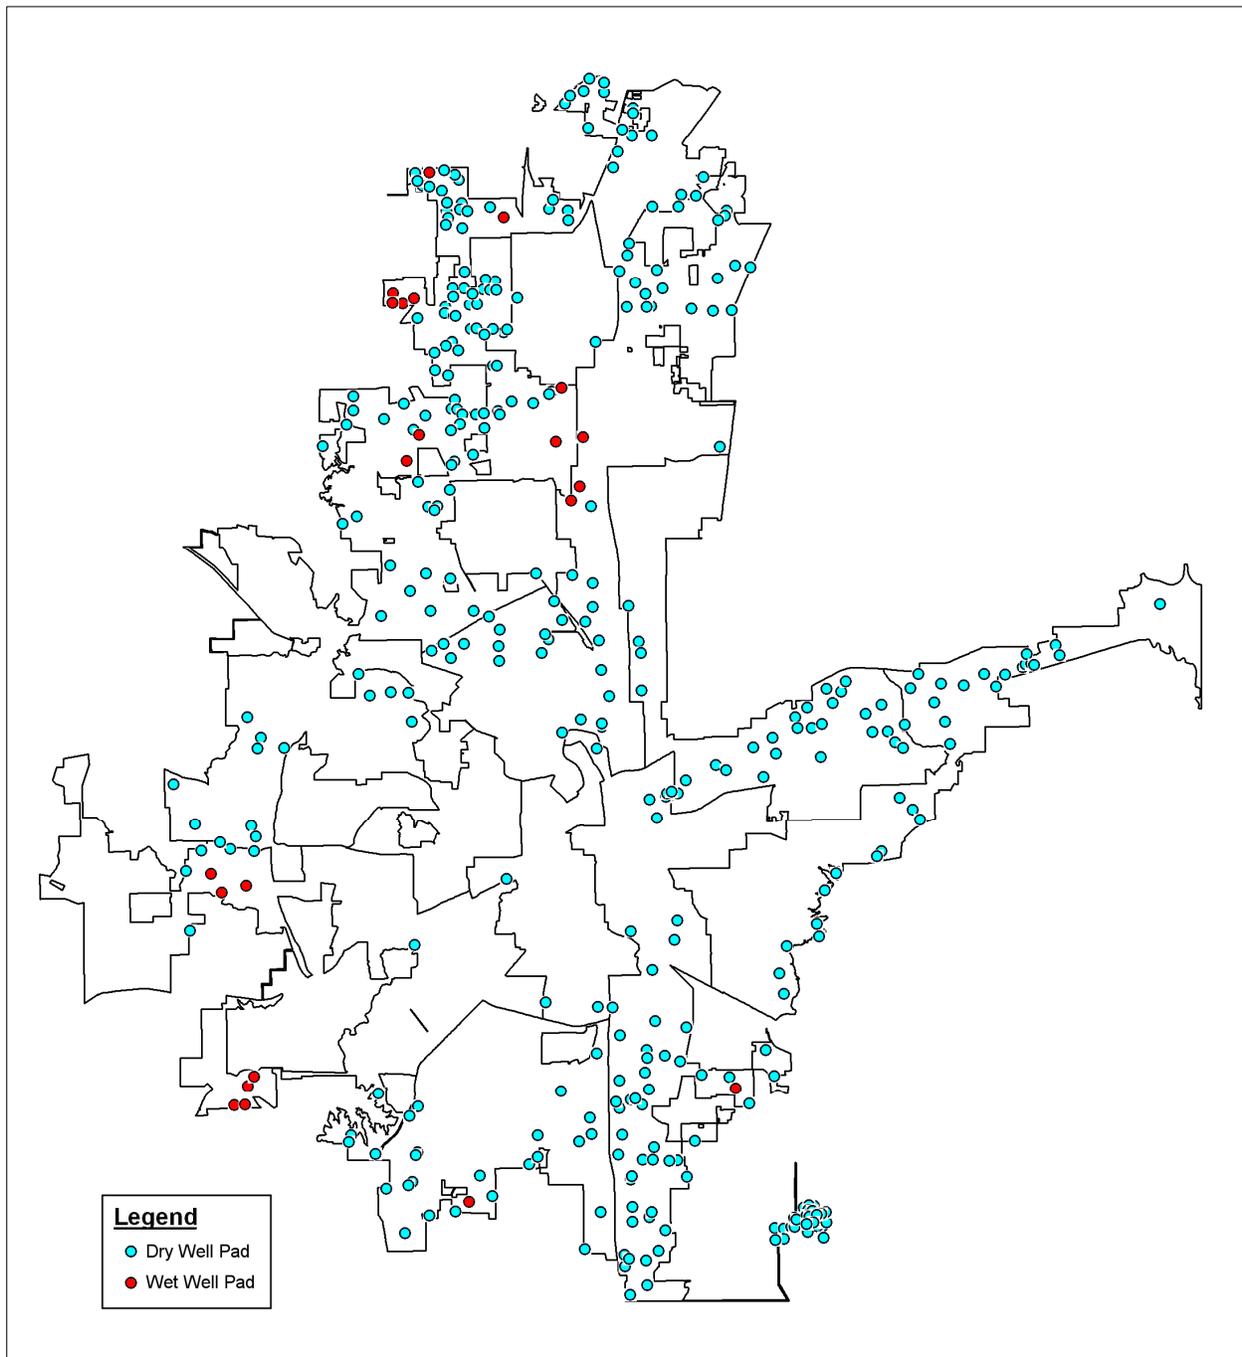

Figure 3.1-2. Wet Gas and Dry Gas Well Pads

3.2.1 The FLIR™ Infrared Camera

FLIR™ infrared cameras were used to survey all equipment in natural gas service at each point source site visited. The IR camera enables rapid detection of large emission sources (for instance, sources with concentrations > 10,000 parts per million by volume (ppmv)). Moreover, the infrared camera is well suited to detecting methane emissions, the largest constituent of

natural gas, as well as ethane, propane, and butane. Figure 3.2-1 illustrates the use of a FLIR™ infrared camera at a well site.

Figure 3.2-1. IR Camera Imaging at a Well Site

Two models of infrared camera were used on this project. One team used the GasFindIR™ camera equipped with a 50 mm lens and an external COWAN™ video recorder. The second team used the FLIR™ Model GF-320 infrared camera. While the two cameras share identical performance characteristics, the GF-320 has more user-friendly features (such as built-in video recorder and digital camera). All infrared camera imaging was performed by trained Level 1 or Level 2 Thermographers.

3.2.2 The Toxic Vapor Analyzer (TVA)

The TVA is a portable, battery-powered, intrinsically safe, hydrocarbon analyzer with a measurement range extending from 0.5 ppmv (parts per million by volume) to 50,000 ppmv hydrocarbon. This instrument was used to screen a random selection of site valves and connectors for leaks below the detection limit of the IR camera. It was also used to measure emissions detected with the camera, although in most cases these measurements resulted in a “flame-out” of the analyzer (that is, a reading greater than 50,000 ppmv). Figure 3.2-2 illustrates the use of a TVA at a well site.

***Key Point: IR Camera and TVA
Detection Limits***

The Infrared camera is typically used to detect large emission sources at concentrations >10,000 ppmv whereas the TVA can detect emissions with concentrations as low as 0.5 ppmv.

Figure 3.2-2. Method 21 Screening with the TVA at a Well Site

Use of the TVA followed EPA Method 21 procedures (40 CFR 60 Appendix A), which prescribes how to screen various components for fugitive emissions. Each TVA was calibrated daily prior to use with methane-in-air calibration standards.

3.2.3 The Hi Flow Sampler

The Hi Flow Sampler is a portable, intrinsically safe instrument designed to measure the rate of gas leakage around various pipe fittings, valve packings and compressor seals found at natural gas facilities. Because of its high flow rate (8 to 10 standard cubic feet per minute (SCFM)) the Hi Flow Sampler is able to completely capture any gas emitting from a component. The rate of the gas leak is determined by accurately measuring the flow rate of the sampling stream and the natural gas concentration. Figure 3.2-3 illustrates the sampling of a tank vent with the Hi Flow sampler.

Figure 3.2-3. Sampling a Tank Vent with the Hi Flow Sampler

To make an emission measurement with the Hi Flow Sampler, an attachment is chosen that is suitable for capturing the entire leak. An assortment of attachments are available to enable testing of a wide variety of components. For instance, for thief hatches or tank vents, a large nylon bag attachment was used. A plunger-style attachment was used to enclose small valves. Flanges were enclosed with a plastic strap and secured with Velcro™. For equipment that could not be enclosed with the standard Hi Flow Sampler attachments, plastic wrapping was used. With one end of the attachment enclosing the emission source and the other end attached to the instrument's main sampling hose, the Sampler was switched on and sampling initiated using the menu options available through the unit's controller. An entire Hi Flow Sampler test run lasted approximately 3 to 5 minutes.

For the point source surveys the Hi Flow Sampler was operated in its Automatic 2-Stage Mode, performing a leak rate measurement first at a high flow rate setting for one minute, and then automatically switching to a lower flow rate for a second minute of additional sampling. The unit calculated the degree of comparison between two measurements and displayed the total sample flow rate in cubic feet per minute (CFM) and the leak as percent methane and as the percent of the sample flow rate (% CFM).

3.2.4 Summa Canisters

Evacuated, six-liter, canisters provided by TestAmerica's™ Austin, Texas laboratory, were used to collect gas samples from selected emission points for VOC and HAP analysis by Gas chromatograph/Mass spectrometer (GC/MS) and for methane analysis by gas chromatography with a thermal conductivity detector (TCD). Canisters were shipped to the field office in a pre-cleaned, evacuated condition. Completed canisters were returned within several days of sample collection, together with chain-of-custody documentation, to TestAmerica™ for analysis. Unused canisters were kept securely stored in the project field office. Figure 3.2-4 illustrates how a canister sample was collected from the exhaust port of the Hi Flow Sampler.

Figure 3.2-4. Collecting a Canister Sample from the Exhaust Port of the Hi Flow Sampler

3.2.5 Miscellaneous Equipment

In addition to the equipment described above the point source teams also employed:

- A GPS receiver to document a site's North and West coordinates.
- A Kestrel Weathermeter™ to measure wind speed, temperature, relative humidity, and barometric pressure during a site visit.
- A laser distance finder to measure heights of emission points.
- An Archer™ field computer to record site data.
- A digital camera for site and equipment photos.

3.3 Point Source Survey and Sampling Procedures

This section discusses pre-test equipment preparation, site survey procedures, and data retrieval/archiving activities. The point source survey and sampling procedures followed were consistent with the Point Source Test Plan previously submitted and approved by the City of Fort Worth. Any deviations from this plan are discussed in the following sections as applicable.

3.3.1 Pre-Test Equipment Preparation

Equipment was prepared for use each morning prior to the first site visit. Preparations included:

- The IR Camera Daily Demo.
- A calibration check of the Hi Flow Sampler.
- A multipoint calibration of the TVA.

IR Camera Daily Demo Quality Assurance Check

The IR Camera Daily Demo provides a validation of the camera's operation by releasing a known mass emission rate of gas (100% propane) and measuring the distance from which the release can be reliably viewed. This validation was performed first thing each morning with both cameras at two mass emission rates: a low emission rate of 10 grams/hour propane and a higher emission rate of 31 grams/hour propane. The distance from which each emission rate could be detected (i.e. sighting distance) was recorded, together with wind direction, wind speed, temperature, relative humidity, barometric pressure, and percent cloud cover information. The equipment used to perform the daily demo included a steel compressed gas cylinder of 100% propane gas, a single stage gas regulator, a calibrated rotameter, flow control valves and tubing to position the emission flow at eye-level. The results of the daily demos are provided in Section 3.6 of this report and further documented in the field log notes included in Appendix 3-B.

Calibration Check of the Hi Flow Samplers

The Hi Flow Sampler contains two sensors – a background sensor and a leak sensor. Both sensors were calibrated at the start of Phase I and at the start of Phase II using certified standards of 2.5% methane-in-air and 100% methane. On a daily basis, prior to testing, the background and leak sensors of each Sampler were calibration-checked with the 2.5% methane standard. If an error greater than 10% resulted, the instrument was re-calibrated. Each Monday, the background and leak sensors of both instruments were calibration-checked with both the 2.5% and the 100% methane standards. Again, errors above 10% required re-calibration of the instrument.

The results of the Hi Flow Sampler daily calibration checks are provided in Section 3.6 of this report and further documented in the field log notes included in Appendix 3-B.

Multipoint Calibration of the TVAs

A multipoint calibration of each TVA was performed daily prior to testing with the following gases:

- Zero gas (<0.1 ppmv total hydrocarbon).
- Low Level Span gas (nominally 500 ppmv methane-in-air).
- Mid Level Span gas (nominally 1,000 ppmv methane-in-air).
- High Level Span gas (nominally 10,000 ppmv methane-in-air).

Following the calibration, each TVA would be re-checked with the same gases. The instrument was considered to be in a state of control if its response to each gas was accurate to within +/- 10%. Failure to meet this criterion required recalibration, repair, or replacement of the instrument.

3.3.2 Final Preparations

Following the instrument performance checks, data from the previous day would be reviewed for completeness and accuracy, the City Chief Gas Inspector would be called with the addresses of the first sites to be visited, and the vans would be loaded with the instrumentation and canisters. There would be a brief group safety discussion, the field office would then be locked, and the each team would depart to the first of their assigned sites for the day.

KeyPoint: Random Site Selection

To reduce bias in the survey relative to owner, operator, location, or any other variable, sites were selected for surveying on a random basis.

Sites were selected for surveying on a random basis. During the day, City Gas Inspectors were only told of the next scheduled site upon departure. These procedures were followed to avoid the possibility of site owners learning of the survey schedule in advance.

3.3.3 Site Arrival

Upon arrival at the designated point source site, the survey team met with the City Gas Inspector who unlocked the site gate to allow entrance to the site. On no occasion did the team enter a site without the City Gas Inspector also being present. Customarily at this time, a picture was taken of the front gate signage as part of the site documentation (Figure 3.3-1 shows an example of front gate signage).

Figure 3.3-1. Front Gate Signage

Immediately after arrival, a brief safety screening of the site would be conducted with the TVA to avoid entering an area of potentially dangerous pollutant concentrations.

One objective of each point source site visit was to document important site parameters such as the number of wells, storage tanks, and compressors, the site's GPS coordinates, the site's Railroad Commission (RRC) postings, and site throughput. Much of this information would be collected on preformatted data forms at the start of the survey. The use of preformatted forms helped to ensure a consistent data collection effort between the two teams as well as between sites. Figure 3.3-2 illustrates the site characterization form on which much of this information was recorded. In the "SITE LAYOUT" section of the form a sketch illustrating the positions of all major pieces of equipment would be drawn. All forms completed during the site surveys are included in Appendix 3-B.

NOTES:

Figure 3.3-2. Point Source Site Characterization Form

3.3.4 IR Camera Survey

The IR camera survey of a site began with the thermographer starting at one end of the site and working his way in logical fashion to the opposite end so that all equipment was surveyed. In a typical route, for instance, the thermographer would begin at the well pads, carefully surveying all of the valves and connectors associated with each well. From the well pads he would proceed to the compressor if one was present. Next, he might image the metering run and from there proceed to the piping and separators inside the tank battery. Finally he would finish the survey with a careful imaging of each storage tank, climbing up the stairs to the tank walkway in order to view each thief hatch and pressure relief valve (PRV) vent line. Depending on circumstances, such as the size and amount of equipment on the site and the number of

detected emission points, an IR camera site survey of a typical well pad might last from one to several hours.

When an emission was detected with the IR camera, a video recording of the IR imaging would be made, a photograph of the emission source would be taken and the following data documented:

- Date and time.
- Equipment description and size.
- Emission point height above ground (feet).
- GPS coordinates of emission point (Phase II only).
- Sighting distance (feet).
- TVA reading of emission (ppmv).
- Tank height and radius if tank emission (feet).
- Video file name.
- Maximum sighting distance (feet) – The maximum sighting distance is the distance from which the emission can be reliably detected with the IR camera and provides a measure of the emission’s magnitude (i.e. large emissions can be detected from further away).
- Weather conditions (Wind Direction, Wind Speed, Temperature, Relative Humidity, Barometric Pressure, and Cloud Cover).

As standard practice, the thermographer would image equipment from different angles. This is necessary since environmental conditions such as sunlight, wind, and background (i.e. air, piping, concrete or heat profiles) can cause an emission stream to be difficult to see from one angle, but easily detected from another.

With the GasFindIR™ camera integration settings would be switched to enable viewing of very hot surfaces (typically found at compressors), manual mode would be used on occasion to verify the absence or presence of a subtle emission, and “nuking” would be employed as required to eliminate optical background noise. Nuking adjusts the GasFindIR’s background so that a more uniform pixel response is obtained.

With the GF-320 camera the thermographer would frequently shift to High Sensitivity mode to confirm or detect a more subtle emission that was hard to see. All field data forms, digital photographs and videos are provided in electronic form in Appendix 3-B.

3.3.5 Method 21 Site Survey with the Toxic Vapor Analyzer

While one team member conducted the IR camera site survey, the second member calculated the total number of site valves and connectors. This was done by first determining the valve count and then applying a multiplying factor to arrive at the number of connectors. For this

project, a connector multiplier of 7 was conservatively used, based upon detailed connector counts performed at the beginning of both Phase I and Phase II. Thus if it was determined that a site contained 245 valves, then a connector count of 1,715 (7×245) was assumed. The 7:1 connector to valve ratio held true for all equipment except at compressor skids where a higher ratio was often noted. Consequently the number of connectors at compressor skids was estimated separately by multiplying the number of compressor valves by factors ranging from 10 to 15, depending on the size and complexity of the compressor.

These component counts were necessary since one objective of the point source testing was to estimate low level emissions (i.e. emissions below the detection limits of the IR camera) from fugitive equipment leaks. This objective was accomplished by screening at least ten percent of the valve and

Key Point: Method 21 Screening

To estimate low level emissions from fugitive equipment leaks, at least 10% of the valve and connector population at each site surveyed was screened.

connector population at each point source site with the TVA. Thus while the IR camera survey was in progress, Method 21 screening of the site's valves and connectors was performed with the TVA on one of every ten valves and one of every ten connectors until ten percent of the total valve and connector counts was reached. This procedure ensured that the required number of components was screened and that the screening population was evenly distributed across all areas of the site. This screening was conducted independent of the IR camera survey. Once it was completed, the TVA was then used to screen any emission points identified by the IR camera.

Following Method 21 procedures, valves were screened at their three primary leak areas: the stem, the packing, and the bonnet flange. Method 21 screening entails placing the TVA's probe at the various leak interfaces and sampling the complete circumference. Flanges were screened by placing the TVA probe at the edge of the flange-gasket interface. Connectors were screened by sampling the circumference of the threaded sections. All other components were monitored through a peripheral traverse of the seal interface. Whenever an elevated reading was obtained the sample probe was left at this elevated point for at least twice the instrument's response time (i.e. at least for 8 seconds) to ensure that the maximum concentration was measured.

When an emission at or above 500 ppmv was detected with the TVA the following data would be recorded:

- Date and time.
- Screening concentration (ppmv).
- Equipment Description.
- Equipment Location (GPS coordinates in Phase II only).

3.3.6 Hi Flow Sampler Emissions Testing

The Hi Flow Sampler, as discussed previously, provides a quick and effective means of quantifying emissions by sampling at a high enough flow rate to capture all the emissions escaping from a component. By accurately measuring the flow rate of the sample stream and the natural gas concentration within the stream, the instrument is able to determine the gas leak rate expressed both as percent methane and percent CFM. When this data is combined with canister analytical data, mass emission rates for individual compounds can be calculated as explained in Section 3.4.

Hi Flow Sampler testing was conducted at all emission points identified with the IR Camera (high level emissions) as well as at each emission point identified through Method 21 screening with a concentration ≥ 500 ppmv (low level emissions). A number of low level emissions in Phase I were below the detection capability of the Hi Flow Sampler. Emissions from these points have had to be subsequently estimated. In Phase II this was remedied by sampling the exhaust stream of the Hi Flow Sampler with the TVA and using the resulting TVA concentration to calculate the low level emission rate.

The following data was documented for each Hi Flow Sampler test:

- Date and time.
- The percent difference in leak rate between the sample flow rates.
- Total sample flow (CFM).
- Background concentration (%).
- Leak rate as % methane (% CH₄).
- Leak rate as % of total sample flow (% CFM).

3.3.7 Canister Sampling

As documented in the Point Source Test Plan, it was originally intended that a canister sample be collected at each emission point identified by the IR camera. However, as Phase I testing commenced, it became apparent that the sampling teams were observing an unexpectedly high frequency of camera-detected emission points. Therefore,

an alternative canister sampling strategy was needed; neither the project budget nor laboratory resources would be able to keep up with the canister demand otherwise. A revised canister sampling plan was developed and subsequently approved by the City of Fort Worth. The revised canister sampling plan was based upon three criteria.

Key Point: Canister Sampling

164 canister samples were collected throughout Fort Worth during the study. Data obtained from the 164 canister samples were used to develop surrogate canister emission profiles and correlation equations to characterize emissions from those points not directly sampled.

A canister sample would be collected from an emission point only if:

1. The % CFM reading obtained with the Hi Flow Sampler from that point exceeded the daily rolling average % CFM for all Hi Flow Sampler tests conducted thus far. In other words, the emission rate had to equal or exceed the average emission rate. The average emission rate was originally expressed as the rolling average of the third quartile % CFM; this was later changed to the rolling average % CFM.
2. Less than three canister samples have been collected from a similar component at other sites.
3. Less than three canister samples had been collected in the general geographical region. Geographical regions will be defined as the north, east, south, and west quadrants of the City of Fort Worth as well as any particular region in which the characteristics of the natural gas are substantially different from other regions (for instance, regions with wet gas and regions with dry gas).

If all of these conditions were not met, a canister sample was not collected. This approach succeeded in reducing the canister demand to a manageable level and was followed through the remainder of Phase I and through all of Phase II (a total of 164 canister samples were collected, not including 8 duplicate canister samples). Data obtained from these 164 canister samples were then used to develop surrogate canister emission profiles and correlation equations to characterize points for which no canister sample was taken.

Figure 3.3-3 provides a map of Fort Worth indicating the locations where canister samples were collected, as well as those locations where no samples were taken. As indicated in the map, the locations where canister samples were collected provide a well distributed characterization of canister samples. In other words, there were no large geographic locations in which there were no canister samples taken.

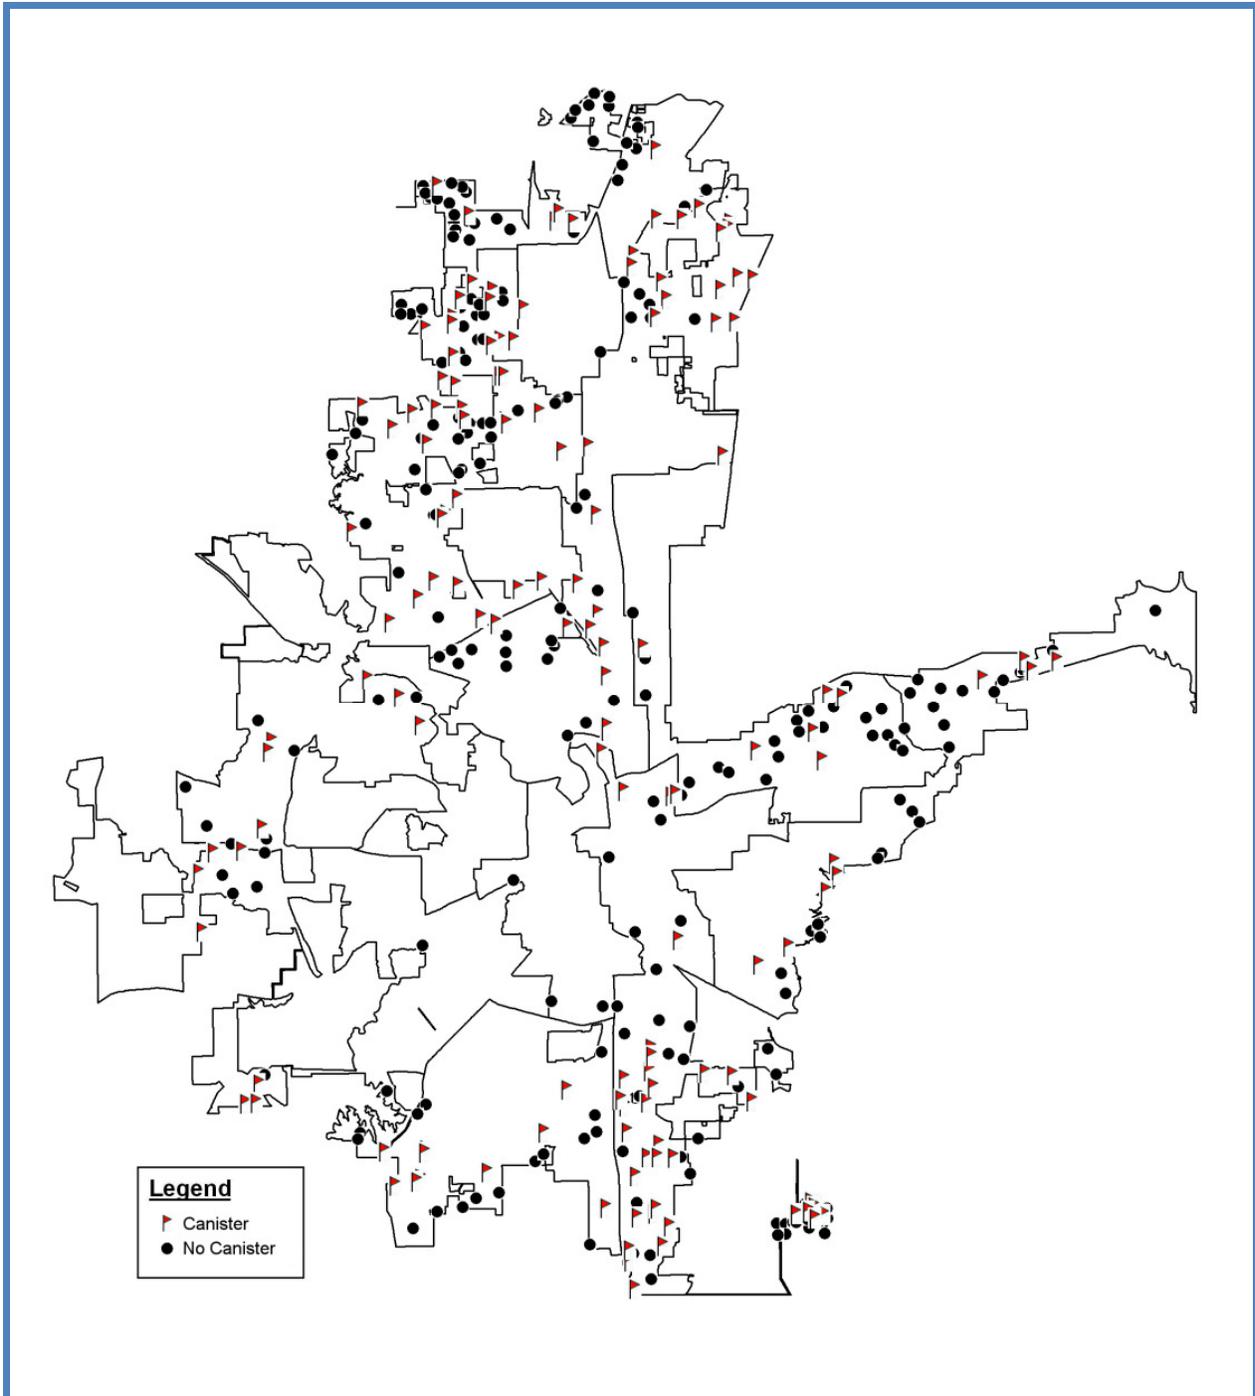

Figure 3.3-3. Canister Sample Locations

Whenever a canister sample was to be collected, the collection process followed specific protocols. A canister sampling manifold (Figure 3.3-4) consisting of a flow control valve and vacuum gauge was connected to the canister inlet port, and the canister's initial vacuum was checked. If less than 25-inches Hg vacuum was measured the canister was not used for sampling and was returned to the laboratory (this occurred only once).

To collect a sample, the canister's sample probe was directed into the exhaust port of the Hi Flow Sampler. Since it was possible, if the canister was opened very quickly, for the canister inlet flow to exceed the exhaust flow of the Hi Flow and thereby dilute the sample with ambient air, the sampling flow was carefully controlled. This was accomplished by adjusting the sample valve located upstream of the vacuum gauge (Figure 3.3-4) to ensure a slow but steady decrease in the canister vacuum. In practice, canister fill times were never less than 20 seconds and more typically, were between 30 seconds and 1 minute, far longer than the less than 2 second fill rate required to overcome the Hi Flow's exhaust rate.

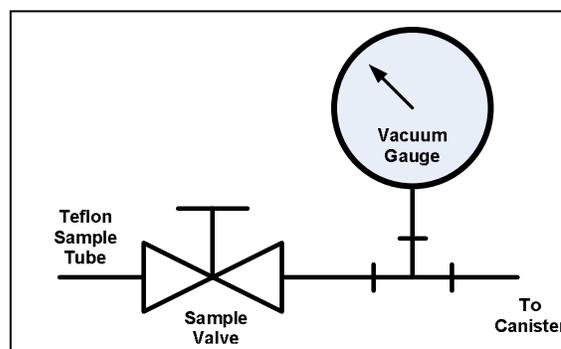

Figure 3.3-4. Canister Sampling Manifold

A canister was never filled completely but rather enough sample was collected to bring the canister vacuum up between 10 to 5 inches Hg. Following the collection of a canister sample the following data was documented both in a canister collection logbook and in the site's data form:

- Sample ID Number.
- Site Address.
- Date and Time.
- Initial Vacuum (inches Hg).

Similar information was also recorded on the canister's tag. Copies of the canister collection logbook entries are provided in Appendix 3-C.

3.3.8 Completion of the Site Survey

Following completion of the IR camera survey, the Method 21 screening, the Hi Flow Sampler testing of low level and high level emission points, and the canister sampling, the major equipment-containing areas of the site were documented both in photographs and with a site layout sketch. Figures 3.3-5, 3.3-6, and 3.3-7 provide typical examples of site photographs. Figure 3.3-8 illustrates a completed site layout sketch. Copies of all field data including site photos and site videos are provided in Appendix 3-B.

Figure 3.3-5. Site Documentation – Wells

Figure 3.3-6. Site Documentation – Tanks and Separators

Figure 3.3-7. Site Documentation – Lift Compressor

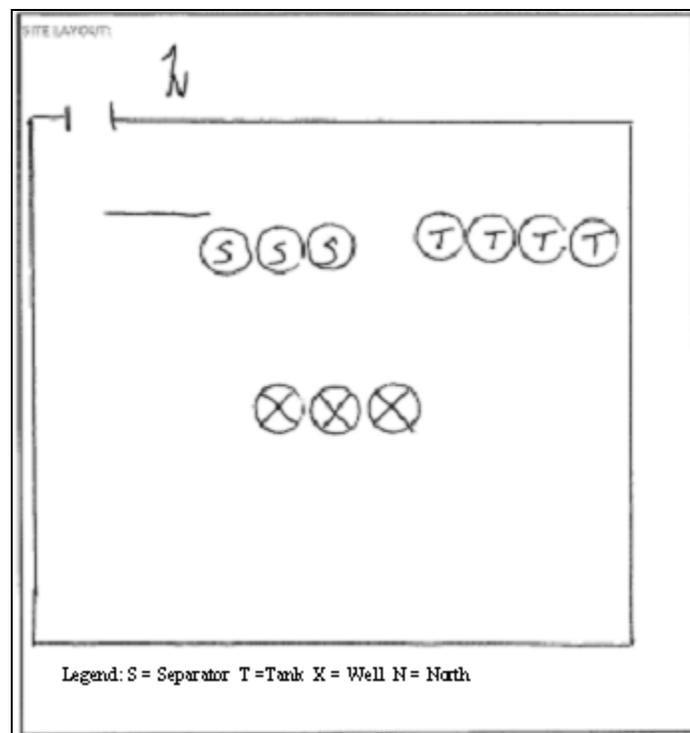

Figure 3.3-8. Example Site Sketch

Following this, the point source team prepared to depart from the site. The site data forms were checked for completeness and accuracy, any temporary flagging was removed the site’s equipment, all well and tank battery gates were closed and secured, and the departure time was documented. The gas inspector was then told the address of the next site to visit, and the facility’s main gate was locked behind the departing vehicles.

At the end of the day both teams returned to the field office where the equipment was off loaded from the project vans. Any canister samples taken that day were securely stored. The collected field data for that day was downloaded to a computer, printed out, and backed up.

Data archiving consisted of setting up separate computer site folders for the site's visited that day. Each folder was populated with the completed data forms, the site IR videos, and the site photos. Each team stored their data on the team computer and backed it up on dedicated hard drives. In addition, hardcopy printouts of the completed data forms were kept in large loose-leaf binders organized in chronological order. While one team member handled the data archiving, the other team member unloaded the van and prepared for the next work day. IR Camera, Hi Flow Sampler, TVA, digital camera and Archer data logger batteries were set up for overnight charging and facility field sketches were copied onto the printed out data forms. The completed data forms were quality control reviewed on a regular basis, either at the end of the day, the first thing the next day, or on the following weekend.

3.4 Emissions Calculation Procedures

This section describes the emissions calculation procedures used to derive a total emissions profile for each point source site. It is important to understand that for this study, not all of the site's emissions were calculated and/or characterized. For purposes of this study, in most cases, the emissions were calculated from only those sources in which emissions were detected and/or could be measured following the procedures described in the previous section. Hence, emissions were only estimated from piping and instrumentation equipment leaks, storage tanks, and compressors, which contribute the majority of emissions from natural gas-related facilities. Other sources of emissions, including but not limited to, storage tank breathing and standing losses, glycol dehydrator reboiler vents, wastewater and/or condensate loading, and flaring were not calculated. Non-routine emissions such as those generated during upsets or from maintenance, startup, and shutdown activities were also not measured or calculated as part of this study unless they were observed at the time of the site visit.

Annual emission estimates for each site were derived based on data obtained during the site visit and by assuming that conditions during the visit were representative of site conditions throughout the year. While it is important to note that emissions at any individual site can fluctuate depending on day-to-day operating and equipment conditions, the variation in emissions over the entire population were captured as a whole and are encompassed in this study as a result of breadth and depth of the point source testing and the use of surrogate emission profiles.

3.4.1 Well Pad, Compressor Station, Gas Plant, and Salt Water Disposal Facility Emissions

Total speciated emissions were calculated for each well pad, compressor station, gas plant and salt water disposal facility visited by the point source teams. These calculations fall into two categories: 1) Direct and 2) Indirect. Direct emission calculations were based upon the analytical results of the canister samples. Indirect emission measurements were derived from

several sources including the emission results from the canister sampling, correlation equations, calculated surrogate emission rates, EPA emission factors, and engine emission data for both natural gas and diesel powered engines. Each site's total emissions were calculated as a combination of direct and indirect emissions results. Figure 3.4-1 illustrates the overall approach followed in calculating total site emissions.

3.4.2 Direct Emission Calculations

Direct calculation of speciated emissions from a canister result was accomplished in 3 steps:

- Step 1: Convert the ppmv canister result to mg/m³ using Equation 5-1:

$$C = \frac{ppmv * MW}{24.45}$$

Where:

- C = Concentration in mg/m³
- ppmv = Parts per million by volume
- MW = Molecular Weight of analyte in gram/mols
- 24.45 = Molar Volume @ 25°C and 1 atmosphere in L/mols.

- Step 2: Convert the actual Hi Flow Sampler gas flow to standard gas flow using Equation 5-2:

$$CFM_{std} = (CFM_{act}) \left(\frac{T_{std}}{T_{act}} \right) \left(\frac{P_{act}}{P_{std}} \right)$$

Where:

- CFM_{std} = Flow rate corrected for standard conditions (ft³/min)
- CFM_{act} = Flow rate at actual conditions (ft³/min)
- T_{std} = Absolute gas temperature at standard conditions (°R)
- T_{act} = Absolute gas temperature at actual conditions (°R)
- P_a = Absolute gas pressure at actual conditions (psia)
- P_{std} = Absolute gas pressure at standard conditions (psia).

- Step 3: Calculate the emission rate using Equation 5-3:

$$ER = C * CFM_{std} * CF * 8760$$

Where:

- ER = Emission Rate (lb/yr)
- C = Analyte Concentration (mg/m³)
- CFM_{std} = Flow rate (ft³/min) corrected to standard conditions
- CF = Units Conversion Factor = 3.75E-06 (1 m³/35.32147 ft³) x 60 minutes/hour x (1 pound/453592.37 mg)
- 8760 = Hours per year

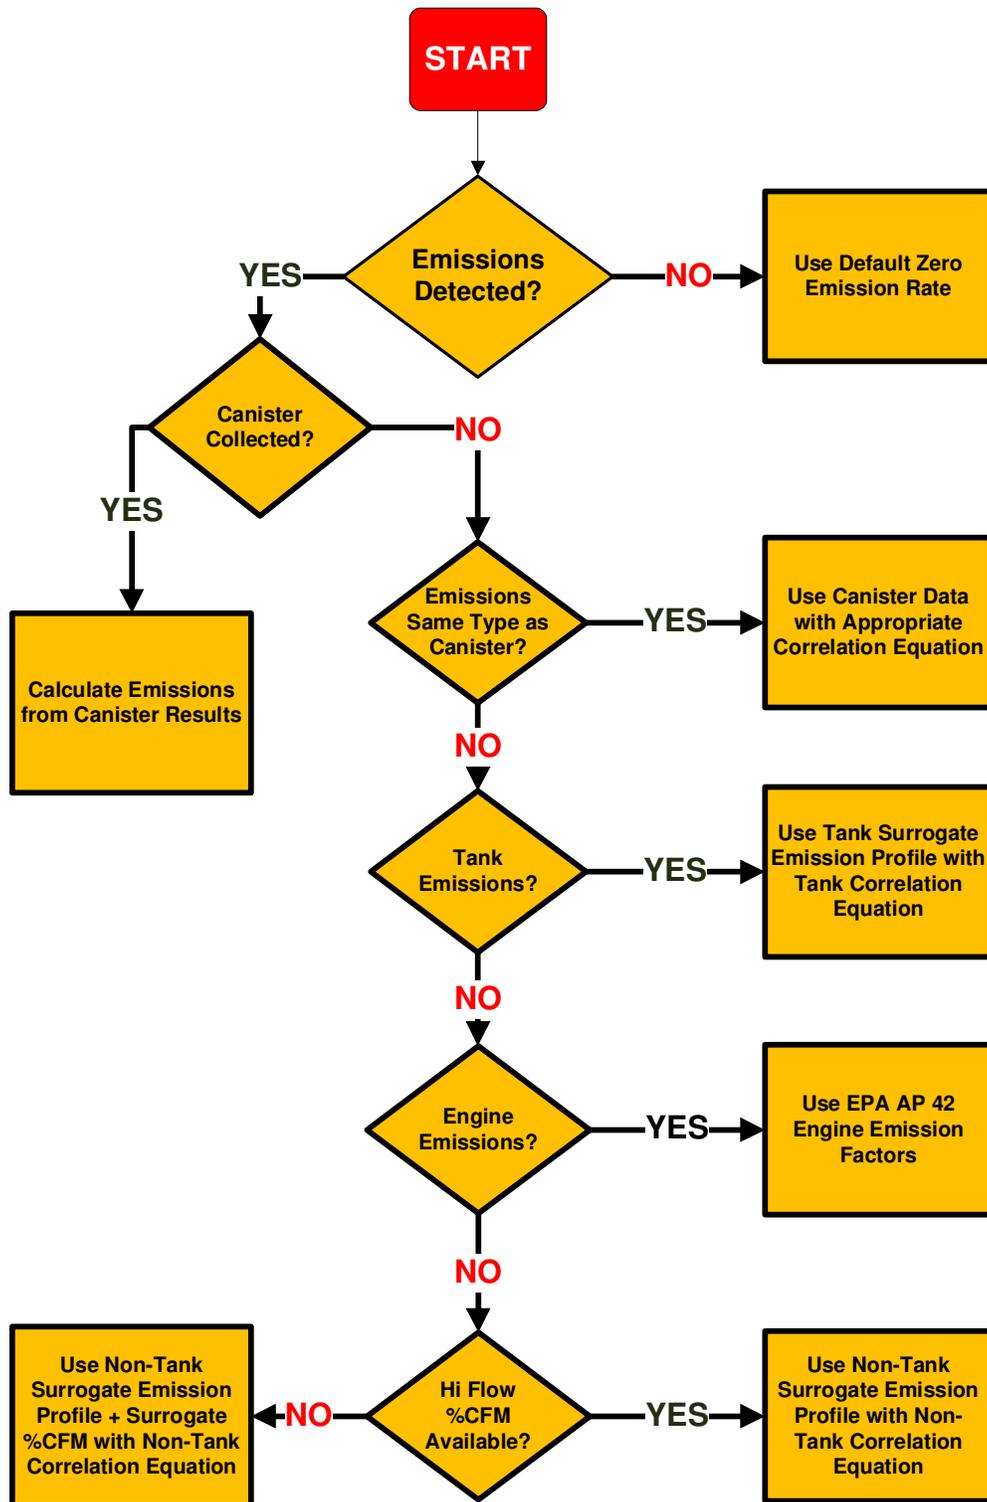

Figure 3.4-1. Emissions Calculation Flowchart

3.4.3 Indirect Emission Calculations -- Correlation Equation Development

The results of the canister samples were used to estimate emissions from those emission points that did not have a canister sample through the use of correlation equations. Two correlation equations, one for tank emissions and one for non-tank emissions, were developed based upon guidance from Section 2 and Appendix B of EPA's 1995 *Protocol for Equipment Leak Emission Estimates*.⁷

The first step in the development of the tank and non-tank correlation equations was the calculation of the natural logarithm of each canister's mass emission of total organic compounds (TOC) (lbs/yr) and its corresponding % CFM value.

The second step performed a linear regression in log space with the TOC values as the dependent variable (Y) and the % CFM values as the independent variable (X). The resulting regression line took the following form:

KeyPoint: Normality Correction

To estimate emissions from those sources not directly sampled with a canister, a correlation equation was developed between the calculated TOC (lb/yr) and the corresponding measured % CFM from those sources that were sampled. Since the data used to develop the correlation was not normally distributed, it was necessary to normalize the data by taking the natural logarithm of the data. A scale bias correction factor was then used to convert back to the arithmetic space.

$$\text{Emission Rate} = \beta_0 + \beta_1(\% \text{ CFM})$$

Where:

Emission Rate = Natural log of the leak rate determined by the canister results;

% CFM_i = Natural log of the % CFM_i;

β_0 = Intercept of regression line, and

β_1 = Slope of regression line.

The Mean Square Error (MSE) was then calculated by:

$$\text{MSE} = \frac{1}{n-2} \sum_{i=1}^n r_i^2$$

Where:

$$r_i = Y_i - \beta_0 - \beta_1 x_i$$

In the final step, the slope and intercept and a scale bias correction factor (SBCF) were used to transform the regression equations from log space to arithmetic space resulting in the tank and non-tank correlation equations:

$$\text{Leak Rate} = \text{SBCF} \times e^{\beta_0} \times \% \text{ CFM}^{\beta_1}$$

Where:

Leak Rate = Emission rate of TOC's from the individual source (lb/yr)

SBCF = Scale Bias Correction Factor

β_0, β_1 = Regression constants, and

% CFM = Cubic feet per minute measured by the Hi Flow Sampler.

The SBCF corrects for the variability of the log space data. It was calculated by summing 15 significant numbers of the terms from the infinite series:

$$SBCF = 1 + \frac{(m-1) * T}{m} + \frac{(m-1)^3 * T^2}{m^2 * 2! * (m+1)} + \frac{(m-1)^5 * T^3}{m^3 * 3! * (m+1) * (m+3)} + \dots$$

Where:

T = MSE/2.

MSE = mean square error from the regression.

m = number of data pairs.

3.4.4 Applying Canister Results to Non-Canister Emission Points

Canister-derived emission profiles were used to characterize non-canister emission points if 1) the non canister emission point was from the same site as the canister sample and 2) if the emission source types were the same (i.e. tank or non-tank).

For instance, if non-canister emissions were detected from a tank source, and if a canister had been collected at that site from another tank source, then that canister's data would be used to characterize the non-canister emission point. If the reverse was true, if the emissions were from a non-tank component, then a surrogate non-tank canister profile was used.

The distinction between tank and non-tank emission sources was made due to the differences in emissions characteristics observed between these two emission types. Tank emissions develop from the volatilization of heavier hydrocarbons entrained in the liquids produced by the facility separators, whereas non-tank emissions (i.e., particularly fugitive equipment leaks) are generally lighter gas emissions. Consequently, the chemical profile of each is somewhat different. For example, Table 3.4-1 provides a comparison of the average TOC, VOC, and HAP emissions resulting from a tank and non-tank canister sample collected during the study.

Table 3.4-1. Comparison of Emissions Between Tank and Non-Tank Emission Sources

| Source Type (Canister Site ID) | TOC (tons/yr) | VOC (tons/yr) | HAP (tons/yr) |
|-----------------------------------|------------------|------------------|------------------|
| Non-Tank (PS-126) | 6.65 | 0.01 | 0.00 |
| Tank (295) | 18.18 | 0.21 | 0.19 |

As indicated by the above comparison, tank emissions commonly exceed fugitive gas emissions.

Pairing a canister sample with a non-canister emission point provides the latter with a chemical composition. To calculate its emission rate, the Hi Flow Sampler results were used as follows:

1. The % CFM for the sample was entered into the correlation equation developed for the emission type (tank or non-tank) to determine the TOC mass emission rate.
2. The constituent contribution for each compound was determined from the weight percentages of the canister sample result.

This was done for each constituent so that the resulting products represented the speciated emission profile for the non-canister component.

For example, in Table 3.4-2 a canister sample (#A002) was collected from a leaking ¼-inch tubing connector – a non-tank sample type. Two other non-tank emission sources were detected at this site – a tee union connector and a pneumatically actuated valve. Since canister samples were not collected from these two sources, their emission profiles were derived as follows:

1. The non-canister total organic compound emission rate was calculated by the non-tank correlation equation. For the tee union with a % CFM of 0.39 the TOC emission rate was 11,644.25 lb/yr calculated as:

$$LR = 2.3759 * e^{9.674501743} * 0.39^{1.250318323} = 11,644.25 \text{ lbs / year .}$$

Where:

LR = TOC Leak Rate.

2.3759 = SBCF

9.674502= non-tank correlation equation intercept.

1.250318 = non-tank correlation equation slope.

2. Similarly, for the pneumatic valve which had a % CFM of 0.05 the TOC emission rate was 892.71 lb/yr calculated as:

$$LR = 2.3443 * e^{9.674501743} * 0.05^{1.2502318323} = 892.71 \text{ lbs / year .}$$

3. The non-canister emissions were assumed to have the same composition as the canister sample since they are both from the same site and from non-tank sources.
4. The speciated emissions of the non-canister were generated by multiplying the canister's speciated results by product of the ratio of each canister compound's emission to the canister TOC emission and the correlation equation TOC emission. The Tee union's methane emission rate, for instance, was 11,643.77 lbs/yr calculated as:

$$\frac{13,993.20}{13,993.78} * 11,644.25 = 11,643.77 \text{ lbs/yr methane.}$$

Where:

13,993.20 = Canister CH₄ lbs/yr.

13,993.78 = Canister TOC lbs/yr.

11,644.25 = Correlation Equation TOC lbs/yr.

Table 3.4-2. Non-Canister Methane Emissions Calculation Example

| Emission Pt. | HF % CFM | Canister ID | Methane (lbs/yr) | Methane (tons/yr) |
|-----------------|----------|-------------|------------------|-------------------|
| ¼-inch tubing | 1.01 | A002 | 13,993 | 6.99 |
| Tee Union | 0.39 | -- | 11,644 | 5.82 |
| Pneumatic Valve | 0.05 | -- | 893 | 0.45 |

3.4.5 Surrogate Canister Profiles

For emission points which could not be directly tied to a canister profile, either because a canister was not collected at the site or because the canister sample from the site was from a non-matching source (i.e. tank vs. non-tank), then a surrogate canister profile was used in the emissions calculations. Two canister surrogate emission profiles with the units of pounds/yr were developed: 1) a non-tank surrogate emission profile and 2) a tank surrogate emission profile (Table 3.4-3). The non-tank surrogate emission profile was used for components associated with valves, connectors, and other piping and instrumentation equipment located at well heads, metering runs, separator pads and compressor skids. The tank surrogate emission profile was used to characterize emissions primarily from tank thief hatches and tank relief vents.

Table 3.4-3. Surrogate Tank and Non-Tank Emission Profiles

| Category | Type | TOC (pounds/yr) | Non-VOC (pounds/yr) | VOC (pounds/yr) | HAP (pounds/yr) |
|-------------|----------|-----------------|---------------------|-----------------|-----------------|
| Wet/Dry Gas | Non-Tank | 13,256 | 13,252 | 4.12 | 0.78 |
| Wet/Dry Gas | Tank | 27,786 | 27,768 | 17.20 | 4.12 |

An attempt was made to further distinguish between emissions from sites in wet gas service versus sites in dry gas service for both tank and non-tank sources, but the number of emission sources in wet gas service turned out to be too small to draw statistically reliable inferences. At wet gas sites, emissions were detected from only 3 tank component types and 6 non-tank component types. At least 30 data points are needed to form reliable statistical conclusions.

The two surrogate emission profiles were developed using standard statistical procedures referenced in EPA's 1995 *Protocol for Equipment Leak Emission Estimates*:

1. The canister data for each emission type was checked for normality using probability plots to evaluate the correlation between the data and a normal distribution.
2. Since, in both cases, the data turned out to be non-normal, a natural logarithmic transformation of both sets of canister data was performed.
3. The normality of the transformed data was again checked using probability plots and found to be sufficiently linear.
4. The surrogate compositions were determined as the anti-logarithmic mean of the transformed data.

For summary purposes, Table 3.4-2 indicates the surrogate emission profiles only for categories of compounds (i.e. TOC, VOC, etc.). It is important to note that each surrogate profile also contains the emission rates for all of the individual compounds found in the aggregate canister samples used to generate the surrogate emission profiles.

Once the use of a surrogate canister profile was applied to an emission point, the emission calculation was performed according to the procedures described above in Section 3.4.3.

In Phase I there were several instances in which a low level emission fell below the detection limit of the Hi Flow Sampler (this limitation was overcome in Phase II by measuring the hydrocarbon concentration of the Hi Flow Sampler's exhaust stream with the TVA). For these occasions a surrogate % CFM was derived as the anti-log mean value of the normalized % CFM readings recorded in Phase II with the TVA.

3.4.6 Calculation of Non-Sampled Low Level Emission Points

While all site piping and instrumentation equipment was surveyed with the IR camera for high level emissions, only ten percent of the components at a site were sampled for low level emissions using a TVA following Method 21 screening procedures. Two separate emission calculations were used to arrive at emission rate estimates for the ninety percent not screened with the TVA:

1. The percent of components found leaking in the Method 21 screening was applied to the total non-sampled population of valves and connectors at the site and the non-tank correlation equation was used to estimate their emissions.
2. The remaining components were assumed to be non-leaking and their emissions were calculated using the Synthetic Organic Chemical Manufacturing Industry (SOCMI) default zero values listed in EPA's 1995 *Protocol for Equipment Leak Emission Estimates* (Figure 3.4-2). Studies by EPA have demonstrated that non-leaking equipment actually have low level emissions. These emission values are termed "default zeros" and are routinely used across the petroleum industry in the calculation of emission inventories.

TABLE 2-12. DEFAULT-ZERO VALUES: PETROLEUM INDUSTRY

| Equipment type/service | Default-zero emission rates ^{a,b} (kg/hr/source) |
|--------------------------|--|
| Valves/all | 7.8E-06 |
| Pump seals/all | 2.4E-05 |
| Others ^c /all | 4.0E-06 |
| Connectors/all | 7.5E-06 |
| Flanges/all | 3.1E-07 |
| Open-ended lines/all | 2.0E-06 |

^aDefault zero emission rates were based on the combined 1993 refinery and marketing terminal data only (default zero data were not collected from oil and gas production facilities).

^bThese default zero emission rates are for total organic compounds (including non-VOC's such as methane and ethane).

^cThe "other" equipment type was developed from instruments, loading arms, pressure relief valves, stuffing boxes, vents, compressors, and dump lever arms. This "other" equipment type should be applied to any equipment type other than connectors, flanges, open-ended lines, pumps, or valves.

Figure 3.4-2. Default-Zero Values

As an example, a site component count indicates a site contains 150 valves and 1,050 connectors. Method 21 screening is therefore performed on 15 of the valves and 105 connectors (i.e. 10%). Emissions at or above 500 ppmv are detected on 3 of the valves (20%) and 2 of the connectors (1.9%). The remaining 135 valves and 945 connectors that were not monitored are assumed to have the same leak percentages. Accordingly an additional 27 valves (20% of 135) and 18 connectors (1.9% of 945) would be assumed to be leaking at this site. The emission rates of these components would be determined as follows:

1. For valves, the valve minor emission % CFM would be multiplied by 27. For connectors a multiplier of 18 would be used.
2. The resulting % CFMs would be entered into the non-tank correlation equation to calculate a single TOC emission for the additional 27 valves and a single TOC emission for the additional 18 connectors presumed leaking.
3. The calculated weight percentages from the non-tank surrogate profile would be applied to derive speciated emissions for each result.

The remaining 108 valves (135-27) and 927 connectors (945-18) would have the valve and connector default zero emission rates applied to them. This would be done by converting the default zero kg/hr emission rates to % CFM as methane. The resulting value would be then entered into the non-tank correlation equation to calculate TOC emissions. Speciated results would be obtained using the calculated weight percentages from the non-tank surrogate profile.

3.4.7 Compressor Engine Emissions

A total of 186 natural gas compressor engines were encountered during the site surveys. Of these, 150 were located at 123 well pad sites, 12 were located at the gas processing facility, 1 was located at the salt water treatment facility, and 23 were located at the eight line compressor stations. The majority of the compressor engines located on well pads functioned as lift compressors.

Emissions from compressor engines were derived from field data collected during the site surveys, vendor specification sheets and published emission factors. In calculating emissions for compressor engines, a 100% compressor duty cycle was conservatively assumed (i.e. 24 hours/day/ for 365 days/year). In addition, it was conservatively assumed that these engines were uncontrolled. Multiple XTO facilities were noted as having catalyst controls on their engines, but as stack testing of the exhaust from compressor engines was not included in the scope of this study, the control efficiency of these engines is unknown.

Key Point: Compressor Engine Controls

Emissions from compressor engines were estimated using the best available data collected during the point source testing. Where data was limited, conservative assumptions were used including but not limited to, the use of uncontrolled emission factors where controls were known to be present but no control efficiency data was readily available.

3.4.8 Well Drilling and Fracking Engine Emissions

Criteria pollutant, VOC and HAP emissions from natural gas and diesel engines used in well drilling and fracking operations were conservatively estimated based upon vendor specifications and published emission factors. Engine emissions from well drilling assume 504 hours of continuous operation (3 weeks, 7 days/week, 24 hours/day). Engine emissions associated with a fracking operation are based upon 120 hours of non-continuous operation (3 weeks, 5 days/week, 8 hours/day).

3.4.9 Calculation of Method 21 TOC Screening Emission Factors

Method 21 screening results were used to calculate VOC emission factors for non-tank equipment in natural gas service so that emissions due to future build out can be predicted based upon Method 21 monitoring results. Emission factors were calculated for the following equipment /screening categories:

- Valves: 500 ppmv to 999 ppmv and 1,000 ppmv to 10,000 ppmv.
- Connectors: 500 ppmv to 999 ppmv and 1,000 ppmv to 10,000 ppmv

- Other (sump pumps, pneumatic valve controllers, regulators, flow meters, knock-out pots, vents, etc.): 500 ppmv to 999 ppmv and 1,000 ppmv to 10,000 ppmv.

The emission factors were derived in a five step procedure:

1. Step 1: Filter for Phase II data since this data contained a larger data set of Hi Flow Sampler emission measurements for low level emissions.
2. Step 2: Sequentially filter the result of Step 1 by component type (valve, connector or other).
3. Step 3: Sequentially filter the result of Step 2 by the desired range of screening values (500 – 999 ppmv or 1000 – 10,000 ppmv).
4. Step 4: Sum the individual TOC emissions for the filtered results to produce total TOC emissions (lbs/hr) for each.
5. Calculate the emission factor for the selected component type and screening value range as the median of the Step 5 results and convert from pounds per hour to kilograms per hour.

3.5 Point Source Emissions Results

A total of 388 point source emissions sites were surveyed, including two repeated sites, for natural gas emissions in the point source study. Of these, 375 well pads and 8 compressor stations were visited, which comprised approximately 75% of the population. This section provides the point source survey results as TOC, VOC, HAP and Criteria Pollutant emissions in tons/yr. TOC are the sum of non-VOCs and VOCs. VOCs are the sum of non-HAP VOCs and HAPs. Criteria pollutants are VOCs, particulate matter (PM), Oxides of Nitrogen (NO_x), Carbon Monoxide (CO), and sulfur dioxide (SO₂).

Table 3.5-1 lists the average and maximum emission rates by site type. Emissions are extrapolated over a one year period (i.e. tons per year) for different site types. The average and maximum values are the same for processing and saltwater treatment facilities because only one of each was surveyed.

Table 3.5-1. Average and Maximum Point Source Emission Rates by Site Type^a

| Site Type | TOC (tons/yr) | | VOC (tons/yr) | | HAP (tons/yr) | |
|------------------------------|---------------|-------|---------------|------|---------------|-----|
| | Average | Max | Average | Max | Average | Max |
| Well Pad | 16 | 445 | 0.07 | 8.6 | 0.02 | 2 |
| Well Pad with Compressor(s) | 68 | 4433 | 2 | 22 | 0.9 | 8.8 |
| Compressor Station | 99 | 276 | 17 | 43 | 10 | 25 |
| Processing Facility | 1,293 | 1,293 | 80 | 80 | 47 | 47 |
| Saltwater Treatment Facility | 1.5 | 1.5 | 0.65 | 0.65 | 0.4 | 0.4 |

^a For values reported as <0.01 see Appendix 3-A for actual emissions expressed in scientific notation.

Table 3.5-2 summarizes the average emission volumes for each site type as measured by the Hi Flow Sampler. Note that engine emission volumes are not included in this table.

Table 3.5-2. Average Point Source Emission Volumes by Site Type

| Site Type | TOC (cubic feet/yr) |
|------------------------------|------------------------|
| Well Pad | 148,552 |
| Well Pad with Compressor(s) | 218,035 |
| Compressor Station | 188,236 |
| Processing Facility | 372,019 |
| Saltwater Treatment Facility | 526 |

Table 3.5-1 shows the contribution compressor engines make to total site-wide emissions. In addition to increasing TOC, VOC and HAP emissions, the exhaust from a compressor engine contains the criteria pollutants (PM, SO₂, CO and NO_x). By way of illustration, Figure 3.5-1 compares the average annual emissions from a well pad without a compressor to one with a compressor. Clearly, compressor engines are a significant contributor of emissions at natural gas-related facilities.

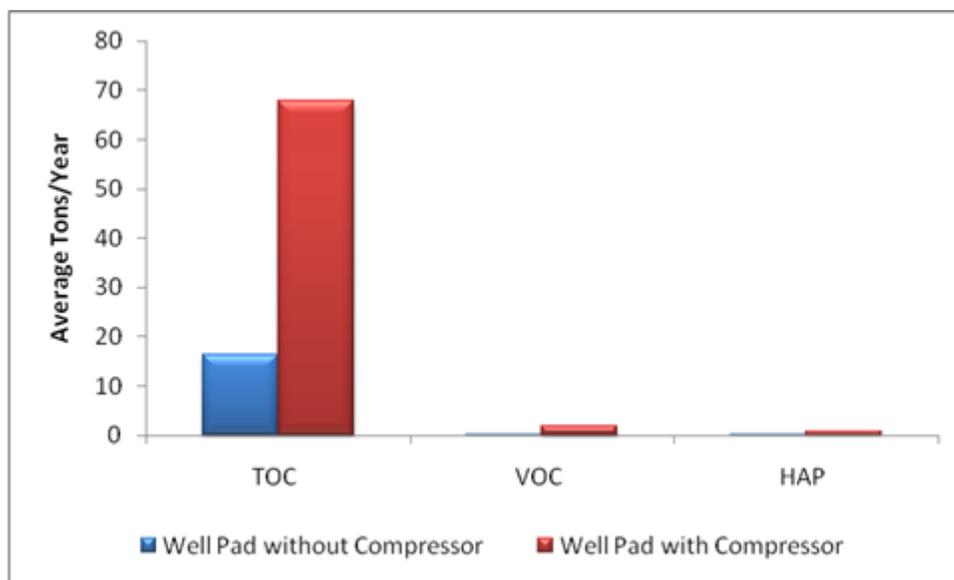

Figure 3.5-1. The Effect of Compressors on Site Emissions

Table 3.5-3 summarizes the emissions rates for all criteria pollutants and HAPs per each site surveyed during the point source testing. For each site, the summary provides the number of emission sources by type (e.g., compressor engines, storage tanks, fugitive leaks) and their contribution to total site-wide VOCs. Furthermore, the table provides for each site surveyed, the number of leaks detected by the IR camera and the number of leaks detected above 500 ppm using Method 21 screening.

Table 3.5-3. Point Source Emissions Summary by Site ^a

| Site ID | Address | Site Type | No. Wells | No. Valves | No. Connectors | No. Tanks | No. Compressors | No. M21 >500 ppm | No. IRs | PM (tons/yr) | NOx (tons/yr) | CO (tons/yr) | SO2 (tons/yr) | VOCs (tons/yr) | | | | HAPS ^b (tons/yr) | | |

^a For values reported as <0.01, see Appendix 3-A for actual emissions expressed in scientific notation.

^b The HAP Total emissions listed include all HAP emissions that were measured and calculated as part of this study. For a complete list of estimated HAPs emissions, see Appendix 3-A.

Figure 3.5-2 shows the average TOC emissions for the three basic component categories found at the natural gas facilities which were surveyed by the point source team: Valves, Connectors, and Other. Valves include manual valves, automatic actuation valves, and pressure relief valves. Connectors include flanges, threaded unions, tees, plugs, caps and open-ended lines where the plug or cap was missing. The category “Other” consists of all remaining components such as tank thief hatches, pneumatic valve controllers, instrumentation, regulators, gauges, vents, etc.

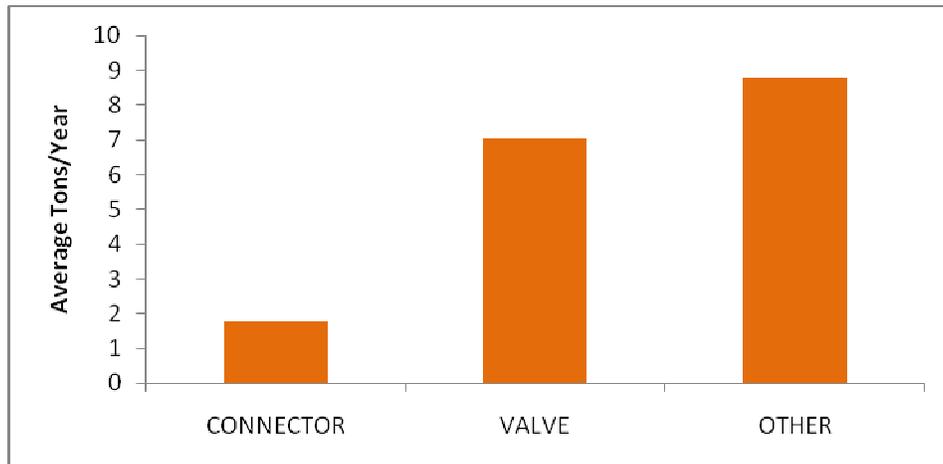

Figure 3.5-2. Average TOC Emissions by Component Category

As indicated in Figure 3.5-2, average TOC emissions from components in the “Other” category exceeded emissions from valves and connectors. Figure 3.5-3 identifies individual equipment types in the “Other” category with the highest average TOC emissions. Among these, tank thief hatches have the largest average TOC emission contribution, followed by miscellaneous equipment, tank vents, pneumatic valve controllers, and gas regulators.

Miscellaneous equipment included a variety of emission sources such as holes and cracks in tank roofs, various types of instrumentation and meters, sumps, compressor shafts, orifice plates, sight glasses, and underground piping.

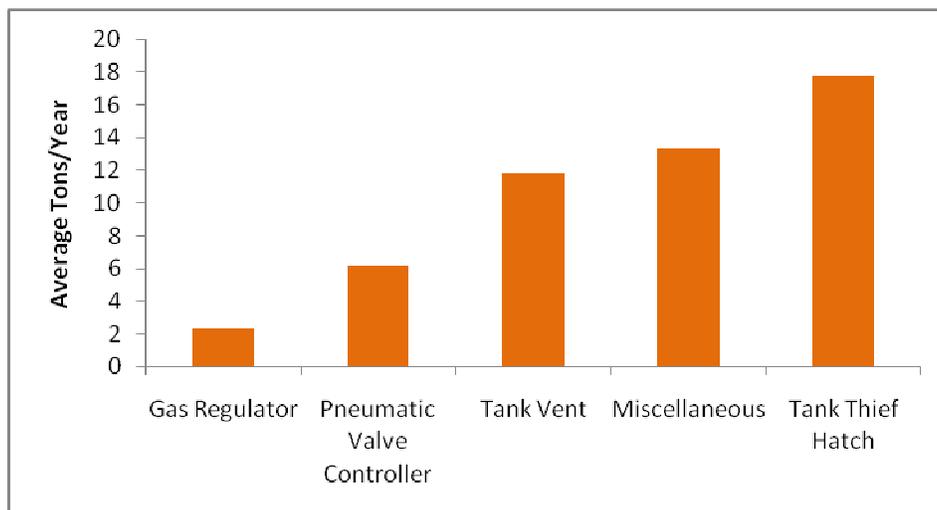

Figure 3.5-3. Average TOC Emissions in Category “Other”

Figure 3.5-4 summarizes the average annual TOC, VOC, HAP, and Criteria Pollutant emissions from compressor engines alone. Criteria pollutant emission data is based upon vendor-provided and published engine emission factors and pertains to those compressors encountered at well pad sites.

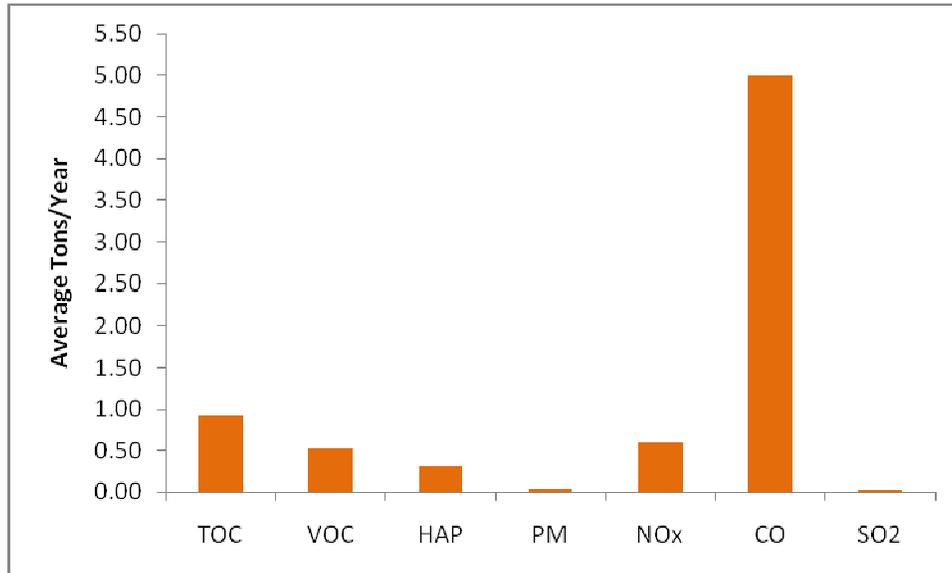

Figure 3.5-4. Average Annual Emissions from Well Pad Compressor Engines

Figure 3.5-5 compares VOC and HAP average annual emissions from Non-Tank and Tank sources.

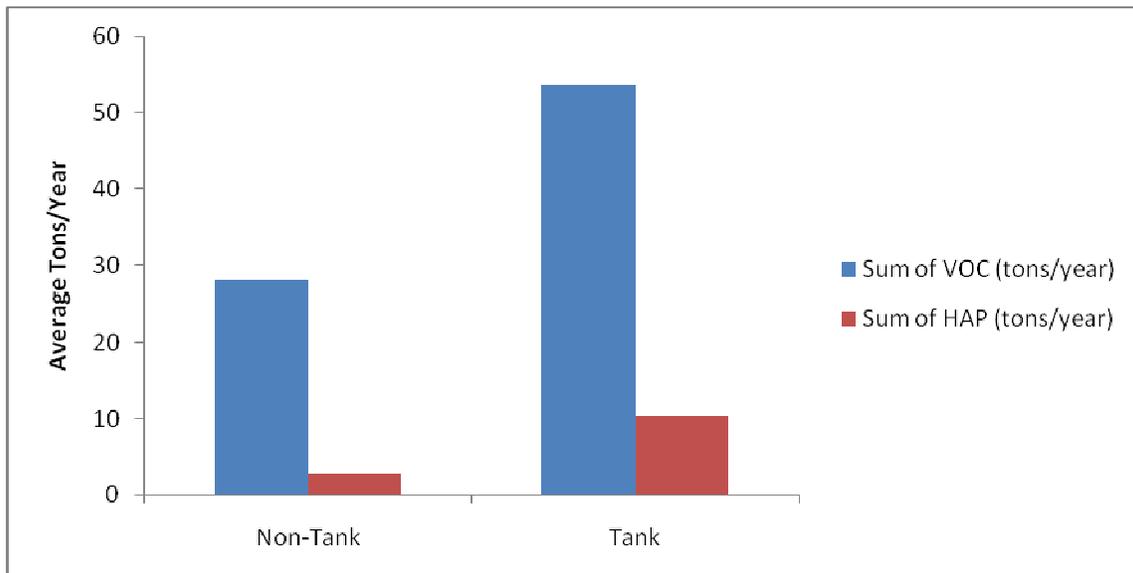

Figure 3.5-5. Non-Tank vs. Tank: Average VOC and HAP Emissions

Figures 3.5-6 and 3.5-7 compare TOC, VOC, and HAP average emissions from dry gas and wet gas sites. For purposes of this study, a site was considered to be a wet gas site if it produced more than 1 barrel of condensate/day as indicated by the Texas Railroad Commission.

Figure 3.5-6 indicates that average TOC emissions from wet gas well pad sites were higher than those from dry gas well pad sites. Also, indicated in Figure 3.5-7, wet gas well pad sites were found to have higher average VOC and HAP emissions.

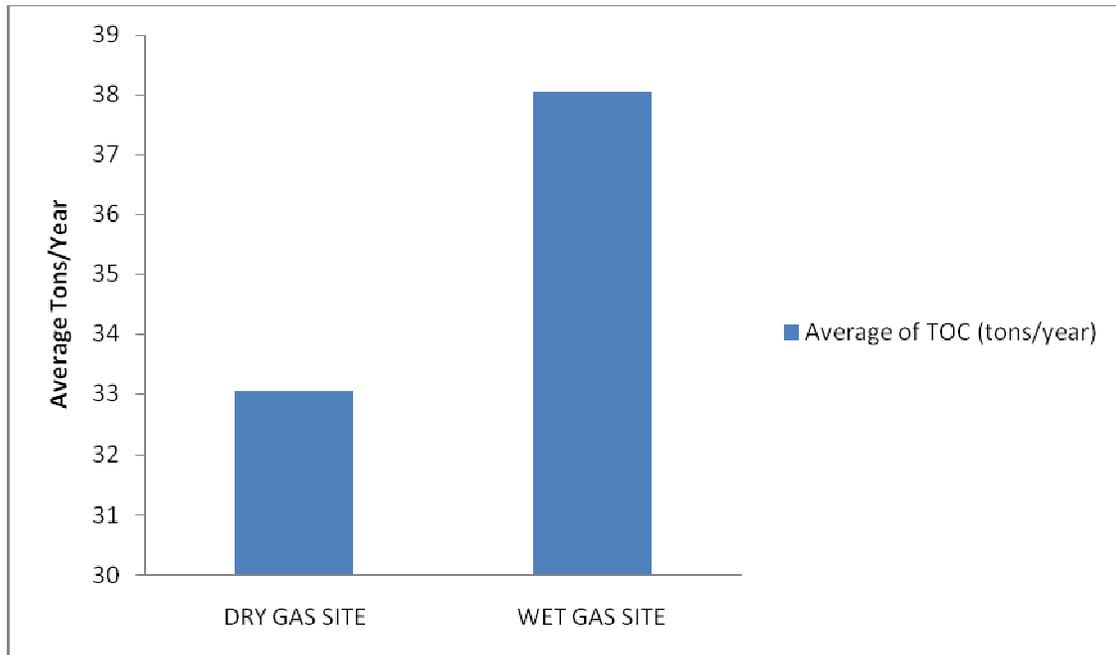

Figure 3.5-6. Average Wet Gas vs. Dry Gas TOC Emissions

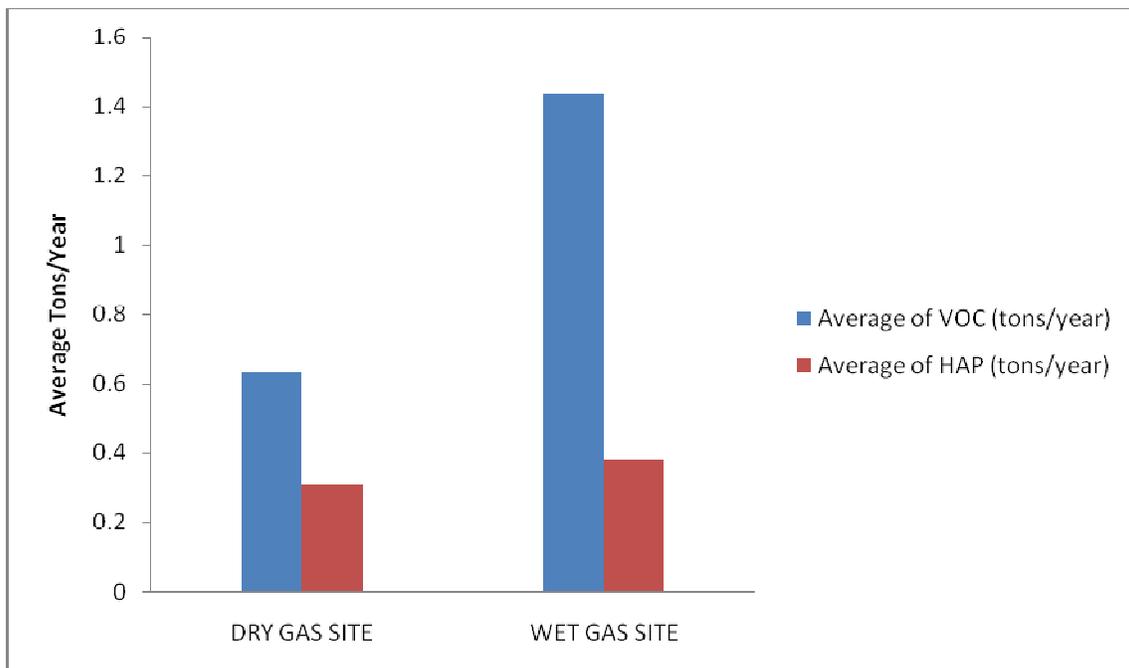

Figure 3.5-7. Average Wet Gas vs. Dry Gas VOC and HAP Emissions

At the City's request, the point source team re-visited two sites in Phase II that had been previously surveyed in Phase I. The Chesapeake site at 2299 Mercado Drive was surveyed on October 20, 2010 (Point Source ID PS -192) and again on February 15, 2011 (Point Source ID 294). The ENCANA site at 11398 West Freeway was surveyed in Phase I on September 21, 2010 (Point Source ID PS -086) and again, in Phase II on February 16, 2011 (Point Source ID 260). Table 3.5-4 summarizes the results of each survey.

Table 3.5-4. Summary of Repeat Surveys^a

| Site/Date | Temp °F ^b | # IR Detects ^c | # M21 Detects ^d | TOC (tons/yr) | VOC (tons/yr) | HAP (tons/yr) |
|---|-------------------------|------------------------------|-------------------------------|------------------|------------------|------------------|
| <i>Chesapeake - 2299 Mercado Drive (Site IDs: PS-192 and 294)</i> | | | | | | |
| 20-Oct-10 | 88 | 12 | 6 | 188 | 2.2 | 1.3 |
| 15-Feb-11 | 64 | 22 | 5 | 181 | 2.15 | 1.2 |
| <i>ENCANA - 11398 West Fwy (Site IDs: PS-086 and 260)^e</i> | | | | | | |
| 21-Sep-10 | 87 | 8 | 4 | 25.7 | 8.7 | 1.9 |
| 16-Feb-11 | 65 | 8 | 4 | 35.7 | <0.1 | <0.1 |

^a For values reported as <0.01 see Appendix 3-A for actual emissions expressed in scientific notation.

^b Ambient site temperature in degrees Fahrenheit

^c Number of emission points detected with the IR camera

^d Number of emission points detected by Method 21 screening procedures.

^e During the first site visit, one canister sample was collected from a tank emission point and the results used to estimate the site's emissions accordingly. During the second site visit, no canister was collected. Therefore, consistent with the point source test plan, a surrogate emission rate was used to estimate the site's emissions during the second visit.

Detailed site-by-site emission results are provided in Appendix 3-A.

3.5.1 Well Activity Emissions

In addition to well pads, compressor stations, a natural gas processing facility and a salt water treatment facility, three types of exploration and stimulation activities were surveyed for emissions:

- Well Drilling.
- Fracking.
- Completion.

Figure 3.5-8 summarizes the hourly emissions from these operations. Since each lasts approximately three weeks or less, emissions are presented on a pounds/hour basis rather than annual basis.

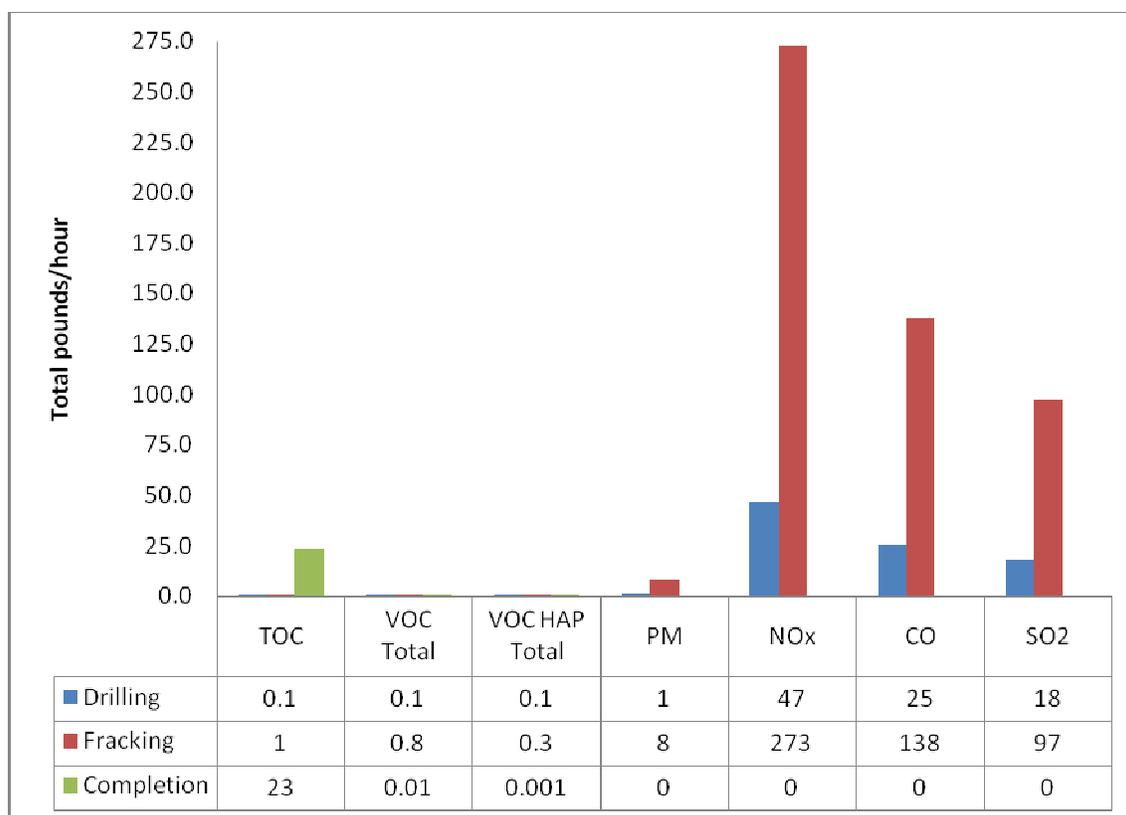

Figure 3.5-8. Well Activity Emissions (lbs/hr)

Well Drilling

A drilling site located at 580 East Rosedale and operated by XTO (Point Source ID PS-128) was surveyed on October 1, 2010. During the time of the site visit, the drilling operation was in process and operating under normal conditions. An IR camera scan was performed on all aspects of the drilling operation. No emissions from leaking components or drilling mud were detected by the camera during this survey. Estimated combustion emissions from the drilling rig engines are based on engine data obtained during the site survey. Detailed combustion emissions are provide in Appendix 3-A.

Fracking

A large fracking operation was surveyed on October 20, 2010 at 5900 Wilbarger (Point Source ID PS-193). During the time of the site visit, the fracking operation was in process and operating under normal conditions. The operation included the following equipment: 8 sand trucks, 11 diesel engine pump trucks, 8 mobile water trucks, 3 sand hoppers, 1 chemical injection flatbed trailer, and 1 chemical injection truck. Two complete IR camera scans were performed on all equipment. No emissions from leaking components or fluids handling were detected by the camera. Combustion emissions from the pump engines have been estimated and are based on engine data obtained during the site survey. Detailed combustion emissions are provide in Appendix 3-A.

Well Completion

A flowback operation was surveyed by the point source team on October 5, 2010 at 5199 Village Creek Road (Point Source ID PS-134). One emission point was detected with the IR camera and five low level emission points were identified with the TVA during Method 21 screening while the flowback operation was in progress. Detailed emissions are provide in Appendix 3-A.

3.5.2 Method 21 TOC Screening Emission Factors

Emission factors for the Method 21 screening ranges 500-999 ppmv and 1,000 to 10,000 ppmv were calculated for the equipment categories valves, connectors, and others according to the procedures explained in Section 3.4.2. Unfortunately, an insufficient number of valves and other equipment were found with emissions in the 500 – 999 ppmv category (two and four respectively) to derive reliable emission factors for this screening range. The remaining categories however were sufficiently populated to enable the derivation of the emission factors provided in Table 3.5-5 below.

Table 3.5-5. TOC Screening Emission Factors

| Concentration Range | Valves | Connectors | Other |
|---------------------|-----------------------------------|------------------------------------|-----------------------------------|
| 500 – 999 ppmv | — | 2.17E-04 kg/hr 4.78E-04 lbs/hr | — |
| 1000 – 10,000 ppmv | 1.10E-03 kg/hr 2.43E-03 lbs/hr | 4.70 E-04 kg/hr 1.04E-03 lbs/hr | 1.60E-02 kg/hr 3.52E-02 lbs/hr |

3.6 Quality Control Results

Point Source project Quality Assurance/Quality Control (QA\QC) was ensured through both field and analytical quality control procedures. Field QC procedures included:

- IR Camera Daily Demo.
- Hi Flow Sampler Daily Calibration Verification.
- TVA Daily Calibration and Drift Checks.
- Regular review of completed field data forms.
- Canister sampling protocols.
- Duplicate canister sample collection.

Analytical QC procedures included:

- Method Blanks.
- Surrogate Recoveries.
- Laboratory Control Samples and Control Sample Duplicates.
- Continuing Calibration Verification.

The results of the field QC checks are provided in the tables following. The results of the analytical QC are provided with the TestAmerica™ laboratory reports in the Appendix 3-C.

3.6.1 IR Camera Daily Demo Results

Three IR cameras were used during this project. IR cameras “GasFindIR” and “GF-320” were used continuously throughout the project. IR camera “Dexter” was used only for one day as a temporary replacement. The sensitivity of each IR camera was evaluated daily prior to testing (i.e. Daily Demo). The Daily Demo was performed at two flow rates: ~10 grams/hour propane and ~30 grams/hour propane. The maximum distance from which the two flow rates could be observed with the cameras was recorded together with current weather data. The results of the IR camera daily demos are provided in Tables 3.6-1 through 3.6-5.

3.6.2 Hi Flow Sampler Calibration Verification

Three Hi Flow Samplers were used during the project. Hi Flow Samplers #QS1002 was used in both Phase I and II. Hi Flow Sampler #QS 1005 was used in Phase I and was replaced in Phase II with Hi Flow Sampler #QX 1007. Each Hi Flow Sampler was calibrated at the start of Phase I and Phase II testing using certified gas cylinders of 2.5% and 99% methane. A calibration verification check of both background and sample sensors was performed daily prior to testing with the 2.5% methane standard. Once each week the calibration verification check of both sensors was performed with the 2.5% and the 99% methane gas standards with an acceptance criterion of +/- 10% agreement. The results of Hi Flow Sampler daily calibration verification checks are summarized in Tables 3.6-6 through 3.6-9.

3.6.3 TVA Calibration Procedures

Several TVAs were used during the point source field surveys. Each TVA was calibrated daily before testing with four certified gas standards:

- Zero Air (<0.1 total hydrocarbon content).
- Low Level Span (approximately 500 ppmv methane-in-air).
- Mid Level Span (approximately 2000 ppmv methane-in-air).
- High Level Span (approximately 10,000 ppmv methane-in-air).

Drift checks were performed during the test day using the Low Level calibration standard. Tables 3.6-10 through 3.6-15 summarize the calibration and drift check results for the project TVAs.

^c Mid Span = 1960 ppm CH₄.

^d High Span = 9860 ppm CH₄.

3.6.4 Field Data Review

Field data was reviewed each week in Phase I by the acting QAIQC Officer. In Phase II, this role was divided between the two field team leaders. Each team leader checked the other team's field data for completeness and accuracy on a daily basis. The team leaders also checked periodically for consistency in sampling procedures and data recording between the two teams.

3.6.5 Canister Sample Collection QC

A strict canister sampling protocol was followed to ensure quality sampling results:

1. All canisters were vacuum checked prior to sampling. Canisters with vacuums less than 25 inches Hg were rejected.
2. Residual vacuums of 2 to 10 inches Hg were left in canisters following sample collection.
3. Canister collection data was recorded on data forms as well as in canister logbooks (one per team).
4. Standard canister Chain-of-Custody procedures were observed.
5. Between use and prior to shipping, canisters were kept securely in the project field office.
6. Five percent of the canister samples were collected in duplicate to provide a measure of total sampling and analytical variability.
