Table S4-2 – Device classification, based on field characterization by site operator (On/OFF or throttle), time series characterization (Intermittent-vent, Continuous-vent, Intermittent-vent*, or Continuous-vent*, and EPA classification provided by the companies.

| Device Identifier | Field Characterization of Device service | Classification based on time series ¹ | Company classification into EPA categories ² |
|-------------------|--|--|---|
| AA01-PC04 | On/Off | intermittent-vent | intermittent |
| AA01-PC05 | Throttle | intermittent-vent | intermittent |
| AA01-PC06 | On/Off | intermittent-vent | intermittent |
| AA01-PC07 | Throttle | intermittent-vent | intermittent |
| AA01-PC08 | On/Off | intermittent-vent | intermittent |
| AA01-PC09 | Throttle | intermittent-vent | intermittent |
| AA01-PC11 | Throttle | intermittent-vent | intermittent |
| AA02-PC04 | On/Off | continuous-vent | intermittent |
| AA02-PC05 | On/Off | intermittent-vent | intermittent |
| AA02-PC06 | On/Off | continuous-vent * | intermittent |
| AA02-PC07 | On/Off | continuous-vent * | intermittent |
| AA02-PC08 | Throttle | continuous-vent | intermittent |
| AA02-PC09 | On/Off | continuous-vent | intermittent |
| AP01-PC01 | On/Off | intermittent-vent | intermittent |
| AP01-PC02 | On/Off | intermittent-vent | intermittent |
| AP01-PC03 | On/Off | intermittent-vent | intermittent |
| AP01-PC04 | On/Off | intermittent-vent | intermittent |
| AP01-PC05 | On/Off | intermittent-vent | intermittent |
| AP01-PC12 | On/Off | intermittent-vent * | intermittent |
| AP02-PC01 | On/Off | intermittent-vent | intermittent |
| AP02-PC02 | On/Off | intermittent-vent | intermittent |

(1) Classification based on time series: *Intermittent-vent*: Clear actuation pattern, returning to zero between actuations. *Continuous-vent*: Non-zero, no temporal variability. A (*) Indicates that the study team made classification based on best judgment due to ambiguity from the time series.

(2) *Intermittent, Low bleed or High bleed*, for sites where all devices had the same classification (non-ambiguous). *Not classified* for sites where companies reported more than one device type.

Table S4-3 – For each device, the manufacturer and model are classified into blinded bins. The table shows measured tubing diameter and tubing length (from the controller to the valve it controls), supply gas pressure, as well as gas hydrocarbon composition for the well each device is servicing.

| Device Identifier | Manufacturer and Model | Supply gas pressure (psig) | Tubing Diameter (in) | Tubing Length (in) | % of C1 in gas (%mol) ¹ | % of C2 in gas (%mol) ¹ | % of C3 in gas (%mol) ¹ | % of C4+ in gas (%mol) ¹ |

Flags:

a: Correction factor was applied to account for the condensation of an oily substance on the sensor of the measuring instrument. Post-field work testing of the Fox A supply gas meter indicated that its readings were 34% lower than the Fox C supply gas meter while the two meters were reading similarly before deployment into the field. Inter-comparisons with HiFlow® measurements indicated that the deposition on the sensor likely occurred between measurements LB06-PC05 and LB07-PC01, which occurred on subsequent days. To account for the oily deposition, all supply gas meter A measurements starting with LB07-PC01 were multiplied by 1.52 $[1/(1-0.34)]$ to correct for the oily substance.

b: Rapid peak in time series attributed to voltage surge associated with vehicle, which was the source of power for the supply gas meters used in the study, being turned on/off rather than with a pneumatic controller actuation.

c: Devices used in volume per actuation analysis for the “zero” pattern emissions.

d: Some ESDs exhibited spikes in emission rate that may not have been actual device actuations but may be related to pressure changes in the supply gas to the device

Table S4-5 –Total measurement time, number of actuations, and frequency of actuations.

| Device Identifier | Total measured time (min) | # of actuations* | frequency of actuations (#/min) |

*Note that a report of no actuations does not necessarily indicate no emissions; a continuous vent device may have emissions with no identifiable actuation

S5. Estimates of emissions from devices with no emissions detected during 15 minute sampling period

The data set includes 241 devices (64%) for which no emissions were detected over a 15 minute sampling period (136 devices) or that had flow below the instrument measurement threshold that was indistinguishable from instrument noise (105 devices). Even though no actuations were detected on these devices during the sampling period, for some of these devices, actuations and the associated emissions per actuation may have been observed if the sampling period had been extended. Not detecting emissions from infrequently actuating devices would be an issue for any finite sampling time; in this work, the approach that was taken was to sample for a 15 minute period, then to estimate potential emissions from infrequently actuating devices. Estimates of the potential emissions from infrequently actuating devices were determined by estimating actuation frequency and volume.

$$\text{Estimated emissions} = \text{actuation frequency (min}^{-1}\text{)} * \text{actuation volume (scf)}$$

It is assumed, in these estimates, that all of these devices for which emissions are estimated are intermittent vent controllers, rather than continuous vent controllers, since the measured emission rates included zero values.

The actuation frequencies and emissions per actuation were estimated based on data for controllers with well-defined actuation patterns. A well-defined actuation pattern exhibited intermittent emissions patterns, returned to a zero emissions baseline between actuations, and had two or more actuations during the 15 minute sampling period. Average actuation volumes for controllers in eight types of service are provided in Table S5-1.

Table S5-1. Counts of devices and average emissions per actuation for controllers in eight application categories; note that for ESDs, the emissions measured during the sampling were device leak rates rather than device actuations.

| Application | Devices with no emissions detected during sampling period | Devices with well-defined actuations | Average volume per actuation for “Actuating” Devices (scf) |
|---------------------------|---|--------------------------------------|--|
| Separator - Level Control | 109 | 26 | 0.349 |
| ESD | 31 | 5 | 0.026 |
| Plunger Lift | 20 | 1 | 0.048 |
| Process Heater | 40 | 1 | 0.191 |
| Other | 10 | 0 | Assumed average from all other devices (0.271) |
| Separator - Other | 9 | 2 | 0.070 |
| Compressor | 7 | 2 | 0.158 |
| Dehydration System | 15 | 1 | 0.398 |

Table S5-1 provides estimates of actuation volumes, categorized by application. Actuation frequency could be estimated using a variety of approaches. An upper bound on the emission rate could be estimated by assuming that all devices for which no emissions were observed over 15 minutes of sampling actually had actuations that occurred immediately before and

immediately after the sampling period (4 actuations per hour, a frequency of 0.067 min^{-1}). This scenario is improbable, nevertheless, it does provide an upper bound. Assuming that devices with no measured emissions actuated every 15 minutes, and had the actuation volumes, consistent with application type, reported in Table S5-1, increases the overall population average emissions by 11% (from 5.52 scf/h to 6.13 scf/h whole gas). As the assumed actuation frequency decreases, the estimated additional emissions decrease, as shown in Figure S5-1. If a 3 hour period between actuations is assumed (0.0055 min^{-1}), the study average emissions rate per device increases by less than 1%.

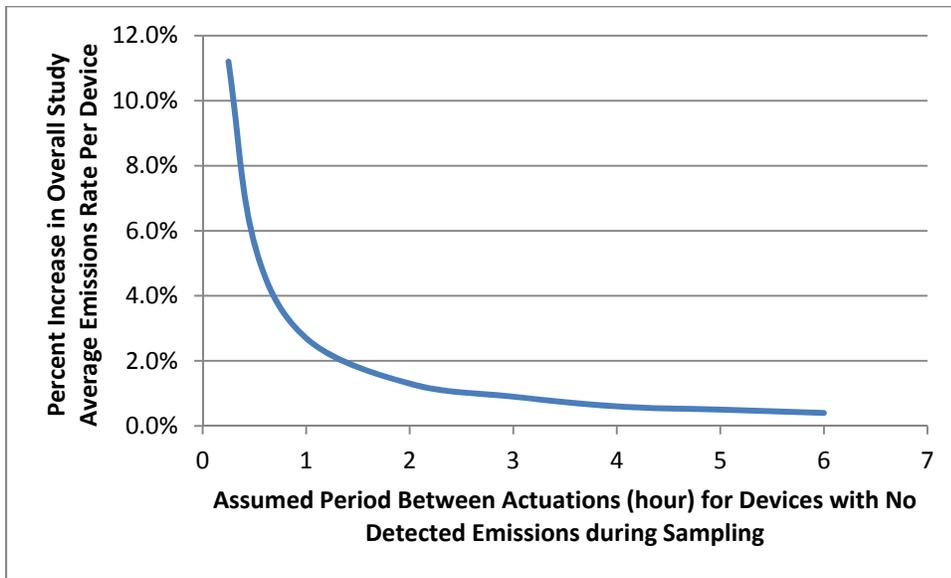

Figure S5-1. Sensitivity of study-average emissions rate per device to the assumed period between actuations.

For some application categories, specifically level control of separators, actuation frequencies, for devices with no actuations detected over 15 minutes of sampling, can be estimated based on the data from devices with observed actuations. Separator level controllers were both the largest category of pneumatic devices measured in this study (50% of total devices) and the largest category of devices with no measured emissions over a 15 minute sampling period (45%). For this category of devices, the actuation frequencies for all intermittent vent controllers with a period between actuations of less than 7.5 minutes (at least two actuations in 15 minutes of observation, 21% of the intermittent vent separator level controllers) are shown in Figure S5-2. The most conservative estimate of the range of periods between actuations for separator level controllers would be a linear extrapolation of the subset of devices with a periodicity of less than 7.5 minutes (Figure S5-2).

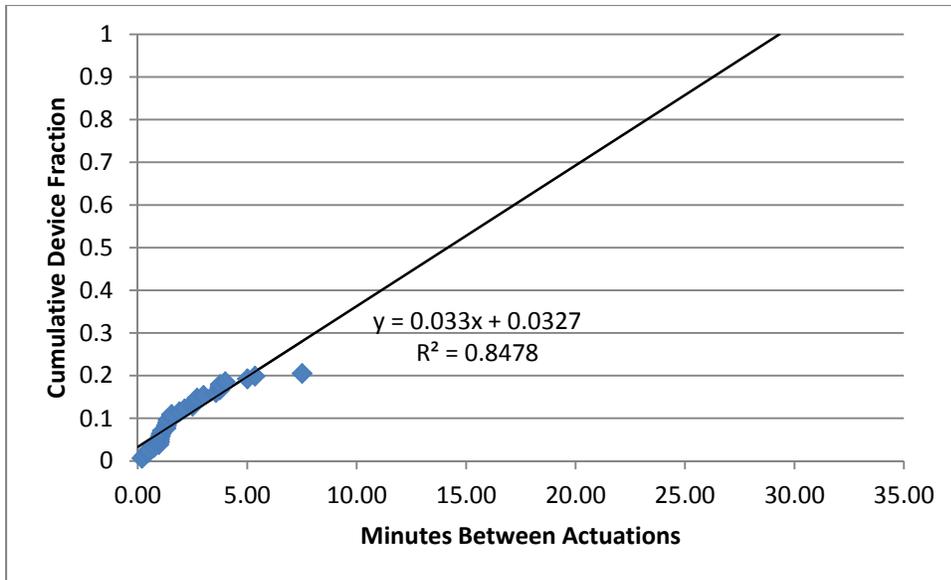

Figure S5-2. Period between actuations for separator level controllers with intermittent vent emissions patterns.

A linear extrapolation of the actuation frequency for separator level controllers with two or more actuations in the sample period to the overall population of separator level controllers indicated that all separator level controllers would undergo an actuation within 30 minutes. Assuming that the minutes between actuations for the separator level controllers for which no emissions were detected during sampling were evenly spaced between 15 minutes and 30 minutes, the increase in the overall study-average per device emissions rate for all devices in all applications would be between 5.1% (assuming that the actual emissions rate from all non-separator level controllers for which no emissions were detected during sampling were negligible) and 8.9% (assuming that all devices without detected emissions during sampling and that were not in separator level controller applications actuated every 15 minutes). This approach likely under-estimates the time between actuations for separator level controllers (over-estimates the frequency). Based on the linear extrapolation shown in Figure S5-2, 25% of devices in separator level control applications would be expected to have actuations between 7.5 minutes to 15 minutes. For devices sampled in the study, only 6% of level controllers on separators recorded a single actuation during a 15 minute sample time or had a periodicity in this range due to two actuations during a sample time longer than 15 minutes. Adjusting the slope of the linear interpolation to fit the data collected between 7.5 and 15 minutes changes the slope to 0.008 and would indicate that all devices would actuate within 121 minutes. Separator level controller emissions would be estimated to increase by 2.9% under this assumption. Under this revised linear interpolation, the estimated average emissions per device from the overall study population could increase between 2.1% and 5.9%, again depending on the frequency assumed for controllers not in separator level control service.

Overall, the study average emission rate for controllers would be expected to increase by 2%-6% if the measurement period had been extended indefinitely. This estimate is based on data for controllers in separator level control service, the most common type of service observed in the study, and a type of service that is likely to result in regular actuations.

S6. Numbers of controllers per well

In this work, a total of 65 sites were visited. The 65 sites had 377 pneumatic controllers on which measurements were performed and 53 for which either time constraints or equipment failure led to no sample being collected. The 65 sites with 430 controllers had 161 wells, for an average of 2.7 devices per well. The median value was 2.0 controllers per well with 25th and 75th percentile values of 1 and 4 controllers per well. The minimum value was 0.4 devices per well, and the maximum value was 11 devices per well. The distribution is shown in Figure S6-1. Table S6-1 provides counts of controllers and wells at individual sites.

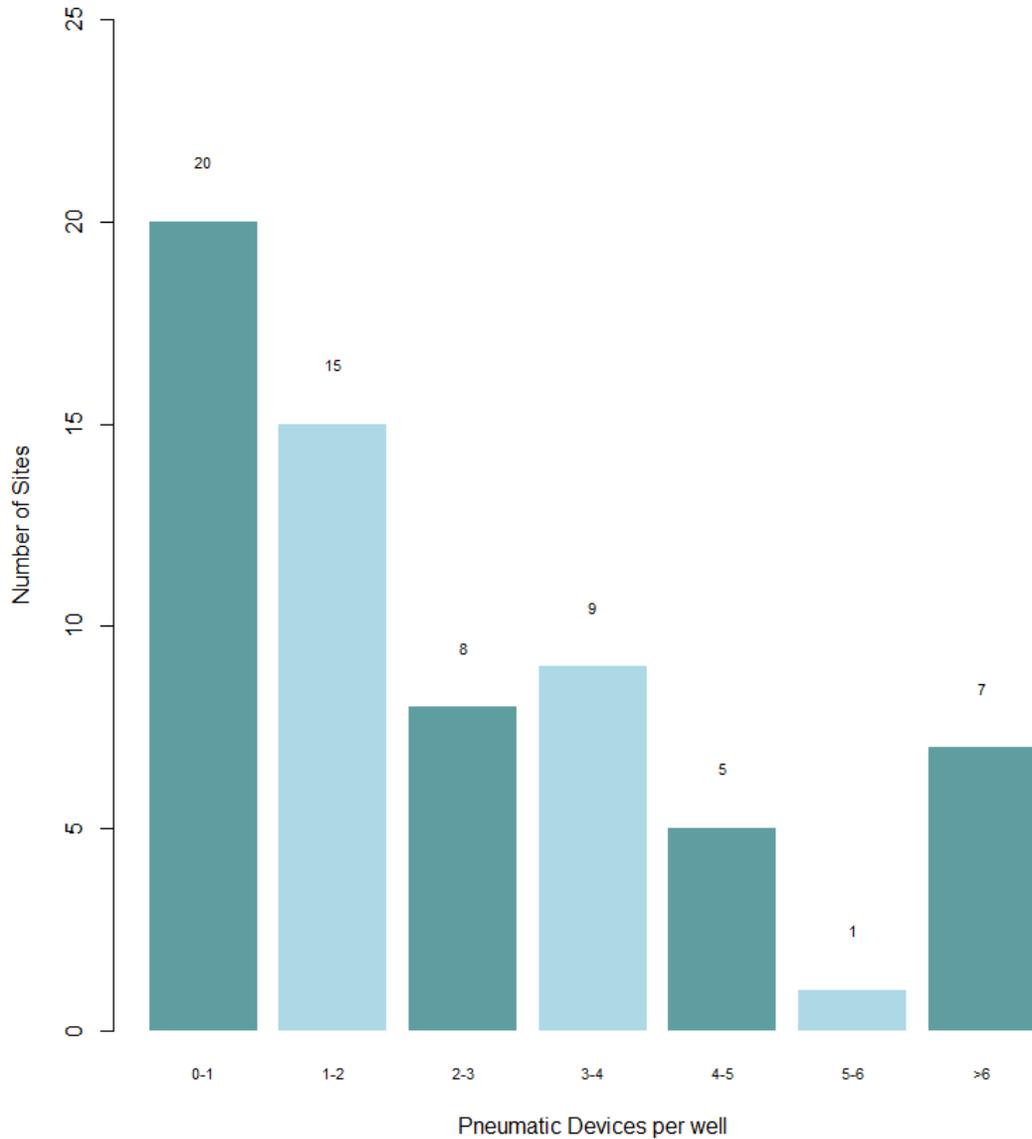

Figure S6-1. Distribution of number of pneumatic devices per well for production sites sampled by the study team.

Table S6-1 Number of pneumatic devices and wells for sites sampled in this work.

S7. Estimates of emissions from pneumatic controllers in the United States

National emissions are estimated by multiplying an average emission measurement by the number of times that emission occurs on the national scale. Emission measurements are often referred to as an “emission factor” or EF, and the data used to scale up the emissions is called the activity factor (AF). Emissions are calculated as:

$$EF_i * AF_i = ER_i \quad (\text{Equation S7-1})$$

where:

EF_i = Emission Factor for region i

AF_i = Activity Factor for region i

ER_i = resulting Emission Rate total for region i

For this work, the activity factors are national estimates of the number of pneumatic controllers. Emission factors are based on average emissions per controller measured in this work. Four combinations of activity factors and emission factors are used to calculate national emission estimates (Table S7-1); these scenarios illustrate the uncertainty in national emission estimates that arise due to uncertainties in activity factors.

Table S7-1. National emission estimates, assuming various activity factor scenarios

| Activity Factor | Emission Factor | National emission estimate |
|---|--|-----------------------------------|
| Number of controllers in EPA 2012 Greenhouse Gas National Emission Inventory, 477,606 controllers | Average emission rate for all controllers measured in this work, 4.9 scf methane/h | 394 Gg/y 20.5 bcf/y |
| Number of controllers in EPA 2012 Greenhouse Gas National Emission Inventory, 477,606 controllers | Average emission rate for controllers measured in this work, not including Emergency Shut Down controllers in the average, 5.5 scf methane/h | 442 Gg/y 23.0 bcf/y |
| Number of wells in EPA 2012 Greenhouse Gas National Emission Inventory, 470,913 wells, with 75% of the wells assumed to have 2.7 pneumatic controllers per well, as observed in this work | Average emission rate for all controllers measured in this work, 4.9 scf methane/h | 786 Gg/y 40.9 bcf/y |
| Number of wells in EPA 2012 Greenhouse Gas National Emission Inventory, 470,913 wells, with all of the wells assumed to have 2.7 pneumatic controllers per well, as observed in this work | Average emission rate for all controllers measured in this work, 4.9 scf methane/h | 1050 Gg/y 54.6 bcf/y |

The range of estimates (394-1050 Gg/y) in Table S7-1 indicates the extent of variability in national emission estimates due to uncertainties in activity data and does not include uncertainty due associated with the emission factors derived from measurements. In the absence of

additional activity data, a central estimate will be assumed to be a mid-point between the second and third scenarios, approximately 600 Gg/yr, equivalent to a scenario in which approximately 75% of wells have pneumatic (as opposed to mechanical) controllers, and approximately 75% of controllers are inventoried as having emissions. These scenarios were selected since at least some of the participants in this study have significant numbers of wells with no pneumatic controllers, and because at least some of the participants do not inventory devices, such as Emergency Shut Down controllers, that are not expected to actuate. If the central estimate and range of emission estimates are added to the emission estimates for liquid unloadings reported by Allen, et al. (2014) and other source categories reported by Allen, et al (2013), total emissions from the natural gas production sector are 2185 Gg (reported to three significant figures as 2180 Gg), as shown in Table S7-2 and Figure S7-1.

Table S7-2. National emission estimates for the Natural Gas Production sector, based on this work for pneumatic controllers, Allen, et al. (2014) for liquid unloadings and Allen, et al. (2013) for other sources

| Category | Emission Estimates Allen, et al (2014) and 2012 EPA NEI Activity Data Gg methane/yr | 2012 National Emission Inventory Estimates Gg methane/yr | Emission Estimates As reported in Allen, et al (2013) Gg methane/yr |
|--|---|--|---|
| Completion flowbacks and workovers from wells with hydraulic fracturing ¹ | 24 ¹ | 217 | 18 (5-27) ¹ (completions) 143 (workovers) |
| Chemical Pumps ² | 73 ² | 65 | 68 (35-100) ² |
| Equipment leaks ³ | 307 ³ | 191 (est. ⁴) | 291 (186-396) ³ |
| Pneumatic Controllers | 600 (394-1050) | 334 | 580 (518-826) |
| Unloadings (non plunger lift) | 80 (50-160) | 155 | 149 |
| Unloadings (plunger lift) | 190 (110-290) | 119 | 108 |
| Other Sources, not measured in Allen, et al., 2013 | 911 | 911 | 891-930 |
| TOTAL methane, Gg | 2185 | 1992 | 2300 |

¹The estimate of 18 Gg for completion flowbacks in Allen, et al. (2013) was based on 8077 well completions, with hydraulic fracturing, in 2011. If this is scaled up to the 10,664 completions and workovers (with hydraulic fracturing) reported in the 2012 NEI, the estimate becomes 24 Gg.

²The estimate of 68 Gg for pneumatic pumps in Allen, et al. (2013) was based on a pump count of 35,013 in 2011. If this is scaled up to the pump count of 37,477 reported in the 2012 NEI, the estimate becomes 73 Gg.

³The estimate of 291 Gg for equipment leaks in Allen, et al. (2013) was based on a well count of 446,745 in 2011. If this is scaled up to the well count of 470,913 reported in the 2012 NEI, the estimate becomes 307 Gg.

⁴Equipment leak emissions from the source categories measured by Allen, et al. (2013) are not all separately reported in the GHG NEI; estimate based on the mid-point of the range reported by Allen, et al. (2013).

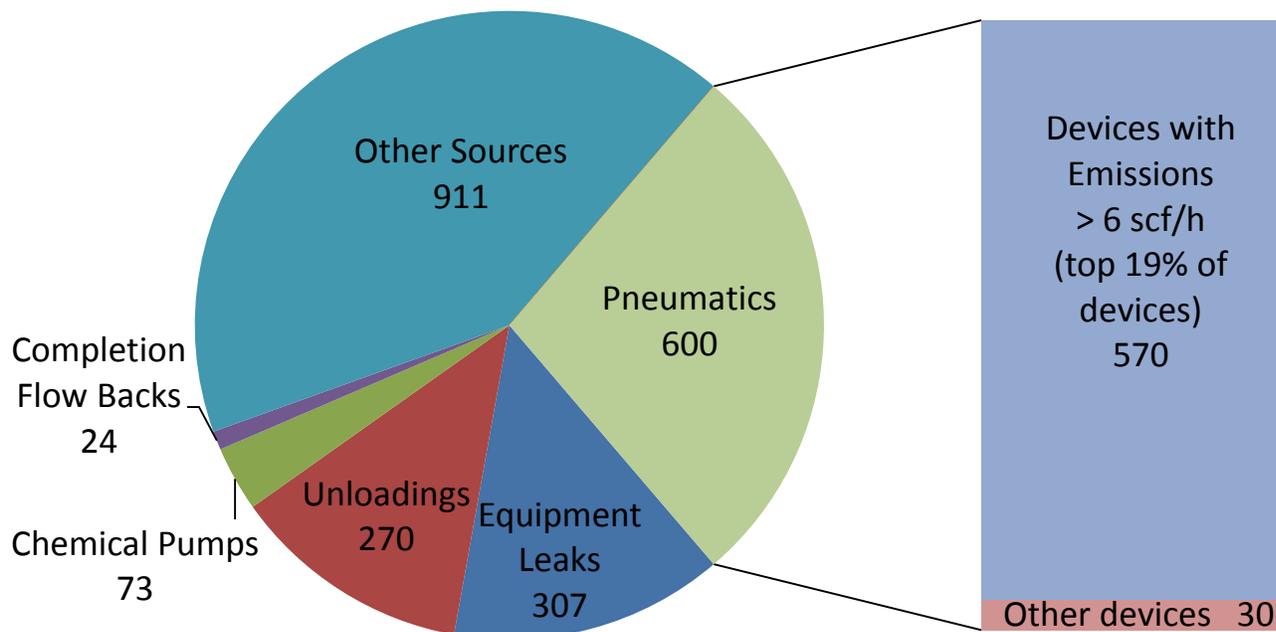

Figure S7-1. Distribution of emissions, by source category in the Natural Gas Production Sector, based on this work.

The total estimated methane emissions from natural gas production (2180 Gg/yr), based on updated estimates for pneumatic controllers and liquid unloadings, is within 10 percent of the emissions estimate in the 2012 GHG NEI (1992 Gg/yr). A larger estimate for pneumatic controller emissions than in the 2012 GHG NEI is balanced by a lower estimate for completion flowback emissions than in the 2012 GHG NEI, resulting in total emissions that are very nearly equal. This result is similar to the comparison reported by Allen, et al. (2013), where total estimated emissions of 2300 Gg/yr was within 10% of the 2011 GHG NEI (as reported in 2013) of 2545 Gg/yr. As in this work, a larger estimate for pneumatic controller emissions than in the 2011 GHG NEI was balanced by a lower estimate for completion flowback emissions than in the 2011 GHG NEI.

The methane emissions reported in Table S7-2 can also be expressed as a percentage of natural gas production. If the 2180 Gg of methane emissions is normalized by total U.S. natural gas gross withdrawals of 29.54 trillion scf (including oil and coal bed, gas, and shale, onshore and offshore) reported by the Energy Information Administration for 2012 (<http://www.eia.gov/naturalgas/>), methane emissions in the production sector are 0.38% (volume basis) of natural gas gross withdrawals. If it is assumed that the natural gas is 78.8% methane, the methane emissions are 0.48% of methane withdrawals. Allen, et al. (2013) reported these percentages as 0.42% and 0.53% based on 2300 Gg of methane emissions and 2011 natural gas gross withdrawals of 28.5 trillion scf. The differences in percentages between this work and

Allen, et al. (2013) are due to both increased withdrawals and decreased emission estimates in the GHG NEI for source categories not measured in this work.

S8. Summary of data on 40 highest emitting devices

Controller characteristics and time series for measured emissions are reported for the 40 devices with the highest measured emission rates. This information was reviewed by technical experts on pneumatic controller operation to assess whether controllers were operating properly. While these 40 controllers were not removed from operation and subjected to a rigorous performance analysis, the data that were collected may reveal some features of operation. For example, if a device had very high rates of nearly continuous emissions, larger than would be expected for the device design and supply gas pressure, it could be hypothesized that the controller/control valve system had a leak. If a device with intermittent actuation emissions, which appeared to be an intermittent vent controller, did not return to zero flow between actuations, it could be hypothesized that the barrier between the supply gas and the controller was not closing completely. It is important to recognize that these are hypotheses, based on expert opinion. The controllers are categorized, based on these hypotheses, as having “equipment issues” or “operating as expected”.

Supporting Information

ABSTRACT: Emissions from 377 gas actuated (pneumatic) controllers were measured at natural gas production sites and a small number of oil production sites, throughout the United States. A small subset of the devices (19%), with whole gas emission rates in excess of 6 standard cubic feet per hour (scf/h), accounted for 95% of emissions. More than half of the controllers recorded emissions of 0.001 scf/h or less during 15 min of measurement. Pneumatic controllers in level control applications on separators and in compressor applications had higher emission rates than controllers in other types of applications. Regional differences in emissions were observed, with the lowest emissions measured in the Rocky Mountains and the highest emissions in the Gulf Coast. Average methane emissions per controller reported in this work are 17% higher than the average emissions per controller in the 2012 EPA greenhouse gas national emission inventory (2012 GHG NEI, released in 2014); the average of 2.7 controllers per well observed in this work is higher than the 1.0 controllers per well reported in the 2012 GHG NEI.

INTRODUCTION

Natural gas production in the United States is increasing; the U.S. Energy Information Administration projects that by 2040, total natural gas production in the United States will increase by 40%.¹ With increased production, natural gas is displacing other fuels,² and this fuel switching has implications for greenhouse gas emissions.

Natural gas may have a lower greenhouse gas footprint than other, more carbon intensive, fossil fuels (coal and petroleum), since the carbon dioxide emissions associated with natural gas combustion are less than those associated with the combustion of coal and petroleum. For example, for identical heat releases on combustion, natural gas generates less than half of the carbon dioxide emissions of a typical coal.³ The greenhouse gas benefits of natural gas relative to other fossil fuels may be eroded, however, by natural gas leaks in the supply chain. Methane, the principal component of natural gas, is a potent, but short-lived greenhouse gas. Because one kg of methane emissions is equivalent to between 28 and 120 kg of CO₂ emissions, depending on the time scale over which impacts are

assessed (100-year to immediate time horizons),^{4,5} methane emissions in the natural gas supply chain amounting to more than a few percent of natural gas use can change the greenhouse gas footprint of natural gas, relative to other fossil fuels.^{5–9} Thus, to characterize the greenhouse gas footprint of natural gas, it is important to determine the magnitude of methane emissions in the natural gas supply chain.¹⁰

Methane emissions in the natural gas supply chain have been estimated using two basic approaches, commonly referred to as top-down and bottom-up approaches. Top-down approaches for estimating methane emissions from the natural gas supply chain involve measuring ambient concentrations of methane near emission sources. These concentrations can be measured using fixed ground monitors,^{11,12} mobile and vehicle mounted ground monitors,^{13,14} aircraft based instruments^{15–17} or

satellite instruments.¹⁸ Brandt et al.¹⁹ and Miller et al.²⁰ have summarized recent top-down estimates of methane emissions and conclude that top-down emission estimates are generally higher than current bottom-up inventories of methane emissions, and some of this difference may be due to methane emissions from the natural gas supply chain. However, these analyses do not reveal which of the many potential sources of methane emissions along the natural gas supply chain might be incorrectly estimated.

Complementing top-down measurements, bottom-up measurements of methane emissions are made directly at the emission sources. In this approach, emission measurements are made at a representative sample of sources; the measurements from the sample population are then extrapolated to larger regional or national populations. The advantage of “bottom-up” approaches is that they can gather much more detail about the emission sources, and therefore can identify which source categories, among many, are responsible for emissions. For example, Allen, et al.²¹ concluded that emissions from well completion flowbacks are overestimated, while emissions from pneumatic controllers may be underestimated, in current inventories of emissions. Both top-down and bottom-up approaches can contribute to an improved understanding of methane emissions from the natural gas supply chain. The work reported here uses bottom-up measurements to improve understanding of emissions from pneumatic controllers on natural gas production sites.

Pneumatic controllers use gas pressure to control the operation of mechanical devices, such as valves. The valves, in turn, control process conditions such as levels, temperatures, and pressures. When a pneumatic controller identifies the need to change liquid level, pressure, temperature or flow, it will open or close a control valve in order to return to a desired set point. The opening and closing of the valve can occur either through discrete (on/off) changes, or through changes that are proportional in magnitude to the deviation from the set point (throttling). Controllers can deliver this type of service (on/off and throttling) through either continuously venting or intermittent venting of gas. Thus, controllers can be grouped into four categories, depending on the type of service (on/off or throttling) and the type of venting (continuous or intermittent). In estimating emissions, the U.S. EPA uses the categories of low continuous bleed (<6 scf/h of gas vented), high continuous bleed (>6 standard cubic feet per hour (scf/h) of gas vented) and intermittent controllers.²² Finally, controllers can also be categorized based on equipment manufacturer, model number, and the type of application (e.g., separator level control) in which they are used. In this work, the primary categorization of controllers will be as either continuous vent or intermittent vent based on the pattern observed during measurement; data on applications, service

types, and EPA categorization for the controllers sampled in this work are provided in Supporting Information (SI).

The U.S. EPA²² reports 477 606 pneumatic controllers are in use at natural gas production sites in the United States. These controllers are estimated to emit 334 Gg/yr of methane (17.4 billion cubic feet (bcf) methane), for an average of 0.7 Mg device⁻¹ yr⁻¹ or 4.2 scf/h methane device⁻¹. These estimated emissions from pneumatic controllers have been based on relatively limited measurements;²³ recent field measurements have suggested that these emissions may be understated.

Allen et al.²¹ made measurements of emissions from 305 pneumatic controllers on well sites in the United States where the wells had been hydraulically fractured. Average emissions were 10.5 scf/h of methane, approximately double the average emission rate per device in the current EPA national emission inventory. Measurements of emissions from 581 pneumatic controllers, made in British Columbia and Alberta, averaged 9.2 scf/h of whole gas,²⁴ an emission rate similar to that reported by Allen et al.²¹ In both of these studies, emissions from controllers exhibited wide ranges. In both sets of measurements, a small subset of controllers accounted for most of the emissions.

While the measurements at hydraulically fractured gas wells in the United States²¹ and the measurements in British Columbia and Alberta²⁴ recorded emissions higher than the average emissions per device in the EPA national emission inventory, the sampled populations for these two sets of measurements were not necessarily broadly representative of U.S. national populations of pneumatic controllers. The measurements reported by Allen et al.²¹ were made exclusively in shale gas production regions, and at sites where the wells had been hydraulically fractured. Many of the sites were recently completed wells, which initially tend to have higher liquid production rates, and therefore may have more frequent actuation of certain types of pneumatic devices than the average for the entire population of gas wells in the United States, leading to potentially higher emissions. The Canadian measurements²⁴ were made exclusively in one production region and on devices with manufacturer specified emission rates in excess of 4.2 scf/h.

The goals of the work presented here were (i) to measure emissions from pneumatic controllers at a wider population of wells, geographically distributed across the United States, including conventional gas wells, shale gas wells and a limited number of oil wells, and (ii) to characterize the features of the controllers with high emissions, which previous work^{21,24} has found to be the major contributor to emissions.

■ MATERIALS AND METHODS

Sampled Population. A total of 377 pneumatic controllers were sampled at 65 sites (some with multiple wells) throughout the United States (an average of 5.8 pneumatic controllers per

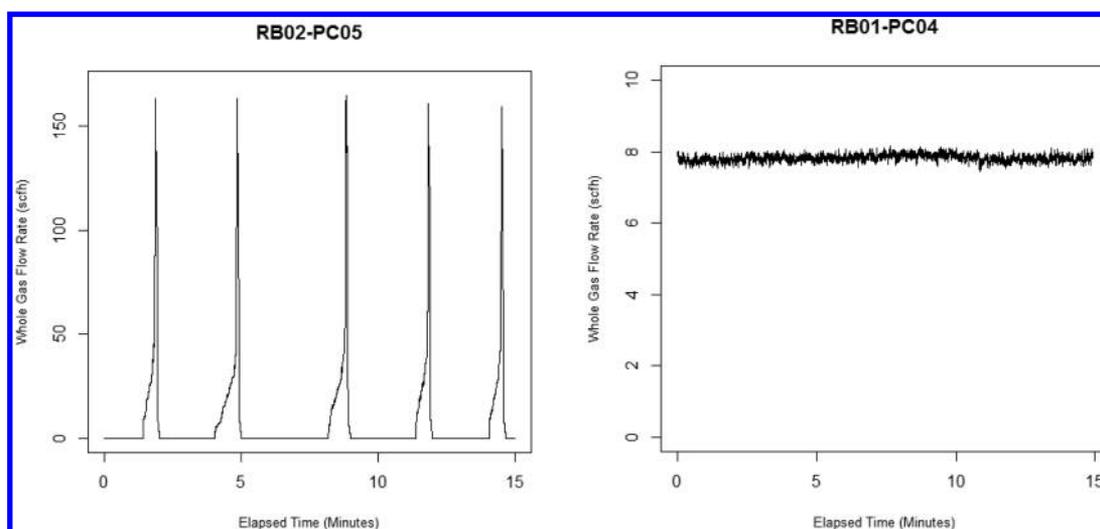

Figure 1. Representative time series for supply gas measurements for intermittent vent (left) and continuous vent (right) controllers; the intermittent vent controller (RB02-PC05) had a total of five actuations during the sampling period and an average emission rate, over the 15 min period of 7.9 scf/h; the continuous vent controller (RB01-PC04) had nearly constant emissions of 8.0 scf/h.

site, 2.7 controllers per well). Measurements were made primarily at natural gas production sites (351 of 377 controllers), and at a limited number of oil sites (26 controllers). Because the definitions of oil and gas wells vary, largely depending on gas to oil production ratios, the data will be treated as a single set. Sampling sites were selected from well sites owned by companies participating in the study using a process designed to yield a random sampling of participant sites (see SI, Section S1). For each well site that was visited, all controllers on the site were sampled using supply gas meters, unless operating conditions, safety issues or other factors prevented sampling. A total of 333 controllers had measurements made using the supply gas meters; 97 controllers could not be measured using the supply gas meter; of the 97 that were not sampled with the supply gas meter, 44 were sampled using exhaust gas measurements, leading to a total of 377 controllers in the sampled population. The applications that the controllers were used in (e.g., separator level control, compressor pressure control) are shown in Table 1. Details of the regions, device types, associated well types, operating methods and other characteristics of each of the 377 controllers sampled in this work are provided in SI, Section S4.

Emission Measurement Methods. Emissions from pneumatic controllers can be determined either by measuring the supply of gas entering the controller or by measuring the gas discharged from the controller. Both approaches were used in this work, and since there is no accumulation of gas in the controller, both measurement approaches should lead to equivalent measurements, if there are no leaks in the equipment downstream of the controller.

Measurements of the gas entering the controller were made by one of three Fox flow meters (model #FT2A); flow meters were inserted into the supply gas line for the controller. This supply gas measurement was the primary measurement method used in this work, and was used to measure emission rates on 333 of the 377 controllers in the sample population (the remainder were sampled by measuring gas emitted by the controller using a HiFlow Sampler described later in this section, see SI for comparisons between the supply gas and exhaust gas measurements). The flow meters reported flows at a sampling frequency of 10 Hz. Two of the Fox model #FT2A

instruments (labeled A and C in this study) had a range of operation of 0–300 scf/h, with a precision of $\pm 1\%$ of flow, and the third Fox model #FT2A (labeled B in this study) had a range of operation of 0–1200 scf/h, with a precision of $\pm 1\%$ of flow. The Fox model #FT2A instruments A and C were used whenever possible because of their greater absolute precision, however, if any instantaneous reading on the A or C Fox model #FT2A was greater than 300 scf/h, the measurement on the pneumatic device was repeated with the B meter to ensure that high leak rates were measured accurately. This happened only once during the measurement campaign, and for this single controller, the flow exceeded 300 scf/h only during a few seconds when the flow from an actuation was peaking (average whole gas flow rate over 15 min of sampling was 3.06 scf/h, a value lower than the average emissions per controller in the sampled population). A repeat test with the B instrument did not detect any actuations.

For each controller measurement using the supply gas flow meter, a site operator depressurized and disconnected the controller supply gas line; the flow meter was inserted and the system was reconnected, repressurized, and allowed to stabilize for several minutes before measurements began. Once the system had stabilized, measurements were made for approximately 15 min. Longer sampling times may have allowed a more complete measurement of emission rates from devices with relatively fewer controller actuations, but would have limited the number of controllers that could be sampled. Figure 1 shows representative 15 min emission time series for pneumatic controllers measured using the supply gas measurement.

All three Fox flow meters were calibrated by the instrument manufacturer and in laboratory testing, using methane. The instruments measure flow based on a thermal conductivity measurement. In this work, since gas composition information was available for each site where measurements were made, site specific correction factors were employed to estimate methane and whole gas emission rates. The method is described in SI Section S2. Results in this work are reported as both methane and whole gas emission rates, based on site specific gas composition data.

For some pneumatic controllers, it was not possible or safe to disrupt the supply gas to insert the supply gas flow meter, so exhaust gas measurements were used as the primary measurement on that subset of devices. Exhaust gas flow rate was measured using a Hi Flow instrument similar to that described by Allen et al.²¹ Briefly, the Hi Flow Sampler is a portable, intrinsically safe, battery-powered instrument that has been used for several decades in measuring emissions of methane in the natural gas supply chain.^{25–27} An emission source is enclosed, using attachments that come with the instrument; leak rate is measured by drawing air from the enclosure, through the sampler, at a high flow rate (up to 8–10 cfm) to capture all the gas emitted by the component, along with a certain amount of entrained surrounding air. By accurately measuring the flow rate of the sampled stream and the background corrected natural gas concentration within the sampled stream, the gas leak rate is calculated. Methane is measured, at concentrations less than approximately 5%, by a catalytic oxidizer unit coupled with a thermal conductivity detector. At methane concentrations greater than approximately 5%, concentrations are measured directly using a thermal conductivity detector. The instrument was calibrated using pure methane and a mixture containing 2.5% methane. The instrument reading based on the methane calibration was corrected for gas composition using site specific gas composition data and laboratory data, as described in SI Section S2. The commercial Hi Flow instrument is designed primarily to measure methane leaks that have a relatively steady flow and flow rates are not normally automatically recorded at high frequency. For this work, the instrument software was modified by the manufacturer to output data every 2–3 s. A 0.3–0.5 Hz reporting frequency was selected based on residence times expected in the leak enclosures at the maximum flow rate of the Hi Flow device (at a 10 cubic feet per minute sample flow, gas in a 1 ft³ sample enclosure has a residence time of 6 s). As with the in-line supply gas measurement, Hi Flow data were collected for approximately 15 min for each controller. A time series from the Hi Flow device, along with a parallel measurement made using a supply gas meter, is shown in Figure 2. The Hi Flow device, because it entrains ambient air in a long sample loop, dampens some of the peak rate. Therefore, the Hi Flow is not able to resolve high frequency actuations as well as the in-line supply measurement. For 24 controller measurements, both supply gas and Hi Flow measurements were made to compare the two measurement methods (for these controllers, the supply gas flow was treated as the primary measurement). The detailed results are provided in SI Section S3. To summarize, 11 of the 24 simultaneous measurements had emissions of less than 0.005 scfh (46%), as recorded by the in-line supply gas meter (the primary measurement device). For five devices which had an average emission rate greater than 6 scfh (measured by the supply gas meter) the supply gas meter to Hi Flow measurement ratio was between 0.7 and 1.1.

RESULTS AND DISCUSSION

Methane emissions from 377 controllers were measured in this work and details of each of the individual measurements are available in SI Section S4. A relatively small subset of devices accounts for a majority of the emissions. At the high end of the emission rate distribution, 20 percent of devices accounted for 96% of whole gas and methane emissions. The 19% of devices that had emissions in excess of 6 standard cubic feet whole gas

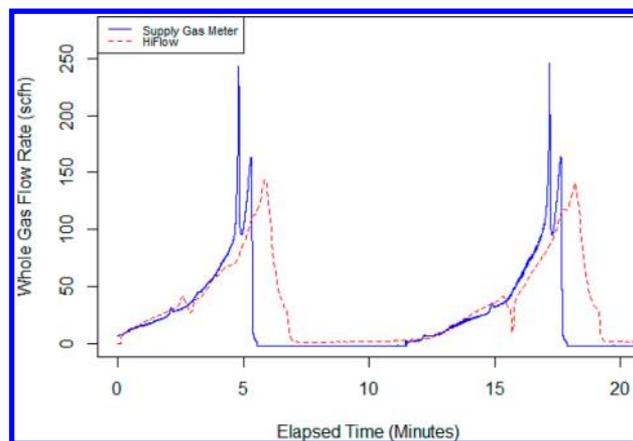

Figure 2. Comparison of supply gas meter (blue line) and Hi Flow measurements (red line) for device LB07-PC04, which was a water level control on a separator. The average emission rate measured by the supply gas meter was 27.0 scf/h as compared to 33.9 scf/h measured by the Hi Flow. Note that the time lag, longer period of emission detection, and the reduced maximum flow rate associated with the Hi Flow measurement is expected because of the dilution that occurs with ambient air in the exhaust enclosure and the flow through the instrument.

per hour (scf/h) accounted for 95% of all whole gas and methane emissions. At the low emission rate end of the distribution, more than half (51%) of the controllers had an emissions rate less than 0.001 scf/h over the 15 min sampling period; 62% had an emissions rate less than 0.01 scf/h over the 15 min sampling period.

The average emission rate for the 377 devices is 5.5 scf/h of whole gas (4.9 scf/h of methane), however, this average emission may be influenced by the estimated emission rates for devices that had no emissions over the 15 min sampling period. If the devices with no emissions detected over 15 min are assigned the lowest emission rate detected (0.001–0.01 scf/h), there is no change in the average emission rate. However, using this minimum detection limit approach may underestimate potential emissions for devices that had little to no detectable emissions over 15 min. Some of these devices may have relatively infrequent actuations that were not sampled. In principle, any device actuating less than four times per hour may not have been detected over a 15 min sampling period. To estimate the emissions from devices with no emissions detected over a 15 min sampling period, the average emission per actuation was calculated for controllers in each application. The average emissions per actuation were multiplied by an estimated frequency of actuation. For example, for separator level controllers, the average volume per actuation was estimated by averaging observed volumes per actuation for separator level controllers; the average frequency of actuation for devices, for which no actuations were observed, was estimated by extrapolating observed actuation frequency data for controllers in separator level control service. A variety of assumptions can be made in extrapolating actuation frequencies. Details of a variety of approaches are available in SI Section S5. Using a variety of approaches, the estimated average emissions associated with devices with no emissions recorded over a 15 min sampling increases the population average emissions by 2–11%. Because this increase is relatively small, for clarity, all of the data reported in this work are based on

Table 2. Whole Gas Emissions from Controllers (scf/h), Categorized by Region and Application^a

^aNumbers of devices sampled in each category are reported in Table 1.

actual measurements, not including additions to the emissions for devices with low (0.001–0.01 scf/h) observed emissions.

To estimate an uncertainty bound on the overall average, a bootstrapping process was used.²⁸ In the bootstrapping procedure, the original data set of 377 devices was recreated by making 377 random device selections, with replacement, from the data set. A total of 1000 of these resampled data sets were created and the mean value of the emissions for each resampled data set was determined. The 95% confidence interval for the average whole gas emission estimate of 5.5 scf/h is 4.0–7.2 scf/h, where the bounds represent the 2.5% and 97.5% percentiles of the means in the 1000 resampled data sets. Similarly, the 95% confidence interval for the average methane emissions estimate of 4.9 scf/h is 3.6–6.5 scf/h.

The measurements showed significant variations among regions, the controller application, and whether the device was continuous vent or intermittent vent. Table 2 summarizes the distribution of emission rates among controllers in various applications, and shows the regional distribution of controller emissions. Measurements made on pneumatics in service on compressors had average emission rates of 14.0 scf/h (12.4 scf/h methane), compared to an average whole gas emission rate of 5.5 scf/h (4.9 scf/h methane) for all devices. Devices in use for level control on separators averaged 8.1 scf whole gas/h (7.1 scf methane/h). Overall, 76% of devices measured with whole gas emission rates greater than 6 scf/h were in service on compressors or as level controllers on separators. Emission rates for continuous vent controllers (57 devices, average emissions of 24.1 scf/h whole gas, 21.8 scf/h methane) were higher than for intermittent vent devices (2.2 scf/h whole gas, 1.9 scf/h methane).

In addition to varying by application and controller type (continuous vent or intermittent vent), emissions also varied by region. Emissions were highest in the Gulf Coast and Mid-Continent regions and were lowest in the Rocky Mountain and Appalachian regions (see SI, Section S4, for geographical boundaries of regions). Controllers on compressors, with high average emissions, were only observed on sampling sites in the Gulf Coast and Mid-Continent regions, so some of the regional differences can be attributed to the presence of compressors. As shown in Table 2, however, if average emissions by region are recalculated without including controllers associated with compressors, the Gulf Coast and Mid-Continent regions still had average emissions greater than those observed in the Rocky Mountain and Appalachian regions.

Another factor that may account for regional differences in emission rates is frequency of actuation. For example, controllers on separators in the Gulf Coast could actuate more frequently due to higher liquid production rates, which could explain higher emission rates in that region. However, the frequencies of actuation for the devices in Gulf Coast were similar to those in most other regions, indicating a larger

emission per actuation for the devices in the Gulf Coast, rather than more frequent actuation. In contrast, the Appalachians showed a considerably higher frequency of actuations and a smaller emission rate, indicating a smaller emission per actuation for those devices (Table 3). Thus, regional differences

Table 3. Frequency of Actuations and Emissions from Intermittent Vent Controllers Where Actuations Were Observed, Categorized by Region

| region | count of devices | frequency of actuations (#/min) | avg. emission rate (scf/h) |
|--------|------------------|---------------------------------|----------------------------|
| AP | 8 | 2.42 | 4.85 |
| GC | 30 | 0.37 | 20.5 |
| MC | 17 | 0.93 | 5.05 |
| RM | 25 | 0.43 | 1.72 |
| total | 80 | average: 0.73 | average: 9.76 |

in pneumatic controller emission rates cannot be completely explained by frequency of actuation of controllers, or by controllers associated with compressors and separator level control (Table 2); much of the difference may be due to differences in controller type (continuous vent vs intermittent vent) among regions. Continuous vent devices, with average whole gas emissions of 24.1 scf/h, were 21% of the controllers in the Gulf Coast and Mid-Continent regions, but only 9% in the Appalachian and Rocky Mountain regions.

This data set of emissions from pneumatic devices has elements that are similar to and different from the previous data sets reported for the United States,²¹ and for British Columbia and Alberta.²⁴ The primary similarity is that all three data sets indicate that a small population of devices dominates total emissions. In this work, 19% of devices with emissions greater than 6 scf/h of whole gas account for 95% of the whole gas and methane emissions. In the previous measurements reported by Allen et al.,²¹ 20% of devices account for 80% of the whole gas emissions and 41% of devices with emissions greater than 6 scf/h of whole gas, account for 90% of the whole gas emissions (88% of the methane emissions). In the measurements for British Columbia and Alberta²⁴ (referred to here as the British Columbia data), which were restricted to pneumatic devices with manufacturer reported bleed rates greater than 4.2 scf/h, 44% of devices with emissions greater than 6 scf/h accounted for 91% of emissions. Both the British Columbia data and the measurements reported in this work had large numbers of devices for which no emissions were detected during the sampling period. For the British Columbia data (again, focused on devices with manufacturer reported bleed rates in excess of 4.2 cfh), 31% of measurements had no detectable emissions over a 30 min sampling period; in this work 62% of devices had emissions less than 0.01 scf/h over the 15 min sampling period.

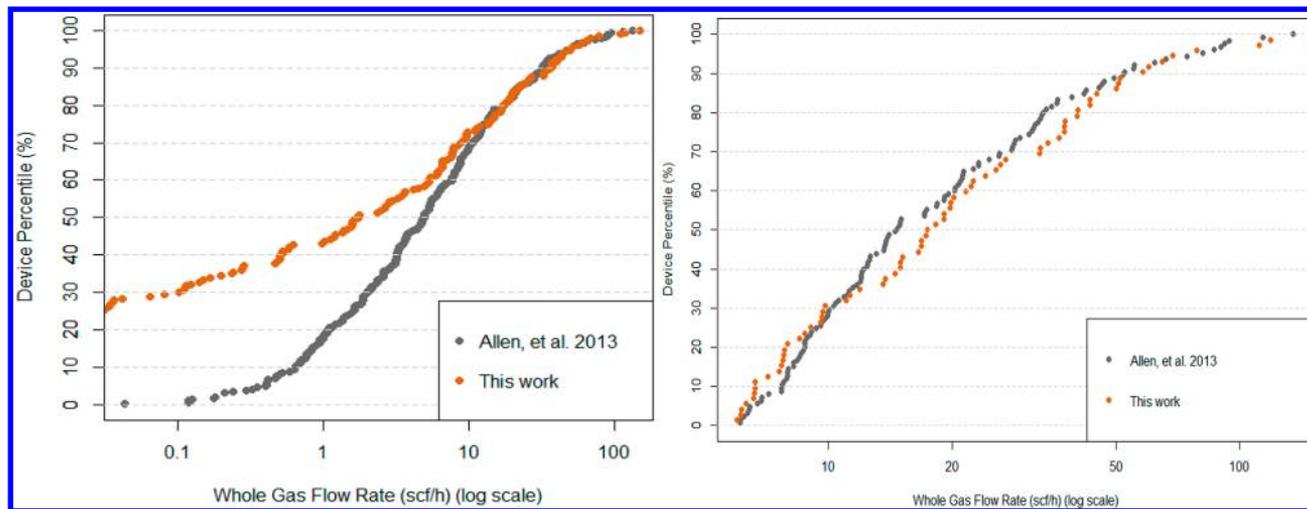

Figure 3. Distributions of emissions for subsets of controllers (38% of devices measured in this work) venting greater than 0.01 scf/h (left) and subsets of controllers venting greater than 6 scf/h of whole gas (right) as reported in this work (the 19% of devices that account for 95% of emissions) and Allen et al.²¹

The overall average emission rates reported in this work are lower than the previous data sets reported by Allen et al.²¹ for the United States, and for British Columbia and Alberta.²⁴ For the British Columbia data this can be attributed to the sampling design for that data set, which selected devices with manufacturer reported bleed rates in excess of 4.2 scf/h. These controller types tend to be found in particular applications. When the emissions from the British Columbia data set are compared to the emissions reported in this work, for devices in similar applications, the results are in reasonable agreement. For example, for the separator controllers that were the most frequent application observed in this work, the British Columbia data report an average emissions rate of approximately 7.8 scf/h (level control) while the average for this work was 8.1 scf/h (separator application).

The lower average emission rates reported in this work, compared to those reported by Allen et al.²¹ is primarily due to the number of controllers with no emissions detected over the sampling period. Figure 3 compares emission rates for controllers sampled in this work, with emissions rates reported by Allen et al.²¹ The results show reasonable agreement between the two studies for controllers with emissions above 6 scf/h. These controllers accounted for 95% of the emissions in this work and 90% of the emissions in the sample reported by Allen et al. (2013).

The primary reason for the differences in the average emission rates reported in this work and in Allen et al.²¹ is the higher percentage of low emission devices (<0.01 scf/h) observed in this work. This could be due to multiple factors. In this work, all controllers on-site were sampled, regardless of whether they would be reported through emission inventories. For example, emergency shut-down (ESD) controllers represented 12% of the sampled population in this work. These controllers do not have planned actuations, so they would not have been sampled in the work of Allen et al.,²¹ and they may or may not be included in controller counts in national emission inventories. In addition, in the work of Allen et al.²¹ about 40% of the inventoried controllers on sites were sampled; while these were intended to be selected randomly from inventoried controllers, there may have been an

unintentional bias toward devices that were observed, with an infrared camera, to have emissions.

Implications for National Emission Estimates. As shown in Table 4, if regional average emission rates determined

Table 4. National Emission Estimates, Based on Regional Device Counts for Pneumatic Controllers and Regional Average Emissions Measured in This Work

| region | count of devices | avg. emission rate whole gas(scfh) | avg. emission rate methane (scfh) | regional emissions (Gg/yr) |
|-----------------|------------------|------------------------------------|-----------------------------------|----------------------------|
| AP | 77 261 | 1.70 | 1.65 | 21.5 |
| GC | 53 436 | 11.80 | 10.61 | 95.4 |
| MC ^a | 222 684 | 5.80 | 4.87 | 182.5 |
| RM ^b | 124 225 | 0.75 | 0.67 | 14.0 |
| total | 477 606 | | | 313.4 |

^aMC totals include equipment counts for Mid-Continent and Southwest regions reported in the 2012 EPA GHG NEI. ^bRM totals include equipment counts for Rocky Mountain and West Coast regions reported in the 2012 EPA GHG NEI.

in this work are multiplied by regional controller counts reported in the 2012 EPA national greenhouse gas emission inventory (2012 GHG NEI, released in 2014), the national methane emission estimate for pneumatic controllers in natural gas service is 313 Gg/yr (within 10% of the 2012 GHG NEI estimate of 334 Gg). If the national average of the emission rates measured in this work (5.5 scf/h of whole gas, or 4.9 scf/h of methane) is multiplied by the total national equipment count in the 2012 GHG NEI (477 606 controllers) the national methane emission estimate is 394 Gg/yr, 17% higher than the 2012 GHG NEI estimate of 334 Gg. Adding an additional 2–11% to the estimated emission totals to account for potential emissions from controllers that had less than 0.01 scf/h of emissions over 15 min, would only slightly change these comparisons with the 2012 GHG NEI. This estimate may represent a lower bound on national emissions, however, since the average emissions per controller observed in this work includes some low- or nonemitting devices, such as ESD controllers, that may not be included in the count of national controllers. If the average emissions per controller from this

work were recalculated with ESD controllers excluded, the average emissions would increase by approximately 15% (see SI, Section S7).

The inclusion or exclusion of ESD controllers in national pneumatic controller counts is just one part of the uncertainty associated with the total count of controllers. The average number of controllers per well observed in this work (2.7 controllers per well) was higher than the average number of controllers per well (1.0 controllers per well) reported in the 2012 GHG NEI, potentially indicating an under-count of controllers in the GHG NEI. Some of the difference between the controllers per well observed in this work and the average pneumatic controllers per well in the GHG NEI is due to wells that use mechanical or other nonpneumatic controllers; as an example of how an alternative controller count could influence national emission estimates, if 75% of wells in the United States have an average of 2.7 pneumatic controllers per well (the remainder having nonpneumatic controllers), and if 75% of the controllers on well sites are inventoried as having emissions, the total count of pneumatic controllers would double the level in the current inventory, roughly doubling emissions to 600 Gg (see SI). It was beyond the scope of this work to develop new national pneumatic controller counts, but the data reported here indicate that this is a topic that merits attention.

Characteristics of High Emitting Devices. Because average emissions are strongly influenced by the highest emitting devices, the characteristics of the 40 controllers with highest emissions rates were examined in detail by experts in pneumatic device operation. These characterizations included the service type, region of use, device type, the numbers of actuations and other temporal features of the emission time series. Based on these analyses, many of the devices in the high emitting group were behaving in a manner inconsistent with the manufacturer's design. For example, some devices not designed to bleed continuously had continuous emissions. This could be the result of a defect in the system, such as a crack or hole in the end-device's (control valve's) diaphragm actuator, or a defect in the controller itself, such as fouling or wear. No additional troubleshooting analysis was performed on these high emitters, so the actual root causes are not known with certainty. The results, however, do indicate that some of the high emissions were caused by repairable issues. Details are provided in the SI (Section S8).

Notes

The authors declare the following competing financial interest(s): Lead author David Allen serves as chair of the Environmental Protection Agency's Science Advisory Board, and in this role is a paid Special Governmental Employee. He is also a journal editor for the American Chemical Society and has served as a consultant for multiple companies, including

Eastern Research Group, ExxonMobil, and Research Triangle Institute. He has worked on other research projects funded by a variety of governmental, nonprofit and private sector sources including the National Science Foundation, the Environmental Protection Agency, the Texas Commission on Environmental Quality, the American Petroleum Institute and an air monitoring and surveillance project that was ordered by the U.S. District Court for the Southern District of Texas. Adam Pacsi and Daniel Zavala-Araiza, who were graduate students at the University of Texas at the time the work in this paper was done, have accepted positions at Chevron Energy Technology Company and Environmental Defense Fund, respectively. John Seinfeld served as a consultant for Shell in 2012. A. Daniel Hill owns ExxonMobil, BP, and ConocoPhillips stock, serves on the Advisory Board for Sanchez Oil and Gas, for which he is compensated, and has been a consultant for Schlumberger and numerous oil and gas operating companies..

■ ACKNOWLEDGMENTS

We thank the sponsors of this work for financial support, technical advice and access to sites for sampling. The sponsors were Environmental Defense Fund (EDF), Anadarko Petroleum Corporation, BG Group plc, Chevron, ConocoPhillips, Encana Oil & Gas (USA) Inc., Pioneer Natural Resources Company, SWEPI LP (Shell), Southwestern Energy, Statoil, and XTO Energy, a subsidiary of ExxonMobil. Funding for EDF's methane research series, including the University of Texas study, is provided for by Fiona and Stan Druckenmiller, Heising-Simons Foundation, Bill and Susan Oberndorf, Betsy and Sam Reeves, Robertson Foundation, Alfred P. Sloan Foundation, TomKat Charitable Trust, and the Walton Family Foundation. We thank the experts who reviewed the data on high emitting devices.

Corrections

PERSPECTIVE

Correction for “Theory of mass-independent fractionation of isotopes, phase space accessibility, and a role of isotopic symmetry,” by Rudolph A. Marcus, which appeared in issue 44, October 29, 2013, of *Proc Natl Acad Sci USA* (110:17703–17707; first published June 28, 2013; 10.1073/pnas.1213080110).

The author notes that, on page 1, middle column, lines 11–16 “Fewer accidental resonances mean less energy sharing and so less statistical behavior with a consequence that they are in equilibrium with the population of accessible states of O_3^* at low pressures, as discussed later.” should instead appear as “Fewer accidental resonances mean less energy sharing and so less statistical behavior with a consequence of a shorter lifetime of O_3^* at low pressures, as discussed later.”

On page 2, middle column, first full paragraph, lines 11–14 “This major difference in the pressure effect indicates a difference in the role of the collisions in these two distant phenomena.” should instead appear as “This major difference in the pressure effect indicates a difference in the role of the collisions in these two distinct phenomena.”

On page 3, middle column, first paragraph, lines 4–7 “The overall deviation from statistical theory for the recombination rate constant was (N. Ghaderi) perhaps a factor of 2.” should instead appear as “The overall deviation from statistical theory for the recombination rate constant was (N. Ghaderi) less than a factor of 2.”

On page 3, middle column, first full paragraph, lines 22–26 “Any chaos in the form of higher-order resonances within a volume element h^N would be coarse grained and so presumably contribute to quantum chaos.” should instead appear as “Any chaos in the form of higher-order resonances within a volume element h^N would be coarse grained and so presumably not contribute to quantum chaos.”

Both the online article and the print article have been corrected.

Edited by Susan L. Brantley, Pennsylvania State University, University Park, PA, and approved August 19, 2013 (received for review March 20, 2013)

Engineering estimates of methane emissions from natural gas production have led to varied projections of national emissions. This work reports direct measurements of methane emissions at 190 onshore natural gas sites in the United States (150 production sites, 27 well completion flowbacks, 9 well unloadings, and 4 workovers). For well completion flowbacks, which clear fractured wells of liquid to allow gas production, methane emissions ranged from 0.01 Mg to 17 Mg (mean = 1.7 Mg; 95% confidence bounds of 0.67–3.3 Mg), compared with an average of 81 Mg per event in the 2011 EPA national emission inventory from April 2013. Emission factors for pneumatic pumps and controllers as well as equipment leaks were both comparable to and higher than estimates in the national inventory. Overall, if emission factors from this work for completion flowbacks, equipment leaks, and pneumatic pumps and controllers are assumed to be representative of national populations and are used to estimate national emissions, total annual emissions from these source categories are calculated to be 957 Gg of methane (with sampling and measurement uncertainties estimated at ± 200 Gg). The estimate for comparable source categories in the EPA national inventory is $\sim 1,200$ Gg. Additional measurements of unloadings and workovers are needed to produce national emission estimates for these source categories. The 957 Gg in emissions for completion flowbacks, pneumatics, and equipment leaks, coupled with EPA national inventory estimates for other categories, leads to an estimated 2,300 Gg of methane emissions from natural gas production (0.42% of gross gas production).

greenhouse gas emissions | hydraulic fracturing

Methane is the primary component of natural gas and is also a greenhouse gas (GHG). In the US national inventories of GHG emissions for 2011, released by the Environmental Protection Agency (EPA) in April 2013 (1), 2,545 Gg of CH₄ emissions have been attributed to natural gas production activities. These published estimates of CH₄ emissions from the US natural gas industry are primarily based on engineering estimates along with average emission factors developed in the early 1990s (2, 3). During the past two decades, however, natural gas production processes have changed significantly, so the emission factors from the 1990s may not reflect current practices. This work presents direct measurements of methane emissions from multiple sources at onshore natural gas production sites incorporating operational practices that have been adopted or become more prevalent since the 1990s.

Horizontal drilling and hydraulic fracturing are among the practices that have become more widely used over the past two decades. During hydraulic fracturing, materials that typically consist of water, sand and additives, are injected at high pressure into low-permeability formations. The injection of the hydraulic fracturing fluids creates channels for flow in the formations (often shale formations), allowing methane and other hydrocarbon gases

and liquids in the formation to migrate to the production well. The well and formation is partially cleared of liquids in a process referred to as a completion flowback, after which the well is placed into production. Production of natural gas from shale formations (shale gas) accounts for 30% of US natural gas production, and this percentage is projected to grow to more than 50% by 2040 (4).

Multiple analyses of the environmental implications of gas production using hydraulic fracturing have been performed, including assessments of water contamination (5–8), criteria air pollutant and air toxics releases (9–11), and greenhouse gas emissions (11–18). Greenhouse gas emission analyses have generally been based on either engineering estimates of emissions or measurements made 100 m to a kilometer downwind of the well site. This work reports direct on-site measurements of methane emissions from natural gas production in shale gas production regions.

Significance

This work reports direct measurements of methane emissions at 190 onshore natural gas sites in the United States. The measurements indicate that well completion emissions are lower than previously estimated; the data also show emissions from pneumatic controllers and equipment leaks are higher than Environmental Protection Agency (EPA) national emission projections. Estimates of total emissions are similar to the most recent EPA national inventory of methane emissions from natural gas production. These measurements will help inform policymakers, researchers, and industry, providing information about some of the sources of methane emissions from the production of natural gas, and will better inform and advance national and international scientific and policy discussions with respect to natural gas development and use.

Author contributions: D.T.A. and M.H. designed research; D.T.A., V.M.T., J.T., D.W.S., M.H., A.H., and S.C.H. performed research; C.E.K., M.P.F., A.D.H., B.K.L., J.M., R.F.S., and J.H.S. analyzed data; and D.T.A. wrote the paper.

Conflict of interest statement: J.M. holds a joint appointment with Barree & Associates and the Colorado School of Mines. She has also served as an advisor to Nexen in 2012. D.T.A. served as a consultant for the Eastern Research Group and ExxonMobil in 2012, and is the current chair of the Science Advisory Board for the EPA. J.H.S. has served as a consultant for Shell in 2012. D.T.A., M.H., C.E.K., and R.F.S. variously serve as members of scientific advisory panels for projects supported by Environmental Defense Fund and companies involved in the natural gas supply chain. These projects are led at Colorado State University (on natural gas gathering and processing), Washington State University (on local distribution of natural gas), and the University of West Virginia (on CNG fueling and use in heavy duty vehicles).

Methane emissions were measured directly at 190 natural gas production sites in the Gulf Coast, Midcontinent, Rocky Mountain, and Appalachian production regions of the United States. The sites included 150 production sites with 489 wells, all of which were hydraulically fractured. In addition to the 150 production sites, 27 well completion flowbacks, 9 well unloadings, and 4 well workovers were sampled; the sites were operated by nine different companies. The types of sources that were targeted for measurement account for approximately two-thirds of methane emissions from all onshore and offshore natural gas production, as estimated in the 2011 national greenhouse gas emission inventory (1). A summary of the scope of the study, along with a rationale for the inclusion or exclusion of sources for direct measurement efforts, is provided in *SI Appendix*. Sampling was conducted from May 2012 through December 2012 at sites throughout the United States (see *SI Appendix* for a map and for the number of sampling sites in each region). All nine companies that participated in the study provided sites for sampling, and at least three companies provided sites in each of the regions (*SI Appendix*).

The data presented in this report represent hundreds of measurements of methane emissions from several types of onshore natural gas production activities; however, the sites sampled still represent a small fraction of the total number of sites nationwide (Table 1). This dataset is designed to be representative of the participating companies' activities and practices, but not necessarily all activities and practices. Multiple methods were used to minimize the potential for bias in the sample set, as described in *SI Appendix*.

Results

Emission measurements were performed for 27 well completion flowbacks, 9 liquids unloadings, 4 well workovers, and 150 production sites with 489 hydraulically fractured wells (Table 1 and *SI Appendix*). Data are summarized here for the well completion flowbacks, liquids unloading, and production site emissions. *SI Appendix* provides additional details. The data on well workovers, collected for workovers without hydraulic fracturing, are not presented because the data set was small and emission estimates for workovers without fracturing represent less than 0.1% of national emission estimates.

Well Completion Flowbacks. After a well is drilled, the well is "completed." Completion is the process of making a well ready for continuous production. Specifically, after drilling and fracturing, before natural gas production can begin, the well must be cleaned of sand and liquid of various types that had been injected into the well. The recovery of these liquids is referred to as a flowback, and gas, including methane, can be dissolved or entrained in the flowback liquids. Some of the methane in the liquids can be sent to sales or emission control devices, but some can be emitted.

Measurements were made of methane emissions during 27 completion flowback events. Emissions data for each of the 27

events is provided in *SI Appendix*. Five of the flowbacks were in the Appalachian region, seven in the Gulf Coast region, five in the Midcontinent region, and 10 in the Rocky Mountain region. The durations of the completions ranged from 5 to 339 h (2 wk). Measured methane emissions over an entire completion flowback event ranged from less than 0.01 Mg to more than 17 Mg, with an average value of 1.7 Mg and a 95% confidence interval of 0.67–3.3 Mg. Measurement and sampling uncertainty are included in the confidence interval; uncertainties due to a limited sample size dominate the overall uncertainty estimate. Methods for determining the confidence intervals are described in *SI Appendix*.

The completions with the lowest emissions were those in which the flowback from the well was sent immediately, at the start of the completion, to a separator, and all of the gases from the separator were sent to sales. The only emissions from these completions were from methane dissolved in liquids (mostly water) sent from the separator to a vented tank. The completion flowback with the highest total emissions, 17 Mg, was the longest in duration (339 h) and had initial flowback into a vented tank with very high methane concentrations. Some of the other relatively high emission completion flowbacks (~3 Mg to 6 Mg of methane) involved large amounts of flared gas (up to 130 Mg of methane to the flare, which was assumed to combust the methane at 98% efficiency, *SI Appendix*). Another completion with emissions of 4 Mg of methane was one in which all gases, for the entire event, were vented to the atmosphere. This type of venting for the entire duration of the completion was observed in 9 of the 27 completions. However, the nine completions of this type showed a wide range of emissions (4 Mg of methane for one completion and 0.5 Mg of methane for another completion of this type for an adjacent well).

These data provide extensive measurements on methane emissions from well completions that can be used in national emission estimates. Current national inventories of methane emissions have been assembled, based on simple engineering models of the completion process. In the most recent EPA national greenhouse gas emission inventory (2011 inventory, released April 2013) (1), 8,077 well completions with hydraulic fracturing are estimated to result in 654 Gg per year of emissions, for an average of 81 Mg of methane per completion flowback (compared with 1.7 Mg per flowback for the events reported here). To understand the reasons for the much lower emissions per event reported in this work, it is useful to define a potential emission for each flowback. The potential of a flowback to emit is defined here, and in the EPA national inventory (1), as the methane that would be emitted if all of the methane leaving the wellhead during the flowback were vented to the atmosphere. Potential emissions for the wells in this work ranged from 0.2 Mg to more than 1 Gg methane, with an average of 124 Mg. The average from the EPA national inventory is slightly higher at 151 Mg. Net emissions are calculated, in the EPA national inventory, by reducing potential emissions by estimates of methane captured or controlled

Table 1. Comparison of sample set size to emission source populations

| Source | No. of events/locations sampled | Total no. of events/locations |
|--------------------|---------------------------------|-------------------------------|
| Well completions | 27 | 8,077* |
| Gas well unloading | 9 | 35,828 [†] |
| Well workovers | 4 | 1782 (11,663) [‡] |
| Wells | 489 | 446,745 [§] |

because of regulatory or voluntary emission reductions. In the current national inventory, emission reductions are roughly one-half of potential emissions (*SI Appendix*). In this work, net or measured emissions for the total of all 27 completions are 98% less than potential emissions. This large difference between the net emissions measured in this work and the net emissions estimated in the national inventory is due to several factors. First, consistent with emerging regulatory requirements (21) and improved operating practices, 67% of the wells sent methane to sales or control devices. Second, for those wells with methane capture or control, 99% of the potential emissions were captured or controlled. Finally, the wells with uncontrolled releases had much lower than average potential to emit. Of the nine wells in this work that had uncontrolled venting of methane, the average potential to emit was 0.83 Mg, which is 0.55% of the average potential to emit in the national inventory. The relative importance of these factors is discussed in *SI Appendix*.

Unloadings. Gas wells often produce liquid hydrocarbons and water along with natural gas. In most new wells, the velocity of natural gas up the production tubing of the well is sufficient to lift any produced water out of the well with the gas. As gas production declines, the velocity may no longer be sufficient to lift the liquids, which begin to accumulate in the wellbore and eventually restrict gas flow from the producing formation. Liquids accumulation therefore needs to be removed to allow the well to continue to produce gas at optimal rates.

There are multiple methods of unloading a gas well, some of which do not result in emissions. In this work, sampling was performed for unloadings in which an operator manually bypasses the well's separator. Unlike automated plunger lift methods, these manual unloading events could be scheduled, allowing the study team adequate time to install measurement equipment. As the flow to the separator, which typically operates at pressures of multiple atmospheres, is bypassed, flow is diverted to an atmospheric pressure tank. This diversion allows the well to flow to a lower pressure destination (the atmospheric pressure tank, rather than the pressurized separator). This lower pressure end point allows more gas to flow, increasing velocity in the production tubing and lifting the liquids out of the well. Gas is discharged from the tanks through the tank vent, unless the tanks have an emissions control system such as a combustor.

The nine unloading events reported in this work were varied in their characteristics. Methane emissions ranged from less than 0.02 Mg to 3.7 Mg. Some unloadings lasted 2 h (or more) and had relatively uninterrupted flow. Other unloadings were as short as 10–15 min with uninterrupted flow, and still others had intermittent flow for short periods and periods of no flow for much of the unloading period. Some of the wells sampled only unloaded once over the current life of the well, whereas others were unloaded monthly. The average emission per unloading event was 1.1 Mg of methane (95% confidence limits of 0.32–2.0 Mg). If the emissions per event for each well are multiplied by the event frequency (events per year) reported by the well operators, the average emission per well per year was 5.8 Mg (an average of 5.9 events per unloaded well per year). The sampled population reflected a wide range of emission rates, with a population of high emitting wells and a population of low emitting wells. When emissions are averaged per event, emissions from four of the nine events contribute more than 95% of the total emissions. *SI Appendix* provides more information about individual unloading events.

Because the characteristics of the unloading events sampled in this work are highly variable, and because the number of events sampled is small, extrapolating the results to larger populations should be done with caution. One source of data on larger populations of wells with unloadings, to which the population sampled in this work can be compared, is a survey reported by

the American Petroleum Institute and America's Natural Gas Alliance (API/ANGA) (22). In this survey, more than 20 companies provided data and well characteristics for 40,000–60,000 wells (with the number in the sample depending on the type of emission event). These API/ANGA data were used by the EPA to arrive at 2011 national inventory emission estimates for 35,828 wells without plunger lift and 22,866 with plunger lift, which vent for unloading. Unloading emissions for the wells in the API/ANGA survey were estimated based on well characteristics such as well bore volume, well pressure, venting time, and gas production rate (3). For the unloading events without plunger lift, 100 of the 2,901 wells (3%) in the survey account for 50% of the estimated emissions. Ninety percent of the estimated emissions in the API/ANGA survey are due to one-half of the wells. Because a small population of wells (3%) accounts for one-half of the emissions, if this relatively small population of high emitting wells is not adequately sampled, it is not possible to accurately estimate national emissions. The wells sampled in this work unloaded relatively infrequently. In contrast, some wells in the API/ANGA survey, including some of the highest emitting wells, unload with a daily or weekly frequency. An average frequency of unloading for the wells in the API/ANGA survey is 32.57 events per year, compared with an average observed in this work of 5.9.

Because a small number of unloading events accounts for a large fraction of emissions in the API/ANGA survey (22), and because some of these wells had frequencies of unloading higher than any of the events observed in this work, the sample set of nine events reported in this work is not sufficient for accurately estimating emissions from unloading at a national scale. Nevertheless, the data reported here provide valuable insights for the design of future sampling campaigns.

One important result from the measurements reported here is that current EPA estimation methods overpredict measured emissions. If the emission estimation method (3) used in the API/ANGA survey is applied to the events sampled in this work, estimates are 5 times higher than measured emissions. Estimates of the emissions for the nine events are 5.2 Mg per event versus measured emissions of 1.1 Mg per event. Emissions were overestimated for every event. The percentage by which emissions are overestimated increases as emissions per event decrease (*SI Appendix*). Possible causes of the overestimate include the assumptions in the estimation method that the entire well bore volume is released in an unloading and that the gas flow during an unloading is continuous.

Overall, the implication of all of these issues is a large uncertainty bound in the national emissions from gas well unloading. If the per well annual emissions from this work are used, a national emission estimate based on counts of wells that undergo unloading is in reasonable agreement with emissions in the EPA national inventory (1). In contrast, another estimate of unloading emissions, based on the per event emissions observed in this work and an estimate of national unloading events (22), would lead to a national estimate five times the estimate based on well counts. This estimate is not supported by the available data, given that the national event count is dominated by high frequency unloading events and the wells observed here unloaded far less frequently with much higher emission estimates per event. A lower estimate of unloading emissions could be suggested based on national well counts, emission estimates, and the finding that emission estimation methods, used in many EPA inventory estimates, overestimate observations made in this work by a factor of 5. All of these methods, however, assume a single scalar value represents a wide range of unloadings; the data presented in this work and in the API/ANGA survey (22) suggest that refined emission estimation methods, taking into account well and unloading characteristics, will be required. Additional measurements of unloading emissions are needed, both to resolve the

Table 2. National emission estimates for the natural gas production sector, based on this work and the 2011 national inventory

| Category | 2011 EPA GHG inventory net emissions,* Gg of methane/yr | Emission estimates from this report, [†] Gg of methane/yr | Comments |
|---|---|--|--|
| Sources with emissions measurements from this work used to generate national emission estimates | | | |
| Completion flowbacks from wells with hydraulic fracturing | 654* | 18 [‡] (5–27) [§] | Decrease in national emission estimate |
| Chemical pumps | 34* | 68 (35–100) [§] | Increase in national emission estimate |
| Pneumatic controllers | 355* | 580 [‡] (518–826) [§] | Increase in national emission estimate; if national emission factors derived from this work are used, this estimate becomes 790 Gg (<i>SI Appendix</i>) |
| Equipment leaks | 172–211** [¶] | 291 [‡] (186–396) [§] | Increase in national emission estimate; this comparison is based on equivalent categories of equipment, not all equipment leaks [¶] (<i>SI Appendix</i>) |
| Subtotal, national emissions, estimated based on this work | 1215–1254 ^{†#} | 957 ± 200 [#] | Decrease of ~250 Gg for national emission estimate |
| Sources with limited measurements; national emissions not estimated | | | |
| Unloadings (nonplunger lift) | 149* (EPA inventory) | | Highly diverse events; small data set collected in this work; preliminary national emission estimates have a broad range of values (25–206 Gg; see text) |
| Workovers (without hydraulic fracturing) | 0.3* (EPA inventory) | | Measurements in this work included only one recompletion and three swabbing events (see text) |
| Other sources, not measured in this work | | | |
| Unloadings (plunger lift) | 108* (EPA inventory) | | No measurements made in this work |
| Workovers (with hydraulic fracturing) | 143* (EPA inventory) | | No measurements made in this work; equipment configurations are similar to completion flowbacks for wells with hydraulic fracturing; if emissions per event are comparable to completion flowbacks, current inventories may overestimate emissions |
| Other sources, not measured in this work | 891–930** [¶] (EPA inventory) | | Includes potential emissions of sources not measured less prorated regulatory and voluntary emission reductions* |
| Total methane, Gg | 2,545 | 2,300 | Decrease of ~250 Gg for estimate |
| Methane emissions,**% [percent of gross gas production] | 0.47% [0.59%] | 0.42% [0.53%] | Brackets: gross gas emitted/gross gas produced (assuming produced gas is 78.8% methane) |

*Emissions from EPA national inventory are based on reported potential emissions less reductions; when reductions are reported for combined source categories, identical percentage reductions of potential emissions are assumed to apply across source categories (*SI Appendix, section S5*).

[†]Emission factors used to estimate national inventories are designed to be representative of the participating companies' activities and practices, but not necessarily all activities and practices.

[‡]National emissions based on a regionally weighted average (*SI Appendix, section S5*).

[§]Ranges are based on 95% confidence bounds of emission factors; activity factors are identical to those used in EPA inventory. Uncertainties in activity factors (e.g., device counts) are not included. Uncertainties associated with whether regional or national averaging is performed are included in the uncertainty estimate (*SI Appendix, section S5.4*).

[¶]Sampling in this work included compressors on well sites, but not all gathering compressors. Well site and gathering compressors are combined in the national inventory. Range reported for national inventory for equipment leaks and "other" sources reflect uncertainty in attributing compressor emissions from national inventory to a specific source category.

[#]Uncertainty bound assumes uncertainties for completion flowbacks, pneumatic pumps and controllers and leaks are independent, and consequently, the combined uncertainty is the square root of the sum of the squares of the individual uncertainties.

**US total gross gas production (oil and coal bed, gas, and shale, onshore and offshore): 547,000 Gg.

differences between estimates and measurements and to better characterize the population of wells with unloading emissions.

Finally, it is also clear from the data that properly accounting for unloading emissions will be important in reconciling emission inventories with regional ambient measurements. Average methane emission rates for a single unloading ranged from roughly 100 g/min to in excess of 30,000 g/min. These rates are much larger than emission rates for production sites (typically tens of grams of methane per minute per well) or from completions (typically a few hundred grams per event per minute). At these emission rates, a single unloading event could, during the short period that it is occurring, result in emissions that are the equivalent of just a few wells in routine production to the equivalent of up to several thousand wells in routine production. Therefore, reconciliation between instantaneous ambient measurements and emission inventories will need to carefully represent the emissions from unloadings.

Well Sites in Routine Production. A well site contains one or more wellheads and may contain separators, pneumatic controllers, water tanks, hydrocarbon tanks (oil or condensate), and possibly other devices such as dehydrators, compressors, and flares. In this work, measurements were made from pneumatic controllers and pumps, because these devices release methane as part of their routine operation, and from equipment leaks detected by using an infrared camera (*SI Appendix*) at well sites.

Emissions for equipment on well sites, in routine production, that were targeted for measurements had much narrower uncertainty bounds than well completion flowbacks or well unloadings. Emissions from pneumatic chemical injection pumps measured in this work averaged 3.7 ± 1.6 g of methane per minute per pump, 9% lower than the EPA emission factor (*SI Appendix, section S2*). Intermittent and low bleed pneumatic devices measured in this work averaged 5.9 ± 2.4 and 1.7 ± 1.0 g

Table 3. Measurement methods used in the study

| Source | Direct measurement methods | Mobile downwind sampling |
|--------------------|---|---|
| Well completions | Measurements from flowback tanks made by using enclosures and temporary stacks with measurements of flow rate and composition | Downwind tracer ratio methods: Metered release of C ₂ H ₂ and N ₂ O on site and downwind measurements of methane to C ₂ H ₂ and methane to N ₂ O concentration ratios |
| Gas well unloading | Temporary stack with measurements of flow rate and composition | |
| Well workovers | Measurements from flowback tanks made by using enclosures and temporary stacks with measurements of flow rate and composition | |
| Production sites | Infrared (FLIR) camera surveys of sites and flow rate measurements using a HiFlow device | Metered release of C ₂ H ₂ and N ₂ O on site and downwind measurements of methane to C ₂ H ₂ and methane to N ₂ O concentration ratios |

of natural gas per device per minute, 29% and 270% higher than EPA emission factors, respectively (*SI Appendix, section S2*). No high bleed pneumatic devices were identified at the sampling sites, and the average emission rate for the population of pneumatic controllers sampled in this work was 3.36 ± 0.65 g of methane per min (3.8 ± 0.69 g of natural gas per min). Equipment leaks measured in this work averaged 1.23 ± 0.44 g of methane per minute per well, which can be compared with an EPA estimate of potential emissions (no regulatory or voluntary emission reductions) of 1.37–1.67, derived from EPA’s inventory for similar equipment types (wellheads, separators, heaters, meters/piping, and dehydrator fugitives), with the range reflecting whether small compressors are added to the comparison (*SI Appendix, section S5*). Comparing to net emissions is challenging because EPA does not assign emission reductions to specific equipment categories. Additional information is provided in *SI Appendix*.

There was significant geographical variability in the emissions rates from pneumatic pumps and controllers, but these regional differences were not as pronounced for equipment leaks. Emissions per pump from the Gulf Coast are statistically significantly different and roughly an order of magnitude higher than from pumps in the Midcontinent. Emissions per controller from the Gulf Coast are highest and are statistically significantly different from controller emissions in the Rocky Mountain and Appalachian regions. Emissions per controller in the Rocky Mountain region are lowest and an order of magnitude less than the national average (*SI Appendix*).

Implications for National Emission Estimates. If the average emissions reported in this work for well completion flowbacks, pneumatic devices, and equipment leaks are assumed to be representative of national populations and are applied to national counts of completions, pneumatic devices, and wells in EPA’s national inventory, emissions from these source categories would be calculated as 957 Gg (with sampling and measurement uncertainties estimated at ± 200 Gg), compared with 1,211–1,250 Gg methane per year in the 2011 EPA national inventory (1) for the same source categories. A large emissions decrease associated with completion flowbacks is partially offset by emission increases from pneumatic controllers and equipment leaks. Reasons for these differences are described in *SI Appendix*.

The estimated uncertainty in the national emission estimates based on this work is $\sim 20\%$ (200 Gg). The sources of uncertainty include measurement uncertainty, uncertainty introduced by the selection of sites, and uncertainty due to choices in performing regional or national averaging of equipment counts and emission factors. These components of the quantified uncertainty are described in *SI Appendix*. The uncertainty estimate does not

include factors such as uncertainty in national counts of wells or equipment and the issue of whether the companies that provided sampling sites are representative of the national population.

The 957 ± 200 Gg in emissions for completion flowbacks, pneumatics, and equipment leaks, coupled with national inventory estimates for other categories, leads to an estimated 2,300 Gg of methane emissions from natural gas production (0.42% of gross gas production). A summary is provided in Table 2, and details of the calculations are available in *SI Appendix*.

Total emissions estimated based on measurements in this work (2,300 Gg) are comparable with the most recent EPA national GHG inventory (2,545 Gg in the 2011 inventory, released in April 2013) (1). Table 2 also compares emissions in specific source categories, estimated based on the measurements made in this work, to EPA estimates of the same categories in the national inventory (1). For some emission categories, such as completion flowbacks and pneumatic controllers, conclusions can be drawn from the comparisons. Specifically, measured emissions from completion flowbacks are roughly 600 Gg lower than the completion flowback emissions in the current inventory; measured emissions from pneumatic controllers are 150–500 Gg higher than in the current inventory. For other emission categories, such as equipment leaks and pneumatic pumps, however, drawing conclusions is more difficult. For these source categories, the national inventory reports potential emissions for each category, but aggregates emission reductions, creating uncertainty in the net emissions in these categories (see *SI Appendix, section S5.5* for more details).

It should also be noted that the national inventory has changed in recent years based on evolving regulations (21) and understanding of emission sources. In this work, comparisons are made to the most recent release of the inventory (2011 final version, released in April 2013) and back casts to previous years by using consistent calculation methodologies. Emissions were estimated as 2,545 Gg in 2011, compared with 2,948 Gg in 2009 and 2,724 Gg in 2010. The work presented here suggests practices such as combusting or capturing emissions from completion flowbacks, as required by New Source Performance Standards subpart OOOO and the revised National Emission Standards for Hazardous Air Pollutants subpart HH (21), are resulting in reduced methane emissions. Other source categories require more data to produce national emission estimates, and adjustments in the inventory may emerge as more emission measurements are performed. Emission estimates may be adjusted downward if workovers with hydraulic fracturing are found to have emissions per event that are similar to completion flowbacks and may be adjusted either upward or downward as more emissions data are collected for liquids unloading or pneumatic devices.

Finally, an emissions intensity of 0.42% is reported in Table 2. The intensity expresses a methane emission per unit of gross gas production. This intensity should be interpreted with caution, because it includes only production operations and implicitly attributes all methane emissions from natural gas wells to natural gas production, although natural gas wells produce substantial amounts of natural gas liquids and oil. The intensity is reported here because it facilitates comparisons with other analyses that have appeared in the literature (23).

Methods

Multiple independent and complementary techniques were used to measure methane emissions. The primary procedures involved direct measurements of CH₄ emissions at their source. A variety of different procedures were used for direct source measurements, depending on the type of source being sampled and the type of natural gas production equipment being used. Table 3 summarizes the direct source methods used in the study; detailed descriptions of the methods are provided in *SI Appendix*.

In addition to direct source measurements, tracer ratio measurements, designed to estimate the total methane emissions from a site, were made at 20% of the well completion flowbacks and 13% of the production sites. The tracer release method was developed in the 1990s to quantify methane emissions from a wide range of natural gas system components (24, 25). Sites for tracer releases were selected for their steady, moderate winds and downwind access. Measurements for sites without downwind access could not be made. Table 3 also summarizes these measurement methods, which are described in detail in *SI Appendix*. In brief, tracer compounds were released at a known rate on-site; downwind measurements of methane (minus

background) and the tracer (minus background) were assumed to be equal to the ratio of emission rates, allowing methane emissions to be estimated. These measurements were performed for a subset of the sampling locations that had relatively open terrain and steady winds, producing well-defined emission plumes downwind of the sites. The tracer studies allowed for an independent measurement of emissions that were also measured by using direct source methods. For completion flowbacks, emission estimates based on the downwind measurements were generally within a factor of 2 of the direct source measurements, supporting the conclusion that emissions from completion flowbacks are roughly 97% below the most recent national estimates and that emissions from completion flowbacks without methane control or recovery equipment, observed in this work, are well below the average potential emissions in current national inventories (1). For the production sites, emissions estimated based on the downwind measurements were also comparable to total on-site measurements; however, because the total on-site emissions were determined by using a combination of measurements and estimation methods, it is difficult to use downwind measurements to confirm the direct source measurements. Tracer study results are summarized in *SI Appendix*.

ACKNOWLEDGMENTS. We thank the sponsors of this work for financial support, technical advice, and access to sites for sampling. The sponsors were Environmental Defense Fund (EDF), Anadarko Petroleum Corporation, BG Group plc, Chevron, Encana Oil & Gas (USA) Inc., Pioneer Natural Resources Company, SWEPI LP (Shell), Southwestern Energy, Talisman Energy USA, and XTO Energy, an ExxonMobil subsidiary. EXECUTIVE SUMMARY

Eureka! Synonymous with discovery and opportunity, California represents an ideal; a state of mind—stunning scenery, recreational opportunities, a thriving economy and a culturally diverse people. However, climate change is threatening this ideal, and our very way of life. It is clear that the impacts of climate change are already upon us. California continues to suffer through historic temperatures, persistent droughts, and more intense and frequent wildfires. Each year seems to bring a new global temperature record, and new evidence suggests sea levels are rising much faster than predicted. What was once, and remains, a generational problem of greenhouse gas (GHG) balance in the atmosphere has now become an immediate threat to our California lifestyle.

The only practical way to rapidly reduce the impacts of climate change is to employ strategies built on the tremendous body of science. The science unequivocally underscores the need to immediately reduce emissions of short-lived climate pollutants (SLCPs), which include black carbon (soot), methane (CH₄), and fluorinated gases (F-gases, including hydrofluorocarbons, or HFCs). They are powerful climate forcers and harmful air pollutants that have an outsized impact on climate change in the near term, compared to longer-lived GHGs, such as carbon dioxide (CO₂). SLCPs are estimated to be responsible for about 40 percent of current net climate forcing. Action to reduce these powerful “super pollutants” today will provide immediate benefits as the effects of our policies to reduce long-lived GHGs further unfold.

While we must continue to steadily reduce CO₂ emissions for long-term climate stability, we also need a global commitment and near-term actions to dramatically reduce SLCP emissions over the next 10–15 years. Deploying existing technologies and resource management strategies globally to reduce SLCP emissions can cut the expected rate of global warming in half and keep average warming below the dangerous 2°C threshold at least through 2050. We can slow sea level rise significantly, reduce disruption of historic rainfall patterns, and boost agricultural productivity by reducing crop losses to air pollution. Cutting global SLCP emissions immediately will slow climate feedback mechanisms in the Arctic and elsewhere that would otherwise further accelerate global warming and make climate change far more difficult to solve and far more costly to live with – as more resources would be required for disaster relief, conflict management, and adaptation. Most importantly, we can dramatically reduce global air pollution, saving millions of lives each year. Many of these benefits will primarily accrue in regions and populations disproportionately impacted by climate change, including the developing world.

Using cost-effective and available technologies and strategies, worldwide anthropogenic sources of SLCP emissions can be largely controlled by 2030 and the global benefits of a collective commitment to substantially reduce SLCP emissions would be profound. Leading efforts by California, the United States, Mexico, Norway, Europe, the Arctic Council, and several countries and non-governmental entities acting through the Climate and Clean Air Coalition to Reduce Short-Lived Climate Pollutants (CCAC) are already targeting SLCPs. Many other countries included SLCP emissions in their commitments made at the Paris climate conference, or are targeting them through separate policies to improve air quality and promote sustainable agriculture and transportation, among other efforts.

California's seminal Global Warming Solutions Act, AB 32 (Nuñez, Chapter 488, Statutes of 2006), charges the California Air Resources Board (ARB or Board) with achieving and maintaining a statewide GHG emission limit, while seeking continuing GHG emission reductions. SLCP emission reductions are critical to achieving this mandate. California is committed to taking further action to reduce SLCP emissions by 2030. Senate Bill 605 (Lara, Chapter 523, Statutes of 2014) requires the ARB to develop a plan to reduce emissions of SLCPs. Additionally, Governor Brown has identified reductions of SLCP emissions as one of "five pillars" to meet an overarching goal to reduce California's GHG emissions by 40 percent below 1990 levels by 2030. This proposed SLCP Reduction Strategy (Proposed Strategy) was developed pursuant to SB 605 and lays out a range of options to accelerate SLCP emission reductions in California, including regulations, incentives, and other market-supporting activities. Governor Brown's 2016-2017 Proposed Budget includes \$215 million from Cap-and-Trade expenditures specifically targeting SLCP emission reductions. These include \$40 million for black carbon residential woodsmoke reductions, \$20 million for HFC reductions from refrigerants, \$100 million for waste diversion, \$20 million for Healthy Soils, and \$35 million for dairy digester development.

An Opportunity for California

Historic action is not enough. Many opportunities to reduce emissions of SLCPs still exist, and California is doubling down on its efforts to control these emissions from all sources. A dedicated commitment, as described in this Proposed Strategy, to achieve sustainable reductions in SLCP emissions in California will provide significant benefits throughout the State.

In this Proposed Strategy, we outline SLCP emission reduction actions that provide a wide array of climate, health, and economic benefits throughout the State. The State's organic waste should be put to beneficial use, such as for soil amendments/compost,

electrical generation, transportation fuel, and pipeline-injected renewable natural gas. Practical solutions must be developed and implemented to overcome barriers to waste gas utilization for pipeline injection and grid interconnection. Additional data on SLCP sources must be collected in order to improve California's SLCP emission inventory and better understand potential mitigation measures. Finally, the State should provide incentives to accelerate market transitions to cleaner technologies that foster significant system-wide solutions to cut emissions of SLCPs. Many of the sources and sectors responsible for SLCP emissions are concentrated in communities with high levels of pollution or unemployment, which could especially benefit from targeted investments to improve public health and boost economic growth.

In the coming years, many billions of dollars in public and private investments are anticipated to support efforts to reduce SLCP and CO₂ emissions and support our agricultural and waste sectors, build sustainable freight systems, encourage low-Global Warming Potential (GWP) refrigerants and grow healthy forests. These investments will strengthen the State as a whole and the communities where they occur. Many of the benefits will accrue in the Central Valley, rural parts of the State, or other areas disproportionately impacted by pollution, such as those along freight corridors.

Stubborn barriers remain, including connecting distributed electricity and biogas projects, which have slowed previous efforts to reduce emissions of SLCPs and capture a wide array of benefits. These barriers are not insurmountable, and now is the time to solve them. State agencies, utilities, and other stakeholders need to work immediately to identify and resolve remaining obstacles to connecting distributed electricity with the grid and injecting renewable natural gas into the pipeline. Supporting the use of the cleanest

technologies with funding and strategies that maximize air quality, climate, and water quality benefits can accelerate their introduction. Building market certainty and value for the energy, soil amendment, and other products that come from compost or anaerobic digestion facilities will help to secure financing to accelerate and scale project development.

Building on California Leadership

This Proposed Strategy builds on California's ongoing leadership to address climate change and improve air quality. It has been developed with input from State and local agencies, academic experts, a working group of agricultural experts and farmers convened by the California Department of Food and Agriculture (CDFA), businesses, and other interested stakeholders in an open and public process. ARB and State agencies collaborated to identify reduction measures for specific sectors, including the dairy, wastewater, and waste sectors. In addition, ARB collaborated with the local air districts to identify SLCP emission reduction measures that could be implemented

through district action. Throughout this process, ARB has sought advice from academic, industry, and environmental justice representatives. Additionally, ARB staff is working closely with manufacturers to determine the feasibility and cost of replacement products for high-GWP refrigerants, and with the dairy industry and academics to evaluate options and costs for reducing emissions of methane at dairies.

While reducing GHG emissions is a key objective for the State, California remains committed to further reducing emissions of criteria (smog-forming) pollutants and toxic air pollutants, as well. Many of the concepts described in this Proposed Strategy have already been discussed in the context of the California Sustainable Freight Action Plan, 2016 Mobile Source Strategy and other efforts related to developing State Implementation Plans for air quality, and plans for bioenergy, waste management, water management, healthy soils, and sustainable management of the state's natural resources. The SLCP Strategy, along with those other planning efforts, will inform and be integrated into the upcoming 2030 Target Scoping Plan Update, which will incorporate input from a wide range of stakeholders to develop an integrated plan for reducing emissions of GHGs, criteria pollutants, and toxic air pollutants through 2030. The process for updating the Scoping Plan began in fall 2015 and is scheduled for completion by 2017.

State agencies and the air districts are committed to continuing to work together to ensure that the concepts outlined in this Proposed Strategy are implemented in a coordinated and synergistic way. The sections below describe goals, regulations, incentives, and other efforts that would:

- Encourage national and international deployment of California's well-established and proven measures to reduce black carbon emissions;
- Further reduce black carbon emissions from off-road and non-mobile sources, including forests;
- Cut in half methane emissions from dairy operations and effectively eliminate disposal of organics in landfills;
- Create and expand industries to capture value from organic waste resources in California;
- Significantly reduce fugitive methane emissions from oil and gas systems and other sources; and
- Accelerate the transition to low-GWP refrigerants and more energy efficient refrigeration systems.

ARB staff will receive and consider comments on this Proposed Strategy and prepare a final Strategy to present to the Board for consideration in fall 2016.

Achieving Significant Emission Reductions

Based on stakeholder feedback on the Concept Paper released in May 2015 and the subsequent Draft Strategy, ARB is proposing planning targets to reduce emissions of methane and HFCs by 40 percent below current (2013) levels by 2030, and

anthropogenic (non-forest) black carbon emissions by 50 percent below current levels by 2030. Meeting these targets will help to achieve the Governor’s goal to cut all GHG emissions in California by 40 percent below 1990 levels by 2030 and help meet federal air quality standards for 2031 and beyond.

The proposed targets are summarized in Table 1. The goals and proposed measures included in this Proposed Strategy will reduce SLCP emissions to levels in line with these targets. Due to the urgency of the issue, and recognizing the climate potency of SLCPs in the near-term, we use 20-year global warming potential values (GWPs) in this report to quantify emissions of SLCPs.

Table 1: California SLCP Emissions and Proposed Target Emission Levels (MMTCO2e)*

| Pollutant | 2013 | 2030 BAU** | 2030 Proposed Strategy |
|---------------------------|------|------------|------------------------|
| Black carbon (non-forest) | 38 | 26 | 19 |
| Methane | 118 | 117 | 71 |
| Hydrofluorocarbons (HFCs) | 40 | 65 | 24 |

*Using 20-year GWPs from the 4th Assessment report of the IPCC for methane and HFCs, and 5th Assessment report for black carbon (the first report to define a GWP for black carbon)

**Business As Usual (BAU) forecasted inventory includes reductions from implementation of current regulations

Black Carbon

Black carbon is not one of the climate pollutants originally included in international climate frameworks, and it is not included in California’s AB 32 inventory. However, recent studies have shown that black carbon plays a far greater role in global warming than previously believed. California has made tremendous progress in reducing black carbon emissions as part of its efforts to reduce carcinogenic diesel particulate matter emissions and improve air quality. California has already cut anthropogenic black carbon emissions by over 90 percent since the 1960s, and existing measures are projected to cut mobile source emissions by 75 percent and total anthropogenic emissions by nearly 60 percent between 2000 and 2020. Putting measures in place to achieve similar levels of reductions worldwide is the quickest way to reduce the impacts of climate change, and would save millions of lives per year.

These reductions have come from strong efforts to reduce on-road vehicle emissions, especially diesel particulate matter. Car and truck engines used to be the largest sources of black carbon emissions in California, but the State's existing air quality

policies will virtually eliminate black carbon emissions from on-road diesel engines within 10 years. These policies are based on existing technologies, which could be deployed throughout the U.S. and the world.

With the large reduction in emissions of black carbon from vehicles, other sources of black carbon emissions will become more significant contributors to the State's black carbon inventory over time. In particular, without additional actions, off-road mobile, fuel combustion in the industrial and power sectors, and woodstoves and fireplaces will account for more than three-quarters of anthropogenic black carbon emissions in California in 2030. However, black carbon emissions from these sources have declined significantly as well, by almost 30 percent since 2000. Continued progress on these sectors—transitioning to cleaner and more efficient uses of energy, reducing emissions

from woodstoves and fireplaces, taking steps to meet federal health-based air quality standards by 2031, and developing and implementing a sustainable freight system—will continue to reduce black carbon emissions and should allow us to meet the targets established in this Proposed Strategy.

The State's 2016 Mobile Source Strategy, 2030 Target Scoping Plan Update, and Sustainable Freight Action Plan, a multi-agency effort to deploy a sustainable and efficient system for goods movement, will build on these measures to reduce black carbon. Additionally, ARB will work with local air districts to further reduce particulate matter and black carbon emissions from woodstoves and fireplaces. Governor Brown's 2016-17 proposed budget includes \$40 million to reduce black carbon from woodsmoke.

The largest source of black carbon emissions in California is, by far, wildfire. An average wildfire season contributes two-thirds of current black carbon emissions in California. As climate change accelerates, our drought-ravaged forests will only become more vulnerable to wildfire and disease. Indeed, many of California's forests are already in a perilous condition and require accelerated management and investment to protect them. Several Federal, State, and local agencies are currently coordinating on forest planning, pursuant to Governor Brown's Proclamation of a State of Emergency on Tree Mortality and through other forums.

This Proposed Strategy focuses on actions to reduce wildfire risk and black carbon emissions by increasing the rate of fuel reduction to improve forest health, aligning financial incentives with beneficial uses of woody waste, supporting management efforts and market development through research, and integrating state planning efforts. The State's Forest Carbon Plan and the 2030 Target Scoping Plan Update will identify additional goals and measures to improve forest health. Goals and actions identified in the 2030 Target Scoping Plan Update and Forest Carbon Plan will include those related to forest carbon storage, which is beyond the scope of this Proposed Strategy. State agencies are coordinating to ensure that the goals and recommendations in each of

these plans complement one another. Any proposed targets or actions will be considered through those public planning processes.

Methane

Methane is responsible for about 20 percent of current net climate forcing globally. In California, about half of methane emissions come from organic waste streams that can be put to valuable use as sources of renewable energy or fuel and soil amendments. The other half mostly comes from enteric fermentation (burps) from dairy cows and livestock and fugitive emissions (leaks) from oil production, processing, and storage, gas pipeline system, or industrial operations. California can cut methane emissions by 40 percent below current levels in 2030 by capturing or altogether avoiding methane from manure at dairies, meeting national industry targets for reducing methane emissions from enteric fermentation, effectively eliminating disposal of organics in landfills, and reducing fugitive methane emissions by 40-45 percent from all sources.

Strong market support and broad collaboration among State agencies, industry, and other stakeholders will be necessary to reduce landfill and manure methane emissions by putting organic waste streams to beneficial use. The State will support early action to build infrastructure capacity and reduce emissions through existing incentives and accelerated efforts to overcome barriers and foster markets. Government agencies and stakeholders will work to foster market conditions to support private sector investment in expanded or new infrastructure, including building markets for compost and soil amendments, overcoming barriers to pipeline injection of biomethane, and identifying optimal financing mechanisms and levels to reach the goals in this Proposed Strategy.

Ultimately, a combination of incentives, State and private sector investment, and regulations will be necessary to capture the value in organic waste streams and ensure lasting emission reductions. For dairies, California will aim to reduce methane emissions from dairy manure management by at least 20 percent in 2020, 50 percent in 2025, and 75 percent in 2030. The State will encourage and support near-term actions by dairies to reduce emissions through financial incentives, collaboration to overcome barriers, and other market support, before subsequent regulations take hold. Following ARB approval of the final SLCP strategy, and in coordination with CDFA and local air quality and water quality agencies, ARB will initiate a rulemaking process to reduce manure methane emissions from the dairy industry in-line with the objectives in this Proposed Strategy. The regulatory process will include consideration of available financial incentives, market support, and the potential for emissions leakage in identifying appropriate timelines and requirements for the industry.

The rulemaking will also include requirements for mandatory reporting and recordkeeping of parameters affecting GHG emissions at California dairy farms. Reported information will be used to refine inventory quantification, evaluate policy effectiveness, and aid in future policy planning and regulatory development. ARB will work with other State agencies and industry groups to improve outreach on new

reporting requirements, as well as merge and streamline reporting activities with current forms and requirements to avoid duplicative reporting wherever feasible.

For landfills, ARB will work with CalRecycle to develop a regulation by 2018 to effectively eliminate organic disposal in landfills by 2025. To support this, CalRecycle will build on its partnerships with local governments, industry, nonprofits, local air districts and water boards to support regional planning efforts and identify ways to safely and effectively develop necessary organics recycling capacity. CalRecycle will also explore new ways to foster food waste prevention and food rescue, to help meet a goal of 10 percent food rescue by 2020, and 20 percent by 2025. Recovering and utilizing food that would otherwise be landfilled can help to reduce methane emissions and increase access to healthy foods for millions of Californians who suffer from food insecurity. Additionally, ARB and CalRecycle will work with the State and regional Water Boards to assess the feasibility and benefits of actions to require capturing and effectively utilizing methane generated from wastewater treatment, and opportunities for co-digestion of food waste at existing or new anaerobic digesters at wastewater treatment plants.

This Proposed Strategy also establishes a goal of reducing fugitive methane emissions from oil and gas by 40 percent below current levels in 2025 and 45 percent in 2030, and from all other sources by 40 percent in 2030. This aligns with the Obama Administration goal of reducing methane emissions from oil and gas operations by 40–45 percent below 2012 levels by 2025.

California has a comprehensive and stringent emerging framework to reduce methane emissions from oil and gas systems. ARB is developing a regulation to reduce fugitive methane emissions from the oil and gas production, processing and storage sector, which will be among the most stringent such regulations in the country. Additionally, pursuant to Senate Bill 1371 (Leno, Chapter 525, Statutes of 2014), the California Public Utilities Commission has launched a rulemaking to minimize methane leaks from natural gas transmission and distribution pipelines. Increases in energy efficiency and renewable energy, as well as more dense development patterns, will reduce oil and gas demand and fugitive emissions. ARB and the California Energy Commission (CEC) have also conducted several research projects to improve methane emission monitoring and accounting, as well as identify emission “hotspots,” which are responsible for large fractions of total fugitive emissions. These efforts will continue, and are critical to accelerating leak detection and fugitive methane emission reductions from all sectors, not just oil and gas. Ultimately, to

eliminate fugitive methane emissions, the State needs to transition away from its use of oil and natural gas.

HFCs

Fluorinated gases, and in particular HFCs, are the fastest-growing source of GHG emissions in California and globally. More than three-quarters of HFC emissions in California come from the use of refrigerants in the commercial, industrial, residential, and transportation sectors. In many cases, alternatives with much lower GWPs are already available and the United States Environmental Protection Agency (U.S. EPA) is beginning to impose bans on the use of F-gases with the highest GWPs in certain applications and sectors. Additionally, there is strong international momentum and interest to phase down the use of HFCs under the Montreal Protocol, as has already been done for other F-gases. The annual Meeting of Parties in November 2015 resulted in a decision to continue working on an HFC phasedown schedule in 2016. In the absence of a sufficiently rigorous international agreement by the end of 2016, ARB will evaluate the feasibility of a phasedown for California that aligns with similar efforts and stringency levels in Australia, Canada, Europe, and Japan.

California can complement these national and potential international actions by taking additional steps to reduce HFC emissions at low cost. Early action, ahead of some of

the phase down schedules being proposed internationally, can avoid locking-in the use of high-GWP refrigerants in new or retrofitted systems in the coming years. Without early action to reduce unnecessary emissions now and into the future, the State would need to take additional—likely more costly—steps to meet its 2030 climate targets. An important step would be developing an incentive program to encourage the use of low-

GWP refrigerants, which could lead to very low cost emission reductions and could be implemented while further regulations are considered or developed. The Governor's proposed 2016-2017 budget includes \$20 million for incentives to reduce HFC emissions from refrigerants. Also, as effective alternatives become available, ARB will consider developing bans on the use of high-GWP refrigerants in sectors and applications not covered by U.S. EPA regulations.

This Proposed Strategy identifies measures that can reduce HFC emissions by 40 percent in California by 2030 and potentially capture additional, available reductions in HFC emissions now, and into the future. Many of these measures could have associated energy efficiency benefits, as well.

A summary of all proposed SLCP emission reduction measures and estimated reductions is presented in Table 2.

Table 2: Summary of Proposed New SLCP Measures and Estimated Emission Reductions (MMTCO₂e)*

| Measure Name | 2030 Annual Emission Reductions | 2030 Annual Emissions |
|--------------|---------------------------------|-----------------------|
|--------------|---------------------------------|-----------------------|

*Using 20-year GWPs from the 4th Assessment report of the IPCC for methane and HFCs, and 5th Assessment report for black carbon (the first report to define a GWP for black carbon)

**Business As Usual (BAU) forecasted inventory includes reductions from implementation of current regulations

***Future emission reduction measures that will be developed to help the State meet its air quality and climate change goals are also expected to help the State meet the black carbon target by 2030. However, an estimate of emission reductions is not currently available, but will be developed as part of these planning efforts.

Cost-Effective Measures with Significant Health Benefits

Significantly reducing SLCP emissions in line with the targets presented in this Proposed Strategy will continue California's long and successful legacy of implementing innovative and effective environmental and health policies while fostering the growth of a vibrant and sustainable economy. The proposed actions can contribute to health, environmental, and economic benefits that will positively impact Californian businesses and individuals. Many of these benefits will be concentrated in disadvantaged communities or other parts of the State most in need of economic development opportunities, including the San Joaquin Valley, rural areas where wood smoke is a primary health concern, and communities along freight corridors.

Collectively, implementing these measures would bring thousands of jobs from several billion dollars of investment in clean technologies and strategies that would lead to significant reductions in SLCP emissions. Potential revenues and efficiency savings could also be significant – and potentially outweigh the costs of some measures. In particular, for projects that utilize organic waste to create transportation fuel, the value of LCFS credits and RIN credits from the federal Renewable Fuel Standard can make these projects profitable. However, there remain significant institutional, market, and technical uncertainties that must be addressed, and continued incentives and State support can help to demonstrate and scale these strategies. In other cases, there may be net costs, but associated SLCP emission reductions may come at relatively low cost or provide other environmental and health benefits. For example, strategies at dairies that may not include energy production and associated revenues can still reduce emissions at low cost, and may deliver other environmental benefits, as well. And the collection of HFC measures identified in this Proposed Strategy could reduce GHG emissions by 260 MMTCO₂e cumulatively through 2030 (20-year GWP) at a very low cost per tonne.

Achieving the targets identified in this Proposed Strategy would help reduce ambient levels of ozone and particulate matter, and the cardiovascular and respiratory health effects associated with air pollution. These and other health benefits can be maximized as part of an integrated approach to ensure that strategies used to reduce SLCP emissions also help to improve air quality and water quality on a regional basis. Many of these benefits would accrue in disadvantaged communities, which are often located near sources of SLCP emissions.

The proposed actions are supported through an integrated set of air quality and climate policies in the State, including the Low Carbon Fuel Standard, Bioenergy Feed-In-Tariff, utility investments to defray the costs of connecting renewable natural gas supplies to the pipeline, and direct investments from State funds. Together, and with additional targeted State support, we can meet the goals identified in this Proposed Strategy and capture additional economic, environmental and health benefits.

Putting the Strategy into Action

All regulatory measures developed pursuant to the SLCP Reduction Strategy would undergo a complete, public rulemaking process including workshops, and economic and environmental evaluations. While this Proposed Strategy is intended to be comprehensive, it is not exhaustive. We will continue to pursue new cost-effective programs and measures as technology and research on SLCP emission sources and potential mitigation measures advances.

Effectively implementing this Proposed Strategy will require working with local, regional, federal and international partners, and strategically investing time and money to overcome market barriers that hinder progress. The extent to which we do so will drive results, which can include a wide range of significant economic and environmental benefits for California broadly, and many of the State's most disadvantaged communities, specifically.

Finally, the State will only realize the full benefits of strong action to reduce SLCP and CO₂ emissions if others take committed action, as well. Strong, near-term action to cut emissions of SLCPs, in conjunction with immediate and continuous reductions in emissions of CO₂, is the only way to stabilize global warming below 2°C. Accordingly, California has signed a number of agreements to work together with other countries, including China and Mexico, to support actions to fight climate change and cut air pollution. Additionally, California is bringing together subnational jurisdictions under the Subnational Global Climate Leadership Memorandum of Understanding (the "Under 2 MOU"), which commits signatories to take steps to reduce SLCP and CO₂ emissions and meet the goal of keeping global average warming below the 2°C threshold by reducing their GHG emissions to under 2 metric tons per capita, or 80–95 percent below 1990 levels, by 2050. To date, a total of 127 jurisdictions have signed or endorsed the Under 2 MOU, collectively representing more than 729 million people and \$20.4 trillion in GDP, equivalent to more than a quarter of the global economy. If the signatories represented a single country, it would be the second largest economy in the world behind only the United States. As it implements the actions identified in this Proposed Strategy and other related climate change planning efforts, California will continue to share its successes and approach with others, to expand action to address climate change and deliver local and global benefits for the State.

I. Introduction: Showing the Way to 2°C

California must achieve deep reductions in short-lived climate pollutant (SLCP) emissions by 2030 to help avoid the worst impacts of climate change and meet air quality goals. Additionally, intensified, global action to reduce these emissions is the only practical way to immediately slow global warming and is necessary to keep warming below 2°C through at least 2050, which is a critical threshold to manage the damaging effects of climate change. A broad scientific consensus has emerged, based on extensive research, that a 2°C (3.6°F) increase in global average temperature above pre-industrial levels poses severe risks to natural systems and human health and well-being. This is an increase of only 1.1°C (2.0°F) above the present level. Even a slight increase in global warming would lead to significant sea level rise, and the overall impact from climate change would be substantially greater if global warming exceeds 2°C. Strong, near-term action to cut emissions of SLCPs, in conjunction with immediate and continuous reductions in emissions of carbon dioxide (CO₂), is the only way to stabilize global warming below 2°C.

In December 2015, at the 21st Conference of Parties (COP21), 25,000 delegates from 196 countries gathered recognizing that “climate change represents an urgent and potentially irreversible threat to human societies and the planet and thus requires the widest possible cooperation by all countries, and their participation in an effective and appropriate international response, with a view to accelerating the reduction of global greenhouse gas emissions.” An agreement was reached to substantially reduce GHG emissions with the aim of limiting a global temperature increase to below 2°C, mobilize investments to support low-carbon development, and create a pathway for long-term de-carbonization. Additionally, the agreement aims to strengthen the ability to deal with the impacts of climate change.

Short-lived climate pollutants, including methane (CH₄), black carbon (soot), and fluorinated gases (F-gases, including hydrofluorocarbons, or HFCs), are among the most harmful to both human health and global climate. They are powerful climate forcers that remain in the atmosphere for a much shorter period of time than longer-lived climate pollutants, including CO₂, which is the primary driver of climate change. Their relative climate forcing, when measured in terms of how they heat the atmosphere, can be tens, hundreds, or even thousands of times greater than that of CO₂. Short-lived climate pollutants contribute about 40 percent to current anthropogenic global radiative forcing, which is the primary forcing agent for observed climate change.^{1,2,3,4,5}

California has taken significant steps to reduce SLCP emissions, especially black carbon from transportation, methane from oil and gas operations and landfill emissions, and HFC emissions from refrigerants, insulating foams, and aerosol propellants. Still, more can and must be done to reduce emissions from these and other sources in the State, including methane from waste management and dairies, black carbon from off-road and non-mobile sources, and HFC emissions from refrigeration and air conditioning systems.

The State is committed to further reducing SLCP emissions. SLCP emission reductions are important, first of all, to continuing and maintaining the GHG emission reductions called for by AB 32, and to ensuring emissions meet the statewide GHG emission limit it established. The Proposed Strategy is identified in the First Update to the Climate Change Scoping Plan as one of the recommended actions to achieve additional GHG emission reductions. Growing SLCP emissions (such as from fluorinated gases) threaten to erode the State's progress towards this limit; in other sectors (such as from oil and gas and agriculture) continued emissions will put increased pressure on the remainder of ARB's regulatory structure to maintain overall emissions below the GHG limit and to continue reductions. Conversely, addressing SLCP emissions will help to ensure that the AB 32 limit is maintained, and will fulfill AB 32's mandate to continue to seek the maximum technologically feasible and cost-effective reductions of GHG emissions. Reducing these powerful climate-forcers early also produces a compound-interest effect through which the effectiveness of future reductions are magnified: those future reductions start from a baseline substantially lower than where they would have started in the absence of aggressive early reduction efforts.

The Legislature directly recognized the critical role that SLCPs must play in the State's climate efforts with the passage of Senate Bill 605 (Lara, Chapter 523, Statutes of 2014), which requires the Air Resources Board (ARB or Board) to develop a strategy by the end of 2015 to reduce SLCP emissions. In his 2015 Inaugural Address, Governor Brown reinforced this commitment and called on California to show the world the path to limiting global warming below 2°C through 2050, while highlighting the role that action to cut SLCPs must play in this effort. In April 2015, the Governor set a target for reducing overall GHG emissions to 40 percent below 1990 levels by 2030, which the actions identified in this report will support.

Reducing abrupt climate change risk using the Montreal Protocol and other regulatory actions to complement cuts in CO₂ emissions. *Proceedings of the National Academy of Sciences of the United States of America*. 2009;106(49):20616-20621. doi:10.1073/pnas.0902568106.
<http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2791591/>

Significant reductions in SLCP emissions can be achieved globally using cost-effective technologies and strategies, some of which have already been demonstrated effectively in California. Over the past several decades, the State's efforts in controlling these harmful emissions have prevented thousands of premature deaths in California, saved the State many tens of billions of dollars in energy and health costs, and have occurred alongside strong economic growth throughout our diverse economy. Applying California's experiences to reduce SLCP emissions globally would help prevent millions of premature deaths each year; boost agricultural productivity; limit disruption of historic rainfall patterns; slow the melting of glaciers, snowpack, and sea ice; reduce sea level rise; and provide trillions of dollars in economic benefits each year.

A. Significant Benefits from Accelerated Action to Cut SLCP Emissions

While reducing CO₂ emissions limits climate change over the long term, reducing emissions of SLCPs will effectively slow the rate of climate change in the near-term. Therefore, the best path forward is to emphasize parallel strategies for reducing SLCP and CO₂ emissions.^{6,7} Studies indicate that available technologies, if universally adopted, can effectively reduce global methane emissions an estimated 40 percent and black carbon an estimated 80 percent below 1990 levels by 2030.⁸ Additionally, a new proposed global phase down of HFCs under the Montreal Protocol (if adopted) and other efforts could cut the expected production of HFCs by up to 70 percent by 2030, and up to 85 percent by 2035.^{9,10}

Achieving this scale of global reductions would deliver significant climate benefits. It would cut the expected rate of global warming in half by 2050, slowing global temperature rise by about 0.6°C,^{11,12} which would reduce the risk of dangerous climate

feedbacks such as accelerated Arctic melting and sea level rise.¹³ It would also increase the probability of staying below the 2°C threshold to more than 90 percent through 2050.^{14,15}

The benefits could be even greater in the Arctic, which is especially vulnerable to black carbon emissions and is warming twice as fast as the rest of the world.¹⁶ Slowing climate change impacts in the Arctic could be critically important for stabilizing climate change and its impacts, as the Arctic is an important driver of sea level rise and weather patterns throughout the Northern Hemisphere.^{17,18} Reducing emissions of SLCPs can slow down the rate of sea level rise by 24–50 percent this century, if efforts to reduce emissions begin now. Mitigating emissions of both CO₂ and SLCPs can reduce the projected sea level rise rate by 50–67 percent by 2100.¹⁹

Deploying existing, cost-effective technologies to reduce SLCP emissions can also cut global emissions of fine particulate matter (PM_{2.5}) by an estimated 50 percent, oxides of nitrogen (NO_x) emissions by 35 percent, and carbon monoxide (CO) emissions by 60 percent.²⁰ If these measures were fully in place by 2030, an estimated 3.5 million premature deaths and 53 million metric tons of crop losses could be avoided globally, each year. The economic value of these climate, crop, and health benefits is estimated to be about \$5.9 trillion annually.²¹ Most of these benefits would accrue in the developing world and places where disproportionate climate impacts are already being felt.

Many of the benefits of cutting SLCP emissions in California will accrue in the most disadvantaged parts of the State, where pollution levels and their health impacts are

often highest, and where further economic development may be most needed. For example:

- Further cutting black carbon emissions from the transportation sector and building a sustainable freight system would have health and economic benefits for communities in the East Bay, Southern California, and the Inland Empire along freight corridors and near ports and railyards where diesel particulate matter concentrations are highest.
- Investments to cut methane and black carbon emissions as part of an integrated strategy to reduce emissions from agriculture and waste can provide important benefits for the Central Valley and other agricultural communities. They can help build an increasingly resilient and competitive agricultural sector by supporting jobs and economic growth, healthy soils, and improved air quality, water quality, and public health in those communities.
- Improving management and health of forests and rural landscapes to sustainably sequester carbon and mitigate black carbon emissions from wildfires can help bring investment, economic, and climate resiliency benefits throughout the Sierra, the North Coast, and other rural parts of California.
- Switching to low-GWP refrigerants can also improve the energy efficiency of refrigeration and air conditioning equipment, which can help to cut electricity bills throughout the State.

B. Building on California's Air Quality and Climate Leadership

California's ongoing efforts to improve air quality and address climate change have already led to important reductions in SLCP emissions, and they provide a strong foundation to support further efforts to reduce emissions of these dangerous pollutants.

- *Black carbon:* California has cut anthropogenic sources of black carbon emissions by more than 90 percent since the 1960s. From 2000 to 2020, California will have cut black carbon from mobile sources by 75 percent. These efforts prevent an estimated 5,000 premature deaths in the State each year, and deliver important climate benefits. If the world replicated this success, it would slow global warming by an estimated 15 percent,²² essentially offsetting one to two decades' worth of CO₂ emissions.²³
- *Methane:* California has the nation's strongest standards for limiting methane emissions from landfills, has offset protocols under our Cap-and-Trade program to encourage the reduction of methane emissions, and has rules under development and being implemented to create a comprehensive approach to limit methane leaks from the oil and gas production, processing, and storage

²² Ramanathan et al (2013) Black Carbon and the Regional Climate of California, Report to the California Air Resources Board, Contract 08-323, April 15. http://www.arb.ca.gov/research/single-project.php?row_id=64841

²³ Wallack, J. and Veerabhadran Ramanathan (2009) The Other Climate Changers: Why Black Carbon and Ozone Also Matter, *Foreign Affairs*, September/October 2009, pp. 105-113. <https://www.foreignaffairs.com/articles/2009-09-01/other-climate-changers>

sector, and the natural gas pipeline system. These efforts are serving to keep methane emissions fairly steady in the State.

- *HFCs*: The State has regulations in place to reduce emissions from refrigerants, motor vehicle air-conditioning, and consumer products that together will cut emissions of HFCs by 25 percent below otherwise projected levels in 2020.

Still, more remains to be done. California is home to some of the highest levels of air pollution in the country, and although the State has substantially reduced particulate matter and black carbon emissions from on-road transportation, vehicles still pollute the air in our communities and harm the lungs of some of our most vulnerable populations. Global methane emissions are responsible for about 20 percent of current global warming,²⁴ and its emissions continue to increase. F-gases, specifically HFCs, are the fastest growing source of GHG emissions in California and globally.

C. Purpose of SLCP Reduction Strategy

The State is committed to further reducing SLCP emissions. The 2014 Update to the Climate Change Scoping Plan (2014 Scoping Plan Update) identified SLCPs as an important aspect of a comprehensive approach to addressing climate change. Senate Bill 605 (Lara, Chapter 523, Statutes of 2014) requires ARB to develop a plan to reduce emissions of SLCPs. Additionally, Governor Brown has identified reductions of SLCP emissions as one of “five pillars” to meet an overarching goal to reduce California’s GHG emissions by 40 percent below 1990 levels by 2030. Senate Bill 605 (Lara, Chapter 523, Statutes of 2014), requires ARB to develop a comprehensive strategy to reduce emissions of SLCPs in the State, and in developing the strategy to:

- Complete an inventory of sources and emissions of SLCPs in the State based on available data;
- Identify research needs to address any data gaps;
- Identify existing and potential new control measures to reduce emissions;
- Prioritize the development of new measures for SLCPs that offer co-benefits by improving water quality or reducing other air pollutants that impact community health and benefit disadvantaged communities, as identified pursuant to California Health and Safety Code Section 39711;
- Coordinate with other State agencies and air districts to develop and implement measures identified as part of the comprehensive strategy;
- Consult with experts in academia, industry, and the community on SLCPs. The topics shall include, but not be limited to, all of the following:
 - Assessment of the current status of controls that directly or indirectly reduce emissions of SLCPs in the State.
 - Identification of opportunities and challenges for controlling emissions.
 - Recommendations to further reduce emissions; and
- Hold at least one public workshop during the development of the strategy.

²⁴ Kirschke, S. *et al.* (2013) Three decades of global methane sources and sinks. *Nature Geosci.* **6**, 813–823. http://www.nature.com/ngeo/journal/v6/n10/full/ngeo1955.html?WT.ec_id=NGEO-201310

ARB developed this proposed SLCP Reduction Strategy report (Proposed Strategy) pursuant to SB 605, in coordination with other State agencies and local air quality management and air pollution control districts. The Proposed Strategy has been developed with input from interested stakeholders in an open and public process and describes a proposed strategy for California to reduce emissions of SLCPs through 2030. It describes ongoing and potential new measures to reduce SLCP emissions from all major sources in the State, and describes current and future research needs for improving the SLCP emission inventory and better understanding potential mitigation measures. California's SLCP emission inventory²⁵ and current and future research needs are included in Appendix A, and research efforts to evaluate potential mitigation measures for each SLCP is included in Appendix B. Measures included in the final SLCP Reduction Strategy would be developed under future public regulatory processes with the appropriate public process, economic analyses, environmental analyses, and consideration of environmental justice.

D. Achieving Science-Based Targets

This Proposed Strategy is designed to meet planning targets of reducing methane and HFC emissions by 40 percent below current (2013) levels by 2030, and black carbon emissions by 50 percent below current levels by 2030. The targets are translated into millions of metric tonnes of CO₂-equivalent (MMTCo₂e) in Table 3. These proposed targets are in-line with science-based assessments of reductions needed globally to limit warming below 2°C through at least 2050, as well as efforts needed in California to reduce overall GHG emissions by 40 percent below 1990 levels by 2030.

Table 3: California SLCP Emissions and Proposed Target Emission Levels (MMTCo₂e)*

| Pollutant | Inventory 2013 | Forecast** 2030 | Targets 2030 |
|--------------------|----------------|-----------------|--------------|
| Black Carbon*** | 38 | 26 | 19 |
| Methane | 118 | 117 | 71 |
| Hydrofluorocarbons | 40 | 65 | 24 |

*Using 20-year Global Warming Potentials and AR4 except Black Carbon, which uses AR5 (the first report to define a GWP for black carbon)

**Includes reductions from implementation of current regulations

***All non-forest sources

These targets are not binding, but provide important indices against which to measure the State's progress to reduce SLCP emissions. California efforts to reduce SLCP emissions, consistent with these targets, are important to further the purposes of AB 32, whose requirements charge ARB with reaching and maintaining the statewide GHG limit, as well as taking steps to continue reductions. Several Executive Orders (EO), including Governor Brown's EO B-30-15, further charge ARB with continuing and

²⁵ Inventory methodology and detailed inventory tables available at: <http://www.arb.ca.gov/cc/inventory/slcp/slcp.htm>

maintaining emission reductions. The measures identified in this Proposed Strategy and their expected emission reductions will feed into the update to the Climate Change Scoping Plan that is currently being developed pursuant to EO B-30-15. The 2030 Target Scoping Plan Update will establish a broad framework for meeting all of California's climate-related targets and will include an evaluation of all proposed GHG reducing activities, for both short-lived and longer-lived pollutants.

Throughout this Proposed Strategy, there is an emphasis on early actions, often supported by public investments and strong policy incentives. This approach is intended to achieve earlier reductions (in the 2020 timeframe), bring projects online quickly, and help scale sector-wide solutions while potential regulatory or other measures to reduce SLCP emissions are developed. By supporting early action through investments and commitments to overcome barriers, we can maximize benefits throughout California, while minimizing the impact of future regulations on businesses in these sectors.

Together with California's previous efforts to successfully reduce black carbon and other SLCP emissions, implementing the measures identified in this Proposed Strategy to meet these targets would put California on the path to meet the Governor's 2030 climate goals, while delivering significant agricultural, air quality, economic, health, water, and other climate co-benefits.

E. Coordinating Research Efforts Related to SLCPs

Many California State agencies sponsor climate-related research. State-sponsored climate research, including research related to SLCPs, has been guided by the needs identified in state laws, Executive Orders, and other policy documents, as well as the best and latest science.

Since 2008, the Climate Action Team Research Working Group (CATRWG) has provided a forum for State agencies to discuss and coordinate their proposed research activities. The CATRWG also facilitates coordination with external groups including academia, federal agencies, the international community, and private entities. Integration and coordination with non-state sponsored research programs is important to leverage State resources and to provide coherent and practical research results for California.

To support these efforts, the CATRWG has created a catalog of relevant research projects supported by the State since the early 2000s.²⁶ The catalog keeps State agencies and interested stakeholders informed about the range of activities and the status of individual projects. The catalog includes a number of projects related to the impacts of SLCPs on regional climate in California, research underway to enhance SLCP inventories, and evaluations of SLCP mitigation strategies.

In 2015, the CATRWG released a Climate Change Research Plan for California.²⁷ The Plan synthesizes the knowledge gaps, and presents research priorities for the next three to five years for policy-relevant, California-specific research. It includes research needs related to the mitigation of SLCPs and specific needs to improve SLCP inventories. The Plan outlines these research needs in order to inform the State's ongoing activities without duplicating federal research activities. This is an unprecedented effort resulting in the first comprehensive climate change research plan developed by any state. The CATRWG will update the Plan every other year, with major revisions every four years. Research related to SLCPs will continue to be a priority in these updates.

Future State-sponsored research will be guided by recommendations in the CATRWG Research Plan, as well as other documents such as the SLCP Reduction Strategy. State agencies will continue to leverage funding and avoid duplication of effort through coordination in CATRWG meetings. State agencies that sponsor research will also continue their individual efforts to align future research needs with input from stakeholders, academic experts and other public and private research entities.

F. Process for Developing the SLCP Reduction Strategy

This Proposed Strategy was developed with input from State and local agencies, academic experts, a working group of agricultural experts and farmers convened by CDFA, and other interested stakeholders in an open and public process. ARB and State agencies collaborated to identify reduction measures for specific sectors, including the dairy, wastewater, and waste sectors. In addition, ARB collaborated with the local air districts to identify SLCP emission reduction measures that could be implemented through district action. The Proposed Strategy will be further refined based on stakeholder input.

In May 2015, ARB released for public review, a Concept Paper to initiate discussion on the

²⁶ California's State-sponsored Research Catalog: <http://cal-adapt.org/research/>

²⁷ Climate Change Research Plan for California (2015) http://www.climatechange.ca.gov/climate_action_team/reports/CAT_research_plan_2015.pdf

development of this Proposed Strategy.²⁸ The paper described initial ideas to be explored as the Strategy was developed, and sought to elicit new ideas and refinement of current measures to reduce emissions of SLCPs throughout the State. The Concept Paper was presented at a public meeting later in May, to solicit public input. After consideration of comments received, staff developed a Draft SLCP Reduction Strategy,²⁹ which was released for public comment on September 30, 2015. Comments received on the Draft Strategy are posted at:

<http://www.arb.ca.gov/lispub/comm2/bccommlog.php?listname=slcpdraftstrategy-ws>

ARB held workshops in October 2015 to solicit comments on the Draft Strategy, including comments related to the development of a California Environmental Quality Act (CEQA) document. After consideration of public comments received, ARB developed this Proposed Strategy and an accompanying draft Environmental Analysis (Appendix C). Additional workshops will be held to solicit comments on this Proposed Strategy, before it is presented to the Board in May 2016. Staff will present the final proposed SLCP Reduction Strategy, the final EA, and written responses to comments received on the EA to the Board for consideration at a public hearing in fall 2016.

²⁹ <http://www.arb.ca.gov/cc/shortlived/2015draft.pdf>

II. California's Approach to Reducing SLCP Emissions

The 2014 Scoping Plan Update described California's approach to climate change as one reliant on science and foundational research. The Update focused on: preserving natural resources that provide for our economy and define our lifestyle in California, fostering resilient economic growth throughout the State, improving public health, and supporting economic, social and environmental justice. The State's commitment to addressing climate change and public health is born of necessity, but provides tremendous opportunity to build competitiveness and resilience into our communities, resources, and economy. We understand that steps we take to reduce emissions and strengthen our State against the impacts of climate change provide economic opportunities today, and untether our future potential from limits imposed by resource constraints and pollution.

This approach continues to guide us as we focus on reducing emissions of SLCPs to meet science-based targets in this Proposed Strategy. Additionally, California's approach to reducing SLCP emissions is framed by the principles described below.

A. Prioritize Actions with Diverse Benefits

The direct benefits of cutting SLCP emissions will be immediately tangible, and can be substantial. As part of an integrated strategy to not only reduce emissions of SLCPs, but also to develop renewable sources of energy and strengthen the competitiveness and resiliency of our agricultural, waste, and other sectors, they can deliver even greater benefits, including:

- Reduced asthma risk, hospitalization, premature death, and associated medical costs from air pollution, especially in disadvantaged communities;
- Reduced global and localized climate change impacts, including sea level rise and disrupted precipitation patterns, and associated costs;
- Reduced crop losses from air pollution;
- Healthier forests, wildlife habitats, and watersheds;
- Healthy soils that are more sustainable and resilient to climate change, sequester GHGs, require less synthetic amendments, and improve water retention;
- The creation of a new industry, mostly in rural parts of the State and the Central Valley, around utilizing organic waste streams to generate renewable energy, fuels, and compost—bringing billions in investment; and
- Stronger agricultural and freight sectors that are well positioned to continue competing globally and growing as a source of jobs and economic development in California.

Clearly, there are a number of drivers and benefits to reducing SLCP emissions that extend beyond mitigating the impacts of climate change. The measures identified in this Proposed Strategy are intended to provide a wide array of climate, health, and economic benefits throughout the State. As they are further developed and implemented, a key focus will be to provide and maximize multiple benefits.

B. Put Organic Waste to Beneficial Use

California's organic waste streams are responsible for half of the State's methane emissions and represent a valuable energy and soil-enhancing resource. Effectively implementing the measures described in this Proposed Strategy will not only reduce methane emissions but provide many other benefits as well, including cutting emissions of CO₂ and boosting economic growth in agricultural and rural communities.

Building infrastructure to better manage organic waste streams could lead to billions of dollars of investment and thousands of jobs in the State.^{30,31} This infrastructure could provide valuable new sources of renewable electricity or biogas, clean transportation fuels, compost other beneficial soil amendments, and other products. Adopting state policies to promote biogas from organic waste would provide a strong durable market signal to industry, agencies, and investors. In addition, this biogas can help the State meet its 33 percent renewable mandate for hydrogen transportation fuel. The State's new 50 percent renewable portfolio standard may drive renewable hydrogen production even higher. Collectively, products from organic waste streams in California, and potential environmental credits from them, could represent a market worth billions of dollars in California.

Utilizing clean technologies to put organic waste streams to a beneficial use can also serve to improve regional air and water quality and support economic growth in

agricultural and other communities throughout the State. For example, most dairies in California currently store manure in uncovered lagoons and use lagoon water to fertilize on-site forage crops. This approach to managing manure has helped to improve the efficiency of dairy farms and milk production over the years. However, these lagoons also create one of the largest sources of methane emissions in the

State, and—when combined with imprecise or improper land application of nutrients, water, and salts via flood irrigation of lagoon effluent—can create adverse groundwater

³⁰ Kaffka et al (2011) Economic, Social, and Environmental Effects of Current and Near-term Biomass Use in California, California Biomass Collaborative, University of California, Davis.

<http://biomass.ucdavis.edu/publications/>

³¹ Due to its large dairy industry, California likely represents more than its share of the estimated 11,000 potential new biogas systems that could be built in the U.S. and the associated \$33 billion in capital deployment, 275,000 short-term construction jobs, and 18,000 permanent jobs.

USDA, USEPA, USDOE (2014) Biogas Opportunities Roadmap: Voluntary Actions to Reduce Methane Emissions and Increase Energy Independence.

http://www.usda.gov/oce/reports/energy/Biogas_Opportunities_Roadmap_8-1-14.pdf

and nutrient management issues on farms. Alternatively, manure can be managed in a way to reduce or avoid methane emissions and open up opportunities for improving farm nutrient management activities.

In order to capture the entire potential value from California's waste resources, significant amounts of infrastructure remain to be built and markets must be fully enabled. Barriers remain to achieving these wide-ranging economic and environmental benefits, and must be addressed.

C. Identify Practical Solutions to Overcome Barriers

Maximizing the diverse benefits of putting organic waste streams to beneficial uses will require overcoming barriers that have hindered such efforts in the past. Barriers affect many parts of the supply and marketing chain, including feedstock, technology, market/economics, permitting, technical feasibility, infrastructure, logistics, and user behavior.

For example, inexpensive and abundant landfill capacity may make diverting organic material relatively costly in some cases. Developing projects to generate renewable energy and soil amendments from this waste stream will require additional investments in clean technology and management practices, aligning economic incentives that currently favor landfilling with the State's objectives to put organic resources to better use, and streamlining various governmental and utility permitting processes.

Technology or market barriers also remain in some sectors. Interconnecting distributed sources of renewable energy onto the electricity grid, or biogas into pipelines, remains an unnecessarily long and costly process in many cases. Utilizing biogas in a conventional combustion engine to create electricity can exacerbate air quality problems in many parts of the State, including the Central Valley and Southern California. Clean engine and fuel options, or low-GWP refrigerants, are not available for all applications. Markets for compost and soil amendments need to be built out and strengthened, which would provide an important value stream for financing anaerobic digestion and compost facilities. Additional support and time may be needed to strengthen existing and emerging markets for renewable natural gas and fuels, soil amendments, and their associated environmental attributes.

But these barriers are not insurmountable. As California develops a SLCP Strategy to reduce SLCP emissions and plans to meet its climate and air quality goals for 2030, now is the time to solve them. This Proposed Strategy identifies strategies and funding mechanisms to encourage the use of the cleanest technologies to advance the State's air quality, water quality, climate change, and other environmental objectives. Solutions that address several environmental concerns—air quality, climate, and water quality—and can be easily financed, are clear winners.

Several existing programs already provide incentives to convert waste streams to various forms of energy, which can be leveraged along with new efforts to increase the

share of renewable biogas used in California buildings, industry, and transportation. For example, the Low Carbon Fuel Standard (LCFS) and federal Renewable Fuel Standard provide strong economic incentives to utilize organic waste resources for production of transportation fuels. At current LCFS and RIN credit prices, anaerobic digestion projects that generate transportation fuels at dairies, wastewater treatment plants, or elsewhere can be profitable (see Chapter VIII). In order to enable this market, however, barriers to pipeline injection of biogas, among others, must be addressed. The CPUC has authorized an incentive program, capped at \$40 million, to offset half of renewable natural gas interconnection costs, up to \$1.5 million per project. State agencies are already collaborating to overcome barriers to pipeline injection of biogas, pursuant to the Governor's call to make heating fuels cleaner,³² and they will redouble their efforts. This includes monitoring market progress pursuant to Assembly Bill 1900 (Gatto, Chapter 602, Statutes of 2012) and considering appropriate adjustments, as needed. Also, supplemental policy options to accelerate biogas projects and access to the pipeline will be considered, including steps that utilities can take, options to accommodate varying heat rates of pipeline gas in certain instances, and potential new policies like a feed-in-tariff for renewable natural gas.

Building market certainty and value for compost and other soil amendment products will also help to secure financing for projects to use organic waste and cut emissions of SLCPs. Soil amendments from organic waste streams in California represent a potential \$200-400 million market in California, exceeding the likely value of energy products from the resource.³³ Efforts to increase composting and anaerobic digestion—

and capture the diverse benefits from doing so—can be supported by efforts to promote and account for the benefits of using compost, manure, and other soil amendments that come from these processes. ARB is coordinating with CDFA and other agencies working on the Healthy Soils Initiative to identify additional research needs to inform the science and accounting methods necessary to quantify the benefits of using compost and other soil amendments and address any potential problems such as buildup of salts or heavy metals in soil. Collaboration among state agencies, water districts, and local governments will help quantify the benefits of using compost for urban storm water management, soil remediation, water conservation, and other beneficial uses.

³³ Informa Economics (2013) National Market Value of Anaerobic Digester Products, Prepared for the Innovation Center for U.S. Dairy, February.

D. Invest in SLCP Emission Reductions and Communities

Achieving significant reductions in SLCPs will require substantial investments to provide incentives and direct funding for priority sectors, sources, and technologies. Public investments should be smart and strategic, to leverage private investment and accelerate market transitions to cleaner technologies that foster significant system-wide solutions to cut emissions of SLCPs, maximize resource recovery from organic waste streams, and provide economic and health benefits in agricultural, disadvantaged, and rural parts of the State. Examples may include targeted support to reduce emissions of SLCPs and CO₂ through integrated strategies at dairies and in organic waste management; throughout the freight system; in commercial refrigeration applications; and from the management of woody waste materials in the urban, agricultural and forestry sectors.

Many of the sources and sectors responsible for SLCP emissions are concentrated in communities with high levels of pollution or unemployment, which could especially benefit from targeted investments to improve public health and boost economic growth. These include SLCP emissions from sources of organic waste and dairies in the Central Valley; ports and freight corridors in the East Bay, Los Angeles area and Inland Empire; and oil production, landfills and other sources of SLCP emissions throughout the State. Many communities in these areas, along with forested and rural communities in the northern part of the State and the Sierra, have some of the worst pollution burdens in the State, and high rates of poverty and unemployment. They are also where many billions of dollars in public and private investment will accrue in the coming years to reduce SLCP and CO₂ emissions and strengthen our agricultural sector, build sustainable freight systems, and grow healthy forests.

Initial estimates regarding State support for infrastructure to meet the goals identified in this Proposed Strategy is similar for both the waste sector and dairy sector. CalRecycle and CDFA both estimate that direct investments or incentives on the order of \$100 million per year for five years could significantly scale project development to cut SLCP emissions associated with dairy manure and waste management. There could also be some opportunity to optimize investments and co-locate infrastructure or utilize existing infrastructure, including excess digestion capacity that exists at many wastewater treatment plants, which could potentially reduce the level of incentive funding needed to reach the targets outlined in this Proposed Strategy. Additional research and working group efforts will focus on opportunities to optimize infrastructure rollout and maximize benefit from any State investment.

The State will need to continue coordinating and utilizing funding sources, such as the Greenhouse Gas Reduction Fund (Cap-and-Trade auction proceeds),³⁴ the Alternative and Renewable Fuel and Vehicle Technology Program (AB 118), Electric Program Investment Charge (EPIC) Program, Carl Moyer program, Air Quality Improvement

³⁴ AB 1532 (Pérez, Chapter 807), SB 535 (De León, Chapter 830), and SB 1018 (Senate Budget Committee, Chapter 39) established the GHG Reduction Fund to receive Cap-and-Trade auction proceeds.

Program, and Proposition 39 to expand clean energy investments in California and further reduce emissions of SLCPs and other GHGs. Additionally, programs including the Bioenergy Feed-In Tariff, created by Senate Bill 1122 (Rubio, Chapter 612, Statutes of 2012), Low Carbon Fuel Standard, Cap-and-Trade, Self-Generation Incentive Program, Federal Renewable Fuel Standard, utility incentives pursuant to Assembly Bill 1900 (Gatto, Chapter 602, Statutes of 2012), and others provide important market signals and potential revenue streams to support projects to reduce SLCP emissions. These programs are described in more detail in Chapter VII.

Potential new funding mechanisms and incentive structures must also be considered. These could include adjusting the waste disposal tipping fee structure to account for the full cost of managing organic materials and landfills, state procurement contracts for renewable natural gas and other fuels in buildings or vehicles as well as for compost and mulch products in landscaping and erosion control, or labeling programs to recognize leading companies in the market place, including those producing milk with low levels of dairy methane emissions or freight haulers using clean technologies.

E. Advance the Science of SLCP Sources and Emissions

Data related to SLCPs and their sources is often less available or of lower quality than it is for CO₂. One reason is that energy-related emissions of CO₂ are often easier to quantify than emissions of other GHGs, which may form through complex biological or other processes where existing reporting guidelines and procedures may not apply. There has also been less of a focus on collecting additional data that could help to quantify GHG emissions from some non-CO₂ sources.

This Proposed Strategy, including Appendices A and B, describes several coordinated research efforts under way and potential new ones. To provide a better understanding of methane emissions from the natural gas system and natural gas and oil supplied to California, dairy operations, landfills, as well as various sources of HFCs and black carbon emissions, others not identified here also may be considered in the future.

For example, methane emissions are emitted from a wide range of biological processes and fugitive and area sources that make estimating emissions difficult. California's methane emission estimates are derived from a variety of surveys, government data sources, growth assumptions and modeling methodologies. ARB staff is continuously assessing ways to improve the methane inventory by incorporating the latest scientific understanding of methane sources, through coordinated research with other agencies, and by using the best available activity data. Additional research and improved data sources will be needed to continue to refine the methane inventory and provide California-specific activity data.

While improving data access and quality is not a prerequisite for many actions to reduce emissions of SLCPs, it is nonetheless important for informing ongoing efforts to reduce SLCP emissions and meet broader climate targets. Improved data and reliable GHG measurements from landfills, dairies, and other more difficult-to-measure sources would also be necessary before these sources could be potentially included in California's Cap-and-Trade Program. State agencies will continue to monitor technology development and support continued research to improve the accuracy and reliability of emissions accounting from these sources.

F. Need for Focused SLCP Programs

This Proposed Strategy outlines specific emission reduction measures that could reduce California's emissions of SLCPs. This reliance on direct regulations, in concert with the existing greenhouse gas Cap-and-Trade Program, is consistent with California's approach on addressing climate change. California has already adopted several direct measures that ensure GHG emission reductions are achieved in specific sectors, including for SLCPs (for example, the Refrigerant Management Program that regulates F-gas emissions). These types of requirements motivate focused change—such as increased deployment of renewable energy (Renewable Portfolio Standard) or transformation of transportation fuels (Low Carbon Fuel Standard)—which may be more readily realized through direct measures than sole reliance on the Cap-and-Trade Program.

The Cap-and-Trade Program covers combustion and process operations. These emissions can be measured according to the accuracy requirements of the Mandatory Greenhouse Gas Emissions Reporting Regulation, which includes accurate quantification methodologies that allow for consistent carbon costs,³⁵ and the sources align with those covered by federal reporting programs.³⁶ In contrast, most fugitive emissions³⁷ (a category into which SLCP emissions generally fall) do not meet these criteria.³⁸ They are frequently difficult to measure, measurements have high

³⁵ *California Air Resources Board (2011) California's Cap-and-Trade Program Final Statement of Reasons*, Response to Comment E-31, at pg. 425. available at <http://www.arb.ca.gov/regact/2010/capandtrade10/fsor.pdf>.

³⁶ *Id.*, Response to Comment E-69, at pg. 448. available at <http://www.arb.ca.gov/regact/2010/capandtrade10/fsor.pdf>.

³⁷ Fugitives from certain oil and gas sources are an exception because, unlike other fugitive emissions, they are possible to quantify with rigor.

³⁸ ARB's responses to comments in the 2011 Final Statement of Reasons for the Regulation and Western Climate Initiative design documentation provide detailed rationale for the treatment of fugitive emissions in specific sectors. For example, the quantification methods that are often used to quantify fugitive emissions, including calibrated bagging, high volume sampling, and a default emissions factor, only provide a snapshot of emissions rather than actual measurements of emissions from the source. See also Western Climate Initiative, Inc. (2010) WCI Comments on the Proposed Mandatory Reporting of GHG Emissions from Proposed Reporting for Oil and Gas Operations (Subpart W), at pg. 44. available at http://www.westernclimateinitiative.org/document-archives/func-download/258/chk,ab6041717dc1be9cd3430f4f7585cb8e/no_html,1/.

uncertainties,³⁹ measurement methods are often difficult and less precise,⁴⁰ and carbon costs are hard to assign with the same reliability as for combustion sources of CO₂.⁴¹ Because of these difficulties, and the importance of seeking SLCP-specific emission reductions, which the Cap-and-Trade Program is not designed to produce, this Proposed Strategy does not recommend expanding Cap-and-Trade Program coverage.⁴² Instead, the Proposed Strategy focuses on specific measures for SLCP-emitting sectors, consistent with the approach ARB adopted while developing the AB 32 Scoping Plan and Cap-and-Trade Program.

ARB notes that stakeholders have expressed divergent views on this basic approach as it relates to animal agriculture. On one hand, the Animal Legal Defense Fund has petitioned ARB to include emissions from that sector in the Cap-and-Trade Program. On the other hand, representatives of many environmental justice and environmental groups have argued that direct, sector-specific measures are preferable, as have representatives of the dairy industry. This Proposed Strategy focuses on direct measures, consistent with the necessity of reducing SLCP emissions from the dairy sector specifically, and in-line with the design principles that underlie the State's climate strategy and the Cap-and-Trade Regulation.⁴³

³⁹ Western Climate Initiative, Inc. (2010) WCI Comments on the Proposed Mandatory Reporting of GHG Emissions from Proposed Reporting for Oil and Gas Operations (Subpart W) at pg. 39. available at http://www.westernclimateinitiative.org/document-archives/func-download/258/chk.ab6041717dc1be9cd3430f4f7585cb8e/no_html,1/.

⁴¹ *Id.*, Response to Comment E-31, at pg. 425. available at <http://www.arb.ca.gov/regact/2010/capandtrade10/fsor.pdf>.

⁴² ARB considered this option in detail, however. Further discussion is available in the California Environmental Quality Act (CEQA) appendix to this Proposed Strategy (Appendix C).

⁴³ The Livestock Project Compliance Offset Protocol is one such more focused measure now in operation. It contrasts with the wholesale coverage of the sector by the Cap-and-Trade Program that some stakeholders suggest. This protocol, focused on encouraging sector-specific reductions, would not operate if facilities in the sector had compliance obligations in the Program. The protocol balances the need for clear quantification methodologies and regulatory program requirements and ensures any credited voluntary GHG emission reductions meet the AB 32 criteria. The quantification methods included in this protocol use conservative factors to ensure that only real emission reductions are eligible for issuance of compliance offset credit.

III. Latest Understanding of Science on SLCPs

Climate change is already beginning to transform life on Earth. Around the globe, seasons are shifting, temperatures are climbing and sea levels are rising. Continued emissions of GHGs will cause further warming and changes in all components of the climate system. Limiting climate change will require substantial and sustained reductions of GHG emissions.

There is growing recognition within the scientific and policy communities that efforts to address climate change should focus not only on reducing CO₂ emissions, but also on reducing emissions of SLCPs. While reducing CO₂ emissions will limit total warming over the long-term, reducing emissions of SLCPs will effectively slow the near-term rate

of climate change. Therefore, the best path forward is to emphasize a coordinated strategy for simultaneous emission reductions for both SLCPs and CO₂,^{44,45} which is needed to keep average warming below 2°C this century.

Short-lived climate pollutants have atmospheric lifetimes on the order of a few days to a few decades, and their relative climate forcing impacts, when measured in terms of how they heat the atmosphere, can

be tens, hundreds, or even thousands of times greater than that of CO₂. Short-lived climate pollutants contribute about 40 percent to the current anthropogenic global radiative forcing, which is the primary forcing agent for observed climate change.

Co-Benefits of Reducing SLCPs

In addition to limiting climate change impacts already underway, SLCP emission reductions would reduce local air pollution and produce other co-benefits. The benefits could be even greater in the Arctic, which is especially vulnerable to black carbon emissions and is warming twice as fast as the rest of the world.⁵¹ This would be critically important for stabilizing climate change and its impacts, as the Arctic is an important driver of sea level rise and weather patterns throughout the Northern Hemisphere. Climate change in the Arctic potentially impacts drought in California and extreme snow and cold in the upper Midwest and New England, although such links have not been definitively proven.^{52,53} Accelerated warming in the Arctic could also lead to irreversible climate “tipping points,” such as the release of vast quantities of CO₂ and methane from melting permafrost.⁵⁴

In California, State and international action to reduce emissions of SLCPs can improve air quality and reduce related health risks. Other benefits to California include reducing damage to forests and crops, reducing background ozone and particulate levels to help meet federal air quality standards, and reducing disruption of historic rainfall patterns. California is working with a set of national and subnational partners throughout the world to fight air pollution and climate change, which will help deliver these benefits to our State while providing significant benefits where emission reductions occur.

Climate Impact

Global mean sea level will continue to rise during the twenty-first century, and the rate of sea level rise will exceed that observed during 1971 to 2010 due to increased ocean warming and increased loss of mass from glaciers and ice sheets.⁵⁵ A recent study raises the possibility of a more rapid rate of sea level rise in this century than forecast

pollutants in World Bank activities: a report prepared at the request of the G8. Washington DC; World Bank. http://www-wds.worldbank.org/external/default/WDSContentServer/WDSP/IB/2013/08/19/000333037_20130819113818/Rendered/PDF/804810WP0G80Re00Box0379805B00OU090.pdf

by the U.N.'s Intergovernmental Panel on Climate Change (IPCC).⁵⁶ The authors conclude that 2° C global warming above the preindustrial level would spur ice shelf melt sufficient to cause a sea level rise of several meters. Sea level rise is an important impact of climate change on California due to the long coastline and large population that lives near coastal waters. Mitigating SLCP emissions can have significant benefits for slowing sea level rise, reducing the rate by 24-50 percent by 2100, if it begins now. Mitigating emissions of both CO₂ and SLCPs can reduce the projected rate of sea level rise by 50–67 percent by 2100.⁵⁷

Climate warming has intensified the recent drought in the southwestern U.S. as part of a trend toward enhanced drought that is projected to intensify through this century.⁵⁸ California droughts may be increasingly intensified due to declining availability of groundwater reserves. In the Central Valley, the current drought has cost California agriculture about \$2.7 billion and more than 20,000 jobs in 2015, and agriculture is expected to face more frequent drought.⁵⁹ The current California drought highlights the critical need for developing drought resilience, even if wet conditions mitigate the current drought.^{60,61}

Achieving Climate Stabilization

Scientific research indicates that an increase in the global average temperature of 2°C (3.6°F) above pre-industrial levels, which is only 1.1°C (2.0°F) above present levels, poses severe risks to natural systems and human health and well-being. Increased climate extremes, already apparent at present day climate warming (~0.9°C), will be

more severe. Studies indicate that available technologies, if universally adopted, can effectively reduce global methane emissions an estimated 40 percent and black carbon an estimated 80 percent below 1990 levels by 2030.⁶² Additionally, a new proposed global phase down of HFCs under the Montreal Protocol (if adopted) and other efforts could cut the expected production of HFCs by up to 70 percent by 2030, and up to 85 percent by 2035.^{63,64} Achieving this scale of global reductions would deliver significant climate benefits. It would cut the expected rate of global warming in half by 2050, slowing global temperature rise by about 0.6°C,^{65,66} which would reduce the risk of dangerous climate feedbacks such as accelerated Arctic melting and sea level rise.⁶⁷ It would also increase the probability of staying below the 2°C threshold to more than 90 percent through 2050.^{68,69}

Global Warming Potential

The IPCC developed the concept of global warming potential (GWP) as an index to evaluate the climate impacts of different GHGs, including SLCPs. This metric provides a comparison of the ability of each GHG to trap heat in the atmosphere relative to CO₂ over a specified time horizon. Global warming potentials account for the lifetime of different GHGs in the atmosphere, and the amount of energy they absorb on a per-kilogram basis, relative to CO₂, to represent the relative climate forcing of a kilogram of emissions when averaged over a time period of interest (for example, 20 years or 10 years). Current practice in most of the world for developing GHG emission inventories, including California's inventory, is to use GWP values from the 4th Assessment Report of the IPCC (AR4), which was released in 2007. For the first time, GWP estimates for black carbon are reported in the 5th Assessment Report of the IPCC (AR5), which includes the independent scientific assessment of black carbon

radiative forcing published by Bond et al.⁷⁰ This Proposed Strategy uses AR4 values for methane and HFCs, but AR5 for black carbon.

Considering ways of comparing the contributions of different climate pollutants to climate change has been raised in the IPCC AR5. The report focuses the discussion on the more well-known GWP and Global Temperature change Potential (GTP), though other concepts are also briefly discussed. The GTP is defined as the change in global mean surface temperature at a chosen point in time in response to an emission pulse, relative to that of CO₂. The Norwegian Environment Agency has recently performed an integrated assessment of climate, health and environmental effects of Norwegian emissions of SLCPs, and proposed measures for reducing such effects by 2030.⁷¹ Specifically, they used the “GTP10, Norway”, a global temperature change potential calculated ten years after the emission occurred in Norway, which they identify as the most practically appropriate metric for analyzing measures for Norwegian emissions of SLCPs in the short term. Overall, there is not one, single metric that describes the comparative climate effects of various short-lived and long-lived climate pollutants perfectly. The use of GWPs with a time horizon of 20 years better captures the importance of the SLCPs and gives a better perspective on the speed at which SLCP emission controls will impact the atmosphere relative to CO₂ emission controls. Thus, the emission estimates presented later in this report are calculated using 20-year GWP. Table 4 illustrates the lifetime and 20-year GWP for each SLCP.

Table 4: Global Warming Potential for SLCPs¹

| Pollutant | Lifetime (years) | 20-year GWP |
|---------------------------------|-------------------|-------------|
| Carbon dioxide | ~100 ² | 1 |
| Methane | 12 | 72 |
| F-Gases (Hydrofluorocarbons) | 1.4 – 52 | 437 – 6350 |
| Black carbon | Days to weeks | 3,200 |

¹All AR4 except black carbon which uses AR5 (the first report to define a GWP for black carbon)

²CO₂ has a variable atmospheric lifetime and cannot be readily approximated as a single number

The following sections describe the major SLCPs. An inventory of sources and emissions, and a discussion of current and proposed new control measures are included in other portions of this report.

A. Black Carbon

Airborne particulate matter (PM) varies in its composition and plays a significant role in human health and the climate system. Particulate matter is emitted from a variety of natural processes and human activities, and tends to remain in the air for only a few days to about a week, resulting in extreme spatial and temporal variability. Among different types of particles, carbonaceous particles (those that contain organic and black carbon) are particularly important because of their abundance in the atmosphere. With respect to climate impact, black carbon is the principal absorber of visible solar radiation in the atmosphere while organic carbon is often described as a light-reflecting compound.

Black carbon is emitted from burning fuels such as coal, diesel, and biomass. Black carbon contributes to climate change both directly by absorbing sunlight and indirectly by depositing on snow and by interacting with clouds and affecting cloud formation. In addition to its climate and health impacts, black carbon disrupts cloud formation, precipitation patterns, water storage in snowpack and glaciers, and agricultural productivity.

Scientists have known for some time that sources that emit black carbon also emit other short-lived particles that may either cool or warm the atmosphere. Lighter colored particles, for example, tend to reflect rather than absorb solar radiation and so have a cooling rather than warming impact. Until recently, it had been thought that the impact of lighter colored and reflecting organic carbon from combustion sources largely offset the warming impact of black carbon from this source. However, new studies have suggested that certain fractions of organic carbon known as “brown carbon” could be a stronger absorber of solar radiation than previously understood.^{72,73} The warming effect of brown carbon may offset the cooling impact of other organic carbon particles; hence, quantification of that absorption is necessary so that climate models can evaluate the net climate effect of organic carbon.

To help characterize and differentiate sources of brown carbon from black carbon and understand their climate impact in California, a current ARB-funded research project is applying advanced measurement methodology along with regional and global climate modeling simulations to characterize the extent to which brown carbon contributes to climate forcing in California. This project will improve our understanding of the fundamental processes that dominate brown carbon formation, and help to determine the potential climate benefit of mitigating sources of brown carbon emissions in California.

B. Methane

Methane is the principal component of natural gas and is also produced biologically under anaerobic conditions in ruminants (animals with a four-part stomach, including cattle and sheep), landfills, and waste handling. Atmospheric methane concentrations have been increasing as a result of human activities related to agriculture, fossil fuel extraction and distribution, and waste generation and processing. The atmospheric lifetime of methane is about 12 years. It is well-mixed within the atmosphere, and like other GHGs, warms the atmosphere by blocking infrared radiation (heat) that is re-emitted from the earth's surface from reaching space. Almost all of methane's impact occurs within the first two decades after it is emitted.

Methane is responsible for about 20 percent of current global warming,⁷⁴ and methane emissions continue to increase globally. There is particular concern among scientists that continued climate warming may cause massive releases of methane from thawing arctic permafrost, and dissolve frozen methane clathrate deposits trapped within shallow ocean sea floors.

A recent study, which examines the interaction of methane with other atmospheric gases, indicates methane emissions may have even greater climate change impacts than previously understood.⁷⁵ In the AR5 report, when all the feedbacks are included, the GWP for methane was increased, from 25 to 28 over a 100-year timespan and from 72 to 84 over a 20-year timespan. However, for consistency with reporting requirements under the United Nations Framework Convention on Climate Change, ARB is using GWP values from the AR4.

Methane also contributes to global background levels of ozone in the lower atmosphere (troposphere). Photo-oxidation of both methane and carbon monoxide lead to net production of global background levels of ozone. Ozone itself is a powerful SLCP as well as a regional ground level air pollutant. Tropospheric ozone is not emitted directly into the atmosphere, but rather formed by photochemical reactions. Its average atmospheric lifetime of a few weeks produces a global distribution highly variable by season, altitude, and location. The radiative forcing of tropospheric ozone is primarily attributed to emissions of methane, but also to carbon monoxide, volatile organics, and nitrogen oxides that eventually form ozone.

Ozone negatively impacts human health, and can lead to asthma attacks, hospitalizations, and even premature death. It impairs the ability of plants to absorb CO₂, thereby suppressing crop yields and harming ecosystems. Ozone also affects evaporation rates, cloud formation, and precipitation levels. In addition to the direct climate benefits of cutting methane emissions, it can also reduce global background

⁷⁴ Kirschke, S. *et al.* (2013) Three decades of global methane sources and sinks. *Nature Geosci.* **6**, 813–823. http://www.nature.com/ngeo/journal/v6/n10/full/ngeo1955.html?WT.ec_id=NGEO-201310

levels of ozone pollution and provide additional climate, health, and other benefits.^{76,77,78}

Regional ozone concentrations reflect contributions from both ozone formed from criteria pollutant emissions (NO_x and volatile organic compounds [VOCs]) on a regional scale, and ozone transported on hemispheric scales (global background levels of ozone). Due to its low reactivity, methane emissions do not affect regional scale ozone production that occurs over hours to days. However, regional methane emissions which are fairly well-mixed in the atmosphere contribute to the global abundance of methane, which in turn contributes to global background levels of ozone. About two-thirds of the rise in global levels of tropospheric background ozone can be attributed to methane emissions. Studies have also shown that the global background ozone concentrations can approach 40 parts per billion and have been increasing in recent years. Increases in background ozone make it harder to attain the health-based ambient air quality standards set by U.S. EPA and California.

C. Fluorinated Gases (Hydrofluorocarbons)

Hydrofluorocarbons (HFCs) are synthetic gases used in refrigeration, air conditioning, insulating foams, solvents, aerosol products, and fire protection. They are primarily produced for use as substitutes for ozone-depleting substances, including chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons (HCFCs), which are being phased out under the Montreal Protocol. Currently, HFCs are a small fraction of the total climate forcing, but they are the fastest growing source of GHG emissions in California and globally, primarily driven by the increased demand for refrigeration and air conditioning.

HFCs vary significantly in their ability to influence climate. Their differing ability is mostly due to differences in their atmospheric lifetimes, which determine how much they accumulate in the atmosphere. The mix of HFCs in current use, weighted by usage (tonnage), has an average atmospheric lifetime of 15 years. HFCs are also potent GHGs, with a warming effect hundreds to thousands of times more powerful than CO₂. The average 100-year GWP of the current mix of HFCs being used is about 1600, and the average 20-year GWP is about 3500. The major concern with respect to HFCs is that their contribution to climate forcing is expected to increase rapidly in the future as

Szopa, R. Van Dingenen, G. Zeng, C. Atherton, D. J. Bergmann, I. Bey, G. Carmichael, W. J. Collins, B. Duncan, G. Faluvegi, G. Folberth, M. Gauss, S. Gong, D. Hauglustaine, T. Holloway, I. S. A. Isaksen, D. Jacob, J. E. Jonson, J. W. Kaminski, T. J. Keating, A. Lupu, E. Marmer, V. Montanaro, R. J. Park, G. Pitari, K. J. Pringle, J. A. Pyle, S. Schroeder, M. G. Vivanco, P. Wind, G. Wojcik, S. Wu, and A. Zuber (2009), Multimodel estimates of intercontinental source-receptor relationships for ozone pollution, *J. Geophys. Res.*, 114, D04301, doi:10.1029/2008JD010816.

they continue to replace ozone depleting substances (ODS), such that they will become very significant contributors. Studies indicate that a lack of action to prevent the growth of HFCs would greatly undermine efforts to address climate change. A recent study concluded that replacing high-GWP HFCs with low-GWP alternatives could avoid 0.1°C of warming by 2050 and warming of up to 0.5°C by 2100,⁷⁹ offering one of the most cost-effective climate mitigation strategies available.

The successful phase-out of CFCs and the ongoing phase-out of HCFCs have made the Montreal Protocol an effective climate treaty.^{80,81} Between 1990 and 2010 the Montreal Protocol reduced CO₂e emissions nearly twenty times more than the initial commitment period of the Kyoto Protocol.⁸² Although HFCs have contributed a miniscule amount of historical climate forcing, they are projected to increase significantly in the absence of control policies. Hence, a global phase down of HFCs is necessary to slow their effect on climate change. International, national, and state efforts to reduce emissions of HFCs are discussed in more detail in Chapter VI.

IV. Reducing Black Carbon Emissions

Black carbon is the light-absorbing component of fine particulate matter (PM) produced during incomplete combustion of fuels. Black carbon does not account for the warming effects of brown carbon. The lifetime of black carbon is very short, from days to weeks, compared to other SLCPs, which may remain in the atmosphere for a few decades.

California has done more than any other jurisdiction in the world to reduce PM and black carbon emissions. As a result, ambient levels of black carbon in California are now 90 percent lower than in the early 1960s, despite the use of diesel fuel more than tripling over the same time period.⁸³ If the rest of the world achieved similar reductions, it could substantially improve health and slow global warming. California's actions can serve as a blue print for other jurisdictions to reduce SLCP emissions and improve public health. California is continuing to explore additional ways to reduce black carbon emissions. Complying with federal air quality standards and reducing localized risk will require substantial reductions in smog-forming and PM emissions from mobile sources and other source categories.

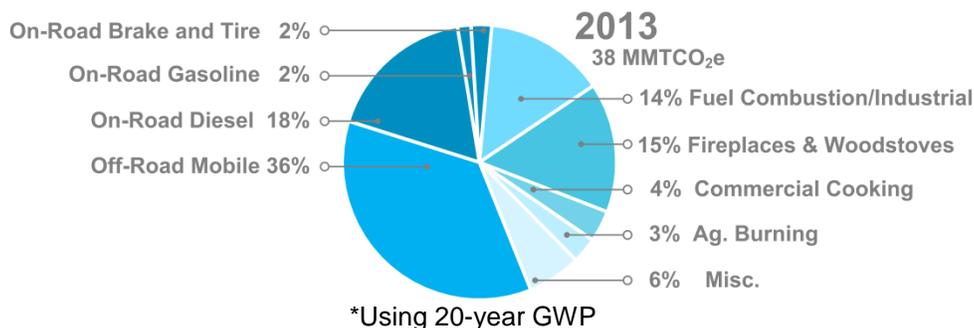

For purposes of this report, black carbon emissions are discussed in two categories, anthropogenic (non-forest) sources and forest-related sources. Anthropogenic sources include on- and off-road transportation, residential wood burning, fuel combustion, and industrial processes. Forest-related sources include prescribed fire and wildfire and are separated to account for the unique challenges associated with inventorying and mitigating these sources. In a typical year, wildfires account for approximately two-thirds of California's black carbon emissions, but this varies from year to year. Prescribed fires also emit black carbon, but are an important tool for forest managers to help restore and maintain forest health, which in turn can reduce wildfire severity and the associated black carbon emissions from catastrophic wildfires.

A. Anthropogenic (Non-Forest) Sources of Black Carbon Emissions

California's major anthropogenic sources of black carbon include off-road transportation, on-road transportation, residential wood burning, fuel combustion, and industrial processes (Figure 1). The fuel combustion and industrial source categories include a variety of stationary and portable equipment such as boilers, turbines, and steam generators, as well as process emissions from industrial operations, such as cement and asphalt production and pulp and paper mills. Sources in the miscellaneous category include dust, waste disposal, unplanned structure and car fires, residential natural gas combustion, and non-agricultural open burning (mostly residential green waste burning).

⁸³ V. Ramanathan et al. 2013. Black Carbon and the Regional Climate of California. Report to the California Air Resources Board No. 08-323. <http://www.arb.ca.gov/research/apr/past/08-323.pdf>

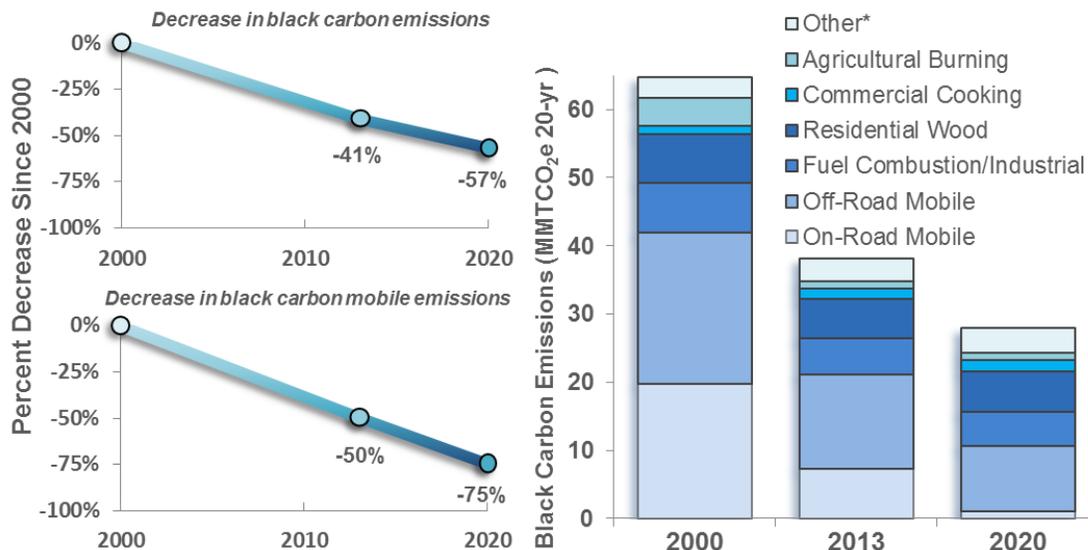

Figure 1: California 2013 Anthropogenic (non-forest) Black Carbon Emission Sources*

1. Progress to Date

California’s program to reduce emissions from transportation sources of black carbon can serve as a blueprint for other jurisdictions seeking to address both the climate change and public health impacts of mobile sources, particularly diesel engines. Over the last few decades, ARB has employed a variety of strategies that has drastically reduced black carbon emissions from mobile sources, including lower emission standards, clean fuel requirements, in-use rules, incentives, and investments in research and new technology. Diesel particulate filters have been instrumental in reducing black carbon in on-road and major portions of the off-road sector. Today’s diesel particulate filter-equipped trucks are more than 99 percent cleaner than those manufactured in 1990. Measures have also been implemented on the State and local level to reduce PM, and thus black carbon, emissions from non-mobile sources, including residential burning, commercial cooking, and agricultural burning. Existing measures are projected to cut mobile source emissions by 75 percent and total anthropogenic (non-forest) emissions by nearly 60 percent between 2000 and 2020 (Figure 2).

Figure 2: California's Black Carbon Emissions between 2000 and 2020 with Existing Measures

California has highlighted our accomplishments in discussions with other jurisdictions, including a SLCP-focused side event, jointly hosted with Mexico, at the Conference of Parties in Lima in 2014 and at international climate conferences in 2015. We will continue to work closely with our partners in other states, in the federal government, and internationally to highlight the successful actions California has taken, and will continue to take, to reduce black carbon from mobile sources.

Mobile Sources

In 2000, ARB approved a Diesel Risk Reduction Plan, calling for an 85 percent reduction in diesel PM emissions by 2020.⁸⁴ Diesel engines often operate for decades after they are purchased, so while lower emission standards provide major emission

reductions, those reductions can take time to materialize as older engines are replaced with new ones meeting the standard. To reduce risk and speed emission reductions, ARB implemented in-use rules for on-road and off-road fleets to meet performance standards through the use of alternative fuels, after-treatment retrofits, or replacement of older vehicles with newer vehicles manufactured to current emission standards. In-use on-road rules are expected to reduce black carbon emissions from on-road sources by 80 percent between 2000 and 2020. ARB's off-road rules

⁸⁴ Final Diesel Risk Reduction Plan available at: <http://www.arb.ca.gov/diesel/documents/rrpapp.htm>

apply to approximately 150,000 off-road vehicles and are expected to reduce diesel PM emissions by 20 percent between 2009 and 2023.

These regulations provide significant reduction in diesel PM exposure in communities located near California's major ports and intermodal railyards and contribute to a larger coordinated effort to reduce black carbon and PM emissions from all sources at ports and railyards.⁸⁵ Overall, since 2005, California has reduced diesel particulate emissions, along with the associated health risks, by 70 percent at the largest ports and 50–70 percent at the highest-risk railyards.

Incentive programs, including the Carl Moyer Memorial Program, AB 923, AB 118 Air Quality Improvement Program (AQIP), Alternative and Renewable Fuel and Vehicle Technology Program (ARFVTP), and Proposition 1B, have provided the means to transform California's mobile fleet into one of the cleanest in the world. These programs have provided more than \$1.6 billion over the past 15 years to clean up diesel engines and simultaneously reduce black carbon.

Cleaner fuels have been a cornerstone of ARB efforts to reduce mobile emissions, enabling cleaner vehicle technologies that have reduced smog-forming emissions by 15 percent and reduced cancer risks from vehicle pollution by 40 percent. The Low Carbon Fuel Standard provides a strong financial incentive to develop clean fuel alternatives, which may also reduce black carbon. For example, renewable diesel and biodiesel may reduce both PM and black carbon emissions compared to conventional diesel, especially in engines where diesel particulate filter technology is not available.

California has also paved the way for increased penetration of zero-emission vehicles (ZEV) through incentive programs and investment in new technology. The ZEV regulation was first adopted in 1990, as part of the Low Emission Vehicle Program. Today California is the world's single largest market for light-duty passenger ZEVs, accounting for 20 percent of all ZEVs on the road.⁸⁶ ARB will continue to lead in this area with the Governor's ZEV action plans to accelerate use of ZEVs and deploy 1.5 million passenger ZEVs in California by 2025. Providing financial and technological pathways to accelerating growth in ZEVs and other advanced engine technologies within California will push market development for clean and zero-emission vehicles throughout the world, providing additional black carbon emission reductions outside of California.

ARB is developing an integrated mobile source strategy to meet California's air quality and climate mandates, reduce petroleum use, and reduce near source risk. Accomplishing this will require a transformation to near-zero and zero emission technologies, cleaner renewable fuels, greater system and operational efficiencies, and

⁸⁵ Dallmann et al. 2011. Effects of Diesel Particle Filter Retrofits and Accelerated Fleet Turnover on Drayage Truck Emissions at the Port of Oakland, *Environmental Science & Technology*, 45, 10773-10779.

⁸⁶ Draft 2015 ZEV Action Plan available at:
http://gov.ca.gov/docs/DRAFT_2015_ZEV_Action_Plan_042415.pdf

new approaches to passenger and freight mobility. These coordinated efforts will provide California a clear path forward to reduce the State's impacts on climate change including reductions in black carbon emissions.

In April 2015, ARB released the *Sustainable Freight Pathways to Zero and Near-Zero Discussion Document* that outlines initial steps ARB is taking to accelerate progress toward zero and near-zero emission freight vehicle and equipment technology in California.⁸⁷ In July 2015, the Governor signed Executive Order B-32-15, that directs the Secretaries of Transportation, Environmental Protection, and Natural Resources to lead staff from the California Department of Transportation (Caltrans), ARB, the California Energy Commission (Energy Commission), and the Governor's Office of Business and Economic Development (GO-Biz), in the development of an integrated action plan, the California Sustainable Freight Action Plan (Action Plan). The agencies must develop the Action Plan by July 2016 that establishes targets, identifies actions to achieve the targets, and initiates work on pilot projects.

In September 2015, ARB staff released the *Mobile Source Strategy Discussion Draft*, which introduced a comprehensive plan to control emissions from mobile sources in order to meet critical air quality and climate goals over the next fifteen years.⁸⁸ Since October, developments in planning efforts have continued to shape staff's mobile source approach. The Mobile Source Strategy will be released in April 2016, reflecting these developments.

Specifically for criteria pollutants, the ARB staff developed the State SIP Strategy that will propose measures to meet federal air quality standards for ozone and fine particulate matter (PM2.5). SIPs are due to U.S. EPA in 2016. Building on measures first introduced in the *Mobile Source Strategy Discussion Draft*, the State SIP Strategy will be also released in April 2016.

As emissions from mobile sources decrease, non-mobile sources will become an increasingly important fraction of the black carbon inventory. The main non-mobile emission sources include residential wood combustion, fuel combustion from stationary and small portable equipment, and industrial sources. Commercial cooking and agricultural burning make up a smaller portion of emissions.

Residential Wood Combustion

A number of local air districts have residential wood combustion rules, and are working to make further progress in this category to meet air quality standards and protect public health.⁸⁹ Strategies in place to reduce emissions from residential wood combustion

⁸⁷ <http://www.arb.ca.gov/gmp/stti/sustainable-freight-pathways-to-zero-and-near-zero-emissions-discussion-document.pdf>

⁸⁸ http://www.arb.ca.gov/planning/sip/2016sip/2016mobsrc_dd.pdf

⁸⁹ Yap and Garcia 2015. Effectiveness of residential wood-burning regulation on decreasing particulate matter levels and hospitalizations in the San Joaquin Valley Air Basin, *Am J Public Health*, 105(4), 772-778.

include winter burning curtailment, opacity emission limits, incentives to replace old wood burning devices with more efficient models, and banning or limiting wood burning devices in new and existing housing. Additionally the U.S. EPA has recently introduced a new source performance standard requiring manufacturers of residential wood stoves, pellet stoves, forced air furnaces, and hydronic heaters to meet national emission standards. Statewide black carbon emissions from residential wood combustion have declined by nearly 20 percent between 2000 and 2013 in response to existing district rules.

Stationary Fuel Combustion and Industrial Sources

Emissions from stationary fuel combustion will be addressed by a number of State and federal planning efforts, including the SIP, Cap-and-Trade Program, increased building energy efficiency and renewable energy goals, and the federal Clean Power Plan (promulgated under Clean Air Act Section 111(d)). California's Cap-and-Trade regulation and the LCFS create market signals to incentivize efficiency improvements as well as the use of biomass-derived liquid fuels that would emit lower levels of PM and black carbon than traditional fossil fuels. The federal Clean Power Plan, which accelerates the transition from coal towards lower carbon-intensive fuels for electricity production, will reduce black carbon emissions, and emissions of other GHGs, across the nation. Further emission reduction opportunities from stationary fuel combustion and industrial processes may also be identified as part of the SIP process.

Commercial Cooking

Commercial cooking emissions are primarily from charbroiling. The two types of charbroilers include chain-driven, where food moves mechanically through a semi-enclosed broiler, and under-fired, where food is cooked on a grill similar to a home barbeque. A number of local air districts require air pollution control technologies for chain-driven broilers, reducing particulate emissions from these charbroilers by over 80 percent. Under-fired charbroilers are a larger source of PM, but no cost-effective air pollution control technology has been identified to date. Air districts are working to develop air pollution control devices for under-fired charbroilers. Demonstration projects for emerging control technologies are in progress and it is anticipated that large districts will develop rules for these emissions going forward.

Agriculture

Agricultural burning was historically used as a cost-effective way to remove agricultural residue left behind on fields, help control weeds and pests, and prevent the spread of plant disease, but emissions impacted local air quality and prompted concern for public health. Various programs are currently administered by the local air districts in

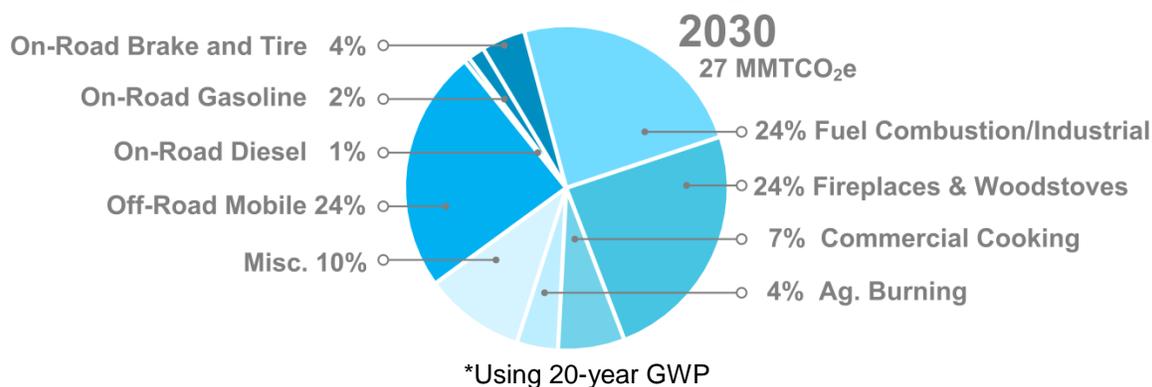

coordination with ARB to reasonably regulate agricultural burning as required by state law. The Sacramento Valley Rice Straw Burning Phasedown Program, local district Smoke Management Programs, and San Joaquin Valley agricultural burning phase down efforts have resulted in an approximately 70 percent reduction in black carbon emissions from agricultural burning between 2000 and 2013. Some agricultural waste that was previously burned went to bioenergy facilities; however, many of these facilities have shut down over the last few years due to their inability to procure long-term power purchase contracts. If this trend continues, the diminishing agricultural waste utilization options could result in the potential for increased agricultural burning. The San Joaquin Valley Air Pollution Control District is considering the need to allow increased agriculture burning of certain crops due to the lack of feasible alternatives to removing this waste in the fields. Programs to support clean energy and fuel production and markets for wood products, similar to the recommendations later in this section for forest woody biomass, would provide opportunities for alternative beneficial uses for this waste material.

Agriculture irrigation pumps are a small source of black carbon on a statewide level, but may be an important local source. Multiple federal, state, and local governments have provided incentives to convert agricultural diesel irrigation engines to either newer cleaner diesel engines or to electric motors. This has led to black carbon emissions from irrigation pumps declining by half between 2000 and 2013, with additional reductions expected going forward in response to existing measures.

California has achieved tremendous reductions in black carbon emissions, especially in the mobile sector, and even more reductions are expected as current measures are fully implemented. In 2000, on-road mobile sources contributed a third of anthropogenic black carbon emissions, but are projected to account for only a small fraction of total emissions by 2030. Off-road mobile emissions, including aircraft, watercraft, trains, small equipment, forklifts and farm equipment, have declined by over a third since 2000, and are projected to decrease by another half by 2030.

However, meeting the 2030 black carbon emission target identified in this Proposed Strategy (for non-forest only) requires additional emission reductions across multiple sectors. Off-road mobile sources, along with stationary fuel combustion and residential wood burning, will make up the majority of emissions by 2030 (Figure 3). Additional 2030 reductions will be realized through implementation of measures identified in plans currently being developed, including the California Sustainable Freight Action Plan and the State Implementation Plans (SIPs). Additional reductions are also expected through a district-lead commercial cooking regulation, but the magnitude of emission reductions is currently unknown.

Figure 3: California’s 2030 Anthropogenic (non-forest) Black Carbon Emission Sources with Existing Measures*

2. Recommended Actions to Further Reduce Non-Forest Black Carbon Emissions

This section describes proposed new measures (summarized in Table 5 below) to assist the State in meeting the proposed 2030 black carbon emission target.

Table 5: Proposed New Black Carbon Emission Reduction Measures and Estimated Emission Reductions (MMTCO₂e)¹

| Measure Name | 2030 Annual Emission Reductions | 2030 Annual Emissions |
|---|---------------------------------|-----------------------|
| 2030 BAU ² | | 26 |
| Residential Fireplace and Woodstove Conversion | 3 | |
| California Sustainable Freight Action Plan State Implementation Plans Clean Energy Goals ³ | 4 | |
| 2030 BAU with new measures | | 19 |

¹Using 20-year GWPs from the 5th Assessment report of the IPCC

²Business As Usual (BAU) forecasted inventory includes reductions from implementation of current regulations

³Additional black carbon reductions will be realized from planned measures and are expected to help the State meet the black carbon target. However, an estimate of emission reductions is not currently available, but will be developed as part of these planning efforts.

Residential Fireplace and Woodstove Conversion Measure

Residential wood combustion is forecast to be the largest individual anthropogenic source of black carbon in 2030 if no new programs are implemented, accounting for a quarter of anthropogenic black carbon emissions. Reducing 2030 residential wood

combustion black carbon emissions by half (3 MMTCO₂e) would set California on a path toward meeting the 2030 target in this Proposed Strategy.

Removal of old fireplaces and woodstoves and replacement with EPA-Certified wood-burning devices, electric heaters, or gas fireplaces can provide long lasting reductions in emissions of black carbon, criterial pollutants, and air toxics in residential neighborhoods. Removed wood burning devices should be destroyed or recycled to ensure permanent emission reductions.

Monetary incentives to stimulate removal of old wood burning devices are popular and can achieve significant emission reductions. Multiple air districts have invested in incentive programs, but additional funding is necessary to continue to realize emission reductions in this category. In addition, programs should be expanded to include all regions of California. Incentive funding to support further district efforts could come from a variety of national, State, and local resources. The Governor's 2016-2017 proposed budget includes \$40 million of Cap-and-Trade expenditure for a residential woodstove replacement incentive program, but this potential incentive program will not be developed and implemented until the Legislature appropriates funds for this Program.

In addition, ARB is proposing to work with the air districts to determine the most effective approach to avoid new residential wood combustion emissions in California. This could include encouraging the installation of non-wood burning centralized heating in new construction. In areas where central heat is cost-prohibitive, the cleanest available burning technology could be required.

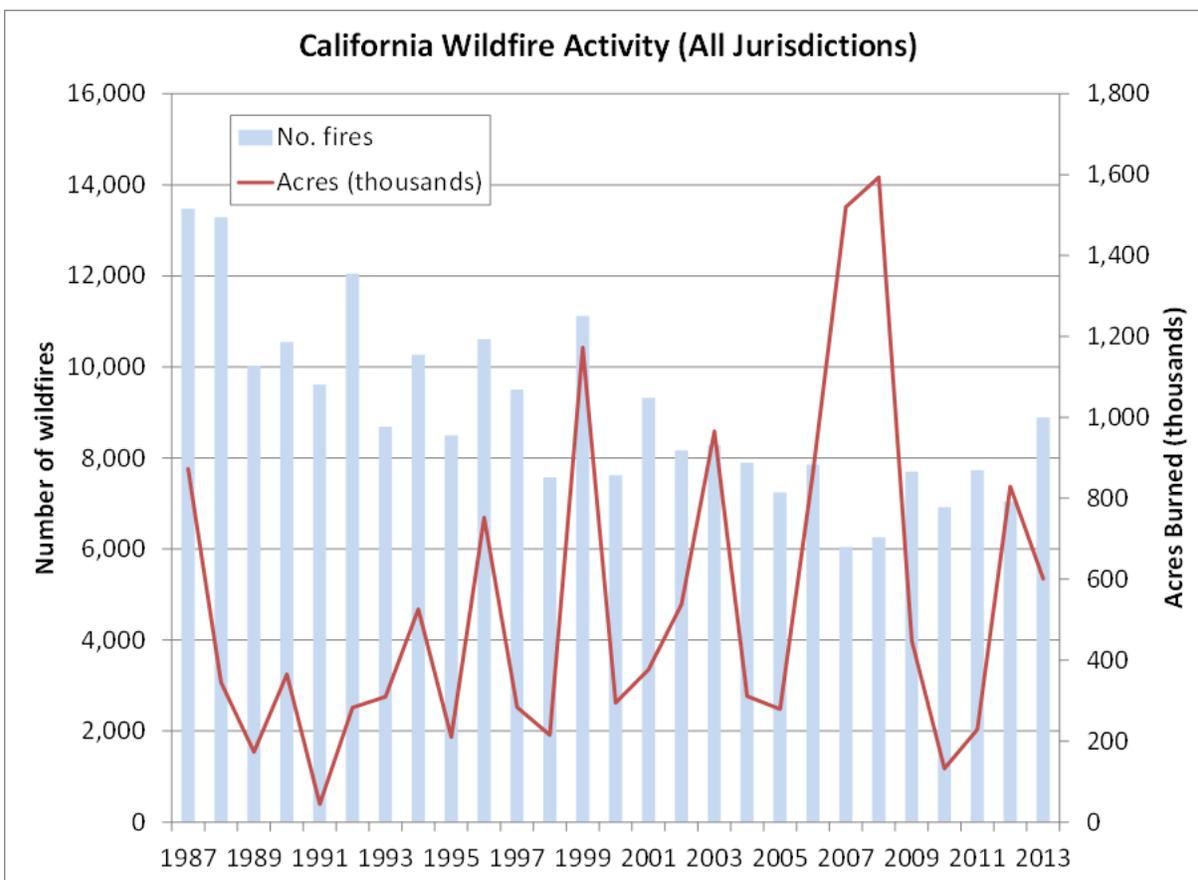

Education and outreach are important tools to reduce emissions from residential wood combustion. A broader public understanding of the health and environmental impacts of wood smoke may cause voluntary changes in behavior to use other heating sources and may cause individuals to avoid unnecessary burning both indoors and outdoors. Education on proper burn practices may reduce emissions when wood is used, and is essential to achieve full emission reductions from EPA-Certified wood burning devices. Some districts have already implemented education programs, which should be expanded to all parts of the State as part of this measure.

B. Forest-Related Sources of Black Carbon Emissions

Wildfires account for the majority of black carbon emissions during a typical year in California. On average, an area the size of Las Vegas burns each year. The extent and severity of wildfire varies significantly from one year to the next and is impacted by forest conditions that are influenced by historic management, drought, and climate change (see Figure 4).

While we must act to reduce wildfire risk in the State, we will never be able to fully control wildfire and associated black carbon emissions to meet specific targets in any given year. Consequently, forest-related emissions are not included in the anthropogenic black carbon emission reduction target identified in this Proposed Strategy. Still, efforts to reduce black carbon from wildfires are critical to California's efforts to cut SLCP emissions. As part of an integrated and long-term effort to sustainably manage forests, California can reduce the risk of catastrophic wildfire and forest-related black carbon emissions in California over time.

Figure 4: Wildfire Activity in California.⁹⁰

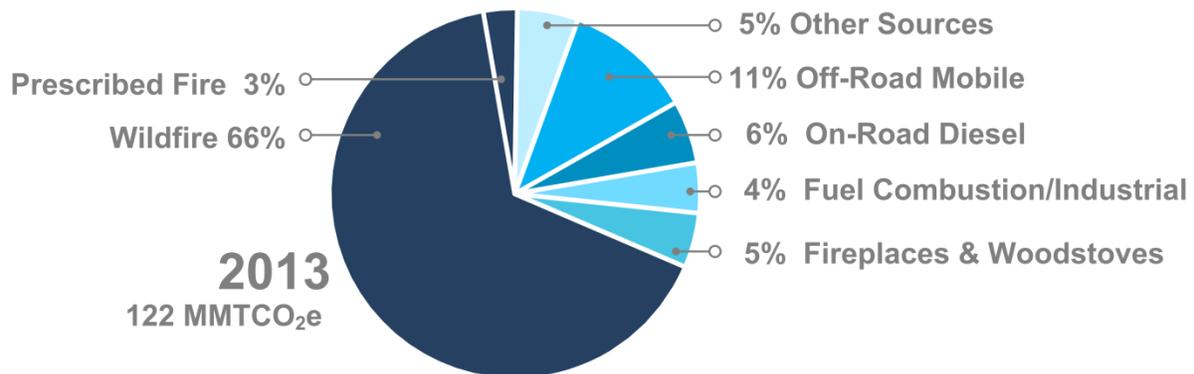

California's black carbon inventory uses the 10-year average from 2001-2011 of PM2.5 emissions from wildfire to represent average conditions and avoid large year-to-year variations in the inventory. Based on these methods, a typical recent wildfire year would account for two-thirds of the State's black carbon emissions in 2013 (Figure 5). The frequency of large fire events and the associated emissions will likely increase in the future, due to climate change, heavy fuel loading, historic fire suppression practices, and development in forested areas.^{91,92}

⁹¹ Westerling et al. 2006. Warming and earlier spring increase western US forest wildfire activity. Science, 313(5789), 940-943.

Figure 5: California 2013 Black Carbon Emissions (including 10-year average emissions from forest-related sources)*

*Using 20-year GWP. "Prescribed Fire" does not include agriculture.

California's forests consist of a range of ecosystems, managed under various regulatory structures by different landowners. This patchwork of regulation and ownership, as well as physical accessibility, affects forest conditions and management practices. Private forests and areas designated as timberlands tend to be less susceptible to wildfire, as they are managed to minimize fuel loads and protect commercial assets. The value of timber harvest can help offset forest management costs, but may not be optimal from an ecological standpoint. More than 35 percent of California's forests are privately-owned, 60 percent of which is managed as timberlands. Federal agencies manage well over half of the nearly 33 million acres of forestland in California. Federal lands are managed for multiple objectives, including timber harvest, but also with ecological restoration as a focal point. Continued coordination with private and federal land owners is necessary to ensure that improved management practices, resulting in overall black carbon and GHG benefits, reach throughout California's forest lands.

1. Progress to Date

After a century of fire suppression, chronic underfunding for forest management at the State and Federal level, and exacerbating impacts of climate change, bark beetle infestations and drought, California's forests are highly vulnerable and potentially a source of increasing black carbon emissions. The current rate of fuel reduction activity is insufficient to improve forest health, avoid catastrophic wildfire, produce resilient forests, and reduce black carbon emissions. For example, the U.S. Forest Service estimates that less than 20 percent of the Forest Service lands in need of fuels reduction treatment have been treated.⁹³ Once treated, these forest stands must be retreated every 15-30 years to be properly maintained. California is accelerating its efforts to improve forest health and reduce wildfire risk, but doing so requires

⁹² Hurteau et al. 2014. Projected effects of climate and development on California wildfire emissions through 2100. *Environmental Science & Technology*, 48(4), 2298-2304.

⁹³ North, M., Collins, B.M., and Scott Stephens (2012) Using Fire to Increase the Scale, Benefits, and Future Maintenance of Fuels Treatments, *Journal of Forestry* 110(7):392-401.

comprehensive planning and strategic investment and will take time before there is a steady trend toward declining wildfire and associated black carbon emissions.

In response to the current epidemic of tree mortality, Governor Brown issued a Proclamation of a State of Emergency on Tree Mortality (Proclamation) in October 2015.⁹⁴ It requires State agencies to identify high hazard zones for wildfire and falling trees and prioritize tree removal in those areas. Among several actions to reduce wildfire risk and support forest management operations, the Proclamation calls for expanding the practice of prescribed burns, extending operation of existing biomass power plants that receive feedstock from high hazard zones, and facilitating power contracts for new facilities. To help implement the Proclamation, the Governor launched the State Tree Mortality Task Force in November 2015. The group includes State, Federal, and local government agencies, as well as key stakeholders, and will also monitor tree removal efforts and forest health and resilience.

This Proposed Strategy is one in a series of planning efforts underway that collectively contribute towards an integrated forest management and climate strategy for the State. Here, the focus is on actions to help reduce wildfire risk and black carbon emissions. The State's Forest Carbon Plan will identify climate-related targets for the natural and working lands sector, including forests, for incorporation into the 2030 Target Scoping Plan Update that will build on these recommendations. Goals and actions identified in the 2030 Target Scoping Plan Update and Forest Carbon Plan will include those related to forest carbon storage, which is beyond the scope of this Proposed Strategy. State agencies are coordinating to ensure that the goals and recommendations in each of these plans complement one another. And any proposed targets or actions will be considered through those public planning processes.

Reducing wildfire risk requires active management to reduce fuel availability and returning forests to more resilient states that can withstand fire. This starts with thinning overstocked forests, removing dead and dying trees, and altering stand characteristics to allow mature, larger trees to proliferate and thrive. Forests may be thinned manually, mechanically, or through the use of prescribed fire. These activities also reduce competition from understory vegetation and remove "ladder fuels" that allow ground fires to propagate into the forest canopy and quickly spread.

Prescribed fire can be a useful management tool, particularly in areas that are not suitable for other fuel reduction treatments. While prescribed fire emits black carbon, it can reduce the risk of crown fires, which are a driver for large, catastrophic wildfires.^{95,96} Unlike wildfire, prescribed fire can be timed with favorable atmospheric conditions and managed to minimize air quality impacts. ARB and the local air districts have smoke

⁹⁴ http://gov.ca.gov/docs/10.30.15_Tree_Mortality_State_of_Emergency.pdf

⁹⁵ Schweizer and Cisernos 2014. Wildland fire management and air quality in the southern Sierra Nevada: Using the Lion Fire as a case study with a multi-year perspective on PM_{2.5} impacts and fire policy. *Journal of Environmental Management* 144, 265-278.

management programs in place to manage the timing and location of prescribed burns to protect public health.

Mechanical or manual thinning produces a large amount of woody biomass. While much of this is not marketable as commercial timber, it represents a potentially valuable resource that can support new industries in rural parts of the State and elsewhere. Currently, however, more than half of it is likely left in the forest, where it is often simply piled up and burned. This produces uncontrolled black carbon emissions and wastes a resource that could preferably be used to produce renewable electricity or low-carbon fuels, create wood products or landscaping materials, or potentially as a soil amendment in the form of biochar. These uses can help to reduce forest-related black carbon emissions, while creating jobs and fostering rural economic development. In addition, enabling markets that would capture value from this resource would help foster broader investment in active forest management practices that are needed to improve forest health and reduce wildfire risk on a lasting basis.

Utilizing more of this resource in a beneficial way to avoid open pile burning requires additional infrastructure to generate clean energy, fuels, or other products in areas near the resource base. Current capacity, mostly in the form of electricity production, is aging and insufficient for the existing resource, much less increased volumes that could come from increased forest management activities. Additionally, many of these facilities face expiring power contracts and are shutting down or in danger of doing so. In the near term, a priority is to keep existing facilities operating that receive woody biomass from high hazard areas, as called for in the Governor's Proclamation.

A longer-term, sustainable biomass management strategy requires increasing the capacity and diversity of uses and prioritizing community-scaled facilities near the forest. The most value from woody biomass may come from converting the feedstock into liquid or gaseous transportation fuels, which is supported by the State's Low Carbon Fuel Standard (LCFS). Additionally, the State's bioenergy feed-in tariff (Senate Bill 1122, Rubio, Statutes of 2012) requires the State's large investor-owned utilities to procure 50 MW of electricity from new, small scale bioenergy facilities using byproducts of sustainable forest management. Finally, part of the funding from the State's Electric Program Investment Charge (EPIC) is dedicated to research and development, deployment, and market facilitation for biomass-fueled facilities.

California, in partnership with Tuolumne County and the U.S. Department of Agriculture Forest Service (USFS), was awarded a \$70 million grant as part of the National Disaster Resilience Competition to develop and implement such an integrated community-scale strategy.⁹⁷ The proposed \$117 million project would create a replicable model for community and watershed resilience that could facilitate transitions to sustainable forest economies in rural parts of California. It includes three pillars related to recovery from the catastrophic Rim Fire in 2013:

⁹⁷ <http://www.hcd.ca.gov/nationaldisaster/ndrc-application.html>

- Forest and Watershed Health: Thinning, biomass removal, restoration, and reforestation activities in the Rim Fire burn area.
- Integrated Biomass and Wood Products Campus: The campus hosts facilities that will provide clean power, cooling and heating, and wood products to utilize biomass material and serve communities near the impacted disaster area.
- Community Resilience Centers: These facilities will provide services during an emergency and also provide year-round services, including education and job training to support forest and watershed work and the biomass facility.

As recent years of historic drought and wildfire have made abundantly clear, California needs to adjust historic forest management practices to reduce wildfire risk in the face of a changing climate. The State is responding quickly and effectively, but more needs to be done to build resiliency into our forests.

2. Recommended Actions to Reduce Wildfire Risk and Black Carbon Emissions

Reducing black carbon emissions from forests requires reducing wildfire risk by actively managing forests to reduce the threats posed by historic fire suppression activities and the increasing effects of drought and climate change. The U.S. Forest Service, which owns and manages approximately 20 million acres in California, has established a restoration goal of 500,000 acres/year in the State, including fuels reduction. Reaching that goal would require an additional \$300 million per year to more than double the current pace of restoration, but could potentially save \$800 million per year in fire suppression costs.⁹⁸ A matching goal for the State and private landowners to treat 500,000 acres per year of non-federal forestlands could require annual investment on the order of \$500 million to \$1 billion⁹⁹

There is a clear need to identify sustainable funding streams to support this level of treatment. Increased State and Federal funding is needed, as well as private sector investment. Enabling markets for the beneficial use of woody biomass can help to support and maximize these investments. For example, coupled with the Low Carbon Fuel Standard, additional steps to help to facilitate affordable and reliable supplies of sustainably harvested woody biomass could help spur a biofuels industry in rural parts of the State that could foster significant private sector investment in forest management activities.

The recommendations below will help reduce wildfire risk by improving forest management, putting woody waste resources to beneficial use to create value from forest management activities, and supporting these efforts with research and ongoing coordination. These actions will help increase public and private investment to unlock a broad array of economic and environmental benefits in rural communities and Statewide.

⁹⁸ <http://www.fs.usda.gov/detail/r5/landmanagement/?cid=stelprdb5412095>

⁹⁹ Assuming average treatment costs of \$1,000-2,000/acre. Actual treatment costs will vary across the landscape.

Increase Rate of Fuel Reduction to Reduce Wildfire Risk

The State is committed to increasing active management of its forests to reduce fuel loadings, wildfire risk, and black carbon emissions. Wherever possible, material should be thinned and put to beneficial use, which in turn, can help to finance fuel reduction activities. Prescribed fire has an important role to play, and should be utilized in manners protective of public health and as part of a scaled effort to improve forest and ecosystem health. Throughout, activities to reduce wildfire risk should be coordinated to support various State priorities, including enhancing forest health, protecting air quality, addressing climate change, and supporting watersheds, biodiversity and other ecosystem services. The State will work in these regards, and with federal and private land owners, to accelerate activities to reduce wildfire risk and associated black carbon emissions:

- **Increase investment in forest health programs.** Governor Brown's Cap-and-Trade Expenditure Plan in his proposed budget for fiscal years 2016-17 includes \$140 million for CAL FIRE to support forest health and resiliency programs that reduce GHG emissions. While additional public and private investment is needed on an ongoing basis, this represents an appropriate and significant increase beyond the \$24 million that these efforts received in the 2014-15 budget year.
- **Foster private sector investment.** The State will continue to support programs such as the Low Carbon Fuel Standard and Bioenergy Feed-In Tariff that support private sector investment to support sustainable forest management and utilization of woody biomass. Additionally, in developing the Scoping Plan and Forest Carbon Plan, State agencies will consider opportunities to support thinning, collecting, and transporting woody biomass to facilities that can beneficially use it. This may come in the form of direct investment, coordination to streamline facility development, or other activities as described below. These efforts will help to scale private sector investment in forest management and clean energy efforts, and reduce black carbon emissions from pile burning and wildfire.
- **Implement Governor Brown's Proclamation.** Among other activities, the Proclamation calls for ARB and CAL FIRE to work with federal agencies and land managers to "expand the practice of prescribed burns, which reduce fire risk and avoid significant pollution from major wildfires, and increase the number of allowable days on a temporary basis to burn tree waste that has been removed in high hazard areas." The agencies will implement this Proclamation to reduce the wildfire risk posed by dead and dying trees, through the public process of the Tree Mortality Task Force.
- **Collaborate with federal and private landowners.** The State is targeting investments to achieve net GHG emission benefits in areas that have high rates of carbon stock and face heightened wildfire risk from overstocked forests and dead or dying trees. Coordinating with public and private land owners in shared watersheds or firesheds is important to maximize the positive impacts of these treatments beyond the immediately treated area. Additionally, CAL FIRE will

continue working with Federal agencies, local jurisdictions and private land owners through existing agreements and mechanisms to support forest management operations.

Align Financial Incentives with Beneficial Use of Woody Waste

Current volumes of woody waste from forests and other sources, let alone increased volumes that will come from improved forest management practices, far exceed the markets and available uses for this material. By helping to develop markets for industries that can utilize this material, the State can help unlock the value intrinsic in California's woody biomass waste streams and capture additional economic and environmental benefits associated with forest management. This will help improve the economics associated with transporting residues from the forest, providing alternatives to pile burning and reducing black carbon emissions associated with forest management. It will also help to scale investment to help sustain forest management operations at necessary levels. Accordingly, the State will take additional steps to support beneficial uses of woody waste:

- **Demonstrate and prioritize integrated, community-based models.** Projects like the one awarded to California as part of the National Disaster Resilience Competition offer a wide array of benefits, including community-scale benefits much broader than those just associated with forest health. This project can serve as a model for rural communities near forested lands to support ecological restoration and hazardous fuels reduction, while supporting economic growth and diversification and community wildfire protection. The State will work with its partners to secure financing and develop this project, with a key focus on replicability and scalability.
- **Support clean energy and fuel production.** As described above, California has several programs in place to support clean energy and fuel production from sustainably harvested forest waste and other organic resources. Some of these programs, such as the bioenergy feed-in tariff, LCFS, and Cap-and-Trade, are relatively new programs and could support more clean projects moving forward. The State will encourage policies, strategies and investments, from both private and public funds, to further support clean energy and fuel production from forest biomass. One potential source of public funding is the \$140 million for healthy forests in the Governor's 2016-17 budget proposal, which includes support for biomass electricity generation projects. Governor Brown's Proclamation directs the CEC to prioritize EPIC grant funding for woody biomass-to-energy technology development and deployment. CEC is now accelerating the schedule for more than \$15 million in EPIC research funding to support woody biomass to energy projects. The State is also evaluating a variety of potential policies that could reduce the cost to collect and transport woody biomass to energy and fuel production facilities, modernize existing biomass facilities, build new community-scale facilities that use the best available emission control technologies, and develop and transfer new technologies to market. To the extent possible,

policies will support technologies and strategies that minimize criteria and air toxic pollutants.

- **Foster markets for sustainably harvested wood products.** A diversified industry infrastructure is necessary to allow different species and sizes of woody biomass to be effectively utilized. Wood products industries are an important element of this infrastructure. They can also be an important part of integrated, community-based models that the State will continue to prioritize. In addition to scaling these models, and pursuant to Governor Brown's Proclamation, State agencies will work to expand and diversify markets for sustainably harvested wood products.

Support Management Efforts and Market Development through Research

Additional research will help support the actions identified above to further target forest management activities to reduce black carbon emissions, accelerate market development for beneficial use of woody biomass, and to maximize the economic and environmental benefits provided by California's forests. Several benefits associated with forest management practices are not well-understood or valued in current markets or policy programs. For example, current research suggests biochar could contribute to significant carbon storage globally, but the benefits of large-scale projects have not been demonstrated or quantified, and several research gaps remain. Healthy, resilient forests provide water supply and quality benefits to major metropolitan areas and agricultural landowners but management is not supported through user fees.¹⁰⁰ Quantifying and verifying these benefits could allow them to be captured in State policies or commercial transactions, supporting private investment in healthy forest management.

- **Improve understanding of the feedstock.** Pursuant to the Emergency Proclamation on Tree Mortality, CAL FIRE and CEC will work with land managers to estimate biomass feedstock availability, storage locations, and volumes that may be available for use as bioenergy feedstock at existing and new facilities. These data will be used to develop medium- and long-range plans to diversify biomass markets, expand existing ones, and for the identification and distribution of incentives.
- **Identify a broad scope of benefits and options to value them.** Resilient forests and healthy watersheds provide valuable goods and services, including but not limited to secure water supply and water quality, wildlife habitat, clean air, carbon storage and reduced forest GHG emissions, timber resources and local economic development opportunities. Investing in forest health has a large multiplier impact, however several of these goods and services are difficult to quantify and even those that can be quantified are often not accounted for when evaluating economic benefits. State agencies will support research and demonstration projects to improve accounting of potential benefits associated with healthy forest management, and will consider incorporating the range of

¹⁰⁰ R Bales, M Conklin et al. (2015) Sierra Nevada Adaptation Management Project, Appendix E: Water Team Final Report.

benefits into programs and cost/benefit calculations where they can be appropriately quantified. If they can be reliably quantified and valued, these benefits may provide a revenue source to support forest management.

Integrate State Planning Efforts and Goals

The actions identified in this Proposed Strategy, and those already underway pursuant to Governor Brown's Proclamation on Tree Mortality, represent immediate steps that the State can take to reduce wildfire risk and black carbon emissions. Additional planning efforts underway will flesh out a broader vision and set of activities to improve forest health and enhance carbon storage over time. Throughout these and other efforts, State agencies will coordinate efforts to align priorities and actions. They will also increase information sharing associated with research, monitoring, and the state of forest management practices.

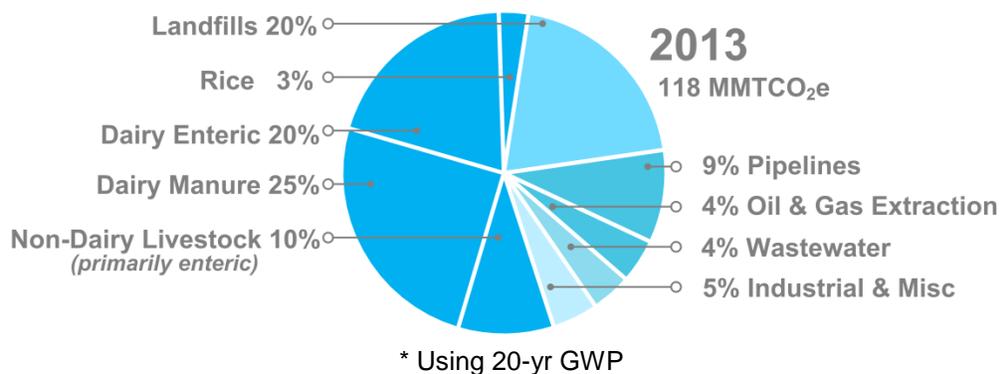

- **Identify targets for forest and climate planning in 2030 Target Scoping Plan Update.** The 2030 Target Scoping Plan Update will include specific climate-related planning targets for natural and working lands, including forests, and an accounting and monitoring framework for monitoring progress toward meeting the targets. Agencies will work together to develop methods for monitoring the black carbon and GHG emission reductions and carbon sequestration associated with these targets, and will report on progress in regular updates to the Scoping Plan.
- **Develop Forest Carbon Plan to outline implementation activities to meet 2030 Target Scoping Plan Update and other targets.** The Forest Climate Action Team (F-CAT) will complete a Forest Carbon Plan, which will cover a broad range of management and conservation priorities for California's forests and implementation mechanisms and strategies for achieving them, including the targets and recommendations included in this Proposed Strategy and the 2030 Target Scoping Plan Update. This coordinated planning process will provide for an ongoing and collaborative forum guiding sustainable forest management activities in California moving forward.

V. Reducing Methane Emissions

Methane is emitted from a wide range of fugitive sources and biological processes, and is the second largest source of GHG emissions globally. Methane emissions are growing globally as a result of human activities related to agriculture, waste handling and treatment, and oil and gas production. Agriculture represents the largest methane source in California, accounting for nearly 60 percent of methane emissions (Figure 6). Landfills are the next largest source of methane, accounting for a fifth of statewide methane emissions. Pipeline leaks, oil and gas extraction, wastewater, and other industrial and miscellaneous sources make up the remainder of emissions. As California continues to rely on natural gas for a large fraction of its energy supply, it is critical to increase supplies of renewable natural gas and minimize fugitive emissions of methane from natural gas infrastructure.

In California, where natural gas may increasingly fuel trucks and heavy-duty vehicles, we must ensure that the use of natural gas provides a climate benefit compared to the diesel fuel it displaces. As we increase the number of facilities producing and using renewable supplies of natural gas, hydrogen, or other fuels in a cleaner energy economy, we must also take steps to minimize potential methane leaks from those facilities. ARB and other agencies are funding research to identify high-methane “hot spot” emitters in the oil and natural gas sector and other sectors throughout California.

Figure 6: California 2013 Methane Emission Sources*

California can cut methane emissions by 40 percent below current levels in 2030 by avoiding or capturing methane from manure at large dairies, meeting industry targets for reducing methane emissions from enteric fermentation, effectively eliminating disposal of organics in landfills, and reducing fugitive methane emissions by 40-45 percent from all sources.

A. Progress to Date

The State has taken important steps to reduce methane emissions from all its major sources, but more needs to be done to control methane emissions, especially from organic waste streams going to landfills and at dairies. In addition to reducing methane

emissions from these sources, capturing methane can provide fuel for power plants, buildings, vehicles and industrial operations to displace fossil-based natural gas use.

Technologies to recover methane are already widely available and used in key sectors. For example, some methane emissions from landfills, wastewater treatment facilities or from manure at dairies are already captured and used as a renewable source of natural gas to fuel vehicles or generate electricity. Some organic materials, such as food waste and yard trimmings, are being redirected from landfill disposal to anaerobic digestion and composting facilities to produce renewable energy, fuel and soil amendments.

Steps are also being taken to reduce natural gas leaks from oil and gas wells, pipelines, valves, and pumps to improve safety, avoid energy losses, and reduce methane emissions associated with natural gas use.

In addition to ongoing efforts and practices to reduce and use captured methane for beneficial purposes, several recent legislative and regulatory actions will further support the reduction or capture of methane within these sectors. These actions prioritize diverting organic

material from landfills and include incentivizing the use of biogas for transportation fuel, pipeline injection, or electricity generation.

- California has established clear goals to reduce waste disposal, and divert organic material from landfills for beneficial purposes. AB 341 (Chesbro, Chapter 476, Statutes of 2011) established a State target to reduce the amount of solid waste sent to landfills by 75 percent by 2020, through recycling, composting, and source reduction practices. The 2014 Scoping Plan Update calls for eliminating the disposal of organic materials at landfills, which would potentially eliminate future methane emissions from landfills.
- The Legislature recently took steps to further increase the diversion of organic materials from landfills. AB 1826 (Chesbro, Chapter 727, Statutes of 2014) requires businesses generating specified amounts of organic wastes to begin arranging for the recycling and diversion of those wastes from landfill disposal beginning in 2016. CalRecycle will provide an annual public update on the disposal, diversion, and recycling of organics, beginning in 2016, pursuant to this mandate. AB 1594 (Williams, Chapter 719, Statutes of 2014) re-classifies the use of green waste for landfill “alternative daily cover” as disposal, beginning in 2020. AB 876 (McCarty, Chapter 593, Statutes of 2015) requires local governments, beginning August 2017, to assess the amount of organic waste that will be generated in a region during a 15-year period and identify locations

for new or expanded organic waste recycling facilities capable of handling this material.

- Methane emissions from landfills are controlled under ARB's Landfill Methane Control Measure, which was approved in 2009. The regulation requires owners and operators of certain previously uncontrolled municipal solid waste landfills to install gas collection and control systems, and requires existing and newly installed gas and control systems to operate in an optimal manner. The regulation allows local air districts to voluntarily enter into agreements with ARB to implement and enforce the regulation and to assess fees to cover costs. .
- Senate Bill 1122 (Rubio, Chapter 612, Statutes 2012), directed the California Public Utility Commission (CPUC) to require the State's investor owned utilities to develop and offer 10 to 20 year market-price contracts to procure an additional 250 megawatts of cumulative electricity generation from biogas facilities that commence operating on or after June of 2013. Eligible projects and sources include biogas-generated electricity from wastewater treatment, municipal organic waste, food processing, dairy manure and agricultural organic material, and sustainable forest materials.
- The Low Carbon Fuel Standard (LCFS) requires transportation fuel providers to procure clean fuels to reduce the carbon intensity of California's fuel mix. In doing so, it provides a market signal to incentivize developing clean fuel options, including capturing or avoiding methane emissions and using associated renewable natural gas as a transportation fuel. Some LCFS pathways related to renewable natural gas have the lowest carbon intensities of pathways to date. Specifically, the production of biomethane from high solids anaerobic digestion of organic (food and green) wastes has a carbon intensity of -15 gCO₂/MJ, and a recently approved pathway for biogas from a dairy digester project has a carbon intensity of -276 gCO₂/MJ. If LCFS credit prices are \$100/MT, as they have been recently, the value of LCFS credits from these pathways is about \$1.50 per diesel-gallon equivalent and \$5.00 per diesel gallon equivalent, respectively (or about \$11/MMBtu and \$36/MMBtu of natural gas, respectively). Transportation fuel derived from biogas may also qualify for Renewable Identification Number (RIN) credits as part of the U.S. EPA Renewable Fuel Standard 2, which could add additional value to these types of projects.
- Assembly Bill 1900 (Gatto, Chapter 602, Statutes of 2012) directed the CPUC to adopt natural gas constituent standards (in consultation with ARB and the Office of Environmental Health and Hazard Assessment). The legislation is also designed to streamline and standardize customer pipeline access rules, and encourage the development of statewide policies and programs to promote all sources of biomethane production and distribution. It also directs the CEC to identify constraints to the use and interconnection of biomethane and offer solutions in its Integrated Energy Policy Report. The CPUC has adopted natural gas constituent standards and created a program to offset a portion of gas

producers' costs of connecting to utility pipelines by providing up to \$1.5 million per biomethane project, up to a cap of \$40 million total.

- Pursuant to Assembly Bill 1257 (Bocanegra, Chapter 749, Statutes of 2013), the CEC has released a report identifying strategies for maximizing the benefits obtained from natural gas as an energy source.¹⁰¹ The report examines strategies and recommendations regarding natural gas, including low emission resources such as biogas and biomethane; the use of natural gas as a transportation fuel; centralized and distributed electricity generation; cooking, cooling, and space heating; engine and appliance applications; its role in the development of zero net energy buildings; and GHG emissions associated with the natural gas system. The report also examines infrastructure and storage needs and pipeline and system reliability concerns.
- ARB's Cap-and-Trade Program will reduce demand of fossil fuels and provide incentives to accelerate efficiency and clean energy. Compliance Offset Protocols under the Cap-and-Trade Program provide methods to quantify, report, and credit GHG emission reductions from sectors not covered by the Cap-and-Trade Program. The Offset Protocols include a livestock protocol, rice cultivation protocol, and mine methane capture protocol.¹⁰² The livestock protocol credits operators who voluntarily install manure biogas capture and destruction technologies. The rice protocol allows compliance offset credits to be issued for emission reductions achieved by switching to rice cultivation practices that reduce methane emissions. The mine methane capture protocol incentivizes capturing methane that would otherwise be vented into the atmosphere from active and abandoned mines.

A broad array of these and other state programs reducing dependence on fossil fuels are also already working to reduce methane emissions, especially from the oil and gas sector. Ultimately, fugitive methane emissions in the oil and gas sector are a function of our demand for these products. As state policies continue pushing our evolution away from conventional oil and natural gas, they will also help to reduce emissions of methane from the production and distribution of fossil fuels. In particular, efforts to improve efficiency or electrify appliances, buildings, and vehicles will not only reduce energy use and CO₂ emissions, but also serve to reduce or avoid fugitive methane

¹⁰¹ *AB 1257 Natural Gas Act Report: Strategies to Maximize the Benefits Obtained from Natural Gas as an Energy Source*, California Energy Commission, September 2015.

<https://efiling.energy.ca.gov/Lists/DocketLog.aspx?doctetnumber=15-IEPR-04>

¹⁰² As is discussed in more length in the CEQA document accompanying this document, the livestock offset protocol would likely cease accepting new projects for offset credits after the effective date of substantive regulations controlling agricultural methane from dairies; however, existing projects could continue generating credits throughout their crediting periods. ARB expects this continued funding stream, along with increased focus on regulatory and incentive measures in this area, to mean many projects now receiving offsets to continue functioning at the end of the crediting period; this, along with new regulations, will produce significant net reductions in methane even if some offset projects cease to function. This transition from offset protocols towards regulations has long been ARB policy.

emissions from the production, and potentially transmission and distribution, of oil and natural gas.

The State has strong targets to reduce the use of natural gas and petroleum by 2030, and several studies show that California must virtually eliminate the use of all fossil fuels to meet its 2050 climate targets. Notably, Governor Brown has called for reducing on-road petroleum use by up to 50 percent by 2030, and Senate Bill 350 (De León, Chapter 547, Statutes of 2015) requires the State to procure 50 percent of its electricity from renewable resources by 2030 and double the rate of natural gas and electricity efficiency savings. ARB's draft 2016 Mobile Source Strategy describes actions to achieve the State's air quality and climate targets from the transportation sector, and cut petroleum use by 50 percent by 2030. The State's Low Carbon Fuel Standard is sending a clear signal to the market that is leading to investment and use of a broad spectrum of cleaner transportation fuels in California including electricity, biogas, as well as biodiesel and renewable diesel, all of which are displacing petroleum. Further, the State's Cap-and-Trade program encourages efficiency and use of non-fossil energy sources across all sectors of the economy, and various programs provide billions of dollars in incentives to support energy efficiency throughout the State.

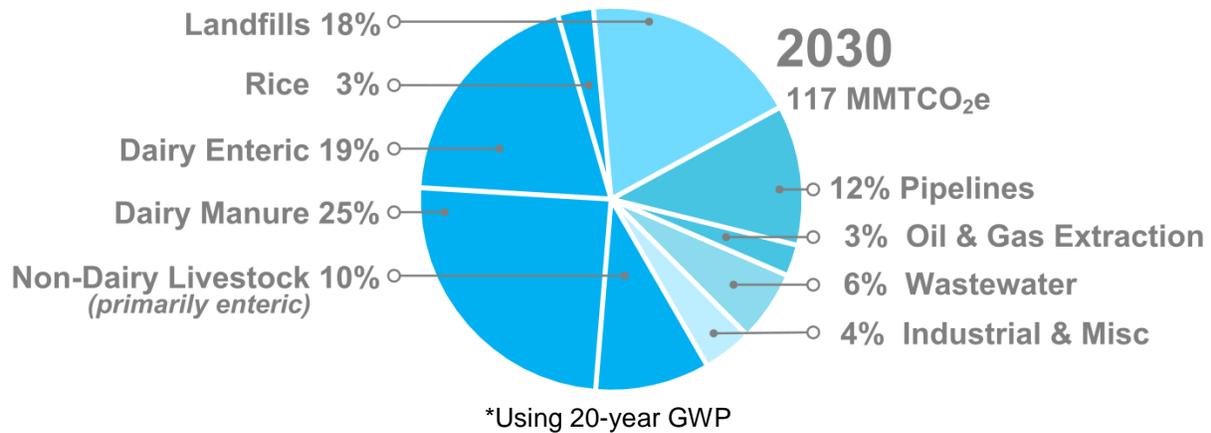

Effectively implementing these actions and programs will significantly cut demand for fossil fuels and associated CO₂ emissions on trajectories we need, while further reducing methane emissions from oil and gas systems. As State agencies implement and refine these programs and plans, they will seek opportunities to better align them with these objectives. Additionally, State agencies will support research to inform appropriate approaches to continue its transition away from fossil fuels.

Further, several efforts are underway at the CEC and ARB to improve emissions monitoring to help identify sources of fugitive methane emissions and reduce them. For example, the CEC provided research funding for operation of a mobile leak detection platform. In 2016, ARB will release a Request for Proposal (RFP) to collect emissions data from oil production wastewater ponds. Results from this contract are expected in 2018, and if they indicate that these ponds are significant sources of methane, ARB may initiate a regulatory process to reduce those methane emissions. Additionally, ARB and NASA's Jet Propulsion Laboratory are collaborating to identify large "hot spot" methane sources through a systematic survey of high methane emitters throughout California. This project will use aerial and ground measurement to survey oil and gas fields and infrastructures, dairies, feedlots, digesters, landfills, rice fields, and wastewater treatment facilities to provide a greater understanding of methane sources. Finally, ARB is actively participating in the Megacities Carbon Project being conducted in the South Coast Air Basin, which is developing and testing methods for monitoring various GHG emissions to link monitored concentrations to emission activity. These efforts will help identify significant fugitive methane sources in California and improve leak detection.

Collectively, these measures will help to keep methane emissions in California fairly steady through 2030. However, the science-based pathway to limiting global warming

below 2°C—including meeting the Governor’s goal to reduce GHG emissions by 40 percent below 1990 levels by 2030—requires further reducing methane emissions in California. Significant opportunity remains to further reduce methane emissions from the major sources in the State (Figure 7). Doing so will require overcoming various economic and institutional barriers, but will provide a wide range of economic and environmental benefits throughout the State, especially where they are most needed.

Figure 7: California’s 2030 Methane Emission Sources with Existing Measures*

B. Recommended Actions to Further Reduce Methane Emissions

California can reduce methane emissions by 40 percent below current levels through a collaborative and mixed approach that combines incentives, public and private investment and partnerships, systematic planning, and regulatory efforts. California’s strategy to reduce methane emissions reflects and supports the variety of approaches and options available to achieve the goal in the most efficient, cost-effective, and environmentally-sensitive manner. This Proposed Strategy promotes and encourages opportunities for industry innovation, the efficient use of existing infrastructure and facilities, and supports the development of integrated systems across various sectors to handle, process, and reuse waste materials and captured methane. For example, significant anaerobic digestion and composting infrastructure capacity needs to be established, and appropriate market opportunities developed for compost and captured methane, before the State can fully use existing organic waste streams for beneficial purposes. State agencies will work with industry and other stakeholders to support and accelerate new project development and activities to maximize methane emission reduction at existing facilities. The State will also work with communities and regional stakeholders to plan and develop integrated infrastructure systems and markets to reduce wastes and associated emissions in the most environmentally-sensitive manner. By investing early and committing to the immediate resolution of issues that hinder progress, California can make significant progress in the near-term, and capture associated benefits.

There are a host of activities underway at the State and Federal level, and by gas utilities, to reduce methane emissions from the natural gas system. In particular,

regulations are being developed to reduce fugitive methane emissions from the oil and gas production, processing and storage sector, and from the natural gas transmission and distribution system. By effectively implementing these policies, and supporting them with continued and improved emissions monitoring, California can match the goals of the Obama Administration to reduce methane emissions from the oil and gas sector by 40-45 percent by 2025. The State will aim to extend successful approaches to reduce emissions from the oil and gas sector to other sectors, and overall, to reduce fugitive methane emissions from all sources by similar levels by 2030.

Table 6, below, describes emission reductions by sector to reduce methane emissions by 40 percent below current levels by 2030. The expected emission reductions for each sector are: 75 percent reduction of dairy manure methane from 2013 levels by 2030; 25 percent reduction of enteric fermentation methane by 2030; 90 percent diversion of organic waste by 2025; 40 percent reduction of wastewater and other industrial sources methane by 2030; and 45 percent reduction of oil and gas methane by 2030.

Table 6: Proposed New Methane Emission Reduction Measures and Estimated Emission Reductions (MMTCO₂e)¹

| Measure Name | 2030 Annual Emission Reductions | 2030 Annual Emissions |
|--|---------------------------------|-----------------------|
| 2030 BAU ² | | 117 |
| Dairy Manure | 21 | |
| Dairy and Livestock Enteric Fermentation | 5 | |
| Landfill | 5 | |
| Wastewater, industrial and Other Miscellaneous Sources | 7 | |
| Oil and Gas Sector | 8 | |
| 2030 BAU with new measures | | 71 |

¹ Using 20-year GWPs from the 4th Assessment report of the IPCC

² "Business As Usual" (BAU) forecasted inventory includes reductions from implementation of current regulations

1. Dairy Manure

California's dairy and livestock industries account for roughly half of the State's total methane emissions and about five percent of the State's overall GHG emissions. About half of the emissions from the State's 5.5 million total beef and dairy cows come from enteric fermentation (mostly belching), and the other half from manure management practices, primarily lagoon storage of flushed manure from milking cows.

California has the most dairy cows in the country and the highest aggregated dairy methane emissions. The State also has higher per-milking cow methane emissions than most of the rest of the United States, due to the widespread use of flush water lagoon systems for collecting and storing manure. Milk production feed efficiency at California dairies, however, is among the best in the world; California dairy cows produce low enteric fermentation emissions per gallon of milk. So if dairy farms in California were to manage manure in a way to further reduce methane emissions, a gallon of California milk might be the least GHG intensive in the world.

Dairy methane emissions may be significantly reduced by switching from flush water lagoon systems without methane capture to solid-scrape (i.e. slurry) or dry manure management practices. Anaerobic digesters can also be installed to capture and utilize manure methane, and can be used with flush water lagoon systems, dry, or solid-scrape manure collection practices. The use of manure systems such as vacuum or scrape also allows for easier transport and storage of manure off-site or to centralized digester systems, which can improve economies of scale, biogas production efficiencies, and nutrient management on the dairy. Dairy manure can also be mixed with other organic materials diverted from landfills or at wastewater treatment plants to improve digester performance and economics, with centralized digesters playing a key role in helping California meet its organic diversion and bioenergy goals.

Dairies with flush water lagoon systems typically flood irrigate dairy feed crops, such as corn silage and alfalfa, to dilute and disperse nutrients from manure in the lagoon. This practice can lead to soil and groundwater contamination despite being subject to regulation by regional water quality control boards, including the Dairy General Order in the Central Valley. Solid-scrape manure management may lead to air quality challenges, however, which need to be fully considered. Ultimately, the optimal mix of technologies and manure management practices to reduce methane emissions, protect air and water quality, and support dairy economics will depend on dairy-specific factors and vary across the State.

In some instances, pasture-based dairy management may be an option, as well, but there are tradeoffs that limit its applicability. In a pasture system, manure is left in the field and decomposes aerobically (versus anaerobically in a lagoon), which avoids methane emissions. Many organic milk producers rely on pasture systems for much of their operations, and it is a fairly common practice in other states and at smaller dairies in coastal and northern parts of California. However, for larger dairies and those in the Central Valley, pasture would require using significantly more irrigated land and may also pose feed production issues and animal welfare concerns due to heat exposure. Pasture dairy operations may still face potential nutrient management and groundwater

issues, and still must maintain some capacity to store liquid coming from milking parlor operations (chilling milk, cleaning facilities, etc.) for the required 100 year stormwater retention. Milk production and feed efficiencies are lower in pasture-based systems, requiring more cows and higher enteric fermentation emissions per unit of milk, and pasture-based systems limit the ability to manage manure as a valuable organic waste resource. Pasture-based systems are a viable option that is appropriate in some cases, but likely challenging to implement at many existing, larger dairies in the Central Valley.

Captured biogas from dairy manure can be used to power farm trucks and equipment, injected into natural gas pipelines, used as a transportation fuel, or used to generate on-site renewable electricity and heat. However, tapping into this resource in California has been complicated in the past due to air quality constraints, especially in the Central Valley and Southern California. Utilizing newer and clean technologies can help to overcome air quality permitting issues that have previously hindered project development. In particular, technologies or strategies that reduce or eliminate criteria pollutant and toxic emissions should be encouraged in both incentive and regulatory programs, particularly in areas with severe or extreme air pollution. For example, using ARB-certified distributed generation technologies, such as microturbines or fuel cells, can significantly cut NO_x emissions compared to internal combustion engines. Injecting biogas into the natural gas pipeline can avoid most new combustion or associated emissions altogether. As part of an integrated strategy that includes replacing diesel trucks and equipment with certified ultra-low NO_x vehicles or equipment, fueling vehicles with dairy-derived biogas could help to reduce criteria pollution in impacted air basins.

California will aim to reduce methane emissions from dairy manure management by at least 20 percent in 2020, 50 percent in 2025, and 75 percent in 2030. If dairy cow populations don't grow in California, in line with current forecasts, these reductions would reduce overall methane emissions from the dairy industry by more than 40 percent in 2030. Through this Proposed Strategy and related efforts, we can quickly and effectively reduce methane emissions from the State's largest source, while creating economic value in farming communities. While barriers remain to building out necessary infrastructure in the State, if the market were fully enabled, anaerobic digestion at California dairies could lead to billions of dollars of investment and thousands of new jobs, concentrated in the Central Valley (see Chapter VIII). Working together, State agencies, dairy farmers, and other stakeholders can achieve this level of reduction through a combination of financial incentives, infrastructure deployment, market development and regulatory actions.

These targets can be achieved by capturing or avoiding methane currently emitted from lagoons or other anaerobically stored manure at a relatively small fraction of the State's dairies. For example, dairy manure emissions can be reduced by 75 percent by capturing or avoiding the methane generated by about 60 percent of the State's milking cows (1.05 million) on about 30-35 percent of the State's dairies (about 500 dairies).¹⁰³

¹⁰³ California has over 1,400 dairies, with approximately 1,000 having more than 500 milking cows which might be suitable for methane capture or abatement (refer to Chapter VIII for a discussion on potential manure methane mitigation options and cost estimates).

The 2020 and 2025 targets could be met by capturing or avoiding methane generated by about 15 percent and 40 percent of the State's milking cows, respectively.

Depending on the strategies pursued to reduce emissions, individual dairies may be able to reduce emissions profitably, and the industry as a whole may be able to meet these targets at little or no net cost (see Chapter VIII). However, revenues in some cases are highly dependent on uncertain environmental credit and energy markets, as well as the ability to interconnect to natural gas pipeline systems, where economic and institutional barriers remain. If regulations impose costs on the industry that cannot be recouped, a result could be emissions leakage, if some dairies relocate outside of California or herd sizes grow elsewhere. This could include places where milk production efficiencies are lower and associated enteric fermentation emissions are higher and could increase mobile source emissions from heavy duty vehicles associated with transport of dairy products to established processing facilities and distribution centers.

Accordingly, the State will encourage and support near-term actions by dairies to reduce emissions through market support and financial incentives. At the same time, ARB will initiate a rulemaking process to develop regulations for dairy manure management in California. This coordinated approach will aim to develop a competitive, low-carbon dairy industry in California and avoid emissions leakage. Specifically, California will take the following steps to significantly cut methane emissions from manure management at dairies:

Accelerate Project Development and Emission Reductions at Dairies

The State will support the industry to accelerate project development and help the industry reduce emissions before regulatory requirements take effect. In particular, the State will work to support improved manure management practices through financial incentives, collaboration to overcome barriers, and other market support.

Continued State funding or incentives should support initial infrastructure investments to convert dairies away from flushwater management systems and support market opportunities for the use of captured or produced biomethane. CDFA estimates that at least \$100 million will be needed for each of the next five years to support the development of necessary manure management infrastructure in the form of grants, loans, or other incentive payments. The economic analysis in

Chapter VIII suggests that this level of funding could significantly accelerate project development by reducing capital costs and economic risks. Different types of funding mechanisms and level of support may be appropriate for different types of projects.

ARB and CDFA staff will establish a working group with other relevant agencies and stakeholders to focus specifically on solutions to barriers to dairy manure projects. The group will aim to ensure and accelerate market and institutional progress. It may cover several topics, including: project finance, permit coordination, CEQA, feed-in tariffs, simplified interconnection procedures and contracts, credits under the LCFS, increasing the market value of manure products, and uniform biogas pipeline standards. This group will be coordinated with similar working group efforts related to anaerobic digestion, composting, energy, healthy soils, and water. Additionally, State agencies will coordinate activities with federal agencies, including the U.S. Department of Agriculture and U.S. Department of Energy, to align common efforts and attract federal investment to California. Further, ARB will work with State and Regional water quality agencies to ensure opportunities for conservation and water quality efforts are developed jointly and with the air districts to ensure opportunities for air quality efforts are developed jointly.

In many cases, converting to scrape systems or installing anaerobic digesters at dairies may not yet be cost-effective, if the only marketable product is energy. However, if compost or other soil amendment products and environmental credits can be monetized from these projects, as well, they may offer attractive rates of return for farmers and investors.¹⁰⁴ Markets for these other products need further support, however, before they can offer reliable returns to help finance projects. CalRecycle, CDFA, and other agencies are working together to support healthy soils through composting and building markets for soil amendment products in the State. Enabling pipeline injection of biomethane and minimizing associated costs will help get dairy biogas into the transportation sector and allow for the generation of LCFS and RIN credits, which could provide an especially valuable revenue stream.¹⁰⁵ The State will continue to support these efforts.

Develop Regulations to Ensure Emission Reductions

While the State will encourage early emission reduction actions by dairies through market support and financial incentives, regulations will be necessary to ensure manure management practices lead to lasting emission reductions. In 2017, and in coordination with CDFA and local air quality and water quality agencies, ARB will initiate a rulemaking process to reduce manure methane emissions from the dairy industry in-line with the objectives in this Proposed Strategy. The regulatory process will include

¹⁰⁴ For example, one report estimates that the average internal rate of return for dairy digester projects in the U.S. that only capture value from energy production would be about 8 percent in a mid-valuation scenario, but would increase to 38 percent if value can be captured from soil amendments and markets for environmental credits.

Informa Economics (2013) National Market Value of Anaerobic Digester Products, Prepared for the Innovation Center for U.S. Dairy, February.

¹⁰⁵ Under the LCFS, ARB recently approved a dairy digester fuel pathway with a carbon intensity of -276 gCO₂e/MJ. <http://www.arb.ca.gov/fuels/lcfs/2a2b/apps/calbio-sum-122115.pdf>
At credit prices of \$100/MT, these credits could be worth about \$5 per diesel gallon equivalent.

consideration of available financial incentives, market support, and the potential for emissions leakage in identifying appropriate timelines and requirements for the industry.

The rulemaking will also include requirements for mandatory reporting and recordkeeping of parameters affecting GHG emissions at California dairy farms. Reported information will be used to refine inventory quantification, evaluate policy effectiveness, and aid in future policy planning and regulatory development. ARB will work with other State agencies and industry groups to improve outreach on new reporting requirements, as well as merge and streamline reporting activities with current forms and requirements to avoid duplicative reporting wherever feasible.

Regulatory requirements to achieve large emission reductions from the industry will affect incentives for dairy methane reduction projects, such as the availability and amount of credits under the Cap-and-Trade program and LCFS. Once a regulation is in place, credits for avoided methane emissions under the LCFS or the Cap-and-Trade Programs would not be available for new projects as the reductions would not be additional to regulation or business-as-usual. However, projects in place before the regulation takes effect would still be able to generate credits for avoided methane emissions for their current crediting period, which is ten years of operation. For new projects after a regulation takes effect, credits under the LCFS would still be available, but would only consider the displacement of petroleum fuel. ARB will clarify the impact of potential regulations on LCFS credits before finalizing a regulation, and will make appropriate adjustments to the Cap-and-Trade Program to ensure only reductions that meet the AB32 offset criteria are credited. Sufficient lead time will be provided before regulatory requirements take effect to allow the market to react.

Research the Reduction Potential of Manure Management Practices

While the need and potential to reduce methane emissions from dairy manure is clear, some potentially effective strategies are still in the development stage. In particular, the use of solid separators and converting flush systems to dry manure management systems could be potentially low cost methods to reduce methane emissions. However, little data exists to quantify costs and benefits associated with these practices. Additionally, some uncertainty remains regarding cross-media impacts and accounting of various dairy manure management practices. ARB and CDFA will continue to support research to eliminate information gaps and improve understanding of potential manure management practices and their associated methane reduction benefits, as well as potential air quality or water quality impacts.

2. Dairy and Livestock Enteric Fermentation

Methane is also produced by the microorganisms involved in the digestive processes in the stomachs of dairy cows and other ruminants, such as sheep, goats, buffalo and cattle. This process is referred to as enteric fermentation. These emissions account for 29 percent of California's methane inventory, making it essential to develop strategies to reduce emissions from these sources to meet State GHG emission reduction targets.

Strategies that have been investigated to reduce enteric fermentation include increasing production efficiencies to reduce the amount of methane produced for a given amount of product, breeding animals for lower methane production, gut microbial interventions, and changes to nutrition and animal management. Further research is needed to fully evaluate the viability of these strategies to California; and to assess their associated costs and co-benefits, potential impacts on animal productivity, on animal and human health, other environmental impacts, and GHG and air toxic emissions associated with feed lifecycles. Strategies to produce more easily digestible feed that lowers enteric fermentation might increase emissions associated with GHG-intensive feed production and transport. Therefore, regionally-specific lifecycle emission assessments of enteric fermentation emission reduction strategies would need to be used to account for any unintended emission increases in other sectors.

The dairy industry in California and the U.S. has been working to increase efficiencies associated with their operations and product. A broad coalition of the national dairy industry set GHG sustainability targets for 2020. The targets include reducing the GHG intensity of fluid milk by 25 percent,¹⁰⁶ and enteric fermentation emissions by 25 percent.¹⁰⁷ If a 25 percent reduction in enteric fermentation emissions from California's dairy cows were achieved by 2030, it would reduce the State's methane emissions by 5 MMTCO₂e (based on a 20-year GWP).

This Proposed Strategy sets those levels as a goal for reducing methane emissions from enteric fermentation in California. Combined with the goals for manure management, this would bring emissions for the dairy industry down by 40 percent below current levels in 2030. By continuing historic annual improvements in milk production efficiency and progressing toward their established voluntary targets, the industry may meet this goal independently. Additionally, various studies are pointing to new feed supplements that have the potential to reduce enteric fermentation emissions 20-30 percent without affecting milk production.^{108,109}

Research Mitigation Strategies for Enteric Fermentation

Federal and State agencies, industry, and academia will support research through available funding mechanisms (e.g. ARB's annual research program, Greenhouse Gas Reduction Fund), and continue to monitor progress to develop strategies that can help to reduce enteric fermentation emissions from dairy cows and livestock in the California context. Once mitigation strategies have been successfully evaluated, long-term emission reduction potential and goals can be established on a broader scale. As ARB develops an emission reduction regulation for manure management, staff will continue to evaluate the latest science of enteric fermentation and identify the best approach to addressing these emissions.

3. Landfills

Landfilling organic materials leads to the anaerobic breakdown of these materials into methane, which can work its way out of the landfill as a fugitive emission. Organic waste constitutes more than 40 percent of California's waste stream, and as with dairy manure, a holistic approach is needed to effectively divert and manage it. This means not only keeping organics out of landfills, either through source reduction or diversion, but also improving the infrastructure for diverting and/or recycling organics, including minimizing and salvaging edible food wastes, composting, anaerobic digestion and other novel processes for energy recovery. In particular, California must have enough in-state composting and in-vessel digestion or other organics processing and recycling capacity to maximize the benefits from this waste stream and effectively minimize the spreading of unprocessed organic waste on open lands, which can have adverse environmental impacts. It also means having markets for this material that are robust and resilient whether as food recovery or waste avoidance, compost, soil amendments, mulch for erosion control, transportation fuels, energy, or other uses. The State can accelerate progress by providing more consistent financial and institutional support for these efforts, and taking steps to align tipping fees and financial incentives in the sector with its organics diversion goals.

Diverting organic wastes can provide a variety of environmental and economic benefits. Food rescue or recovery is the practice of utilizing edible foods that would otherwise go to waste from restaurants, grocery stores, dining facilities and produce markets and distributing it to local food programs. Food recovered from farms, which would otherwise be plowed under, is typically gathered by volunteers. The main benefit of food rescue programs is that they provide healthy foods to those in need, but they also reduce organic waste disposal. Food wastes that may not be easily utilized for human consumption may alternatively be used as animal feed. Composting returns nutrients to the soil, builds soil organic matter, improves water holding capacity, increases carbon sequestration in the landscape, and avoids the use of fossil fuel-intense inorganic fertilizers. Anaerobic digestion can support the State's efforts to obtain at least 50 percent of its electricity from renewable resources, aid in reducing the carbon intensity of transportation fuels, and displace fossil natural gas consumption. As described in Chapter II, eliminating the disposal of organics in landfills as part of a broad

effort to put California's organic waste streams to beneficial use can generate thousands of jobs and provide billions of dollars in value, much of it concentrated in the Central Valley and other rural areas.

Eliminating the disposal of organics in landfills would align California with a growing range of efforts to do so in other states and countries. In California, San Francisco and Alameda County require that food waste be separated and kept out of the landfill, and both Los Angeles and San Francisco, along with other cities, have plans in place to become zero-waste.

The State has already established its intent to phase out the disposal of organics from landfills. Existing law sets a goal of diverting 75 percent of solid waste from landfills by 2020 and provides other measures and requirements to support diverting organics from landfills. California will build on that intent and progress, with market and institutional support, and divert 90 percent of organics from landfills by 2025, effectively eliminating the disposal of organics in landfills.¹¹⁰ Due to the multi-year timeframe required to breakdown landfilled organic material, emission reductions from organics diversion accumulate over time. These actions would reduce landfill emissions by 5 MMTCO_{2e} in 2030,¹¹¹ increasing to 21 MMTCO_{2e} by 2050 (using a 20-year GWP).

Still, waste-in-place will continue to emit methane for decades to come. California has a Landfill Regulation in place that requires owners and operators of certain uncontrolled municipal solid waste landfills to install gas collection and control systems. This effort has improved management of landfills in California and reduced methane emissions. There may be additional opportunities to employ best practices and further reduce methane emissions from landfills over time.

However, quantifying emissions from landfills is difficult, due to their area-wide nature and several landfill-specific factors (size, age, materials deposited, local atmospheric conditions, soils, landfill cover, and gas collection system). In the GHG inventory, and its climate programs, ARB assumes a methane capture efficiency of 75 percent at landfills. This conforms with common practice nationally. In its Landfill Regulation, ARB estimated that the landfill regulation may increase the collection efficiency at regulated landfills to 80-85 percent.

Estimates of methane collection efficiency at landfills, both with and without gas collection systems, vary widely. In the U.S. EPA landfill database, the weighted

¹¹⁰ Specifics of this measure will be developed during the regulatory process. For the sake of calculating emission reductions in this plan, it is estimated that 75 percent of organics will be diverted from landfills by 2020 and 90 percent will be diverted by 2025 (this would amount to an 80 percent reduction below current levels).

¹¹¹ Methane emission reductions from landfills (Table 6) are calculated assuming regulated landfills achieve methane capture efficiencies of 80 percent by 2030 and 85 percent by 2050, and that the State effectively eliminates organic disposal at landfills by 2025 by meeting the organics diversion targets identified in this Proposed Strategy.

average of collection efficiencies at California landfills is 78 percent.¹¹² However, this data is self-reported and the emission estimation method does not incorporate emission changes due to California's regulation. Additionally, various studies suggest that California's methane inventory is underestimating methane emissions in the State. The source(s) of potential incremental methane emissions has not been identified. Continuing evaluation of major sources of methane in the State is necessary, and this includes landfill emissions.

The State will support research to improve understanding of emissions from landfills and engage stakeholders in potential opportunities to further control them. Once more is understood about emissions from California's diverse set of landfills, ARB may update the assumptions regarding collection efficiency used in its inventory and various programs and consider whether additional actions, including a "phase 2" of the landfill regulation, would deliver further cost-effective GHG emission reductions.

Uncertainty around landfill emissions does not suggest that the existing Landfill Regulation is not reducing emissions or that steps to divert organics from landfills should be delayed. To the contrary, what is certain is that best management practices at landfills reduce methane emissions, diverting organics from landfills can provide a wide range of economic and environmental benefits in California, and that doing so is the only reliable way to avoid methane emissions from landfills on a lasting basis.

The State will take the following actions to reduce methane emissions from landfills in California:

Require Organics Diversion from Landfills

ARB, in conjunction with CalRecycle, will develop a regulation by 2018 to effectively eliminate the disposal of organics in landfills by 2025. Under this proposed regulation, the agencies will explore and prioritize opportunities to recover organic materials through local food waste prevention and rescue programs, which could account for 10 percent food waste reduction by 2020 and 20 percent reduction by 2025 in California. Food waste prevention includes activities such as education regarding food preparation and storage, refining food purchasing practices, and software that can help inform food ordering and menu selections. Rescue includes local organizations such as homeless shelters, food banks and community kitchens that provide food for people in need. Material that cannot be effectively recovered would be diverted to organics recycling facilities to make useful products,

¹¹² The average collection efficiency at California landfills in 2013, according to EPA's database is 76 percent. When weighted by methane generation, the average is 78 percent. <http://www3.epa.gov/airtoxics/landfill/landflpg.html>

including compost, fuel or energy. These facilities may be developed at existing landfills, other waste management sites, or at new stand-alone sites. Organic wastes could also be diverted to regional wastewater treatment plants or dairies for co-digestion with wastewater sludge, biosolids, or manure. Local governments must play an important role in diverting organics both as land use and permitting authorities for recycling facilities and as partners in implementing diversion requirements. The State will work with its local partners to develop helpful tools such as programmatic EIRs or guidance documents. Community engagement in the planning and environmental review processes is critical, both for understanding and mitigating potential negative health and environmental impacts and for understanding the positive economic and health and environmental benefits afforded by such projects.

Align Financial Incentives with Organics Diversion

Eliminating organics disposal in landfill will require additional infrastructure capacity to process and reuse diverted organic waste from landfills—through composting (including chipping and grinding), anaerobic digestion, or other methods. Continued, increased State funding is critical to building this necessary infrastructure. An increase in California's Integrated Waste Management Fee is also needed to support the establishment of food rescue programs, discourage the landfilling of organic waste and other recyclables, and provide funding to support organics recycling infrastructure. CalRecycle estimates that State support of at least \$100 million per year for five years, in the form of grants, loans, or incentive payments, will be needed to leverage private sector financing and local rate structure changes to support the development of necessary organic infrastructure and help to foster markets.

Collaborate to Overcome Barriers

State agencies will collaborate to resolve existing constraints in the permitting process and provide clear standards and compliance pathways for all public health and environmental goals. The beneficial use of methane produced at organic waste processing facilities faces many of the same obstacles described for dairy manure or wastewater treatment, and a common workshop or work group effort to address barriers to beneficial use of organic waste streams may be useful. Also, appropriate standards should be developed to guide the direct application of organic materials on land and ensure this activity does not pose a threat to human or environmental health.

Foster Recovery Programs and Markets

CalRecycle will work collaboratively with other agencies and departments to help establish food rescue programs and to identify, develop, and expand markets for the use of compost, mulch, and renewable fuels and energy. CalRecycle and CDFA will continue their efforts to incentivize the use of compost on agricultural lands in support of the Healthy Soils Initiative, including developing best management practices for agricultural use. They will also work with the State Water Resources Control Board to evaluate potential mechanisms to account for the use of compost and its impacts on

nitrogen budgets in the Irrigated Lands Program. CalRecycle will continue to work towards strengthening State procurement requirements relative to compost and mulch. Finally, building on the existing use of mulch and compost as a water conservation practice that is essential for climate adaptation with respect to drought, State agencies will support research to quantify water conservation and other potential benefits and consider developing mechanisms to account for and value them.

Improve Understanding of Landfill Emissions

ARB and CalRecycle will support research to improve understanding of emissions from California landfills and identify opportunities to further reduce emissions from existing waste-in-place. ARB will consider the latest science and whether adjustments to emissions accounting in the inventory or other programs is warranted. Based on this information, ARB, in collaboration with CalRecycle, may consider additional actions to further reduce and capture methane emissions from landfills in the future.

4. Wastewater Treatment and other Miscellaneous Sources

Wastewater treatment, industrial operations, rice cultivation, septic tanks, and other sources of methane account for about nine percent of the State's methane inventory.

Wastewater treatment plants provide a promising complementary opportunity to help divert a portion of organic wastes from landfills and create useful byproducts such as electricity, biofuels and soil amendments.

Wastewater treatment plants are designed to remove contaminants from wastewater, primarily from household sewage, but with infrastructure improvements could increase acceptance of food waste and fats, oils, and grease (FOG) for co-digestion. Anaerobic digestion is a typical part of the wastewater treatment process employed at most of the larger plants, with many plants capturing the methane they currently generate for on-site heating or electricity needs.

Many of these plants may have spare capacity, and can potentially take in additional sources of organic waste for anaerobic digestion. Existing or new digesters at these facilities can be designed to co-digest materials such as food waste and FOG from residential, commercial, or industrial facilities. Many of the largest plants are ideally located close to population centers and could potentially obtain and process significant amounts of food and other suitable waste streams within the region. The State proposes to take the following actions to evaluate this opportunity.

Develop Regional Opportunities to Co-Digest Waste

ARB will work with CalRecycle, the State Water Resources Control Board, Regional Water Quality Control Boards, and others to determine opportunities to support the co-digestion of food-related waste streams at existing and new digester facilities, including wastewater treatment plants.

Align Financial Incentives with Methane Capture and Reuse at Wastewater Treatment Facilities

A program that relies on financial incentives and/or regulatory actions could be implemented to ensure that new and existing wastewater treatment plants in California fully implement methane capture systems (ideally to produce on-site renewable electricity, transportation fuel, or pipeline biogas), and maximize digestion of regional organic materials. The potential actions would need to be tailored to each wastewater treatment plant based on size or capacity, and other factors such as potential for co-digestion expansion, proximity of organic waste streams, and regional air quality standards and rules. The Water Boards could develop permit terms and other regulatory tools to support the program while achieving water supply, water quality, and related co-benefits.

Collaborate to Overcome Barriers

Many wastewater treatment plants are permitted to burn digester biogas through flaring and are classified as industrial facilities. Capturing the biogas to produce electricity, such as through a combined heat and power (CHP) system may result in re-classifying the facility's purpose as "electricity generation" and subject the plant to more onerous emission compliance and abatement equipment rules. In addition, the beneficial use of methane generated at wastewater treatment facilities faces many of the same hurdles faced by dairy digesters and organic waste composting facilities. Support for technologies and strategies to capture biogas to generate electricity, supplement natural gas pipeline fuel, or for use as a transportation fuel, is needed to overcome some of these barriers and may open up more valuable fuel and credit markets. ARB will work with other relevant State and local agencies to identify and remove financial and regulatory barriers that hinder the productive use of waste streams processed at wastewater treatment plants.

5. Oil and Gas

California has a large oil and gas industry with more than 50,000 oil and 1,500 gas wells, including off-shore platforms. The majority of the oil wells are located in Southern California with most of the gas fields located in Northern California. An extensive network of oil and gas pipelines within the State transport California's crude oil from import terminals and on- and off-shore oil fields to refineries, and distributes finished fuels to more than 70 product terminals throughout the State.

California also has about 215,000 miles of natural gas transmission and distribution pipelines; 22 compressor stations; and 25,000 metering and regulating stations (M&R) stations. Natural gas is currently California's largest source of fuel for electricity generation, and supplies most of the energy used for industrial operations. Natural gas is also a primary source of energy used for residential and commercial space heating and cooking, and represents the primary source of GHG emissions from the residential and commercial sectors.

Much of the equipment in the oil and gas industry has been regulated for decades by the local air districts. The districts have rules and regulations to limit VOC and NO_x emissions because they are precursors of ground-level ozone. Many of the VOC controls also reduce methane as a co-benefit. In 2015, U.S. EPA proposed additional federal measures that could address methane primarily at new oil and natural gas sources, with coverage at some existing sources. Additional actions to reduce methane from the oil and gas sector should also reduce VOC and toxic air contaminant emissions, although those co-benefits have not yet been estimated.

California has an emerging, comprehensive framework in place to reduce methane emissions from oil and gas infrastructure. Effectively implementing this framework can reduce methane emissions from oil and gas systems by 40-45 percent in 2025, matching federal commitments.¹¹³ Additional opportunities may emerge to further reduce emissions from infrastructure and will be considered when they do. But further reducing methane emissions from the oil and gas sector will ultimately require reducing in-state demand. A rapid decline for demand for oil and natural gas is also necessary to meet the State's 2030 and 2050 climate targets, more broadly.

About 90 percent of California's natural gas comes from out of State, and ultimately, action by other jurisdictions is needed to minimize leaks associated with our natural gas use. The Obama administration has taken steps to address oil and gas sector methane emissions, especially at the point of production, but more may need to be done to reduce emissions from pipelines and other equipment out-of-state. There may be steps that California agencies or utilities can take to ensure that infrastructure supplying gas to the state has minimal leakage, and to ensure that natural gas is providing environmental benefits compared to use of other fossil fuels in the State.

The State's framework on oil and gas methane emissions includes the following elements:

Adopt and Implement a Greenhouse Gas Emission Standards For Crude Oil and Natural Gas Facilities Regulation

ARB is currently working with local air districts and other stakeholders to develop a regulation for Board consideration by mid-2016. The proposed regulation, still being developed, will likely require:

¹¹³ For the purposes of calculating emission reductions in 2030, Table 6 assumes a 45 percent reduction below current levels by 2030.

- Vapor collection on uncontrolled oil and water separators and storage tanks with emissions above a set methane standard;
- Vapor collection on all uncontrolled well stimulation circulation tanks;
- Leak Detection and Repair (LDAR) on components, such as valves, flanges, and connectors, currently not covered by local air district rules, as well as from soil at underground natural gas storage well sites;
- Vapor collection of large reciprocating compressors' vent gas, or require repair of the compressor when it is leaking above a set emission flow rate;
- Vapor collection of centrifugal compressor vent gas, or replacement of higher emitting "wet seals" with lower emitting "dry seals";
- "No bleed" pneumatic devices and pumps; and
- More frequent methane monitoring at underground natural gas storage facilities.

This regulation would uniformly expand some local regulations to all air districts and include additional infrastructure components (such as valves, flanges, and seals) that are not currently covered by local district programs. ARB staff is investigating ways to ensure that any combustion-based controls will not interfere with efforts to achieve and maintain compliance with ambient air quality standards in cases where methane and VOC emissions cannot be sent into existing sales lines, fuel lines, or reinjection wells, and are instead captured by installing new vapor collection on existing storage tanks, with the collected vapors being sent to a low-NOx incinerator that will replace an existing flare.

Improve Monitoring and Standards to Detect and Minimize Emissions

ARB and DOGGR are working together to ensure that both above and below ground monitoring of storage facilities is improved. As mentioned above, ARB is considering improved above-ground methane monitoring of underground storage facilities in its upcoming Oil and Gas Production, Processing, and Storage Regulation. In January 2016, DOGGR released notice of an emergency regulatory action to implement protective standards specifically designed to ensure that operators of underground gas storage facilities are properly minimizing risks and taking all appropriate steps to prevent uncontrolled releases, blowouts, and other infrastructure-related accidents. The emergency regulations will ensure that operators of existing underground gas storage facilities monitor for and report leaks to DOGGR, function test all safety valve systems, perform inspections of wellheads and surrounding area and equipment, develop risk management plans that require verification of mechanical integrity and corrosion assessment and monitoring, and provide DOGGR with complete project data and risk assessment results. Immediate implementation of these standards will ensure that underground gas storage facilities are properly operated, minimizing the potential that an incident such as the gas leak at the Aliso Canyon Natural Gas Storage Facility does

not recur.¹¹⁴ ARB and DOGGR will coordinate on the monitoring provisions to ensure consistency and comprehensiveness while limiting duplication.

Additionally, Assembly Bill 1496 (Thurmond, Statutes of 2015, Chapter 604) requires ARB, in consultation with scientific experts and other state, local, and federal agencies, to undertake monitoring and measurements of high-emission methane “hot spots” and conduct lifecycle GHG emission analysis for natural gas produced in and imported into California. Pursuant to this bill, ARB will continue its efforts related to hot spots monitoring and lifecycle greenhouse gas accounting for fuels, and will host a scientific workshop to collect the best available knowledge on these topics. ARB will update relevant policies and programs to incorporate any new information gathered as a result of these efforts.

Effectively Implement SB 1371 to Reduce Emissions from Pipelines

Senate Bill 1371 (Leno, Chapter 525, Statutes of 2014) directs the CPUC, in consultation with ARB, to adopt rules and procedures to minimize natural gas leaks from CPUC-regulated intrastate transmission and distribution gas pipelines and facilities. Among other requirements, SB 1371 directs the CPUC to adopt rules and procedures that provide for the maximum technologically feasible and cost-effective avoidance, reduction, and repair of leaks and leaking components. In January 2015, the CPUC launched a rulemaking proceeding (R.15-01-008) to carry out the intent of SB 1371. Under this proceeding, CPUC published a report that identifies new gas leak detection technologies that can be used to optimize methane reductions from transmission, distribution and storage processes. CPUC also required utility companies and gas suppliers to report natural gas emission data and best leak management practices by May 15, 2015. In June 2015, CPUC conducted a prehearing conference to discuss the draft scoping memo of relevant topics to be deliberated during the 24-month timeframe of the proceeding.

ARB continues to actively participate in the proceeding and will lead efforts to analyze collected utility emission data, develop quantification protocols, and identify potential mitigation strategies. In particular, ARB will focus on the emission reduction potential of the proceeding in keeping with the objectives of AB 32 as they pertain to:

- Comparing the data collected under SB 1371 with the Mandatory Reporting Regulation;

¹¹⁴ Preliminary estimates suggest the incident resulted in about 8 MMTCO₂e (AR5 20-year GWP) of methane emissions, an approximately 20 percent increase in statewide methane emissions for the duration of the leak (October 23, 2015–February 17, 2016). Governor Brown’s January 2016 Aliso Canyon Proclamation directs the ARB to develop a mitigation plan for the leaked methane emissions by March 31, 2016. It can be accessed at: http://www.arb.ca.gov/research/aliso_canyon/arb_aliso_canyon_methane_leak_climate_impacts_mitigation_program.pdf

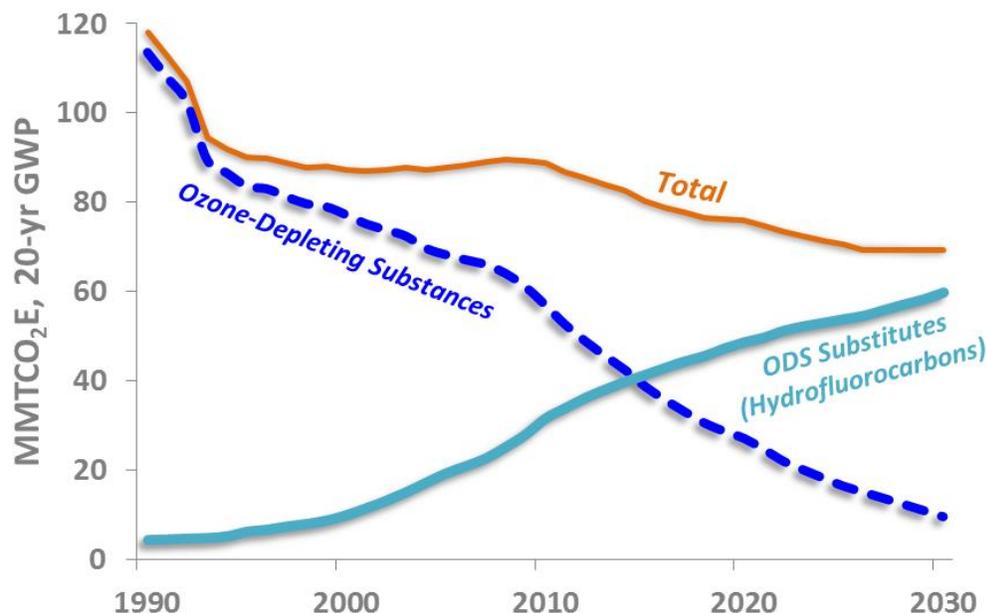

- Analyzing emission data to determine potential mitigation strategies. For example, the proceeding may require the replacement of older pipelines or pipelines constructed of a certain material;
- Identifying any remaining data gaps;
- Establishing procedures for the development and use of metrics to quantify emissions; and
- Reviewing and evaluating the effectiveness of existing practices for the operation, maintenance, repair, and replacement of natural gas pipeline facilities to determine the potential to reduce methane leaks and where alternative practices may be required.

The final decision on potential rules and procedures by the CPUC, including ratemaking and financial incentives to minimize gas leaks, is anticipated in the Fall of 2017. Upon evaluation of the industry's compliance with the decision, ARB will determine whether additional regulatory actions or incentives are required to further reduce methane emissions from this source.

VI. Reducing HFC Emissions

Hydrofluorocarbons (HFCs) are the fastest-growing source of GHG emissions both globally and in California. HFCs are fluorinated gases (F-gases), which also include the ozone-depleting substances (ODS) that are being phased out under the Montreal Protocol. HFCs currently comprise four percent of all GHG emissions in California, although annual HFC emissions are expected to increase 60 percent under business-as-usual by 2030 as HFCs continue to replace ODS (Figure 8).

Figure 8: Emission Trends of ODS and ODS substitutes (hydrofluorocarbons) – (as ODS are phased out, HFCs increase)

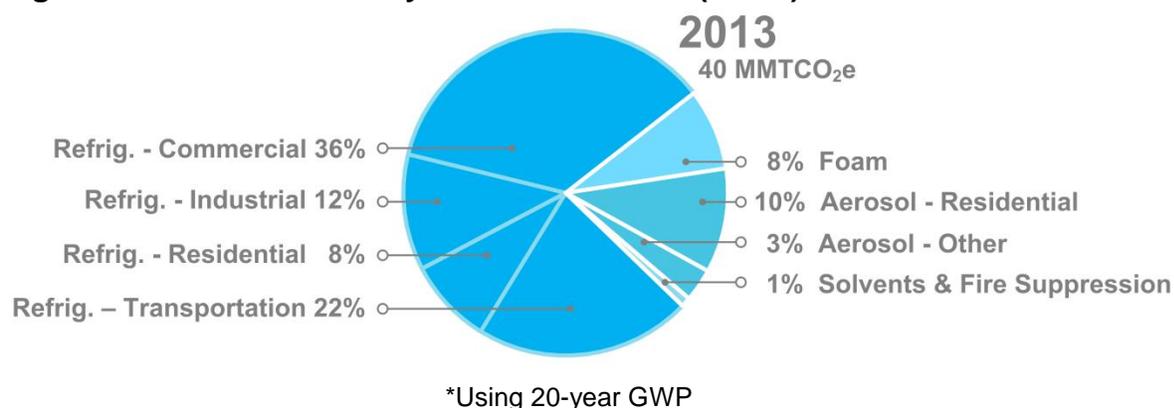

The majority of HFC emissions come from fugitive emissions of refrigerants used in refrigeration and air-conditioning (AC) systems. The largest uses of HFCs are in commercial and industrial refrigeration and air-conditioning, which comprise 48 percent of HFC emissions. More than half of refrigeration and air-conditioning equipment currently uses HCFC-22, a high-GWP ODS which is scheduled for a complete phase-out of new production and import in the U.S. by 2020. The HCFC-22 refrigerant is being replaced with HFCs that have higher GWPs, thus increasing the GHG impact of refrigerants. We expect that in anticipation of the HCFC-22 phase-out by 2020, most owners of equipment using HCFC-22 will either replace the equipment by 2020, or at a minimum replace the HCFC-22 refrigerant in the same equipment (retrofit) with a high-GWP HFC refrigerant. A window of opportunity exists in the next five years to accelerate the transition of refrigeration and air-conditioning equipment to lower-GWP refrigerants, before another generation of equipment is locked into using higher-GWP refrigerants over their average lifetimes of 15 to 20 years.

HFC emissions from transportation are largely from mobile vehicle air-conditioning (MVAC), and as California and the U.S. EPA implement the MVAC credits programs

under their light-duty vehicle GHG emission standards, and the MVAC leakage standards under their heavy-duty vehicle GHG emission standards, the share of HFC emissions from the transportation sector will decline. Aerosol propellants (industrial, consumer, and medical dose inhalers) comprise 13 percent of HFC emissions, and insulating foam expansion agents contribute another eight percent of HFC emissions. Solvents and fire suppressant emissions contribute one percent of all HFC emissions. Figure 9 shows the emissions sectors that contribute to California's overall HFC emissions. (ODS emissions are not shown because they are being completely phased out under the Montreal Protocol and are not included in the AB 32 GHG emission reduction targets.)

Figure 9: California 2013 Hydrofluorocarbons (HFCs) Emission Sources*

This Draft Proposal identifies measures that can reduce HFC emissions by 40 percent in California by 2030. They represent a reasonable path forward for California, but the State's approach on HFCs could be affected by a potential international agreement that may be reached in 2016 to phase down the use of HFCs globally.

A. Progress to Date

California is among the world's leaders in reducing HFCs and other F-gas emissions. Measures adopted under AB 32 have reduced emissions from a variety of sources. The State's Cap-and-Trade offset protocol for ozone depleting substances incentivizes the capture and destruction of ODS refrigerants and foam expansion agents. The biggest reductions of high-GWP F-gases are coming from ARB's Refrigerant Management Program, which requires facilities with refrigeration systems to inspect and repair leaks, maintain service records, and in some cases, report refrigerant use. The Refrigerant Management Program has helped change industry practices to become more proactive in preventing refrigerant leaks, which has helped businesses save money by avoiding system repairs and downtime as well as the cost of replacement refrigerant. Other measures already in place include low-GWP requirements for consumer product aerosol propellants and a self-sealing valve requirement for small cans of automotive refrigerants purchased by "do-it-yourself" mechanics.

California's efforts to reduce emissions of F-gases are part of a broader set of national and international commitments. World leaders have agreed to work together and

through the Montreal Protocol to phase down the production of HFCs. The U.S. EPA

can impose federal bans on F-gases under the Significant New Alternatives Policy (SNAP) Program. In July 2015, the U.S. EPA adopted future bans on specific HFCs with very high GWPs used in new commercial refrigeration systems, the manufacture of polyurethane foam, and new light-duty motor vehicle air-conditioning systems.¹¹⁵ In many cases, these national bans copied programs that were first demonstrated in California.

The U.S. national bans are expected to decrease HFC emissions in California by ten percent annually below business as usual by 2025. The European Union (EU) has adopted the world's leading F-gas regulation that will phase down the production and import of HFCs by almost 80 percent from 2014 levels by 2030.^{116,117}

Additionally, in response to President Obama's Climate Action Plan, in September 2014, and again in October 2015, the White House announced private sector commitments and executive actions to reduce emissions of hydrofluorocarbons (HFCs).^{118,119} U.S. industry is leading the way by investing billions of dollars to develop and deploy the next generation of HFC alternatives that are safer for the environment. These investments span the entire HFC supply chain— from where the chemicals are produced, to where they are used in manufacturing, to where consumers see them in stores.

Further private sector commitments were made in February 2016, when both the Air Conditioning Heating & Refrigeration Institute (AHRI) and the Association of Home Appliance Manufacturers (AHAM) made voluntary commitments to phase down the use of high-GWP HFCs in new equipment.^{120,121}

¹²⁰ AHRI and Natural Resources Defense Council (NRDC) February 1, 2016 petition to U.S. EPA Significant New Alternatives Policy (SNAP) Program to remove high-GWP HFCs from the list of

In March 2016, the U.S. EPA proposed additional bans on high-GWP HFCs in new retail food refrigeration, cold storage, chillers used for air-conditioning, and household refrigerator-freezers.¹²² The proposal had not been adopted as of April 2016.

Substantial progress has also been made to safely use natural refrigerants (such as CO₂, ammonia (NH₃), and hydrocarbons (HCs), with GWPs at or near zero) all over the world, especially in Europe and Asia. The refrigeration and air-conditioning industry is looking closely at which applications suit which natural refrigerants. Reports summarizing the progress made in North America show nearly 300,000 pieces of light commercial equipment using CO₂ or hydrocarbons, more than 250 stores using CO₂ systems, and over 250 “next-generation” small-charge ammonia systems in industrial installations. Large companies investing in natural refrigerants include end users, and a wide range of equipment manufacturers.

In addition to the natural refrigerants, a new generation of fluorinated refrigerants known as hydrofluoro-olefins (HFOs) have been developed that are non-ODS and have GWP values less than five. HFOs can be used in pure form for some cooling applications, such as motor vehicle AC, and are also used in blends with HFCs for other cooling applications, such as commercial and industrial refrigeration. Initial results indicate that the newest generation of fluorinated refrigerants perform as well as the high-GWP HFCs they replace.

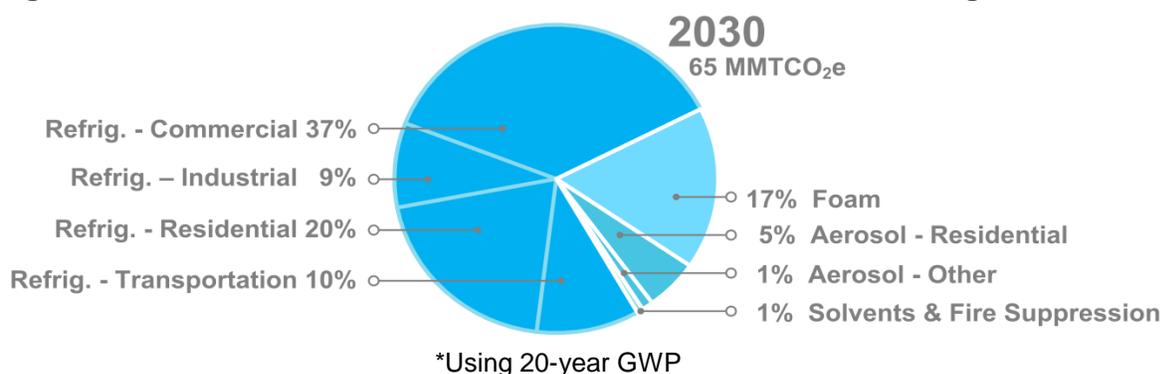

These State and national efforts will lead to significant reductions in HFC emissions in California through 2030, compared to where they would be otherwise. Still, HFC emissions in California are expected to grow by more than 60 percent without additional action (Figure 10).

acceptable substitutes in new air-cooled and water-cooled chillers using centrifugal, screw, scroll, and all other compressor types.

Figure 10: California's 2030 HFC Emission Sources with Existing Measures*

B. Recommended Actions to Further Reduce HFC Emissions

The State supports strong, national, and international actions to reduce HFC emissions. The U.S. EPA has already taken a number of steps to prohibit the use of new high-GWP HFCs in consumer product aerosol propellants, polyurethane insulating foam, and light-duty mobile vehicle air-conditioning. An international agreement could be reached in 2016 to phase down the production and use of HFCs under the Montreal Protocol. The proposed Montreal Protocol HFC phase down amendments, if adopted, will reduce HFC emissions significantly by 2050.

However, if additional measures can be applied in California to achieve further GHG emission reductions in the near-term and at low cost, California will consider them to support the State's 2020 and 2030 GHG targets. Specifically, as effective alternatives become available, ARB will consider developing bans on the use of high-GWP refrigerants in sectors and applications where lower-GWP alternates are feasible and readily available. All refrigerants and substitutes to high-GWP F-gases must first be approved by the U.S. EPA's SNAP Program to ensure the alternatives meet health and safety criteria. The approval process is designed to minimize the risk of using newer alternatives to F-gases by identifying substitutes that offer lower overall risks to human health and the environment.

Also, in the absence of a sufficiently rigorous international agreement by the end of 2016, ARB will evaluate the feasibility of a phasedown for California that aligns with similar efforts and stringency levels in Australia, Canada, the EU, and Japan.

Even with a strong international agreement to phase down the use of HFCs, additional opportunities remain to reduce their emissions in California in the near-term and through 2030 at low cost. Early action, ahead of some of the phase down schedules being proposed internationally, can avoid locking-in the use of high-GWP refrigerants in new or retrofitted systems in the coming years

For example, the State should consider developing an incentive program to encourage the use of low-GWP refrigerants, which could lead to very low-cost emission reductions and could be implemented while further regulations are considered or developed. This

would provide long-term avoided emissions by countering the current trend of replacing HCFC-22, the most common refrigerant for both refrigeration and air-conditioning, with higher-GWP HFCs. This trend is accelerating in the U.S. in response to the 2020 phase-out of HCFC-22 under the Montreal Protocol.

In light of ongoing international discussions, this Draft Proposal describes a set of potential measures that can reduce HFC emissions by 40 percent in California by 2030 (see Table 7). This set of measures has been designed to minimize regulatory requirements and achieve fast and assured emission reductions.

Table 7: Proposed New HFC Emission Reduction Measures and Estimated Emission Reductions (MMTCO₂e)¹

| Measure Name | 2030 Annual Emission Reductions | 2030 Annual Emissions |
|--|---------------------------------|-----------------------|
| 2030 BAU ² | | 65 |
| Financial Incentive for Low-GWP Refrigeration Early Adoption | 2 | |
| HFC Supply Phasedown | 19 | |
| Sales ban of very-high GWP refrigerants | 5 | |
| Prohibition on new equipment with high-GWP Refrigerants | 15 | |
| 2030 BAU with new measures | | 24 |

¹Using 20-year GWPs from the 4th Assessment report of the IPCC

²"Business as Usual" (BAU) forecasted inventory includes reductions from implementation of current ARB and U.S. EPA regulations

Incentive Programs

In his 2016-2017 Proposed Budget, Governor Brown includes \$20 million for a financial incentive program to defray the potential added cost of installing new low-GWP refrigeration equipment or converting existing high-GWP systems to lower-GWP options. This program could provide immediate and ongoing emission reductions. A loan or grant program would support qualifying facilities that take action to reduce emissions prior to any national or state requirements to do so.

Data reported under the existing Refrigerant Management Program indicates that more than 2,400 facilities with large commercial refrigeration systems in California currently use HCFC-22 refrigerant. This refrigerant has not been allowed in new equipment since January 2010, and all new production and import will cease by January 1, 2020. Therefore, these facilities must either buy increasingly scarce recycled HCFC-22 to maintain their systems, or replace or retrofit their existing systems with another refrigerant within five years.

Although lower-GWP options are currently available and can be cost effective, in most cases with improved energy efficiency, there are two main barriers to more widespread adoption of low-GWP commercial refrigeration: 1) potentially higher up-front costs, and 2) lack of familiarity with low-GWP refrigeration. The incentive program could remove the added initial cost barrier and build familiarity with low-GWP refrigeration systems to help them scale throughout the sector.

One of the advantages of an incentive program is that it could fund early adoption of low-GWP technologies, with substantial long-term effects on avoided emissions. The incentive program would “lock in” early and permanent GHG reductions prior to any mandatory measures.

Phasedown in Supply of HFCs

An HFC phasedown allows industry the flexibility to make market-based decisions on when and where to continue using high-GWP HFCs before transitioning to lower-GWP options. The EU has recently adopted a supply phasedown, at the top level of supply for both production and import (first arrival of virgin refrigerant). The EU model identified the existing market based on past production and import and aims to reduce it 79 percent by 2030. Broad-based national or international agreements are the most effective phasedown approaches, minimizing the possibility of simply displacing emissions to other locations.

In the international arena, countries met in Dubai in November 2015 to discuss an HFC phasedown amendment to the Montreal Protocol. The meeting did not result in a specific phase-down agreement, but the outcome was viewed as positive by most participants, with countries agreeing to a series of meetings in 2016 designed to reach an international phase-down. If a national or international HFC phasedown agreement cannot be reached in 2016, ARB may pursue a California HFC phasedown schedule that will help meet the State GHG emission reduction goals. California would seek a partnership with the EU, Canada, Japan, and Australia, all of which are currently pursuing their own separate HFC phasedown programs.

Phasedown programs offer several advantages over other regulatory approaches, such as fees or fixed limits on the maximum GWP of HFCs allowed. A broad-based phasedown program significantly reduces the number of regulated entities compared to downstream regulation, causes minimum disruption to industry, and guarantees emission reductions. Industry stakeholders generally favor a phasedown approach as a technically feasible, fair, and cost-effective means of reducing HFC emissions, while allowing them flexibility in transitioning to low-GWP alternates.

Prohibition on the Sale of New Refrigerant with Very-High GWPs

This measure would prohibit the sale or distribution of refrigerants with 100-year GWP values of 2500 or greater, beginning January 1, 2020. Refrigerants that are certified reclaimed or recycled would be exempt from the sales ban.

In July 2015, the U.S. EPA adopted a ban on using refrigerants with a very-high 100-year GWP of 2500 or greater in new and retrofitted refrigeration systems at retail food facilities beginning in the second half of 2016. Several refrigerants are currently available with a 100-year GWP of less than 1500 that can be used in existing equipment designed for higher-GWP refrigerants.

A sales ban on very high-GWP refrigerants is enforceable and provides immediate reductions. Such a ban facilitates a much faster transition from very high-GWP refrigerants to lower-GWP alternatives in existing equipment (thus avoiding the ongoing high-GWP emissions from equipment that typically lasts for 15 years or longer).

High-GWP Refrigerant Prohibitions in New Stationary Systems

This measure would prohibit the use of high-GWP refrigerants in new commercial, industrial, and residential stationary refrigeration and air-conditioning equipment, as follows:

| Stationary Refrigeration or Stationary Air-Conditioning Sector | Refrigerants Prohibited in New Equipment with a 100-year GWP Value: | Proposed Start Date |
|---|--|----------------------------|
| Non-residential refrigeration | 150 or greater | January 1, 2020 |
| Air-conditioning (non-residential and residential) | 750 or greater | January 1, 2021 |
| Residential refrigerator-freezers | 150 or greater | January 1, 2021 |

Certain exceptions could be made to any maximum GWP limit if a low-GWP refrigerant is not technically feasible in a specific application. GWP limits may be subject to change as additional low-GWP refrigerants become available. For example, low and medium-pressure chillers used for air-conditioning may be able to use refrigerants with a GWP less than 150.

Low-GWP commercial refrigeration using ammonia is already extensively used in food processing and cold storage. Additionally, more than 250 retail food stores in the U.S. have begun using CO₂ as the primary or secondary refrigerant. In Europe, CO₂ refrigeration is used in more than 5,200 retail food stores, and generally is cost neutral compared to HFC refrigeration systems. In the hotter climate zones of California, using 100 percent CO₂ refrigeration may not be as energy-efficient as HFC refrigerants, although newly demonstrated adiabatic cooling technology has promise to neutralize energy efficiency concerns. Alternatively, manufacturers are currently developing blends of HFC refrigerants combined with a new class of very-low GWP synthetic refrigerants known as hydrofluoro-olefins (HFOs). The HFO-HFC blends have 100-year GWPs between 88 and 1400, and their use would reduce GHGs in these systems by

more than 75 percent compared to business as usual.¹²³ Hybrid refrigeration such as secondary loop and cascade systems, using a small HFC central charge and a larger CO₂ charge, experience no energy penalty, even in hotter climates.

With respect to air-conditioning, in September 2014, the Air-Conditioning Heating & Refrigeration Institute (AHRI), an industry association representing 90 percent of U.S. air-conditioning manufacturing and 70 percent of the global industry, made a commitment through the White

House Council on Environmental Quality to spend \$5 billion over the next ten years to develop low-GWP options for refrigeration and air-conditioning. Many commercially available lower-GWP air-conditioning options are expected by 2020. In order to comply with the EU F-gas regulation that went into effect January 1, 2015, manufacturers

are already developing air-conditioning systems that use refrigerants with a 100-year GWP of less than 750. Large chillers used primarily for office building air-conditioning are already commercially available that use an HFO refrigerant with a GWP of one.

Current fire and appliance codes do not allow the use of hydrocarbon refrigerants, which are flammable, unless the system is below a small charge size threshold of 150 grams for commercial refrigerators, and 57 grams for household refrigerators. Experience in Europe and other jurisdictions demonstrates that these codes can be designed to allow for the use of these refrigerants while ensuring safety, where current limits are 150 grams for household refrigerators and up to 1.5 kg for commercial uses. More work is required to update the safety codes in the U.S. before slightly flammable refrigerants can be used in more applications while maintaining safety.

A prohibition, or ban on the use of high-GWP HFCs in new equipment would result in certainty of reductions in applications where alternatives are readily available. By requiring equipment manufacturers to sell only ARB-compliant equipment in California, the enforcement focus is on the manufacturers and is not placed on the end-user.

Additional measures that may be more effectively addressed at the Federal level include prohibitions on high-GWP HFCs in the following sectors: consumer product aerosol propellants, insulation spray foam, heavy-duty motor vehicle air-conditioning, transport refrigeration units (TRUs), and refrigerated shipping containers. ARB will continue to work with the U.S. EPA on reducing HFC emissions from these sectors, and may pursue state-level measures if progress is not made on the Federal level.

¹²³ HFOs are hydrofluoro-olefins, an emerging class of F-gas with very low GWPs of 1-5, but which are classified as slightly flammable (A2L). By blending HFOs with HFCs, refrigerant blends which are non-flammable have been created and U.S. EPA SNAP-approved for certain applications.

C. Sulfuryl Fluoride

Sulfuryl fluoride (SO_2F_2) is a pesticide fumigant and one of the most common replacements for methyl bromide, an ozone-depleting substance whose use is being phased out. Sulfuryl fluoride is regulated by the California Department of Pesticide Regulation (DPR), and was listed as a toxic air contaminant (TAC) in 2006. As a pesticide and TAC, sulfuryl fluoride's use is strictly controlled. In December 2015, DPR submitted a report to the Legislature, which provided an update on adopted control measures for sulfuryl fluoride,¹²⁴ as required by AB 304 (Williams, Chapter 584, Statutes of 2013). DPR plans to develop additional mitigation measures by September 2016, to address unacceptable exposures of sulfuryl fluoride to bystanders and residents. Sulfuryl fluoride is not registered for use as a field soil fumigant and is not used on agricultural fields.

Until 2009, sulfuryl fluoride was believed to have a negligible GWP. Further research concluded that SO_2F_2 has a 20-year GWP of 6840, with a lifetime of several decades. According to the DPR, 3 million pounds of sulfuryl fluoride were used in California in 2013 (most recent data available).¹²⁵ Its main use is as a structural pest control fumigant to kill drywood termites in homes and buildings, accounting for 82 percent of all usage in 2013. Sulfuryl fluoride is also a common fumigant for dried fruits, nuts, and other agricultural commodities that must be kept pest-free during storage prior to shipping (15 percent of all usage in 2013). The remaining three percent of sulfuryl fluoride application was for other fumigation uses. A complete listing of sulfuryl fluoride usage in California by commodity is listed in Appendix A.

Because sulfuryl fluoride was not identified as a high-GWP gas by the time AB 32 was enacted, it was not initially included as a part of ARB's statewide GHG inventory. However, the annual usage of sulfuryl fluoride is inventoried by DPR as a highly-regulated pesticide and ARB uses this data to track emissions. In 2013, the 3 million pounds of SO_2F_2 usage was equivalent to 9.4 MMT CO_2E emissions (using 20-year GWP values), or approximately 20 percent of all F-gas emissions.

Identifying less toxic or lower-GWP alternatives to sulfuryl fluoride remains problematic. Methyl bromide (CH_3Br), with a 20-year GWP of 17, was the pesticide fumigant of choice for many applications until its use was almost completely phased-out by the Montreal Protocol because of its ozone-depleting potential. Currently, sulfuryl fluoride is the only fumigant registered for treating structural pests in California. Termites or other wood-destroying pests are detected in over 250,000 California homes each year, with the cost of control and repair of damage from dry-wood termites in California exceeding \$300 million annually (with 80 percent of fumigations occurring in Southern California).

¹²⁴ Report to the Legislature Required by AB 3014 (2013) Food & Agricultural Code Section 140124(c)(2)(A): Update on the Adoption of Control Measures for the Toxic Air Contaminant Sulfuryl Fluoride. Report submitted by the California Department of Pesticide Regulation to the California Legislature, December 22, 2015.

¹²⁵ Summary of Pesticide Use Report Data 2013 - Indexed by Commodity, California. California Department of Pesticide Regulation, May 2015. Available at: http://www.cdpr.ca.gov/docs/pur/pur13rep/13_pur.htm.

For agricultural commodity fumigation storage (primarily dried fruits and nuts), methyl bromide is still used on a limited basis through special use exemptions, although its use is decreasing annually. An alternative fumigant, phosphine (PH₃), with a GWP of 0, is also used as an alternative to methyl bromide and sulfuryl fluoride. However, reported insect tolerance to phosphine has limited its widespread usage.¹²⁶ Non-chemical commodity treatment has been studied since 1995, including irradiation, and controlling the atmosphere to “suffocate” insects in either low-oxygen or high carbon dioxide environments.¹²⁷ Chemical treatment remains dominant due to cost and feasibility issues of non-chemical alternatives.

The effectiveness of less toxic (and lower-GWP) alternatives to sulfuryl fluoride in structural fumigation for drywood termites is the subject of much research, opinion, and disagreement. Structural fumigation generally includes tenting the entire structure and treating it to kill termites, or more rarely, wood-boring beetles and other pests living in the structure. While many termite control companies only use sulfuryl fluoride, many others have begun using alternative termite control methods, including orange oil, structure heating or extreme cooling, microwaves, and electricity. Additional research is required before sulfuryl fluoride mitigation measures can be proposed. ARB will continue working with the DPR to assess mitigation measures to sulfuryl fluoride emissions. Additional discussion on potential research of sulfuryl fluoride mitigation is included in Appendix B.

VII. Achieving Success

Successfully implementing a strategy to reduce SLCP emissions will require integrated planning to achieve multiple objectives, coordination and collaboration among agencies at all levels of government, and focused investments and market support.

A. Integrate and Coordinate Planning

The SLCP Reduction Strategy fits within a wide range of ongoing planning efforts throughout the State to advance economic and environmental priorities. Integrated planning to achieve multiple objectives requires coordination among planning agencies and across sectors, systems, and government jurisdictions. Development of a strategy to reduce emissions of SLCPs is being closely coordinated with other relevant planning efforts. For example, this Proposed Strategy acknowledges that further reductions in black carbon from California's freight system will be realized through strategies identified in the California Sustainable Freight Action Plan. That plan is currently being developed by ARB and other state agencies, and will accelerate emission reductions and implementation of zero and near-zero technology in California's freight transport system. Also, ARB staff and local air districts will develop additional strategies through the upcoming SIPs process, which is expected to reduce black carbon emissions from both mobile and non-mobile sources.

The 2014 Scoping Plan Update identified the important role of SLCPs to reduce climate change impacts and provided suggested recommended actions for further emission reductions. Those recommendations were evaluated and expanded upon in this Proposed Strategy.

The ARB is embarking on the next update to the Scoping Plan to describe how the State can meet the Governor's goal of reducing total GHG emissions by 40 percent by 2030. This SLCP strategy is a forerunner to the Scoping Plan, providing justification for accelerated action on SLCP. The next Scoping

Healthy Soils Initiative

Plan will augment the strategies presented in this document with measures focused on CO₂, providing a balanced portfolio of near-term and long-term measures.

Other concurrent planning efforts in the State could also identify additional activities that may serve to reduce SLCP emissions. For example, CEC's Integrated Energy Policy Report, the Healthy Soils Initiative, and the Forest Carbon Plan are all ongoing efforts that intersect with many of the concepts described in this Draft Report. ARB will collaborate with other agencies developing those plans to identify and prioritize activities to reduce SLCP emissions that would also support other State priorities and integrated planning efforts. Climate action planning efforts by city, county, and other local government entities will also play a key role in reducing SLCP emissions, especially if these action plans begin to incorporate SLCP emission inventories and mitigation actions.

B. Enable Local and Regional Leadership

State policy is most effective with the support, engagement, and complementary actions of regional and local efforts. As the State shifts its climate-protection focus to the long-term and increases its efforts to reduce SLCP emissions, regional and local governments and agencies will play an increasingly important role in achieving California's GHG goals. The efforts of regional agencies, such as air districts, water districts, and municipal solid waste authorities, to incorporate GHG emission reduction strategies into their respective jurisdictions increases the State's leverage to further reduce SLCP emissions from various sources.

Local air districts have a key role to play in reducing regional and local sources of SLCP emissions, because air pollution reduction strategies employed by air districts often also reduce GHG emissions. City and county governments also play a pivotal role in reducing emissions of SLCPs. Many GHG emission reduction strategies identified by cities and counties in their local Sustainability or Climate Action Plans directly correlate to strategies necessary for SLCP emission reductions, such as improved waste management (increased recycling and composting), use of alternative and renewable fuels, and simply reducing vehicle miles traveled. These local government Climate Action Plans encourage, and sometimes mandate at the local level, actions taken by households and businesses within a community. Often times, these actions involve behavior change by individuals, which leads to increased conservation and sustainability, ultimately driving both community-scale GHG and SLCP emission reductions.

Below are examples of local and regional government efforts that are helping the State reduce SLCP emissions.

Methane

In California, agriculture and landfills are the primary sources of methane emissions. Aside from air district rules to reduce methane emissions at landfills, upstream efforts by

cities, counties, and regional agencies to both reduce and divert food waste and other organic materials from the waste stream have the potential to greatly reduce landfill-related methane emissions. Additionally, local municipalities and solid waste agencies are working collaboratively with air districts to foster renewable fuel opportunities, such as waste-to-energy and waste-to-fuel projects. For example, through its leadership role with Clean Cities, the Sacramento Metropolitan Air Quality Management District is working closely with numerous partners to build awareness and increase separation and diversion of organic waste to a local anaerobic digester.

Local agencies also play a role in utilizing methane beneficially at wastewater treatment plants. Many local agencies own and operate wastewater treatment facilities and are implementing strategies for on-site energy production. Local strategies to improve management and utilization of organic waste throughout the State may also have the ability to help reduce methane emissions throughout the agricultural sectors. Wastewater treatment plants offer a tremendous opportunity to divert organics from landfills and utilize them for producing energy, transportation fuel, and soil amendments. Many treatment plants are located near population centers and could potentially utilize significant amounts of food and other organic waste streams that come from cities and towns. Collaboration amongst local and regional agencies, such as solid waste management and wastewater agencies, is the key to success.

Black Carbon

Local air districts have worked with ARB to develop programs to comply with federal air quality standards for PM (that will also reduce black carbon), such as mandatory and voluntary rules to restrict residential wood-burning in fireplaces and wood stoves, along with incentive programs to switch to cleaner burning devices. In fact, in October 2015, the Bay Area Air Quality Management District adopted a new rule banning all wood burning devices in new construction. Districts have also enacted rules regulating commercial cooking and smoke management programs addressing agricultural, forest and rangeland burning operations, which have reduced black carbon and PM emissions.

In addition to air district efforts, metropolitan planning organizations, in coordination with city and county governments, can be credited with efforts to reduce vehicle emissions, and ultimately on-road related emissions, particularly through their Sustainable Community Strategy planning and implementation efforts. Local governments have stepped up by beginning with their own fleets. For example, in Sonoma County, the Board directed County staff to reduce emissions from the County's on-road fleet by 20 percent by 2010.

Local efforts to reduce diesel particulate matter, such as farm and construction equipment rules and incentive programs by air districts, play a significant role in the reduction of black carbon emissions such as the San Joaquin Valley Air Pollution Control District's program to replace diesel agricultural irrigation pump engines with electric motors. In addition, efforts by local port authorities, such as the San Pedro Bay Standards, have resulted in the establishment of more aggressive targets to reduce black carbon emissions, health risks, and further improve air quality, particularly for those in nearby disadvantaged communities.

HFCs and other F-gases

Local air districts can play an instrumental role in aiding the reduction of HFC emissions, including developing regulations to require low-GWP replacements. For example, the South Coast Air Quality Management District has three regulations to reduce refrigerant emissions from stationary air conditioning and refrigeration systems and motor vehicle servicing, as well as restrictions on CFCs and halons from sterilization, fumigation, and fire extinguishing equipment. In addition, many local governments are also tracking emissions of refrigerants, and some have adopted policies to reduce refrigerant emissions from city-owned air conditioning units, vehicles, and refrigerators.

C. Investments

Investments in financial incentives and direct funding are critical components for successful implementation of SLCP emission reduction strategies. Many existing State funding programs work in tandem to reduce emissions from GHGs (including SLCPs), criteria pollutants, and toxic air contaminants, and are helping foster the transition to a clean energy economy. In particular, State law (Senate Bill 535, De León, Chapter 830, Statutes of 2012) requires focused investment in communities disproportionately impacted by pollution. Many of these communities, especially in the Central Valley, along freight corridors, and in rural parts of the State, stand to benefit from dedicated action and investment to reduce emissions of SLCPs.

Although California has a number of existing incentive programs, the pool of funds is limited and it is critical to target public investments in ways that encourage system-wide solutions to produce deep and lasting public benefits. Significant investments of private capital, supported by targeted, priority investments of public funding, are necessary to scale deployment and to maximize benefits. Public investments can help incentivize

early action to accelerate market transition to cleaner technologies, which can then be supported by regulatory measures. The State must coordinate funding sources such as the California Climate Investments, supported by the Greenhouse Gas Reduction Fund (GGRF), Alternative and Renewable Fuel and Vehicle Technology Program (AB 118), Electric Program Investment Charge (EPIC) Program, Carl Moyer Program, Air Quality Improvement Program, and Proposition 39 to expand investments in California's clean economy and further reductions in SLCPs and other GHG emissions. Current activities and funding allocations for a few of these programs are described herein.

The GGRF is an important part of California's overall climate investment efforts to advance the goals of AB 32 (Nunez, Chapter 488, Statutes of 2006) and target investment in disadvantaged communities. To guide the investment of Cap-and-Trade auction proceeds, the Department of Finance, in consultation with the Air Resources Board and other State agencies, is required to submit a triennial Investment Plan to the Legislature. The Investment Plan identifies priority investments that will help California achieve its GHG emission reduction goals while realizing additional health, economic, and environmental benefits. The Investment Plan is required to identify near-term and long-term greenhouse gas emission reduction goals and targets, analyze gaps in current State funding for meeting these goals, and identify priority investments that facilitate GHG emission reduction. The second Investment Plan for Fiscal Years 2016-17 through 2018-19 was submitted to the Legislature in January 2016. The Second Investment Plan identifies potential State investment priorities to help achieve GHG emission reduction goals, benefit disadvantaged communities, and yield valuable co-benefits within the Transportation & Sustainable Communities, Clean Energy & Energy Efficiency, and the Natural Resources and Waste Diversion categories. The priorities identified in the Second Investment Plan would reduce a range of GHGs, including short-lived climate pollutant emissions. The Second Investment Plan informed Governor Brown's 2016-2017 Proposed Budget, which includes \$215 million of Cap-and-Trade expenditures specifically targeting SLCP emission reductions. These include \$40 million for black carbon residential woodsmoke reductions, \$20 million for HFC reductions from refrigerants, \$100 million for waste diversion, \$20 million for Healthy Soils, and \$35 million for dairy digester development.

A critical piece of the State's investment strategy, which is overseen by ARB and focused on clean transportation incentives, is the Low Carbon Transportation Investments and the Air Quality Improvement Program (AQIP). Consistent with the First Investment Plan, these programs have identified zero-emission passenger transportation and low-carbon freight transport as investment priorities, which reduce criteria pollutant and toxic emissions with concurrent reductions in GHG emissions, including black carbon. ARB has focused AQIP investments on technology advancing projects that support long-term air quality and climate change goals in addition to providing immediate emission benefits. In recent years, funding has included rebates for zero and near-zero emission passenger vehicles through the Clean Vehicle Rebate Project (CVRP), vouchers for hybrid and zero-emission trucks and buses through the Hybrid and Zero-Emission truck and Bus Voucher Incentive Program (HVIP), and the

Truck Loan Assistance Program for small business truck owners in need of truck replacements or retrofits.

The CEC administers an additional key GHG reduction investment program for the transportation sector – the Alternative and Renewable Fuel and Vehicle Technology Program (ARFVTP). Funds that are collected from vehicle and vessel registration fees, vehicle identification plates, and vehicle smog fees provide up to \$100 million per year for projects that will transform California’s fuel and vehicles to help attain the State’s climate change policies. Investments in alternative fuel production and infrastructure, and vehicle projects can contribute to SLCP emission reductions through reduced diesel consumption, capture and use of biogas from waste management activities as a transportation fuel, demonstration and early commercialization of advanced technology trucks that utilize biogas, and avoided fugitive methane emissions from fossil fuel production and distribution operations.

Another CEC-administered program, the Electric Program Investment Charge (EPIC) Program, supports investments in clean technologies and strategies to improve the State’s electricity systems. The program provides opportunities to support SLCP emission reductions from reduced or avoided fugitive methane emissions stemming from fossil fuel production and distribution via investments such as improved energy efficiency technologies in building, industrial, agricultural and water sectors; demand response; distributed renewable generation; electric vehicle infrastructure; demonstration of biomass-to-energy conversion systems; advanced energy storage interconnection systems; and vehicle-to-grid power transfer for electric vehicles.

CDFA administers the Dairy Digester Research and Development Program. This incentive-based program supports digester development in California and can provide grants for research and demonstration projects that improve scientific and technical understanding of technologies and practices that reduce methane and other greenhouse gases emissions on dairies. CalRecycle administers greenhouse gas reduction grant and loan programs that include incentives for infrastructure supporting organics diversion.

These programs represent just a portion of opportunities that exist at the federal, State, and local levels to incentivize SLCP and GHG emission reductions. The availability of dedicated and long-lasting funding sources is critical to help meet AB 32 objectives and help provide certainty and additional partnership opportunities at the national, State, regional, and local levels for further investing in projects that have the potential to reduce emissions of SLCPs.

D. Coordinate with Subnational, Federal, and International Partners

California is working with a set of national and subnational partners throughout the world to fight air pollution and climate change. This includes signatories to the Under 2 MOU, as well as others in Mexico, China, India, the U.S., Canada, and elsewhere.

Many of the efforts underway through these collaborations will help reduce emissions of black carbon from the transportation sector and emissions of other SLCPs.

At the 2014 United Nations (UN) Climate Summit, ARB became the first state-level entity to sign onto action statements of the Climate and Clean Air Coalition to Reduce Short-Lived Climate Pollutants. At the 2014 UN Conference of Parties in Lima, California co-sponsored an event with Mexico on SLCPs and their role in an international framework to contribute to national commitments to reduce emissions. At UN climate meetings in New York and Paris in 2015, Governor Brown presented the targets described in this Proposed Strategy, and suggested that action on SLCPs may be the most important and most immediate need to address climate change. The State continues to be committed to acting both bilaterally and multilaterally to cooperate with other jurisdictions to cut SLCP emissions, and will explore additional opportunities to further reduce air pollution, greenhouse gas, and SLCP emissions through partnerships.

Building on leadership around SLCPs can provide an important example for action in other countries and jurisdictions, and is one of the most significant opportunities to accelerate international progress to fight climate change. California is in a unique position to serve as a model for action for other countries and jurisdictions to accelerate their progress to reduce emissions of both SLCPs and CO₂, based on the State's demonstrated leadership on air quality and climate change, commitments to set stringent, science-based targets to reduce emissions of both CO₂ and SLCPs, and integrated planning efforts, like this one, to develop a comprehensive policy framework to achieve those goals.

As we have done for decades already, California's actions on SLCPs can demonstrate win-win opportunities for both the most developed countries, where reducing SLCP emissions is an important element of broad efforts to cut GHG emissions, as well as for the least developed countries, where SLCP emission reductions have tremendous benefits for air quality and human health.

Ultimately, each state, region, or country has its own mix of SLCP sources, needs, and opportunities to reduce emissions. Coordinated planning to meet scientific-based emission targets, like this Proposed Strategy does, is important to successfully reducing emissions and maximizing local and global benefits.

California will share this planning effort with others, and encourage them to adopt specific SLCP emission reduction targets and plans to achieve them. A few already have; President Obama has set specific targets to cut methane emissions from the oil and gas sector, Mexico has included targets to cut black carbon emissions in its Intended Nationally Determined Contribution to the United Nations Framework Convention on Climate Change, Europe and other countries have taken steps to phase down the use of HFCs, Australia and Brazil are working to reduce methane from agriculture, and Norway has developed an SLCP action plan of its own.¹²⁸ These types

¹²⁸ NEA (2014) Summary of Proposed Action Plan for Norwegian Emissions of Short lived Climate Forcers, Norwegian Environment Agency, March.

of commitments and planning efforts need to be adopted more broadly. By developing a comprehensive plan to achieve necessary SLCP emission reductions in an effective and beneficial way, California can foster broader action beyond its borders and demonstrate effective processes and strategies to address climate change.

VIII. Evaluations

This chapter discusses the economic, public health, and environmental justice evaluations of the proposed new measures in this Proposed Strategy. It also discusses the environmental analysis that was prepared for the Proposed Strategy. It should be noted that to the extent that any of the proposals in the Proposed Strategy result in regulatory action, each proposed regulation will be subject to its own public process with workshops, opportunities for stakeholder discussion, consideration of environmental justice, and legally required analyses of the economic and environmental impacts.

A. Economic Assessment of Measures in the Proposed Strategy

This section presents the economic analyses for the new measures identified in this Proposed Strategy. Supporting documentation for this analysis is presented in Appendix D. Activities already underway separately—including development of the California State Implementation Plan to meet federal health-based air quality standards, the California Sustainable Freight Action Plan, the 2030 Target Scoping Plan, and implementation of Senate Bill 1371 (Leno, Chapter 525, Statutes of 2014)—will have important impacts on SLCP emissions in California, but are not evaluated here. Also, economic impacts associated with improved forest management to reduce black carbon emissions from wildfires and address additional State goals for forest management are not considered here, as many of those goals and potential actions to are currently under development through separate planning processes. As described in Chapter IV, improving forest management in California requires a significant financial commitment, on the order of \$500 million to \$1 billion annually, which can complement efforts to put organic waste resources to beneficial use in California, as described in this section for the dairy and waste sectors.

The analyses presented here consider direct economic costs associated with new technologies and management strategies that can help to reduce SLCP emissions. They also consider direct economic benefits in the form of savings as a result of efficiency improvements, or revenue from marketable products. This analysis does not include a macroeconomic analysis at the statewide level, nor does it include a monetary accounting of societal benefits, such as the value of reducing exposure to fine particulate pollution or reducing the impacts of climate change.

While there are potentially significant market opportunities associated with some of the proposed measures, including putting organics to beneficial use, there are also substantial costs and funding needs. These include costs to increase market penetration of existing technologies and research and development of innovative advanced technology. Initial analyses and various literature sources suggest that SLCP emissions from several sources, including those identified in this Proposed Strategy, can be reduced at low, and sometimes negative, lifetime costs.

Long-term regulatory signals can play a vital role in facilitating low cost SLCP emission reductions. The Low Carbon Fuel Standard (LCFS) and the federal Renewable Fuel

Standard (RFS) incentivize the use of renewable natural gas as a transportation fuel, creating large revenue potential within the dairy manure and organic diversion measures. These programs in particular can help support cost-effective projects to reduce methane from the dairy and waste sectors. Without the LCFS and RFS programs, additional sources for financial incentives and funding may be needed.

The measures laid out in this Proposed Strategy are transformative, leading to uncertainty in the potential costs and revenue of proposed measures as well as the ultimate pathway to compliance. There is a wide range of potential costs and savings, uncertainty in how the strategies will be met, and uncertainty in some cases for how costs in literature translate in the California context. In conjunction with State agencies, ARB will continue to work closely with stakeholders and manufacturers to evaluate the feasibility and costs of existing and developing technologies to determine the best approaches to meeting the targets in the Proposed Strategy.

The measures included in the Proposed Strategy will also strengthen California's environment and the economy by developing infrastructure, generating cost savings, and creating jobs. Measures that reduce methane emissions through waste digestion will have a large impact on the California economy, including disadvantaged communities.

The dairy manure measure has the potential to create jobs in California's Central Valley. These jobs include construction jobs to build digesters and farm and waste management jobs to operate and maintain the facilities. In this analysis, it is assumed that the construction of an anaerobic digester for a 2,000 head dairy farm can result in 25 to 60 construction jobs and 2 to 5 full-time farm jobs.¹²⁹ As the dairy manure measure is estimated to impact 1.05 million dairy cows, many in the San Joaquin Valley, the measure could result in over 30,000 construction jobs and 2,500 permanent jobs potentially providing employment opportunities in disadvantaged communities.

Diverting organic waste can also result in increased employment, providing an estimated 2 jobs per 1,000 tons of diverted organic material.¹³⁰ In 2030, this could result in 32,000 jobs in waste management and garbage collecting, food recovery and distribution. As demonstrated in the CalRecycle funded Food to Share project, food waste prevention programs not only produce emission reductions, but employment and nutritious meals to California's most vulnerable populations.¹³¹

The proposed measures will also build on and support existing California efforts related to climate change and air quality. Measures will support infrastructure, research, development, and deployment of advanced technologies that will help achieve

¹²⁹ Sample of industry information relied upon for the estimate: <http://www.gundersenenvision.org/renewable-energy/turning-cow-waste-into-energy-middleton> and http://www.usda.gov/oce/reports/energy/Biogas_Opportunities_Roadmap_8-1-14.pdf.

¹³⁰ <http://www.calrecycle.ca.gov/publications/Documents/1463%5C20131463.pdf>

¹³¹ More information available at: <http://greenlining.org/wp-content/uploads/2015/10/CAClimateInvestmentsCaseStudies.pdf>.

California's near- and long-term climate and air quality goals. Encouraging the collection of methane gas from waste streams, for example, can provide renewable fuel to reduce the carbon footprint of the transportation sector. Plans that stand to benefit from proposed SLCP measures include the 2030 Target Scoping Plan Update, the California State Implementation Plan, and California's Sustainable Freight Action Plan.

The 2030 Target Scoping Plan, expected to be finalized in 2016, will include a detailed macroeconomic assessment of ARB's complete climate change strategy, including those contained in the final SLCP Strategy. While this Proposed Strategy begins to explore the costs and benefits of proposed measures, detailed economic analyses will allow for a comprehensive assessment of the impact of California's climate strategy on Californians, businesses, and the California economy.

All proposed regulatory SLCP strategies will also be subject to the economic requirements of the Administrative Procedures Act (APA) as part of the public regulatory process. Prior to finalization, regulatory measures will be analyzed in a public process including an Economic Impact Statement, Economic Impact Assessment, and a Standardized Regulatory Impact Assessment for major regulations. Therefore, there will be many opportunities to assess the economic impact of measures in the Proposed Strategy.

The costs, savings, and potential revenue streams of the five measures are assessed in the following sections, 1 through 5. Collectively, implementing these measures would require several billion dollars of investment in clean technologies and strategies that would lead to significant reductions in SLCP emissions. Potential revenues and efficiency gains could also be significant - potentially outweighing the costs of some measures. In other cases, there may be net costs, but associated SLCP emission reductions may come at relatively low cost or provide other environmental and health benefits. While uncertainties remain – especially for costs and revenues associated with some strategies that utilize either emerging technologies or those that haven't been widely deployed already in California – these measures can help to significantly cut SLCP emissions in California at reasonable cost. With ongoing, targeted financial and market support, coordinated with regulatory development and other economic and environmental priorities where appropriate, California can meet the targets identified in the Proposed Strategy plan while delivering a broad range of benefits.

1. Residential Wood Combustion Black Carbon Emission Reductions

Residential wood combustion (RWC) constitutes 15 percent of California's non-forestry black carbon (BC) emissions, and is projected to be the largest individual source of BC by 2030. This Strategy recommends a 3.0 MMTCO₂e (20-yr GWP) reduction in RWC BC emissions by 2030 to meet the SLCP BC emission reduction target.

There are a variety of ways to reduce RWC emissions, and multiple air districts have already put measures in place. Past incentive programs to replace old polluting wood-burning devices with the cleanest EPA-certified devices have been popular and

effective. However, rural districts that rely most heavily on RWC for their primary source of heat are largely located outside of regions that provide incentives. Additionally, past incentive programs have not acquired sufficient funding to achieve the substantial emission reductions proposed in this strategy.

The cost share of this strategy between homeowners and governmental incentives primarily depends on the incentive amount provided per device, and total costs depend on the emission reduction achieved per device. Both of these factors will vary by region and by household, thus incentives funding and homeowners share of costs are calculated as a range. The cost to replace a device can range between \$3,000 and \$5,000.¹³² Purchase and installation of woodstoves was assumed to cost \$4,000 while gas devices were assumed to cost \$4,500. Incentives typically cover a portion of the cost, from \$1,000¹³³ up to the full installation price.¹³⁴ In many rural areas that rely heavily on wood combustion as a source of heat will require nearly full coverage of the installation price to spur voluntary participation; therefore, the incentive range was assumed to be \$1,000 to \$4,500.

The BC emission reduction per household depends on how much wood is burnt per year, the density and moisture content of the wood, the old device type, and the new device type. Emissions were calculated for two replacement cases. The “wood to wood” case assumes conversion of non-certified woodstove to EPA certified wood stove.¹³⁵ The “wood to gas” case assumes conversion of non-certified woodstove to gas device. An incentives program may contain a mixture of different replacement types and these two cases are used to bound potential reductions and costs. Other parameters used in emission reduction calculations were provided by the US EPA residential wood combustion replacement calculator, which includes California-specific data when available (Table 8).¹³⁶ The calculator was updated to account for replacement with cleaner EPA certified wood burning devices that will be required by 2020.

Table 8: Emission Summary

| Parameter | Wood to Wood | Wood to Gas |
|---|--------------|-------------|
| Cords wood burnt per year ¹³⁷ | 1.5 | 1.5 |
| Wood Density (tons/cord) ¹³⁸ | 1.04 | 1.04 |
| PM _{2.5} Emissions Reduction per device (tons/yr) ¹³⁹ | 0.0218 | 0.0245 |
| BC Speciation (fraction of PM _{2.5}) ¹⁴⁰ | 0.125 | 0.125 |
| BC Reduction per device per year (MTCO _{2e} , 20-yr GWP) | 7.9 | 8.9 |
| BC Emissions Target 2030 (MTCO _{2e} , 20-yr GWP) | 3,000,000 | 3,000,000 |
| Number of average replacements needed to meet target | 379,000 | 337,000 |

The cost of incentives was calculated by multiplying the number of replacements needed to meet the target (Table 8) by the range of incentives that could be provided, from \$1,000 to the full cost of replacement.¹⁴¹ The cost to homeowners was calculated as the total replacement cost, minus the portion covered by incentives. The “low incentives” case in Table 9 is a scenario where only \$1,000 in incentives is paid, and homeowners pay a portion of the replacement. In the “high incentives” case, incentives cover 100 percent of replacement costs and homeowners pay no money out of pocket. Costs to oversee and administer the incentives program were assumed to be similar in either case, because a similar number of devices are replaced (Table 8), and were calculated as 10 percent of the lower incentive value.¹⁴² Educational and outreach costs were estimated at 1 percent of the lower incentives value. Education and outreach includes education about the health effects of wood smoke and educating residents about proper use of their new devices to minimize emissions and maximize the lifetime of the equipment. Studies indicate that education and outreach are vital components of RWC replacement programs.¹⁴³ A summary of costs can be found in Table 9. The results in Table 9 show that the total costs for either a low incentives or high incentives case would be the same, but the distribution of costs between incentives and homeowner responsibility is different. These scenarios represent extremes use to bound the range of possible costs; actual program implementation may lie between the low and high incentives cases presented in Table 9.

¹⁴¹ \$4,000 for woodstove installation and \$4,500 for gas devices.

¹⁴² <http://www.epa.gov/sites/production/files/201508/documents/howtoimplementawoodstovechangeout.pdf>

¹⁴³ <http://www.epa.gov/sites/production/files/201508/documents/howtoimplementawoodstovechangeout.pdf>

Table 9: Range of Costs (Million Dollars)¹⁴⁴

| Cost | Low Incentives | High Incentives |
|------------------------------|-----------------------|------------------------|
| Incentives | \$340 | \$1,500 |
| Oversight and Administration | \$34 | \$34 |
| Cost to Homeowners | \$1,180 | \$0 |
| Education and Outreach | \$3.4 | \$3.4 |
| Total Cost | \$1,557 | \$1,537 |

Savings associated with this plan include reduced wood use in more efficient devices or any savings (or cost) to convert from wood fuel to natural gas. US EPA estimates that EPA-certified devices burn a third less wood for the same heat output.¹⁴⁵ Table 10 summarizes the range of potential savings depending on the conversion scenario.

Wood to wood total savings were calculated using the average annual amount of wood burnt (Table 8), the fraction of residents who pay for wood,¹⁴⁶ the cost of a cord of wood, and the assumption that a third less wood is used by the replaced devices. This analysis assumes 20 percent of wood is gathered for free, and would not provide a savings to the resident. The cost of a cord of wood will vary from approximately \$100 to \$480 depending on location and type of wood¹⁴⁷. This analysis uses the midpoint value of \$290 per cord. Reducing annual wood consumption from 1.5 to 1 cord per year would save the average resident \$145 per year. Approximately 379,000 wood to wood conversions (Table 9) would result in savings of approximately 44 million dollars per year to consumers receiving incentives to replace their inefficient wood stove.

Wood to gas savings can be calculated assuming 1.5 cords of wood are not purchased (Table 8), the cost of wood is \$290 a cord, and that the heat-equivalent amount of natural gas must be purchased, and assuming 337,000 devices are replaced (Table 9). The price of natural gas was assumed to be \$11.51 per thousand standard cubic feet.¹⁴⁸ The savings from not purchasing wood is nearly in balance with the additional cost of purchasing natural gas using these assumptions (Table 10).

¹⁴⁴ Low incentives are \$1,000 and high incentives cover 100 percent of device purchase and installation costs (\$4,000-\$4,500 depending on the device). Under the high incentive there is no out of pocket expense to homeowners.

Table 10: Savings Associated with Residential Wood Stove Conversion (Million Dollars)

| Conversion Scenario | Savings on Purchase of Wood | Increased Cost for Natural Gas | Net Fuel Savings |
|---------------------|-----------------------------|--------------------------------|------------------|
| 100 % Wood to Wood | \$44 | \$0 | \$44 |
| 100 % Wood to Gas | \$117 | \$109 | \$8 |

2. Methane Emission Reductions from Dairy Manure

As noted in Chapter V, emissions from dairy manure can be reduced by 75 percent by capturing or avoiding methane produced by about 1.05 million of the State’s 1.4 million milking cows whose manure is managed anaerobically. Achieving these targets for the industry could lead to significant GHG emission reductions – 22 MMTCO₂e annually by 2030, and 168 MMTCO₂e cumulatively through 2030 (8 MMTCO₂e and 58 MMTCO₂, respectively, using a 100-year GWP).

Several options exist to reduce methane emissions from manure management in California. Five strategies were considered in this analysis, which are described in further detail in Appendix D:

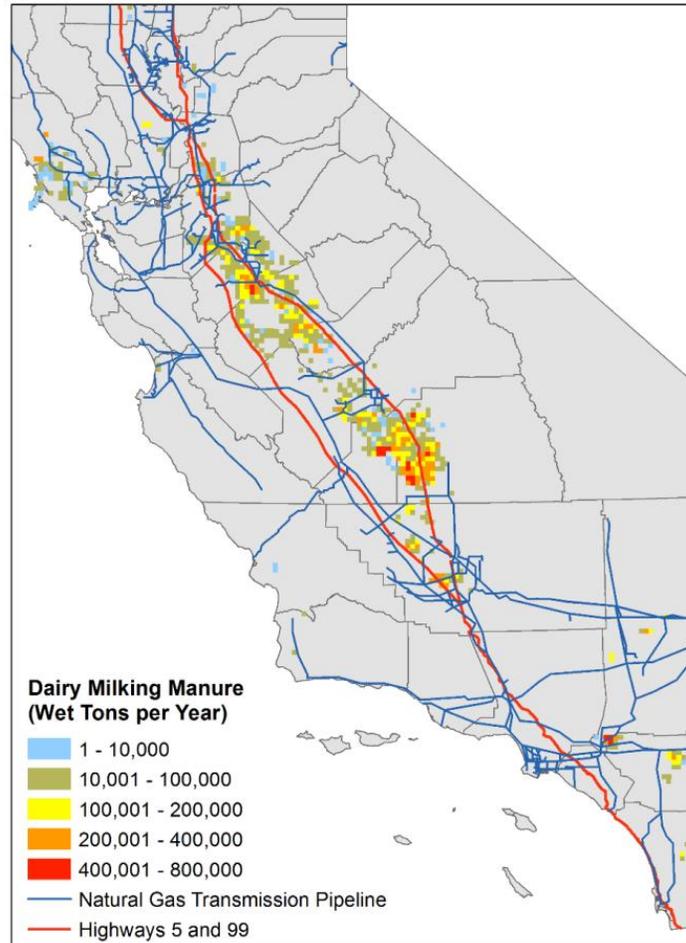

1. Scrape conversion and onsite manure digestion producing pipeline-injected renewable natural gas vehicle fuel
2. Scrape conversion and transport of manure offsite for centralized digestion producing pipeline injected renewable natural gas as a vehicle fuel
3. Scrape conversion, collection and open solar drying of manure onsite
4. Scrape conversion and onsite manure digestion for onsite production of renewable electricity
5. Conversion of dairy operations to pasture-based management

These represent example pathways that could be important to a sector-wide approach to reduce emissions, but they are not meant to rule out other solutions. The cost and efficacy of some options, such as solids separation, are not yet known with certainty and could not be included in this analysis. Solids separation and other potential mitigation methods deserve additional study of both emission reduction potential and economic feasibility.

The strategies considered here aim to balance cost and feasibility, while prioritizing economic and environmental benefits. Specifically, they aim to address water quality issues on dairies by including conversion to scrape systems, maximize renewable natural gas production by utilizing above ground tank/plug flow digesters, and avoid increases in criteria pollutant emissions (most notably oxides of nitrogen, or NO_x) and maximize potential revenues by prioritizing pipeline injection of renewable natural gas. Prioritizing these goals adds costs compared to a pathway that focuses on methane mitigation only, but deliver important environmental, health and potential economic benefits.

ARB conducted a Geographic Information System (GIS) analysis of dairies throughout the State to inform the scenario development. GIS informed estimates related to the number of dairies that could feasibly inject renewable natural gas into the pipeline, associated costs, availability and costs associated with “clustering” dairies to centralize digestion and pipeline injection, and opportunities for converting to pasture-based operations. Figure 11 provides a spatial analysis of manure from milking cows in California.

Figure 11: Location of Manure from Milking Cows in California

The analysis was informed by direct consultation with CDFA, academic researchers at UC Davis and elsewhere, project developers, and stakeholders. In particular, as part of developing this Proposed Strategy, ARB supported research at UC Davis to inform cost and performance estimates for dry scrape conversions, anaerobic digesters, and other

pathways.¹⁴⁹ Additional research was also used to inform the cost and performance parameters assumed for this analysis, which are detailed in Appendix D.¹⁵⁰

Potential revenues from energy or electricity sales and environmental credits were included. For the value of energy and credits, the current or estimated average value through 2030 was used. No revenue was included for soil amendment products that could be potentially generated from these pathways, and provide value,¹⁵¹ because their market potential remains uncertain at this time. The LCFS, Cap-and-Trade, and federal Renewable Fuel Standard program are all assumed to be in place through at least 2030. Cap-and-trade offsets are not available for projects built after a regulation takes effect, assumed here to be in 2025, and the carbon intensity for LCFS accounting is assumed to increase for new projects from -276 gCO₂e/MJ to +13 gCO₂e/MJ at that point, as well.

The first two strategies produce biomethane that is injected into the pipeline and used as transportation fuel. They receive revenue for energy sales at the price of wholesale natural gas (\$3.46/Mscf), as well as LCFS credits (\$100/MT) and cellulosic RIN credits (\$1.85/RIN)¹⁵² from the federal Renewable Fuel Standard program. In the first strategy, digesters are developed onsite at each dairy, while the second captures economies of scale by utilizing centralized digesters, biogas upgrading, and pipeline injection points for “clustered” dairies. The third pathway mitigates manure methane emissions by converting from flush management to scrape systems, but is assumed to generate no revenue. This represents a low cost option, but low value, as well. In the fourth strategy, manure is digested onsite to produce electricity using microturbines (to limit NO_x emissions). This pathway receives revenue from electricity sales (\$0.126/kWh) and Cap-and-Trade offsets (\$13/MTCO₂e). Finally, in the fifth strategy, dairies convert to pasture-based operations. No revenue is assumed from this pathway.

Costs and revenues for these strategies, normalized to a dairy with 2,000 milking cows, are summarized in Table 11. The table includes the net present value for each over a 10-year time horizon, assuming a 10 year loan on capital at 7 percent interest, and a 5 percent discount rate.

¹⁵⁰ In particular: Sustainable Conservation (2015) Combating Climate Change: Dairies Key in Reducing Methane, July: <http://www.suscon.org/blog/2015/07/combating-climate-change-dairies-key-in-reducing-methane/>.

¹⁵¹ Soil amendment products from dairy digesters could provide greater potential revenues than energy sales from the digesters, potentially as much as \$300 per cow per year in California. Informa Economics (2013) National Market Value of Anaerobic Digester Products, Prepared for Innovation Center for U.S. Dairy, February.

¹⁵² The assumed cellulosic RIN credit value of \$1.85 includes a D5 RIN (\$0.85), cellulosic waiver credit (\$0.90) and value from the Blenders Tax Credit (\$0.10 per D5 RIN).

Table 11: Economic Analysis for Projects at a Representative Dairy with 2,000 Milking cows Over 10-year Accounting Period¹⁵³

| | Strategy | | | | |
|--|--|---|----------------------------|---|-----------------------------------|
| | 1 Onsite Digestion to Fuel | 2 Central Digestion to Fuel | 3 Scrape Only | 4 Onsite Digestion to Electricity | 5 Convert to Pasture |
| Capital (million dollars) | \$5.4 | \$3.3 | \$1.6 | \$5.8 | \$5.0 |
| O&M (million dollars) | \$3.5 | \$2.4 | \$0.4 | \$3.5 | \$2.8 |
| Revenue (million dollars) | \$11.3 | \$11.3 | -- | \$3.6 | -- |
| NPV (million dollars) | \$2.5 | \$5.5 | -\$2.1 | -\$5.7 | -\$7.8 |
| \$/MT CO₂e (20-yr GWP) | -\$5.8 | -\$13.0 | \$4.9 | \$13.5 | \$18.2 |
| \$/MT CO₂e (100-yr GWP) | -\$16.6 | -\$37.6 | \$14.2 | \$38.8 | \$52.5 |
| Breakeven Upfront Grant (million dollars) | -- | -- | \$1.9 | \$5.3 | \$7.1 |

Based on the assumptions used here, projects that generate transportation fuel and can capture LCFS credits can generate a positive return (strategies 1 and 2). These pathways may also contribute to regional air quality benefits, as part of an integrated approach to utilize renewable fuel in low-NOx engines. But revenue for these strategies, and the resulting project economics (as measured by net present value), are highly dependent on the value of LCFS and RIN credits. As shown in Table 12, the net present value can fluctuate by several million dollars, depending on the value of these revenue streams. Without these programs, these projects would have net present values similar to strategies 4 and 5.

Table 12: Net Present Value for Strategies Producing Transportation Fuel, as a Function of LCFS and RIN Credit Prices (Million Dollars)

| | | Strategy 1: Onsite Digestion to Vehicle Fuel | | | | | Strategy 2: Centralized Digestion to Vehicle Fuel | | | | |
|--|---------------|---|-------------|--------------|--------------|--------------|--|-------------|--------------|--------------|--------------|
| | | LCFS Credit Price | | | | | LCFS Credit Price | | | | |
| | | \$0 | \$50 | \$100 | \$150 | \$200 | \$0 | \$50 | \$100 | \$150 | \$200 |
| Cellulosic RIN Credit Price | \$0.00 | -\$8.2 | -\$5.0 | -\$1.7 | \$1.6 | \$4.8 | -\$5.1 | -\$1.9 | \$1.4 | \$4.7 | \$7.9 |
| | \$0.50 | -\$7.1 | -\$3.8 | -\$0.6 | \$2.7 | \$6.0 | -\$4.0 | -\$0.7 | \$2.5 | \$5.8 | \$9.0 |
| | \$1.00 | -\$6.0 | -\$2.7 | \$0.5 | \$3.8 | \$7.1 | -\$2.9 | \$0.4 | \$3.6 | \$6.9 | \$10.2 |
| | \$1.85 | -\$4.1 | -\$0.8 | \$2.5 | \$5.7 | \$9.0 | -\$1.0 | \$2.3 | \$5.5 | \$8.8 | \$12.1 |
| | \$2.50 | -\$2.6 | \$0.6 | \$3.9 | \$7.2 | \$10.4 | \$0.5 | \$3.7 | \$7.0 | \$10.3 | \$13.5 |
| | \$3.00 | -\$1.5 | \$1.8 | \$5.0 | \$8.3 | \$11.6 | \$1.6 | \$4.9 | \$8.1 | \$11.4 | \$14.6 |
| | \$3.50 | -\$0.4 | \$2.9 | \$6.1 | \$9.4 | \$12.7 | \$2.7 | \$6.0 | \$9.2 | \$12.5 | \$15.8 |
| | \$4.00 | \$0.7 | \$4.0 | \$7.3 | \$10.5 | \$13.8 | \$3.8 | \$7.1 | \$10.4 | \$13.6 | \$16.9 |

¹⁵³Summation may not be exact due to rounding. Capital costs amortized over 10 years with 7% interest. Discount rate is 5%. Costs normalized to representative 2,000 cow dairy.

Other types of dairy projects may not generate positive returns without additional support and/or other potential revenue streams, such as for soil amendments. The third strategy requires the lowest capital outlay among strategies considered in this analysis, but it is not assumed to generate any revenue, leading to a net present value loss of about \$2.1 million over 10 years. Still, this pathway represents fairly low cost emission reductions (\$4.9/MT using a 20-year GWP) and could break even with an upfront grant, or its equivalent, of about \$1.9 million.

The fourth strategy provides revenue streams that are more stable than for the transportation fuel pathways in strategies 1 and 2, but they are also significantly lower, and the project economics are less favorable. The net present value of this project over ten years is -\$5.7 million, and an upfront grant of \$5.3 million would be needed to break even. Note, however, that if electricity generated from biogas is used to charge electric vehicles, biogas used to generate electricity can be credited with cellulosic RIN credits, which could add another valuable revenue stream. In this case, RIN credits would more than double revenue and add more than \$4 million in net present value over 10 years. That type of project, based on the assumptions here, would still represent a net loss of \$1.6 million over ten years, but it could break even with an upfront grant of \$1.5 million. Costs of emission reductions over 10 years would fall to \$4/MTCO_{2e} using a 20-year GWP (\$11/MTCO_{2e} using a 100-year GWP).

Converting to pasture-based systems is assumed to have relatively high costs and no revenue, leading to a pathway with a net present value of -\$7.8 million over 10 years. Three-quarters of the estimated capital cost and over 90 percent of the estimated operating costs come from irrigation, so if dairies were to convert to pasture in areas where less irrigation may be needed (perhaps in northern parts of the State), they might be able to significantly cut costs associated with reducing methane from their operations. In general, little information is available on the economics associated with converting to pasture, and additional research and potential demonstration projects could help to evaluate the viability of this strategy to reduce dairy methane emissions in California.

Costs and Revenues for Sector-Wide Scenarios to Meet Proposed Targets

These individual pathways were combined into three industry-wide scenarios (Table 13) for reducing methane emissions from manure management at California dairies by 20 percent in 2020, 50 percent in 2025 and 75 percent by 2030:

- Scenario A: All strategy 3 (scrape to manure collection and drying)
- Scenario B: Mixed approach (including all five strategies)
- Scenario C: All strategy 2 (centralized digestion and pipeline injection)

**Table 13: Mix of Strategies in Scenarios:
Number of Milking cows Covered by Projects in 2030**

| Strategy | A | B | C |
|---|------------------|------------------|------------------|
| (1) Scrape conversion and onsite manure digestion producing pipeline-injected renewable natural gas vehicle fuel | | 350,000 | |
| (2) Scrape conversion transport of manure offsite for centralized digestion producing pipeline injected renewable natural gas as a vehicle fuel | | 300,000 | 1,050,000 |
| (3) Scrape conversion, collection and open solar drying of manure onsite | 1,050,000 | 200,000 | |
| (4) Scrape conversion and onsite manure digestion for onsite production of renewable electricity | | 150,000 | |
| (5) Conversion of dairy operations to pasture-based management | | 50,000 | |
| Total | 1,050,000 | 1,050,000 | 1,050,000 |

Results for the scenarios are summarized in Table 14. Scenario A represents a low cost, zero revenue case where a sufficient number of dairies transition to scrape operations to reduce methane emissions from manure management by 75 percent by 2030. This could have potential benefits, as described in Chapter V, for nutrient management and water quality on the farm. There could also be potential revenue (along with added costs) if manure were composted and sold, which is not considered here. The sector-wide, net present value through 2030 for this scenario is -\$636 million, which represents emission reductions of about \$4/MTCO_{2e} using a 20-year GWP (\$11/MTCO_{2e} using 100-year GWP).

Table 14: Economic Analysis for Sector-Wide Scenarios Through 2030 (Million Dollars)¹⁵⁴

| | Scenario | | |
|---|-----------------|----------|----------|
| | A | B | C |
| Capital | \$493 | \$1,235 | \$995 |
| O&M | \$142 | \$837 | \$788 |
| Revenue | \$0 | \$2,157 | \$3,237 |
| Net Present Value \$100 LCFS Credit \$1.85 RIN Credit | -\$636 | \$84 | \$1,454 |
| \$/MT CO₂e (20-yr GWP) | \$3.8 | -\$0.5 | -\$8.7 |
| \$/MT CO₂e (100-yr GWP) | \$10.9 | -\$1.5 | -\$24.9 |
| Net Present Value \$40 LCFS Credit \$1.00 RIN Credit | -\$636 | -\$926 | -\$176 |

Scenario B includes a mix of all five strategies. Collectively, with LCFS credits assumed to be valued at \$100/MT and RINs at \$1.85, this scenario meets the targets in this Proposed Strategy with a positive net present value of \$84 million through 2030. If the portion of milking cows in this scenario utilizing Strategy 4 were to use generated electricity for transportation fuel to capture RIN credits, it would increase revenues and net present value by about \$200 million. Again, revenues are highly dependent on LCFS and RIN credit values. If LCFS credits were \$40/MT and RINs were \$1.00, the net present value of this scenario would fall by about \$1 billion, to -\$926 million (and -\$823 million if the electricity is used as transportation fuel).

The value of LCFS and RIN credits is even more noticeable in Scenario C, where all emission reductions are achieved through centralized digestion that generates renewable natural gas for transportation fuel and LCFS credits. If instead of the assumptions used here, LCFS and RIN credits were valued at \$40/MT and \$1.00, respectively, the net present value would fall by \$1.6 billion, and the scenario would have a net loss of \$176 million through 2030.

Altogether, this analysis suggests that the dairy industry in California can significantly cut methane emissions and deliver low-cost GHG reductions. There are important uncertainties associated with project costs and potential revenues, however, which may limit project development without targeted support. And the State may wish to support

¹⁵⁴ Summation may not be exact due to rounding. Capital costs amortized over 10 years with 7% interest. Discount rate is 5%. In Scenarios B and C, beginning in 2025, regulation eliminates availability of C&T offsets for new electricity generating projects (Strategy 4) and for those that have been operating for 10 years. For projects producing transportation fuel (Strategy 1 and 2), beginning in 2025, the carbon intensity for LCFS credits for new projects and those that have been operating for 10 years increases from -276 to 13 gCO₂e/MJ. The impact of regulation on existing projects under the LCFS has not been determined, and this simply an assumption used for the sake of this analysis.

some higher cost strategies, including conversions to scrape or pasture-based systems, for other environmental reasons.

A mix of grants, especially for projects with lower revenues, and other mechanisms for pathways with higher revenues may be appropriate. This funding could come from federal sources, California's Greenhouse Gas Reduction Fund (GGRF), utility programs, the programs included in this analysis, or other sources. Limited federal grant funding is currently available, and more should be pursued. In his proposed 2016-17 Budget,¹⁵⁵ Governor Brown has proposed committing \$55 million in GGRF funding for climate smart agriculture, including dairy digesters and healthy soils. And under a rulemaking by the CPUC pursuant to Assembly Bill 1900 (Gatto, Chapter 602, Statutes of 2012), California's natural gas utilities will offset half of renewable natural gas interconnection costs, up to \$1.5 million per project and \$40 million Statewide.

These programs provide a strong starting point for supporting the industry in reducing methane emissions and achieving the targets and benefits identified here. They should be built upon and bolstered. A financial working group may be helpful in recommending ways to leverage private sector investment and significantly scale efforts to rapidly cut methane emissions in California. Through careful investments and structured market-based incentives, project development may be accelerated to achieve emission reductions more quickly than the targets identified in this Proposed Strategy, and ahead of potential regulation of the industry.

3. Methane Emission Reductions from Diversion of Landfill Organic Waste

As noted in Chapter V, diverting organic materials from landfills can reduce landfill emissions by 5 MMTCO₂e in 2030, increasing to 21 MMTCO₂e by 2050 (using a 20-year GWP). Achieving these methane reduction targets requires optimized use and disposal of methane generating organic materials. To that end, the Proposed Strategy recommends reducing organics deposited to landfills by 90 percent by 2025, consistent with AB341. This ambitious target requires putting organic materials to the highest feasible use and developing infrastructure and markets to optimize the economic and environmental value of California's waste streams across sources.

When considering waste diversion options it is essential to balance environmental and economic benefits with any potential impacts on criteria pollutant emissions and ecosystem and human health, especially in disadvantaged communities. Avoiding organic waste generation entirely is the best option to reduce emissions, protect health, and minimize costs. However, once generated, there are many options for creating environmental and economic benefit through the appropriate utilization organic waste. Organics can be diverted to waste facilities with existing excess capacity, including composting facilities, stand-alone anaerobic digesters (AD), and wastewater treatment anaerobic digesters. New facilities can be also built in optimized locations.

¹⁵⁵ <http://www.ebudget.ca.gov/2016-17/BudgetSummary/BSS/BSS.html>

In this analysis three scenarios were considered that can achieve the organic diversion target outlined in the Proposed Strategy. The three scenarios are based on projected waste data and potential diversion outlined in Appendix D. The only difference between the scenarios is the waste utilization of grass and leaves. The three scenarios evaluate the costs and revenues for utilizing food waste and grass and leaves in three pathways:

1. New anaerobic digestion facilities
2. Existing excess capacity at wastewater treatment anaerobic digestion facilities
3. New compost facilities

The actual future utilization of food waste and grass and leaves will most likely be some mix of these options. Since it is not possible to predict the exact mix of utilization pathways, these three scenarios were developed to bound potential costs and revenues. The scenarios considered here aim to balance cost and feasibility, while prioritizing economic and environmental benefits. To this end, the analysis focuses on the capture and pipeline injection of renewable natural gas from diverted organic waste. Using renewable natural gas as a transportation fuel can result in significant potential revenue streams and reduce criteria pollutant emissions from the transportation sector. Prioritizing the use of biomethane as a transportation fuel may increase costs relative to scenarios that focus solely on methane mitigation. However, important environmental, health, and economic benefits may be realized by prioritizing pipeline injection of renewable natural gas.

Within scenario 1, food waste and a portion of grasses and leaves are handled through new centralized AD facilities and the resulting methane is pipeline injected. New AD facilities are assumed to accept 100,000 tons per year of organic waste. The costs of scenario 1 include facility construction and permitting, operating and maintenance (O&M), waste and digestate processing and transportation, and the costs associated with pipeline injection of renewable natural gas. These include pipeline, interconnection, and biogas upgrading costs. Potential revenue streams include tipping fees, the sale of biogas, LCFS credits, and RIN credits, as outlined in Appendix D.

Scenario 2 assumes that food waste is diverted to wastewater treatment facilities with existing excess capacity. The analysis assumes that, with modification, existing wastewater treatment facilities can accept 50,000 tons of organic material per year on average by 2030, with some facilities accepting more or less depending on size. Costs for this scenario include upgrading and permitting costs that may be required for facilities to accept food waste, waste and biosolid processing and transportation, O&M, as well as the costs associated with pipeline injection of renewable natural gas. Potential revenue streams include tipping fees, sale of biogas, LCFS credits, and RINs.

Scenario 3 assumes that all food waste and grasses and leaves are composted at new facilities with a throughput of 100,000 tons per year. Costs within the scenario include facility construction, O&M, and transportation of organic materials to the compost facility. The only revenue stream included in scenario 3 is the tipping fee, though additional revenue streams could result from the sale of compost.

A principal difference in outcomes from these three scenarios is the number of new facilities needed to achieve the organic diversion targets. Table 15 shows the number of new compost or AD facilities needed for each scenario.¹⁵⁶

Table 15: Estimated Number of New Facilities

| Scenario | Estimated Number of New Compost Facilities to Achieve Target | | | Estimated Number of New AD Facilities to Achieve Target | | |
|------------------|--|------|------|---|------|------|
| | 2020 | 2025 | 2030 | 2020 | 2025 | 2030 |
| 1. New AD | 43 | 52 | 54 | 40 | 56 | 58 |
| 2. Existing WWTP | 50 | 62 | 65 | - | - | - |
| 3. Compost Only | 76 | 97 | 102 | - | - | - |

There is uncertainty regarding the costs, savings, and potential revenue streams associated with organic waste diversion. Social welfare impacts, including those related to health, noise, odor, ecosystem benefit, and water impacts, are not included in this analysis but require additional consideration and analysis prior to the implantation of any organic diversion measure. Additional uncertainty related to existing infrastructure and technology development may also create economic impacts not analyzed in this analysis, which relies on available data from California agencies, academic researchers, and industry to estimate the direct economic impact, including costs, fuel and energy savings, and potential revenue streams, of achieving the organic waste diversion target in the Proposed Strategy.

Net present value calculations were used to estimate the potential profitability of the three scenarios. By calculating the present value of future cost and organic diversion over a 10-year financing period, the net present value calculation provides insight into the feasibility of projects at the facility level, including the need for upfront grants and incentives as well as the significant opportunities and uncertainty surrounding revenue streams based on existing regulations.

Costs and revenues for the three scenarios are summarized in Table 16. The table includes the net present value for each scenario over a 10-year financing period

¹⁵⁶ This analysis assumes existing wastewater treatment facilities can handle 50,000 wet tons of food waste per year, while new AD facilities and compost facilities have a throughput of 100,000 wet tons per year. Additional information regarding the projected organic waste streams by waste, the assumptions surrounding required facilities, and the handling of residuals are presented in Appendix D.

Table 16: Cumulative Estimated Costs and Revenues by Scenario Over 10-Year Accounting Period (Million Dollars)

| Scenario 1: New AD | Component | Capital Cost | O&M | Revenue |
|----------------------------------|------------------|---------------------|----------------|----------------|
| New AD | 54 Facilities | \$1,200 | \$2,100 | \$5,800 |
| New Compost | 58 Facilities | \$600 | \$650 | \$1,200 |
| Total | | \$1,800 | \$2,750 | \$7,000 |
| 10-Year Net Present Value | | \$2,500 | | |
| Scenario 2: WWTP | Component | Capital Cost | O&M | Revenue |
| New Compost | 65 Facilities | \$720 | \$790 | \$1,500 |
| Existing Wastewater Treatment | 118 Facilities | \$1,300 | \$3,700 | \$5,100 |
| Total | | \$2,020 | \$4,490 | \$6,600 |
| 10-Year Net Present Value | | \$162 | | |
| Scenario 3: Compost | Component | Capital Cost | O&M | Revenue |
| New Compost | 102 Facilities | \$1,000 | \$1,100 | \$2,100 |
| Total | | \$1,000 | \$1,100 | \$2,100 |
| 10-Year Net Present Value | | -\$43 | | |

Table 16 suggests that under Scenario 1 and Scenario 2, organic waste diversion can generate a positive return. These scenarios may also contribute to regional air quality benefits, through reduced transportation emissions. However, revenue for these strategies, and the resulting net present value, is highly dependent on the value of LCFS and RIN credits. As shown in Table 17, for representative wastewater treatment and new AD facilities, the net present value of diverting organic materials – at the facility level – is negative without revenue from LCFS credits and RINs.

Table 17: Net Present Value of Representative Wastewater Treatment and New AD Facility under Varying LCFS Credit Prices and RIN Credit Prices (Million Dollars)

| | | Wastewater Treatment Facility | | | | | New AD Facility | | | | |
|------------------------------|--------|-------------------------------|---------|--------|--------|--------|--------------------------|---------|---------|---------|---------|
| | | <u>LCFS credit price</u> | | | | | <u>LCFS credit price</u> | | | | |
| | | \$0 | \$50 | \$100 | \$150 | \$200 | \$0 | \$50 | \$100 | \$150 | \$200 |
| Cellulosic RIN credit prices | \$0.00 | -\$17.0 | -\$12.1 | -\$7.2 | -\$2.2 | \$2.7 | -\$34.4 | -\$18.9 | -\$3.4 | \$11.9 | \$27.3 |
| | \$0.50 | -\$8.1 | -\$3.1 | \$1.8 | \$6.7 | \$11.7 | -\$14.4 | \$0.9 | \$16.4 | \$31.8 | \$47.3 |
| | \$1.00 | \$0.9 | \$5.8 | \$10.8 | \$15.7 | \$20.7 | \$5.4 | \$20.9 | \$36.3 | \$51.8 | \$67.2 |
| | \$1.85 | \$16.3 | \$21.2 | \$26.1 | \$31.1 | \$30.0 | \$39.3 | \$54.8 | \$70.2 | \$85.6 | \$101.1 |
| | \$2.50 | \$27.9 | \$32.9 | \$37.8 | \$42.8 | \$47.8 | \$65.2 | \$80.7 | \$96.1 | \$116.7 | \$133.9 |
| | \$3.00 | \$36.9 | \$41.9 | \$46.9 | \$51.8 | \$56.8 | \$85.2 | \$100.6 | \$116.0 | \$131.5 | \$146.9 |
| | \$3.50 | \$46.0 | \$50.9 | \$55.9 | \$60.8 | \$65.8 | \$105.1 | \$120.5 | \$136.0 | \$151.4 | \$166.9 |
| | \$4.00 | \$55.0 | \$59.9 | \$64.9 | \$69.9 | \$74.8 | \$125.0 | \$140.5 | \$155.9 | \$171.4 | \$186.8 |

State resources could be deployed to supplement financing of biomethane projects through mechanisms such as upfront grants, loan assistance programs, and tax incentives. For example, the illustrative wastewater treatment facility in Table 17 would break even over a 10-year financing period with an upfront grant of \$16 million. Looking at LCFS credits and RINs in isolation, without revenue from LCFS credits, this illustrative wastewater treatment facility would break even with a RIN price of \$1 over the 10-year financing period. In the absence of revenue from RINs, the facility would breakeven at an LCFS credit price of \$173. The US EPA’s Renewable Fuel Standard (under which RINs are generated and sold) and California’s LCFS program can offset large upfront capital costs that otherwise may prevent project development.

In the absence of revenue from the sale of LCFS credits, a RIN price of \$0.87 is required for a representative new AD facility to breakeven over a 10-year financing period. In the absence of RIN credit revenue, an LCFS credit price of \$112 is required for that same facility to breakeven over a 10-year financing period. Without revenue from RINs or LCFS credits, an upfront grant of \$32 million would be required in order for the illustrative new AD facility to breakeven over a 10-year financing period.

Altogether, this analysis suggests that the diversion of organic waste can result in environmental and economic value to California. There are important uncertainties associated with facility costs and potential revenues, however, which may limit project development without additional support. In the absence of revenue from LCFS credits and RINs, significant financial support, may be required to achieve the target identified in this Proposed Strategy and deliver other environmental benefits. Through careful research, investments, and structured market-based incentives, the State can work with industry to significantly and permanently reduce methane emissions and divert organic waste.

4. Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities Regulation

The Proposed Strategy has a four-pronged approach to methane reductions in the oil and gas sector including regulation of production, processing, and storage facilities and implementation of SB 1371. The process to adopt rules and procedures to minimize natural gas leaks from natural gas pipelines under SB 1371 is just beginning and an analysis of the costs and potential benefits of SB 1371 will be conducted as measures are implemented.

ARB is developing a regulation to address methane from oil and gas production, processing, and storage facilities for Board consideration in 2016. The regulation is anticipated to deliver environmental benefits that include an estimated reduction in GHG emissions through 2030 of about 13.8 MMTCO₂e from oil and gas related emissions in California. In addition, the measure is expected to save about 650 million standard cubic foot (scf) per year of industrial natural gas through reductions of leaks and through vapor recovery systems, the monetized value of which is approximately \$2.7 million per year.¹⁵⁷

While air districts are currently combatting volatile organic compounds (VOC) leaks locally, these rules vary by district and are not addressing any methane only leaks. This measure is designed to expand upon existing local rules, promote statewide uniformity, minimize the administrative burden on local air districts, harmonize state requirements with current and near-future local and federal requirements, and achieve further methane reductions to achieve the goal outlined in this strategy of reducing fugitive methane emissions from all sources in the oil and natural gas sector by 45% by 2030.

The Oil and Gas measure proposes eight main control provisions that are designed to achieve emission reductions in crude oil and natural gas operations. These provisions build upon and in some ways increase existing local air district requirements to monitor, replace, and expand current capital at crude oil and natural gas facilities.

The cost of this measure includes capital costs to: Install Vapor Recovery Units for tanks, well stimulations tanks, and centrifugal compressors; replace rod packing on reciprocating compressors; and change pneumatic devices. In addition, a leak detection and repair program (LDAR) as well as emissions reduction and leak monitoring plans will have ongoing costs in each year beginning in 2018. The amortized¹⁵⁸ capital cost plus the ongoing costs yield an overall cost of the measure of just over \$190 million through 2030. These costs are offset by natural gas collection from the reduction in leaks and vapor recovery; these savings amount to savings of almost \$33 million through 2030 and persisting thereafter. The costs, cost-savings, and emission reductions are outlined in Table 18 by each provision.

¹⁵⁷ <http://www.energy.ca.gov/2014publications/CEC-200-2014-001/CEC-200-2014-001-SF.pdf>. Using a value of \$4.10 per Mscf, which is the value of the natural gas prices are based upon wholesale prices that are forecasted by the California Energy Commission using their NAMGas general equilibrium model.

¹⁵⁸ Using a 5% discount rate.

Table 18: Costs and Emissions for Oil and Gas Measure

| Segment of Regulation | Total Reductions to 2030 (MTCO₂e) | Annual Cost | Annual Savings | Total Cost to 2030 | Total Savings to 2030 |
|----------------------------------|---|---------------------|-----------------------|---------------------------|------------------------------|
| VRU for Tanks | 6,456,000 | \$4,674,000 | \$653,000 | \$56,088,000 | \$7,836,000 |
| Reciprocating Compressors | 804,000 | \$203,000 | \$230,000 | \$2,436,000 | \$2,760,000 |
| LDAR | 2,640,000 | \$8,902,000 | \$756,000 | \$115,726,000 | \$9,450,000 |
| Pneumatic Devices | 3,828,000 | \$1,153,000 | \$1,043,000 | \$13,836,000 | \$12,516,000 |
| Well Stimulations | 60,000 | \$186,000 | \$17,000 | \$2,232,000 | \$204,000 |
| Centrifugal Compressors | 36,000 | \$4,000 | \$12,000 | \$48,000 | \$144,000 |
| Monitoring Plan | TBD | TBD | TBD | TBD | TBD |
| Total | 13,824,000 | \$15,122,000 | \$2,711,000 | \$190,366,000 | \$32,910,000 |

5. Hydrofluorocarbon (HFC) Emission Reductions

Hydrofluorocarbons (HFCs) are used primarily as refrigerant substitutes to ozone-depleting refrigerants, and although not ozone-depleting, HFCs have high-global warming potentials (GWP) between 500 and 12,000 (20-year GWP values). HFCs currently account for 4 percent of California’s GHG emissions, but are expected to double in emissions in the next few decades without additional reduction actions. Four HFC measures are proposed in this strategy to reduce cumulative HFC emissions by 260 MMTCO₂E (20-year GWP) by 2030 to meet the SLCP emission reduction target.

The proposed reduction measures include the following:

- Financial incentive program to install new low-GWP refrigeration and air-conditioning (AC) equipment
- Sales ban on refrigerants with very-high GWPs
- Phasedown in the supply of high-GWP HFCs

- Prohibitions on high-GWP refrigerants in new stationary refrigeration and AC equipment

The cost of strategies to reduce HFCs is highly dependent upon assumptions of the added initial cost of low-GWP equipment, which is estimated to be approximately 10 percent higher than baseline high-GWP equipment, as detailed in Appendix D. The additional initial cost ranges from \$500,000 for a large cold storage facility, and \$200,000 for a supermarket; to \$400 for a residential AC system, and \$140 for a residential refrigerator-freezer. In many cases, the added initial cost is offset or reversed through energy savings of low-GWP refrigeration and AC. Additionally, low-GWP refrigerants such as carbon dioxide refrigerant, ammonia, and hydrocarbons are less expensive than HFCs. The main barrier to adoption of low-GWP refrigeration equipment is the added initial cost. For low-GWP AC, the barriers include added initial cost and current building codes that do not allow very slightly flammable low-GWP refrigerants.

Measure costs were derived using the incremental per-unit equipment cost over the number of new units replacing retiring units each year. The total cost savings result from less energy use and less expensive refrigerant over the lifetime of the equipment. The cumulative costs and savings are outlined in Table 19.

The cost and savings from HFC reduction measures were estimated separately for each measure and then summed together to show total estimated cost and total estimated savings from all measures. This approach was used to avoid double-counting emission reductions, cost, and savings from measures that overlap significantly. For example, businesses installing low-GWP refrigeration because of the early adoption incentive program would not be subject to required prohibitions of high-GWP refrigerant in new equipment, and would not be affected by an HFC phasedown. An HFC phasedown could incentivize new equipment to use low-GWP refrigeration and AC, and a prohibition on high-GWP refrigeration and AC would largely overlap with HFC phasedown requirements. Detailed cost and savings for each individual measure are presented in Appendix D.

Table 19: HFC Measure Costs and Savings Through 2030 (Million Dollars)

| | Total Cost | Total Savings | Net Cost | Emission Reductions (MMTCO₂e) |
|-------------------------------|-------------------|----------------------|-----------------|---|
| HFC Reduction Measures | \$5,060 | (\$4,850) | \$210 | 260 |

GHG reductions from direct refrigerant emissions are estimated by modeling equipment sectors using a constant refrigerant charge size and annual leak rate, with the only variable that of the refrigerant's GWP. The reduction per unit per year is the difference between the emissions of the high-GWP equipment and the emissions expected from the new, low-GWP equipment. Indirect GHG emissions from less energy usage were also estimated using the default carbon intensity of California's

electricity from the Cap and Trade Program. Note that the indirect emission reductions account for less than 4 percent of GHG reductions from refrigeration and AC (the carbon intensity of electricity generation used to power cooling equipment is overwhelmed by the very-high GWPs of HFC refrigerants).

B. Public Health Assessment

Short-lived climate pollutants are not only powerful climate forcers but are also harmful air pollutants with many direct and indirect impacts on health. The focused efforts identified in this Proposed Strategy will not only help to limit the impacts of climate change that are already underway, but also reduce local air pollution and produce other co-benefits. The World Health Organization (WHO) describes the direct and indirect impacts of SLCP emissions, on a global level, as follows:¹⁵⁹

Since SLCPs contribute to ambient levels of ozone and PM2.5, SLCP [sic] emissions are directly associated with cardiovascular and respiratory diseases, including heart disease, pulmonary disease, respiratory infections and lung cancer. SLCP emissions thus contribute significantly to the more than 7 million premature deaths annually linked to air pollution.

Indirectly, the SLCPs ozone and black carbon reduce plant photosynthesis and growth, thus decreasing agricultural yields, which in turn threatens food security. They also affect weather patterns and the melting of snow and ice, which may harm and endanger health through extreme weather events such as floods.

Furthermore, in its report on *Reducing global health risks through mitigation of short-lived climate pollutants*,¹⁶⁰ the WHO notes that certain efforts to cut emissions of SLCPs may provide other types of health benefits not associated with air pollution. These include improved diets or more opportunities for safe active travel and physical activity. As described in this Proposed Strategy, some strategies to cut emissions of SLCPs in California could have important benefits for water quality, and potentially for water supply in the State, as well.

The measures and goals identified in this Proposed Strategy could deliver many of these types of benefits in California, which might accrue especially in disadvantaged communities (see Section C). As they are further developed and implemented, it will be important to consider a broad array of potential impacts and benefits to ensure that prioritized strategies to cut SLCP emissions also maximize other health benefits. For example, as part of an integrated strategy that includes use of ultra-low-NOx vehicles

¹⁵⁹ World Health Organization, "Reducing global health risks through mitigation of short-lived climate pollutants," accessed April 1, 2016. http://www.who.int/phe/health_topics/outdoorair/climate-reducing-health-risks-faq/en/

¹⁶⁰ WHO (2015) Reducing global health risks through mitigation of short-lived climate pollutants, Summary report for policymakers, World Health Organization, October. <http://www.who.int/phe/publications/climate-reducing-health-risks/en/>

and renewable natural gas in the transportation sector, converting manure management operations to scrape systems and injecting renewable natural gas into the pipeline can help to improve air quality and water quality near dairies and elsewhere in California. A discussion of the health impacts associated with the measures in this Proposed Strategy is provided below. A more detailed public health impacts analysis will be developed as part of any potential subsequent regulatory process.

Black carbon is a component of fine particulate matter (PM_{2.5}). A large number of studies, particularly epidemiological (population-based) studies, have linked exposure to PM_{2.5} to a number of adverse health effects, including premature death, hospital admissions for the worsening of chronic cardiovascular and lung diseases, and emergency room visits for asthma.^{161,162,163} Diesel particulate matter is a subset of PM_{2.5}, and consists of black carbon particle cores that are coated with a variety of other chemical substances, including over 40 carcinogenic organic compounds, nitrates, sulfates, and heavy metals. To date, no studies have directly investigated potential health effects of black carbon. However, since black carbon particulate matter is a subset of PM_{2.5}, which has been clearly shown to be related to adverse health effects, the scientific community has concluded that diesel and black carbon particulate matter likely have similar adverse effects as PM_{2.5}. As part of its periodic reviews of the national ambient air quality standards, the U.S. EPA draws conclusions as to the strength of the relationship between exposure to air pollution and broad categories of adverse health effects. In its most recent integrated science assessment for the PM standards, it concluded that PM_{2.5} plays a “causal” role in premature death and cardiovascular effects, and a “likely causal” role in respiratory effects.¹⁶⁴

As a result of State and local efforts over the past decades to improve air quality, California has significantly cut particulate matter emissions from anthropogenic sources, especially from diesel engines. The result is that black carbon emissions are about 90 percent lower than they were in the 1960s and approximately 5,000 premature deaths are avoided in the State each year. Current NO_x and PM emission standards for on-road and off-road diesel engines that phase in between 2012 and 2020 will lead to significant additional reductions in primary PM_{2.5} emissions from

diesel equipment.¹⁶⁵ (NO_x emissions are also projected to decrease, which could reduce ozone and secondary PM.) As a result, the health-related impacts associated with diesel PM_{2.5} are expected to continue to decrease through 2030.

Residential wood burning (fireplaces and woodstoves) is another important source of black carbon emissions and local air pollution, and its share of the State's black carbon inventory is increasing, as emissions from diesel engines fall. Fireplaces and woodstoves produce PM_{2.5}, carbon monoxide, volatile organic compounds, and hazardous air pollutants. In ARB's black carbon inventory, emissions from these sources are assumed to increase between 2013 and 2030, due to increased residential construction. Actions outlined in this Proposed Strategy, such as restricting residential wood-burning fireplaces and promoting the conversion to cleaner wood-burning stoves, can help reduce these emissions and health-related impacts, which especially impact rural areas.

Methane contributes to global background levels of ozone in the lower atmosphere (troposphere). Global background ozone (tropospheric ozone) concentrations have roughly doubled since preindustrial times, and are projected to continue to increase. Ozone itself is a powerful SLCP as well as a regional ground level air pollutant. Ozone exposure has been linked to increases in emergency room visits for worsening of asthma, hospitalizations due to respiratory disease, and premature death. Additionally, ozone suppresses crop yields; harms ecosystems; and affects evaporation, cloud formation, and precipitation.¹⁶⁶ Thus, reducing methane emissions as part of a broader effort to address climate change can complement local and regional efforts to reduce ground-level ozone.

Strategies to reduce methane emissions from dairy manure management can deliver important health benefits, especially if developed as part of a systematic approach to addressing air quality and water quality. For example, converting operations to pasture-based systems would likely reduce concentrations of and exposure to potentially harmful constituents, such as hydrogen sulfide, ammonia, and particulate matter. One study suggests that ammonia emissions could be 30 percent lower for pasture-based than for confinement systems.¹⁶⁷ It could also improve nutrient management on farms, helping to reduce soil and groundwater contamination. This strategy could be an important element of a sector-wide approach to reducing dairy methane emissions, but may have limited applicability. ARB estimates that about 25

¹⁶⁵ Primary particles are directly released into the atmosphere by combustion processes (such as soot or black carbon and a large variety of organic carbons). "Secondary" particles also form in the atmosphere from other gaseous pollutants, particularly sulfur dioxide, nitrogen oxides (NO_x), ammonia, and volatile organic compounds (VOCs). The transportation sector is an important source of secondary particulate matter such as ammonium nitrate, especially in the winter.

¹⁶⁶ UNEP and WMO (2011) Integrated Assessment of Black Carbon and Tropospheric Ozone, United Nations Environment Programme and World Meteorological Association. http://www.unep.org/dewa/Portals/67/pdf/BlackCarbon_report.pdf.

¹⁶⁷ Perry, A. (2011) Putting dairy cows out to pasture: An environmental plus, USDA-ARS Agricultural Research Magazine, May-June. <http://www.ars.usda.gov/is/AR/2011/may11/cows0511.htm>

dairies in the State could convert to pasture-based operations without reducing herd size or procuring new land.

Other strategies could also deliver environmental and health benefits. Converting dairies from flushwater manure management systems to dry manure management systems would also improve nutrient management, thereby helping to improve groundwater quality. It is possible that farms may choose some management strategies which could increase or decrease emissions of pollutants of concern. If emissions increase, measures should be implemented to mitigate the impacts as part of the permitting process.

Strategies that capture or produce methane and utilize it for production of renewable energy and fuels could lead to additional sources of combustion, but as part of a regional approach to utilize low-NO_x vehicles and renewable fuels, can displace diesel combustion and help to improve air quality. If electricity is generated onsite using dairy derived biogas, using microturbines or fuel cells can minimize new emissions of NO_x and PM, minimizing potential local health impacts. To the extent that renewable natural gas is produced and injected into the natural gas pipeline network, or used in low-NO_x engines to displace diesel combustion, air quality impacts can be avoided. Prioritizing pipeline injection and onsite usage in low-NO_x vehicles, in addition to a coordinated effort to increase use of low-NO_x vehicles with renewable fuels in areas surrounding dairies and elsewhere can reduce air pollution regionally and statewide. These emission reductions translate directly into health benefits, especially in disadvantaged communities near dairies and along transportation corridors, and in areas of non-attainment for ambient air quality standards.

Diverting organics from landfills to compost facilities and anaerobic digestion facilities, along with implementing food rescue and recovery programs, will significantly reduce the need for further landfill development in California, and may help reduce the lifespan of existing landfills, many of which are located in or near environmental justice communities. Phasing out the landfilling of organic materials will also help reduce future levels of fugitive methane emissions from landfills during their operational and post-closure stages. The number and frequency of heavy vehicle or truck trips to existing landfills, through neighboring communities, could potentially be reduced as organic materials are directed to anaerobic digestion facilities and regional compost facilities. To the extent that truck trips are reduced to and from landfills, they could increase in areas where facilities handling diverted organic waste are located. The net effect on overall truck trips in the State and associated emissions is uncertain, and could potentially increase as a result of changes in organic waste management, depending on how strategies are implemented. Many of the same issues associated landfilling organic waste—potential criteria pollutant emissions, water quality impacts, and odors—could be issues at anaerobic digestion or compost facilities. In many cases, these can be effectively limited with available technologies and management strategies, including limiting trucking emissions by utilizing zero emission vehicles or renewable natural gas in low-NO_x engines associated with these operations.

Food rescue and recovery could deliver additional potential health benefits by utilizing useable food to relieve food insecurity and provide better access to healthy foods. Increasing edible food recovery—especially from large-scale food producers, processors, and users—and safely redirecting food to those in need could increase access to healthy fruits and vegetables and benefit millions of Californians who suffer from food insecurity.

Reducing leaks from the oil and gas sector will also reduce VOC emissions, which contributes to ground level ozone formation and related health impacts. For example, ARB's oil and gas regulation is expected to reduce VOC emissions and toxic air contaminants that are emitted from uncontrolled oil and water storage tanks and released from well stimulation recirculation tanks. The estimated reduction in VOCs from this measure is approximately 3,000 tons per year, or about 8 tons per day, statewide.

The measures identified in this Proposed Strategy for HFCs are unlikely to have noticeable health impacts. HFCs have negligible impacts on smog formation and are exempt from U.S. EPA's definition of volatile organic compounds. At higher concentrations that could result from an accidental release in occupational settings, they might be toxic, and emissions of vapors containing HFCs in the workplace environment should be prevented. But at ambient concentrations, HFCs pose no significant health risk, and efforts described in this Proposed Strategy to phase down their use are not expected to deliver noticeable health benefits. Some potential replacements for HFCs could result in emissions of VOCs and particulate matter, but they would be negligible.

C. Environmental Justice and Disadvantaged Communities

The State of California defines environmental justice in statute as, "the fair treatment of people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations and policies." (Government Code Section 65040.12). ARB is committed to continuing to strengthen its outreach efforts to ensure that all California communities have the opportunity to participate in its public processes and benefit from the State's climate-related programs, policies, and regulations.

ARB endeavors to integrate environmental justice into all of its programs, policies, and regulations and is taking additional steps to strengthen its work with the environmental justice community. Specifically, every major program, policy, plan or strategy, and rulemaking explicitly discusses environmental justice and promotes the fair treatment of people from all races, cultures, geographic areas, and income levels—especially in disadvantaged communities. As part of the development and implementation of the AB 32 Scoping Plan, ARB convened an Environmental Justice Advisory Committee (EJAC). ARB has briefed the EJAC on this Proposed Strategy development multiple times, and at its April 2016 meeting, the EJAC discussed and made recommendations on this Proposed Strategy. ARB also works extensively with local air districts and

stakeholders during the development and implementation of its programs to respond to concerns about environmental justice.

The EJAC developed the following recommendations for inclusion in this Proposed Strategy:

- (1) Create a declining methane target specific to dairies that would lead to a 40% reduction mandate for dairies by 2030.
- (2) The dairy emission target should include all methane emissions from dairies, not just from manure handling.
- (3) The Proposed Strategy should explicitly say no disposal of food waste to landfills or incinerators.
- (4) Explore synergies with methane reductions from dairies and the management of organic waste, such as wood waste.
- (5) Include Concentrated Animal Feeding Operations (CAFO) in the methane emission reduction goal.
- (6) Mitigate all additional ancillary emissions generated through achieving the methane emission reduction goal.

This Proposed Strategy includes a measure that would create a regulatory program to achieve a 75 percent reduction in methane emissions from dairy manure management by 2030. It also includes a commitment to work to further examine enteric emissions and reduction opportunities. The GHG inventory includes methane emissions associated with CAFO facilities, which are primarily from enteric fermentation and manure management. The organic diversion measure identified in this Proposed Strategy will virtually eliminate organics from landfills, including food waste.

ARB staff has been working with staff from other state agencies to develop an holistic and synergistic approach to reducing methane emissions, and will continue to work with them to implement these measures. ARB staff will continue to consult with environmental justice communities as we implement the measures to ensure minimum impact and maximum benefit to environmental justice communities. Furthermore, the EJAC recommendations will be taken into consideration as specific actions and policies discussed in this Proposed Strategy are developed into regulatory measures.

The California Environmental Protection Agency and pursuant to Senate Bill 535 (De León, Chapter 830, Statutes of 2012), has identified the communities in California that are most disproportionately burdened by pollution for the purposes of expenditure of California Climate Change Investment Funds. Of the 12 indicators of pollution included in its methodology, three are directly related to SLCP emissions (fine particle emissions, diesel particulate emissions, and solid waste sites and facilities), and at least six others (mostly related to water quality and air quality) are at least related to sources of SLCP emissions.

The distribution of these communities aligns with locations of SLCP emission sources, including sources of organic waste streams and dairies in the Central Valley; ports and

freight corridors in the East Bay, Los Angeles area and Inland Empire; and oil production, landfills and other sources of SLCP emissions throughout the State. Many communities in these areas have some of the worst pollution burdens in the State and high rates of poverty and unemployment. Forested and rural communities in the northern part of the State and the Sierra also are stricken with high rates of poverty and unemployment. They are also where many billions of dollars in public and private investment will accrue in the coming years to reduce SLCP and CO₂ emissions and strengthen our agricultural sector, build sustainable freight systems, and grow healthy forests. To the extent new facilities are built to manage organic waste streams in the State, care must be taken to locate, design, and operate them in a manner that protects local air quality.

The integrated strategy to reduce SLCP emissions from agriculture and waste, developed in this Proposed Strategy, can be part of an integrated strategy to improve air and water quality in agriculture regions, such as in the Central Valley. Additionally, the Healthy Soils Initiative will improve California's agriculture economy and support further economic development in these communities. California's commitment to improve the health and management of forests will boost California's forest economy and limit black carbon emissions and many other air pollutants from wildfires.

The measures identified in this Proposed Strategy will be further developed in a formal public process that specifically considers environmental justice concerns. Opportunities for public participation will be provided during the development of each measure, and regulatory language will be made available in easily understood and useful formats, such as program-specific webpages and slide presentations.

D. Environmental Analysis

ARB, as the lead agency for the Proposed Strategy, prepared a Draft Environmental Analysis (EA) in accordance with the requirements of the California Environmental Quality Act (CEQA) and ARB's regulatory program certified by the Secretary of Natural Resources (California Code of Regulation, title 17, sections 60006-60008; California Code of Regulation, title 14, section 15251, subdivision (d)). The resource areas from the CEQA Guidelines Environmental Checklist were used as a framework for a programmatic environmental analysis of the reasonably foreseeable compliance responses resulting from implementation of the proposed measures discussed in the Proposed Strategy. The Draft EA provides an analysis of both the beneficial and adverse impacts and feasible mitigation measures for the reasonably foreseeable compliance responses associated with the proposed measures under each of 17 environmental resource areas. Collectively, the Draft EA concluded implementation of these actions could result in the following short-term and long-term beneficial and adverse impacts : beneficial long-term impacts in reduced greenhouse gas emissions; less than significant impacts to air quality, biological resources, energy demand, geology and soils, greenhouse gases (short-term), hazards and hazardous materials, hydrology and water quality, resources related to land use planning, mineral resources, noise, population and housing, public services, and recreational services; and

potentially significant and unavoidable adverse impacts to aesthetics, agriculture and forest resources, air quality, biological resources, cultural resources, geology and soils, hazards and hazardous materials, hydrology and water quality, resources related to land use planning, noise, transportation/traffic, and utilities and service systems. The potentially significant and unavoidable adverse impacts are primarily related to short-term construction-related activities, which explains why some resource areas are identified above as having both less-than-significant impacts and potentially significant impacts. Please refer to the Draft EA in Appendix C for further details.

ARB will prepare written responses to all comments received on the Draft EA, which will be presented to the Board for consideration along with the Final EA.

IX. Next Steps

This Proposed Strategy and an accompanying draft Environmental Analysis (EA), was released for public comment. Staff will provide an update to the Board on the Proposed Strategy in May 2016. In fall 2016, staff will present the final proposed SLCP Reduction Strategy, the final EA, and written responses to comments received on the EA to the Board for consideration.

To the extent that the proposals in the SLCP Reduction Strategy result in regulatory action, each proposed regulation will be subject to its own public process with workshops, opportunities for stakeholder discussion, consideration of environmental justice, and legally required analyses of the economic and environmental impacts.

While this Proposed Strategy is intended to be comprehensive, it is not exhaustive. We will continue to pursue new cost-effective programs and measures as technology and research on SLCP emission sources and potential mitigation measures advances. Effectively implementing this Proposed Strategy will require working with local, regional, federal and international partners, and diligently investing time and money to overcome market barriers that hinder progress. The extent to which we do so will drive results, which can include a wide range of significant economic and environmental benefits for California broadly, and many of the State's most disadvantaged communities, specifically.

Appendix B: Economic Analysis

ECONOMIC ANALYSIS

A. Summary of Proposed Costs and Impacts

The proposed Regulation for the Reduction of Greenhouse Gas Emission Standards from Crude Oil and Natural Gas Facilities (proposed regulation) is intended to reduce GHG emissions from oil and gas production, processing, storage and transmission compressor stations. The economic impacts of the proposed regulation are discussed in this section, and include impacts and benefits to businesses, individuals, and government agencies. This section also includes a discussion of the estimated cost of the proposed regulation and an analysis of alternatives.

The proposed regulation increases costs on the complying industries, which are primarily involved with oil and gas extraction, and natural gas storage and transmission. These industries, referred to as primary industries, pay for control equipment and services from secondary industries but may also achieve operational cost savings through recovery of natural gas captured by the proposed control strategies. ARB estimates the proposed regulation will cost about \$23 million dollars per year, or about \$14 million per year without the Monitoring Plan, and is expected to reduce GHG emissions by about 1.5 Million MT CO₂e per year on a 20 year horizon. However, considering the size and diversity of the California economy, the economic impacts of the proposed regulation on the California economy are negligible, including the impact on growth of employment, investment, personal income, and production.

B. Major Regulations

For a major regulation proposed on or after January 1, 2014, a Standardized Regulatory Impact Assessment (SRIA) is required. A major regulation is one “that will have an economic impact on California business enterprises and individuals in an amount exceeding fifty million dollars (\$50,000,000), as estimated by the agency.” (Govt. Code Section 11342.548) Further, the Health and Safety Code Section 57005(b) defines a “major regulation” as any regulation that will have an economic impact on the state’s business enterprises in an amount exceeding ten million dollars (\$10,000,000), as estimated by the board, department, or office within the agency proposing to adopt the regulation in the assessment required by subdivision (a) of Section 11346.3 of the Govt. Code.

When amortized, the proposed regulation will cost \$23 million per year; however, the largest expenditures will be in 2018 when most of the capital equipment is expected to be purchased. This upfront cost is estimated to be over \$40 million in direct costs in 2018, resulting in an overall economic impact of over \$50 million. Due to the estimated economic impact of compliance exceeding \$50 million in a 12 month period during 2018, the proposed

regulation was determined to be a major regulation and required a SRIA. A SRIA was submitted to the Department of Finance (DOF) in April 2015. On May 28, 2015, ARB received a letter from the DOF acknowledging the status of a major regulation, and commenting on the information presented in the SRIA. These comments are addressed at the end of this Appendix.

Since the submittal of the SRIA, the proposed regulation has undergone several changes. In addition to changes in the standards, there have been changes to the methodology of estimating the cost and emissions for provisions of the proposed regulation due to the availability of updated data and feedback from industry representatives and other stakeholders. Although these changes have been made after the submittal of the SRIA, staff believes the conclusions of the SRIA continue to be accurate, since the overall annual cost, emissions, reductions, and impacted industries are similar.

In addition to changes made to the standards of the proposed regulation, ARB is now using the 20 year AR4 value (72) of GWP for methane instead of the 100 year AR4 value (25) to determine the reductions in CO₂e. The use of GWPs with a time horizon of 20 years better captures the importance of the short lived climate pollutant (SLCP) and gives a better perspective on the speed at which SLCP emission controls will impact the atmosphere relative to CO₂ emission controls. Also, the value assigned to natural gas saved changed from \$4.10 per mscf to \$3.44 per mscf. This value was changed to reflect the most recently available data and is the average wholesale price that is specific to California over the last 12 months of available data, from November 2014 to October 2015 (EIA, 2016). Also, the compliance dates for the regulation have changed from starting January 1, 2017, to starting January 1, 2018.

In addition to the changes discussed above, some of the methodologies of estimating the potential costs and emissions have changed. This is due to the availability of better data, stakeholder comments, as well as the continued development of the proposed regulation. These changes are described in detail below. All SRIA emissions use a GWP of 25, and all current emissions use a GWP of 72 in the descriptions.

1. Changes from SRIA by Category

a) Reciprocating Compressors

In the SRIA version of the proposed regulation, all reciprocating compressors would need to replace a rod packing after three years of use. In the current version of the proposed regulation, compressors at production facilities are no longer subject to a rod packing leak standard, but instead are required to meet an LDAR standard. Many of the compressors at production facilities are smaller, may be portable, and handle a different composition of gas than compressors

at processing, storage or transmission facilities. Also, most of the available data concerning leak rates and rod packing cost and performance are from larger compressors that are typically not found at production facilities. The provision to exclude production type compressors eliminated over 600 of almost 1000 compressors from this segment, for determining cost and emissions. In addition, industry provided data on the leak rate by compressor for a large subset of the remaining compressors. This new data was used in place of the emission factors previously used. With the reduction in number of compressors, the change from a time based standard to a performance based standard, and using measurement data instead of emission factors, the estimated reduction of emissions has changed from 143,000 MT CO₂e to about 68,000 MT CO₂e. Based on the decrease of compressors potentially impacted by the standard for rod packing leaks, the estimated cost of compliance has decreased from about \$600,000 per year to about \$260,000 per year.

b) Centrifugal Compressors

In the SRIA version of the proposed regulation, twenty five centrifugal compressors with wet seals were anticipated to need a vapor recovery system or to be converted to a dry seal. In an effort to verify this data from ARB's 2009 Oil and Gas Industry Survey (ARB, 2013), staff contacted the facilities that would be impacted by this provision in the proposed regulation. All centrifugal compressors, except for one, were reported with wet seals in error, are no longer in use, have been replaced with a compressor with a dry seal, or now have a vapor recovery system installed to control emissions. In addition, measurement data taken directly from this single compressor was used in place of the emission factors used to generate the emissions and reductions for the SRIA. Due to the updated number of impacted units, the emissions dropped from about 20,000 MT CO₂e to about 3,700 MT CO₂e and the reduction estimates dropped from about 11,000 MT CO₂e to about 3,500 MT CO₂e. The associated cost of compliance decreased from about \$375,000 per year to about \$6,000 per year.

a) Leak Detection and Repair (LDAR)

In the SRIA version of the proposed regulation, the emissions did not include a small percentage of super emitter components, which are responsible for the majority of emissions. In addition, the LDAR program was changed from an annual inspection to a quarterly inspection requirement. These changes were made to address stakeholder comments, and ensure emissions were determined with the best available data. The estimated emissions reduction has

changed from about 1,200 MT CO₂e to about 590,000 MT CO₂e, and the estimated cost has changed from about \$2 million per year to about \$10 million per year.

b) Pneumatic Devices

At the time of the SRIA, all continuous bleed pneumatic devices were required to change to a low bleed pneumatic device. Based on stakeholder feedback, this has been changed to require a no bleed pneumatic device in the current proposed regulation to maximize emission reductions with no increased cost. Also, after a review of the data, the count of continuous bleed devices was overestimated by about 170. The anticipated emissions reduction from this segment have changed from about 124,000 MT CO₂e to about 320,000 MT CO₂e, and the estimated cost has changed from about \$1.3 million per year to about \$1.2 million per year.

c) Tank and Separator Systems

The provisions for tank and separator systems have changed from requiring a vapor recovery system for all uncontrolled systems, to require vapor recovery and comply with a NO_x emission standard, but only for uncontrolled systems that are anticipated to have over 10 MT per year of CH₄ emissions. Due to this change, the estimated number of systems impacted changed from over 600 to about 300. It is now assumed that a low NO_x incinerator will be used to comply with the NO_x emission standard in place of a flare. The emissions are now calculated with the throughput to the separators instead of reported emissions from the 2009 Survey. The estimated emissions reductions have changed from about 252,000 MT CO₂e to about 540,000 MT CO₂e. The estimated cost has changed from about \$16 million per year to about \$4.7 million per year.

d) Well Stimulations

The current proposal uses emission factors from WSPA (WSPA, 2015) to estimate emissions from well stimulations. These emission factors became available after the submittal of the SRIA when the best available data projected much greater emissions. The estimated emissions reduction from this segment of the proposed regulation has changed from about 24,400 MT CO₂e to about 5,000 MT CO₂e. The estimated cost has changed from about \$200,000 per year to about \$460,000 per year due better cost data becoming available and inclusion of additional compliance equipment in the current Proposed Regulation.

e) Liquids Unloading

The requirement for controls for liquids unloading were removed for the proposed regulation, and replaced with a reporting requirement. The estimated reductions of about 350 MT CO₂e have been eliminated, and the expected cost of \$450,000 per year has been replaced with a cost of about \$6,000 for recordkeeping, reporting and other administrative tasks.

f) Monitoring Plan

The proposed regulation now includes a requirement for operators of natural gas underground storage facilities to follow a Monitoring Plan, which includes daily monitoring of natural gas storage wells, and continuous ambient air monitoring. This was not included in the SRIA version of the proposed regulation. The cost for the Monitoring Plan is estimated to be about \$8.7 million per year.

C. Summary and Interpretation of the Results of the Economic Impact Assessment

The proposed regulation encourages the use of more efficient and potentially cost-saving technology to ensure maximum production of natural gas. Much of the capital equipment purchased, such as vapor recovery for tanks, have lifetimes that far exceed the pay-off period. Though at some point the primary industries no longer are making payments for the capital required for compliance, they continue to enjoy the natural gas savings that are provided by that capital. Therefore the primary industries, oil and gas extraction and natural gas distribution, are required to make minor changes to their production facilities, these modifications include increases in efficiency. Secondary industries face increased product demand, resulting in increased output and employment in those industries.

The proposed regulation was analyzed using generally high estimates and GHG emission reduction estimates, thus the analysis may serve as an upper bound of anticipated impacts. To the extent there are greater cost savings due to increased product capture, the economic impacts of the proposed regulation would be less negative in all years, and likely show a benefit to the economy. This result would persist in later years and the primary industries, having made a large initial investment in the capital necessary to prevent substantive leaks, would continue to see savings long after the payments for the capital are finished.

The proposed regulation is unlikely to significantly impact California's economy, including the growth of employment, investment, personal income, output, and GSP does not represent a significant change from Business as Usual (BAU).

D. Benefits

The proposed regulation is anticipated to deliver environmental benefits that include an estimated annual reduction in GHG emissions, beginning in 2018, of about 1.5 million MT CO₂e per year from oil and gas related operations in California. In addition, the proposed regulation is expected to save primary industries about 800 million standard cubic foot (scf) per year of industrial natural gas through reductions of leaks and vapor recovery systems¹. This will result in a savings of about \$3 million per year, assuming the value of this gas is \$3.44 per Mscf. The cost per ton of the proposed regulation is estimated to be approximately \$15 per MT CO₂e reduced. These estimates use the 20-year GWP for methane (i.e., 72) from the Intergovernmental Panel on Climate Change's (IPCC) Fourth Assessment Report (AR4).

Reducing SLCPs, such as methane, can produce near term results that deliver immediate and tangible climate, air quality, economic, and health benefits while longer-term changes are being implemented.

The proposed regulation is expected to provide co-benefits of reductions in emissions of VOCs and toxic air contaminants that are emitted from uncontrolled oil and water storage tanks and released from well stimulation circulation tanks. The estimated reduction in VOCs is approximately 3,630 tons per year, or about 10 tons per day statewide. There was the potential for NO_x increases for vapor recovery units if the facility used a flare. Since ARB is requiring a NO_x standard in these cases, the tank measure provides a benefit of 1.6 tonnes per year but there are NO_x impacts from LDAR, leading to an overall impact that is neutral for the state as a whole. Table B-1 summarizes reductions of all pollutants, and detailed calculations are in Appendix D.

¹ This assumes gas is 94.9% CH₄.

Table B-1. Summary of Non-GHG Pollutant Reductions

| Category | Total Hydrocarbons | VOCs | Benzene | Toluene | Ethyl-Benzene | Xylenes | NOx |
|--|--------------------|--------------|-----------|-----------|---------------|-----------|--------------------|
| Vapor collection on uncontrolled oil and water separators, tanks, and sumps with emissions above a set methane standard ¹ | 10,458 | 1,362 | 23 | 11 | 1.7 | 8.5 | 1.6 |
| Control of vapors from uncontrolled well stimulation circulation tanks | 96 | 12 | 0.2 | 0.1 | <0.1 | <0.1 | <0.1 |
| Leak Detection and Repair (LDAR) on components, such as valves, flanges, and connectors currently not covered by local air district rules | 9,698 | 1,264 | 22 | 10 | 1.5 | 7.9 | (1.6) ² |
| Inspection and repair requirements for reciprocating natural gas compressors | 1,318 | 172 | 3.0 | 1.4 | 0.21 | 1.1 | NA |
| Vapor collection of centrifugal compressor wet seal vent gas, or replacement of higher emitting "wet seals" with lower emitting "dry seals" | 68 | 9 | 0.2 | <0.1 | <0.1 | <0.1 | NA |
| Replacement of pneumatic pumps, and replacement or retrofitting of pneumatic devices under certain circumstances | 6,199 | 808 | 14 | 6.5 | 1.0 | 5.0 | NA |
| TOTAL (benefits from proposed regulation) | 27,837 | 3,627 | 62 | 29 | 4.6 | 23 | (<0.1) |
| ¹ All estimated emission reductions from this category are occurring in the San Joaquin Valley Air Basin. ² ARB estimates that increased LDAR will result in increased NOx from vehicle emissions by 1.6 tons/year. | | | | | | | |

1. Benefits to Individuals

The proposed regulation will not directly affect individual consumers; however, as a result of the anticipated decrease in methane emissions, VOCs, and other toxic air contaminants, the proposed regulation will provide health and climate benefits.

Like emissions of other GHGs, emissions of methane due to human activities (anthropogenic emissions) have increased markedly since pre-industrial times. Of the GHGs emitted as a result of human activities, methane is the second most important GHG after carbon dioxide (CO₂), accounting for 14 percent of global GHG emissions in 2005. Though methane is emitted into the atmosphere in smaller quantities than CO₂, its global warming potential (i.e., the ability of the gas to trap heat in the atmosphere) is 72 times that of CO₂, resulting in methane's stronger influence on warming during its atmospheric life time.²

Emissions reductions of GHGs, VOCs and other pollutants have been correlated with a reduction in the risk of premature deaths, hospital visits, and a variety of other health impacts, especially in sensitive receptors including children, elderly, and people with chronic heart or lung disease. Methane is a contributor to ground level ozone, and cutting methane emissions reduces smog, which is associated with higher rates of asthma attacks. Ozone affects respiratory health, crop productivity, and ecosystems, and recent studies have shown substantial evidence that ozone influences premature mortality.³⁴

2. Benefits to California Businesses

The proposed regulation requires the oil and gas industry to purchase, retrofit, and service capital equipment. The requirements of the regulation would increase the demand for these services and increase business opportunities for secondary industries both within and outside of California. Additionally, the proposed regulation is designed to reduce industrial natural gas leakage, which will result in cost savings for the regulated parties. For example, many of the proposed control strategies are designed such that natural gas can be recovered and either used on site as energy or captured for sale. These savings are estimated to be about \$3 million per year. While the primary industries are not small businesses, some of the secondary industries contain small businesses. If these businesses were able to meet

http://www.htap.org/meetings/2006/2006_01/posters/West_methane.pdf

the increased demand and provide the capital equipment and services to the primary industries for compliance, small businesses would see increased demand, output and, likely, employment.

ARB estimates that more than \$25 million each year will be spent on control equipment and inspection services. This includes over \$10 million to comply with the LDAR provisions in the proposed regulation, and over \$8 million to comply with the Monitoring Plan. Companies involved in LDAR inspections may see an increase in business or expansion. In areas of the state that previously did not have an inspection program, there will be new demand for a previously unneeded service, which may result in new businesses being created.

In areas without existing VOC based regulations for LDAR or higher pressure natural gas systems, LDAR is likely to be more cost effective. In addition, we believe that with the advent of newer technologies, the efficiency of LDAR inspections will improve.

While direct costs to the primary industries exceed \$40 million in the first year of implementation, these industries achieve savings of about \$3 million annually from leakage prevention strategies within the proposed regulation. Secondary industries also achieve benefits, as demand for their equipment, services, or other products such as natural gas increases yielding positive economic benefits.

3. Costs per Ton

Table B-2. Summary of Cost, Emissions, and Cost per Ton

| Provision | Annual Cost | Annual Savings | Reductions (MT CO2e) | Cost per Ton (\$ / MT CO2e reduced) | Cost per Ton with Savings (\$ / MT CO2e reduced) |
|---------------------------|---------------------|--------------------|----------------------|-------------------------------------|--|
| VRU for Tanks | \$4,700,000 | \$500,000 | 540,000 | \$ 9.00 | \$ 8.00 |
| Reciprocating Compressors | \$260,000 | \$180,000 | 68,000 | \$ 4.00 | \$ 1.00 |
| LDAR | \$10,000,000 | \$1,500,000 | 590,000 | \$ 17.00 | \$ 14.00 |
| Pneumatic Devices | \$1,200,000 | \$840,000 | 319,000 | \$ 4.00 | \$ 1.00 |
| Well Stimulations | \$460,000 | \$0 | 5,000 | \$ 91.00 | \$ 91.00 |
| Centrifugal Compressors | \$6,000 | \$9,000 | 3,500 | \$ 2.00 | \$ (1.00) |
| Monitoring Plan | \$8,700,000 | \$0 | 0 | - | - |
| Total | \$25,400,000 | \$3,000,000 | 1,500,000 | \$17.00 | \$15.00 |

All Figures are in 2015 dollars

E. Direct Costs

1. Direct Costs on Individuals

For 2017, the baseline projected outputs for oil and gas extraction and natural gas distribution industries are approximately \$25 billion and \$19 billion respectively. The ratio of compliance cost to total output is less than 0.5 percent for both industries, making pass-through of costs unnoticeable. However, to the extent that any potential costs are passed on to individual consumers, minor increases in the price of natural gas and electricity may occur.

2. Direct Costs on Typical Businesses

Any business involved with crude oil or natural gas extraction, natural gas storage, crude oil processing excluding refineries, natural gas processing (including gas plants), crude oil tank farms (excluding tank farms at refineries), or transmission of natural gas will potentially be impacted by the proposed regulation. In February 2009, ARB conducted an Oil and Gas Industry Survey for crude oil and natural gas production, processing, and storage facilities in California (ARB, 2013). The survey was completed by 325 companies representing over 1,600 facilities and approximately 97 percent of the 2007 crude oil and natural gas production in California. Out of these companies, 272 companies that responded to the survey are expected to be impacted by the provisions in our proposed regulation.

ARB estimates the direct cost to industry for the proposed regulation to be approximately \$25.4 million per year. This includes the amortized cost of capital equipment, and annual costs for labor, maintenance, reporting and recordkeeping. ARB generally used high estimates throughout for estimating emissions, costs, and reductions. The average impact each of the 272 businesses is expected to be about \$100,000 per year. The typical businesses are not small because the primary industries are ineligible to be classified as small under government code.⁵ Therefore, the increased costs on industry do not directly impact small businesses.

3. Cost Analysis

This section describes the sources and methodology to determine the emissions, cost, and cost per ton of our proposed regulation. In general, for each segment of the regulation, staff identified the number of devices affected, estimated the cost to comply with the regulatory provisions, estimated emissions and reductions, and accounted for any savings to be included in the cost per ton. The methodology to determine these items for each segment of the regulation is described below.

The indirect costs and economic impacts were modeled using a computational general equilibrium model of the California economy known as Regional Economic Models, Inc. (REMI). The REMI model generates year-by-year estimates of the total regional effects of a policy or set of policies. These results and analysis are included with the SRIA in Attachment E. The results helped evaluate the impact of the proposed regulation on California's economy, including business impacts, job creating, and impacts to

⁵ California Government Code Section 11342.610(b). 2016. <http://www.leginfo.ca.gov/cgi-bin/displaycode?section=gov&group=11001-12000&file=11342.510-11342.610>

individuals. Finally, alternatives to the proposed regulation were evaluated and fiscal impacts to ARB and local air districts were estimated.

The cost estimate of the proposed regulation follows guidelines recommended by the California Environmental Protection Agency (Cal/EPA), and is consistent with the methodologies used in previous cost analyses for ARB regulations (ARB, 1999; ARB, 2000; ARB, 2004; ARB, 2005; ARB, 2007). The segments analyzed for this proposed regulation include control strategies for reciprocating compressors, centrifugal compressors, oil and water separators and storage tanks, pneumatic devices, circulation tanks for well stimulations, and a leak detection and repair (LDAR) program. Information from the 2009 Survey, of which parts were later updated by staff to account for changes since 2009, was used to form the basis of the number and types of facilities potentially impacted, number and types of equipment, and estimated emissions reduction from the standards in the proposed regulation. After the number and types of equipment impacted were identified, the direct cost to industry was estimated for each component of the regulation. Sources of data include ARB's 2009 Survey, ICF's Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries (ICF Report), EPA documents including their Gas Star Program, industry groups, and communications with operators of potential control equipment, and other stakeholders.

4. Methodology

One-time costs, such as the cost for purchasing capital equipment, are amortized to reflect that businesses generally do not pay the total cost up front, and allows for annual cost to be compared to an annual emission reduction. The Capital Recovery Method for amortizing fixed costs is recommended by Cal/EPA guidelines (Cal/EPA, 1996). This method of amortizing a fixed cost was used for all capital costs of equipment, installation, and costs of testing.

The CRF is calculated as follows:

$$CRF = \frac{i(1+i)^n}{(1+i)^n - 1}$$

where,

CRF = Capital Recovery Factor

I = discount interest rate (assumed to be 5%)

n = project horizon or useful life of equipment

With regard to the discount rate, Cal/EPA recommends 2 percent plus the current yield for a U.S. Treasury Note of similar maturity to the project horizon and adjusted for inflation (Cal/EPA, 1996). The primary rationale for using a real discount rate of five percent is that it is equivalent to rate of return on an inflation-adjusted 10-year treasury security, (about 2 percent in the past five years) , plus the California Environmental Protection Agency recommended 3 percent risk premium. The five percent real discount rate has been used for several recent ARB regulations, and follows guidelines for economic analysis in the AB 32 Scoping Plan (ARB, 2010b). Additionally, the five percent is the average of what the US Office of Management and Budget recommends (7 percent) and what US Environmental Protection Agency has used historically for regulatory analysis.

The project horizon was chosen to reflect the expected equipment lifetime, and is based on the amortization period used by ICF when applicable (ICF, 2015). In cases when cost estimates were outside of the scope of the ICF report, the equipment lifetime is based on communications with equipment manufacturers. These values and the calculated capital recovery factors are summarized in Table B-3.

Table B-3. Equipment Lifetime and Capital recovery Factor for Control Equipment

| Equipment | Amortization Period | Capital recovery Factor |
|--|---------------------|-------------------------|
| Rod Packing for Reciprocating Compressors | 3 | 0.367 |
| Vapor Recovery for Centrifugal Compressors | 10 | 0.130 |
| No Bleed Pneumatic Devices | 7 | 0.173 |
| Vapor Recovery Equipment for Tanks and Well Stimulations | 10 | 0.130 |
| Gas Separator for Well Stimulation | 10 | 0.130 |
| Monitoring Plan Equipment | 10 | 9.130 |
| Flash Test ⁶ | 3.3 | 0.333 |

⁶ Flash tests are required on uncontrolled tank and separator systems, and controlled systems with uncontrolled water tanks every year for the first three years, and once every five years thereafter. Over 20 years, tests are conducted on average every 3.3 years.

This capital recovery factor was multiplied by all non-recurring costs, including capital costs for equipment and installation, and testing costs. This value was added to the total ongoing costs, such as labor, maintenance, recordkeeping, and fuel costs to determine the total cost per year.

$$\text{Total Cost per Year} = \text{Annualized Nonrecurring Costs} + \text{Annual ongoing Costs}$$

Where,

$$\text{Annualized Nonrecurring Costs} = \text{CRF} \times \sum (\text{Nonrecurring Costs})$$

$$\text{Annual Ongoing Costs} = \text{Labor Costs} + \text{Maintenance Costs} + \text{Fuel Costs}$$

The emissions were calculated from a combination of emission factors, survey data, and other data provided by stakeholders. There are two primary methods used to determine emissions based on the available data. The first method to determine emissions involves converting a volume of gas into a mass of CO₂e. This method was used for calculating emissions from reciprocating compressors and, centrifugal compressors. Combining this method with the appropriate conversion factors yields a mass of methane from cubic feet of gas. To perform these calculations, the following conversion factors and equations were used.

$$\text{Mass of Methane (kg)} = \frac{\text{Volume of Methane (scf)} \times \text{Molar Mass of Methane}}{\text{Conversion Factor}}$$

$$\text{Emission Reductions in MT CO}_2\text{e} = \frac{\text{Mass of Methane (kg)} \times \text{GWP}}{1000}$$

where,

$$\text{Conversion Factor} = 836.2 \text{ scf/kg mol (API, 2009)}$$

$$\text{Molar Mass of Methane} = 16.04 \text{ kg/k mol}$$

$$\text{kg} = 1000 \text{ g}$$

$$\text{Metric Ton (MT)} = 1000 \text{ kg}$$

$$\text{Global Warming Potential (GWP) of Methane} = 72$$

Additional factors used include:

$$\text{Mole Percentage of Methane in Gas from Production} = 78.8\% \text{ (API, 2009)}$$

Cubic meter = 35.13 scf

The second method to determine emissions from a given segment was to use an emission factor. These emission factors expressed emissions in either the mass of methane emitted per equipment device per unit of time for the LDAR, tank and separator systems, and pneumatic devices segments (CAPCOA, 1999; API, 2004; API, 2009), or MT CO₂e per event (WSPA, 2015) for well stimulations. Again combining this with the appropriate emission factors yields total mass of methane and CO₂e.

Emissions = Emission Factor X Number of Devices X Usage per Year

The reciprocating compressors, centrifugal compressors, LDAR, pneumatic devices and portions of the vapor recovery for tank and separator systems segments of the proposed regulation would have a corresponding increase in product with the decrease of leaks or emissions. The value of the gas saved under these segments was counted as a cost savings as a result the standards imposed by the proposed regulation. Since only the reciprocating compressors, centrifugal compressors, and pneumatic pumps had emissions that were calculated directly from a volume of gas, it is convenient to back calculate a volume of gas from the mass of CO₂e since this value is shared across all segments. In a similar fashion to how mass of CH₄ was determined from a volume of gas, the volume of gas saved was determined from the mass of CH₄.

$$\text{Volume of Methane (scf)} = \frac{\text{MT CO}_2\text{e} \times \text{Conversion Factor}}{\text{Molar Mass of Methane} \times \text{GWP} \times 1000}$$

Where,

Conversion Factor = 836.2 scf/kg mol (API, 2009)

Molar Mass of Methane = 16.04 kg/kg mol

Global Warming Potential (GWP) of Methane = 72

Metric Ton (MT) = 1000 kg

Savings were calculated using price data obtained from the U.S. Energy Information Administration (EIA). We chose to use the average wholesale price for the period of November 2014 to October 2015. This represents the cost of gas that a utility would pay to a producer. Since this gas has higher methane content than what is typical of gas in production, this volume was

converted into an equivalent volume of gas with a composition of 94.9% CH₄ gas (EPA, 2011; PG&E, 2016).

$$\text{Volume of Gas (scf)} = \frac{\text{Volume of CH}_4 \text{ (scf)}}{.949}$$

The value of this volume of gas was determined by using the average wholesale price for California from November 2014 to October 2015 (EIA, 2016), or \$3.44 per mscf.

The cost per ton is the ratio of total dollars to be spent to comply with the standard (as an annual cost) to the mass reduction of the pollutant to be achieved by complying with that standard. In this case, we calculated the cost per ton both with and without including savings.

$$\text{Cost Per Ton} = \frac{\text{Total Cost per Year (\$)}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

$$\text{Cost Per Ton with Savings} = \frac{\text{Total Cost per Year (\$)} - \text{Savings per Year}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

The cost, emissions, savings, and cost per ton for each segment are described in detail below.

5. Recordkeeping

To comply with the proposed regulation, several provisions have recordkeeping and reporting requirements. This includes 799 facilities that are required to keep records of inspection and repair for the LDAR provisions, flash tests for 1,065 tank and separator systems, 93 liquids unloading operations that are required to keep records, 255 facilities with well casings for heavy oil production, and leak records for 979 reciprocating compressors. The recordkeeping and reporting requirements impact 272 businesses. For each of the businesses impacted, an annual report to ARB was estimated to cost \$144, or take 3 hours at \$48 per hour. A Recordkeeping event, or keeping inspection and repair records for LDAR, a flash test, a liquids unloading calculation, or a recording of a leak rate for reciprocating compressors was assigned a cost of \$48. These estimated costs of recordkeeping and reporting are in line with costs used with EPA's recordkeeping cost estimate for their proposed emission standards in the oil and natural gas sector (EPA, 2015). The total estimated cost for recordkeeping and reporting is about \$330,000 per year.

F. Vapor Recovery for Separator and Tank Systems Provision

Under the proposed regulation, systems that are currently uncontrolled and emit greater than 10 metric tons per year of methane would be subject to vapor recovery requirements.

To determine the cost and emissions from tank and separator systems, we used the ICF report, industry information, ARB's 2009 Survey, and EPA's GasSTAR Document "Installing Vapor Recovery Units on Storage Tanks" (EPA, 2006b).

According to ARB's 2009 industry survey, there are 1150 uncontrolled tank and separator systems. Of these, 317 systems at 19 facilities had emissions greater than 10 TPY of methane. Twenty six of these systems had no vapor recovery systems, and 291 had only an uncontrolled water tank.

1. Cost of the Vapor Recovery for Tanks and Separators Provision

The separator and tank systems subject to vapor recovery will need to install systems and if the gas is being routed to an existing or new combustion device, that device must meet a NO_x standard if the facility is located in a non-attainment area. Using data from ARB's survey, there are anticipated to be no new combustion devices and all impacted existing flares are expected to be in San Joaquin Valley non-attainment area.

Therefore, at each facility routing to a flare, it is anticipated that the current flare would need to be replaced by a low-NO_x incinerator.⁷ As a conservative assumption, we chose the smallest flare to be replaced. The incinerators we chose for our cost estimate range in price from \$160,000 to \$295,000, depending on size, and can operate with a capacity of up to 380,000 scf per day (Aeron, 2015a). We chose an appropriate size for each facility based on separator throughput from our survey data. It should also be noted that, through follow-up contacts, one facility was determined to be at three separate and unconnected locations, so each location would need its own incinerator and removal of a flare. Once the total throughput per day was determined, an appropriately sized incinerator was chosen from Table B-4 below. In some cases, a single facility reported to our survey was located in different physical locations. In these instances, each of the physical locations was treated as a separate facility for purposes of determining the correct size of incinerator, flare removal, and throughput.

$$\text{Throughput per Day (scf)} = \frac{\text{Volume from Newly Captured Emissions per Day} + \text{Throughput of Smallest Flare per Day}}{\text{Throughput of Smallest Flare per Day}}$$

⁷ A low NO_x incinerator is one option for meeting the NO_x standard. It is considered the most likely compliance route.

$$\begin{aligned} & \text{Volume of Newly Captured Emissions per Day (scf)} \\ &= \frac{\text{Total CH}_4 \text{ Emissions (MT)} \times \text{Conversion Factor} \times 1,000}{\text{Molar Mass of CH}_4 \times \text{CH}_4 \text{ Composition} \times 365} \end{aligned}$$

Where,

Conversion Factor = 836.2 kg/ k mol (API, 2009)

Molar Mass CH₄ = 16.04 (API, 2009)

CH₄ Composition = 78.8% (API, 2009)

Volume to Incinerator from Smallest Flare (scf/day)

$$= \frac{\text{Annual Throughput} \left(\frac{\text{scf}}{\text{year}} \right)}{365 \frac{\text{days}}{\text{year}}}$$

Table B-5 summarized the data used to choose an appropriately sized incinerator for the facilities that need to replace an existing flare. The production of one of the facilities was spread across three different locations, and this was taken into account when determining throughput for the 11 systems that would need incinerators at 9 facilities.

Table B-4. Incinerators for Tank and Separator Systems

| Uncontrolled Systems | | | | |
|---------------------------------|----------------------------------|--|------------------------------------|-----------------------------------|
| Total # of Systems | Number of Systems w/o VRS | Flare Throughput of smallest flare on site (scf/yr) | Total CH4 Emissions (MT/yr) | Total Throughput (scf/day) |
| 22 | 19 | 1,825,000 | 413.06 | 79,869 |
| 1 | 1 | 2,107,083 | 18.81 | 9,183 |
| 2 | 2 | 375,945 | 30.44 | 6,547 |
| Uncontrolled Water Tanks | | | | |
| Total # of Systems | # of Systems w/o VRS | Flare Throughput of smallest flare on site (SCF) | Total CH4 Emissions (MT/yr) | Total Throughput (scf/day) |
| 12 | 0 | 482,681 | 1372.92 | 250,169 |
| 14 | 0 | 5,660,000 | 1028.16 | 201,865 |
| 60 | 0 | 42,558,000 | 1788.00 | 440,679 |
| 3 | 0 | 48,298,000 | 76.65 | 146,216 |
| 1 | 0 | 6,780,000 | 10.40 | 20,460 |
| 3 | 0 | 31,023,000 | 46.68 | 93,455 |

Data from ARB's 2009 Survey

Table B-5. Incinerator Costs

| Operating Capacity | Capital Cost | Installation Cost | Number Required |
|---------------------------|---------------------|--------------------------|------------------------|
| Up to 36,000 scf per day | \$ 160,000 | \$ 80,000 | 6 |
| Up to 270,000 scf per day | \$ 235,000 | \$ 117,500 | 4 |
| Up to 606,000 scf per day | \$ 295,000 | \$ 147,500 | 1 |

Data from equipment manufacturer (Aereon, 2015a)

Once the number of incinerators was estimated, the cost was determined as follows:

$$\text{Cost of Incinerator} = \text{Number of Devices} \times \text{Cost per Device} \times \text{Capital Recovery Factor}$$

Where,

Capital Recovery Factor = 0.130 From Table B-3

Therefore,

Cost of 36,000 scf per day Incinerators = 6 X (\$160,000 + \$80,000) X 0.130 = \$186,480

Cost of 270,000 scf per day Incinerators = 4 X (\$235,000 + \$117,500) X 0.130 = \$182,595

Cost of 606,000 scf per day Incinerator = 1 X (\$295,000 + \$147,500) X 0.130 = \$57,304

Total Annual Cost of Incinerators = \$186,480 + \$182,595 + \$57,304 = \$426,379

In total, ARB estimates 11 flares would need to be removed and replaced with a low NOx incinerator. According to the ICF report, the cost of a flare was estimated to be about \$50,000. We assumed the cost for removing this equipment would be 50% of the capital cost, which is in line with installation costs from EPA's GasSTAR estimates (EPA, 2006b). All costs were amortized over 10 years, which was taken from the period of amortization from the ICF report for vapor recovery units and represents the expected lifetime of equipment.

Cost of Flare Replacement = Number of Flares Replaced X Cost to Replace Flare X Capital Recovery Factor

Where,

Number of Flares Replaced = 11

Cost to Replace Flare = \$25,000 (ICF, 2015; EPA, 2006b)

Capital Recovery Factor = 0.130 From Table B-3

Cost of Flare Replacement = 11 X \$25,000 X 0.130 = \$35,613

All 317 uncontrolled systems above the 10 metric tons per year threshold would need a vapor recovery system. In cases where only the water tank is uncontrolled, the new vapor recovery system for the water tank would route to the existing vapor recovery and control system. For each of these systems, an appropriately sized vapor recovery system was chosen based EPA's GasSTAR estimates (EPA, 2006b). The cost of these vapor recovery

units ranged from about \$20,000 to \$26,000 in capital costs, and about \$15,000 to \$20,000 in installation costs.

Table B-6 shows the emissions and throughput from the facilities that would need to control emissions from water tanks. This data was used to choose an appropriately sized vapor recovery system.

$$\text{Volume of Gas per Day (mscf / day)} = \frac{\text{Crude Water CH}_4 \text{ Emissions (MT/yr)} \times \text{Conversion Factor} \times 1,000 \text{ kg / MT}}{\text{Molar Mass of CH}_4 \times 365 \times \text{Number of Systems} \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}$$

Where,

Conversion Factor = 836.2 kg/ k mol

Molar Mass of CH₄ = 16.04

Table B-6. Emissions and Throughput from Water Tank

| Emissions Total # of Systems | Crude Water CH4 Emissions (MT/yr) | Volume Gas per day (mscf per day) |
|---|--|--|
| 7 | 42 | 0.9 |
| 22 | 204 | 1.3 |
| 19 | 29 | 0.2 |
| 1 | 9 | 1.3 |
| 2 | 15 | 1.1 |
| 9 | 129 | 2.0 |
| 19 | 243 | 1.8 |
| 7 | 83 | 1.7 |
| 12 | 1,373 | 16.4 |
| 14 | 1,028 | 10.5 |
| 1 | 49 | 7.0 |
| 1 | 198 | 28.3 |
| 1 | 21 | 2.9 |
| 52 | 848 | 2.3 |
| 17 | 65 | 0.6 |
| 44 | 821 | 2.7 |
| 60 | 1,788 | 4.3 |
| 25 | 444 | 2.5 |
| 3 | 77 | 3.7 |
| 1 | 10 | 1.5 |
| 22 | 32 | 0.2 |
| 3 | 47 | 2.2 |
| 317 | | |

Data from ARB's 2009 Survey

Once the throughput from water tank emissions was determined, a vapor recovery system was chosen from Table B-7. Most emissions from water tanks had throughput far below the smallest capacity vapor recovery system described in EPA's GasSTAR document "Installing Vapor Recovery on Storage Tanks" (EPA, 2006b).

Table B-7. Vapor Recovery Costs

| Design Capacity | Capital Cost | Installation Cost | Ongoing Costs | Number Required |
|------------------------|---------------------|------------------------------|--------------------------|----------------------------|
| 25 mscf / day | \$ 20,421 | \$15,316 | 7,367 | 316 |
| 50 mscf / day | \$ 26,327 | \$19,745 | 8,419 | 1 |

Data from EPA's "installing Vapor Recovery Units on Storage Tanks." (EPA, 2006b)

The total cost of vapor recovery systems for the water tank emission were determined as follows:

Cost of Vapor Recovery
= Number of Devices X (Cost per Device X Capital Recovery Factor + Ongoing Cost)

Where,

Capital Recovery Factor = 0.130 From Table B-3

Therefore,

Cost of 25 mscf per day Vapor Recovery = 316 X ((\\$20,421 + \\$15,316) X 0.130 + \\$7,367) = \\$3,790,442

Cost of 50 mscf per day Vapor Recovery = 1 X ((\\$26,327 + \\$19,745) X 0.130 + \\$8,419) = \\$14,408

Therefore,

| |
|--|
| <i>Total Annual Cost of Vapor Recovery = \\$3,790,442 + \\$14,408 = \\$3,804,828</i> |
|--|

A flash test of both the oil and water portion is required of all uncontrolled tank and separator systems with greater than either 50 bbl per day oil throughput, or 200 bbl per day of water throughput. This test is required every year for the first three years, then once every 5 years thereafter. The estimated cost for this test is \$560 each for the oil and water portion (OEC, 2016) including travel and sampling. About 1,100 facilities would need to perform this test. To account for variability in testing frequency, these costs are amortized over 3.3 years.

Testing Cost = ((Number of Oil Flash Tests + Number of Water Flash Tests) X \$560) X Capital Recovery Factor

| |
|---|
| <i>Testing Cost = ((1,065 + 1,073) X \$560) X .33 = \$395,102</i> |
|---|

2. Recordkeeping, reporting, and testing costs are estimated as follows:

Recordkeeping and Reporting Cost = Cost of Businesses Making an Annual Report + Cost of Recordkeeping for Tanks and Separators

Where,

Businesses Impacted by Tank and Separator Provision = 72

Cost of Annual Report = \$144

Number of Flash Tests for Recordkeeping = 2,138

Cost of Recordkeeping = \$48

Therefore,

$$\text{Recordkeeping and Reporting Cost} = ((72 \times \$144) + (2,138 \times \$48) \times .33) = \$37,287$$

The total cost of this provision is the sum of the previous parts of the cost estimate.

Total Annual Cost = Annual Cost for Incinerators + Annual Cost for Vapor Recovery + Amortized Cost for Flare Removal + Annual Cost for Recordkeeping and Reporting + Annual Cost for Testing

$$\text{Total Annual Cost} = \$3,804,828 + \$426,379 + \$35,613 + \$37,287 + \$395,102 = \$4,699,209$$

3. Emissions from the Vapor Recovery for Tanks and Separators Provision

To estimate emissions impacts from the implementation of the proposed regulation, staff used data from ARB's 2009 Survey. Staff used the number of separators in the Survey to determine the number of systems⁸ at each facility. Staff then used Western States Petroleum Association (WSPA, 2015) and California Air Resources Board crude and water tank flash data to determine emission factors in metric tons per barrel for methane, volatile organic compounds (VOC), and Benzene, Toluene, Ethylbenzene, and Xylene (BTEX). The emission factors were applied to the system throughputs of crude, water, and dry gas water, giving total methane, VOC, and BTEX emissions per system. The systems that will be subject to the Oil and Gas regulation are systems found to be uncontrolled with methane emissions exceeding 10 metric tons per year. A detailed description of these calculations is included in Appendix D.

⁸ For purposes of this analysis, a system is defined as a separator and associated crude oil and water tanks.

Total emissions from uncontrolled tanks and separators is estimated to be 7,865 MT of CH₄, or 566,005 MT CO₂e using a GWP of 72. Reductions are expected to be 95%, or about 537,705 MT CO₂e.

4. Savings from the Vapor Recovery for Tanks and Separators Provision

Savings are estimated to be about 2,637 MT CH₄, based on the number of facilities that staff anticipates will either route the vapor collected through a collection system or will use it on site to operate a steam generator, or other equipment. Based on data from the 2009 survey, we considered emission reductions at facilities that had a collection system without an active flare, or the ability use the collected gas for an application on site, such as for a steam generator, to go towards savings. Savings are estimated to be \$498,259.

$$\text{Volume of Gas (scf)} = \frac{\text{Mass of CH}_4 \text{ (MT)} \times \text{Conversion Factor}}{\text{Molar Mass of CH}_4 \times .949 \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}$$

Where,

$$\text{Conversion Factor} = 836.2 \text{ kg / k mol}$$

$$\text{Molar Mass of Methane} = 16.04 \text{ (API, 2009)}$$

Therefore,

| |
|---|
| $\begin{aligned} \text{Volume of Gas (scf)} &= \frac{2,637 \text{ MT CH}_4 \times 836.2 \left(\frac{\text{kg}}{\text{k}} \text{ mol}\right) \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}{16.04 \times .949} \\ &= 144,842,833 \text{ scf} \end{aligned}$ |
|---|

$$\text{Value of Gas Saved} = \text{Volume of Gas} \times \text{Cost per mscf}$$

Where,

$$\text{Cost per mscf} = \$3.44 \text{ (EIA, 2015)}$$

$$1 \text{ mscf} = 1,000 \text{ scf}$$

Therefore,

| |
|---|
| $\text{Value of Gas Saved} = \frac{144,842,833 \text{ scf} \times \$3.44}{1000 \text{ scf/mscf}} = \$498,259$ |
|---|

5. Cost per ton of the Vapor Recovery for Tanks and Separators Provision

Cost per ton is estimated to be about \$8.73 per MT CO₂e reduced, or about \$7.80 per MT CO₂e reduced with savings.

$$\text{Cost Per Ton} = \frac{\text{Total Cost per Year (\$)}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

$$\text{Cost Per Ton with Savings} = \frac{\text{Total Cost per Year (\$)} - \text{Savings per Year}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

Where,

$$\text{Total Cost per Year} = \$4,699,209$$

$$\text{Savings per Year} = \$498,259$$

$$\text{Total Emissions Reductions per Year} = 537,705 \text{ MT CO}_2\text{e}$$

$$\text{Cost Per Ton} = \frac{\$4,699,209}{537,705 \text{ (MT CO}_2\text{e)}} = \$8.74 \text{ per MT CO}_2\text{e}$$

$$\text{Cost Per Ton with Savings} = \frac{\$4,699,209 - \$498,259}{537,705 \text{ MT CO}_2\text{e}} = \$7.81 \text{ per MT CO}_2\text{e}$$

G. Reciprocating Compressor Provision

The proposed regulation requires rod packings on reciprocating compressors to be replaced if the leak rate is above 2 scfm per cylinder. This applies to reciprocating compressors located at gathering and boosting compressor stations, natural gas processing plants, underground natural gas storage facilities, and transmission compressor stations.

According to ARB's 2009 Oil and Gas Industry Survey (ARB, 2013), there are 911 reciprocating compressors in the oil and gas sector in California. Also in 2009, ARB conducted a Natural Gas Transmission and Distribution Survey (ARB, 2015) which adds an additional 68 reciprocating compressors at transmission stations for a total of 979 compressors. The reciprocating compressors from the 2009 Survey include all upstream compressors. However, the proposed regulatory requirements vary by location with production compressors not subject

to the 2 scfm per cylinder requirement. In order to separate the production compressors, staff used horsepower as a proxy for location and chose to exclude compressors that were reported to operate at an average load of less than 250 hp. Using this split, staff determined there were 325 compressors that would be subject to the 2 scfm per cylinder standard. This includes all 68 compressors from the transmission and distribution survey. The remaining compressors under 250 hp were assumed to be production field compressors, and are included in the LDAR program.

To estimate the portion of the 325 reciprocating compressors that may be over our proposed standard of 2 scfm per cylinder, staff relied on data provided by industry. . The data included measurements from rod packing vents for 55 reciprocating compressors taken over a four year period. According to the data, about 14% of the measurements indicated a leak rate of over 2 scfm per cylinder. Based on the data, staff estimated that 46 out of 325 non-production reciprocating compressors would have a leak rate of over 2 scfm each year, and would require a rod packing replacement to comply with the proposed regulation. Staff estimated that for each of these 46 compressors, two of the rod packings would need to be replaced to bring the leak rate into compliance. In total, 92 rod packings would need to be replaced each year to comply with the proposed regulation.

1. Costs of the Reciprocating Compressor Provision

According to ICF's "Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries" (ICF, 2014), the cost of replacing a single rod packing on a reciprocating compressor is estimated to be \$6,000. This includes installation. These costs are amortized over a period of three years, which reflects methodology used by ICF, and mirrors EPA's recommended period of replacement of 26,000 hours. The total cost of 92 rod packing replacements at \$6,000 per replacement amortized over three years plus recordkeeping costs is about \$260,000 per year for all businesses, as shown below.

Cost of Rod Packing Replacement
= Number of Devices X Cost per Device X Capital Recovery Factor

Where,

Number of Devices = 92 Rod Packing Replacements per Year

Cost per Device = \$6,000 per Rod Packing Replacement (ICF, 2015)

Capital Recovery Factor = .367 from Table B-3

Therefore,

$$\text{Cost of Rod Packing Replacement} = 92 \times \$6,000 \times 0.367 = \$202,548 \text{ per Year}$$

Businesses are required to keep records of rod packing leak rates, and make an annual report to ARB.

2. Recordkeeping, reporting, and testing costs are estimated as follows:

$$\text{Recordkeeping and Reporting Cost} = \text{Cost of Businesses Making an Annual Report} + \text{Cost of Recordkeeping for Reciprocating Compressors}$$

Where,

$$\text{Businesses Impacted by Reciprocating Compressor Provision} = 55$$

$$\text{Cost of Annual Report} = \$144$$

$$\text{Number of Reciprocating Compressors} = 979$$

$$\text{Cost of Recordkeeping} = \$48$$

Therefore,

$$\text{Recordkeeping and Reporting Cost} = (55 \times \$144) + (979 \times \$48) = \$54,912$$

Total Annual Cost

$$= \text{Cost of Rod Packing Replacement} + \text{Recordkeeping and Reporting Cost}$$

$$\text{Total Annual Cost} = \$202,548 + \$54,912 = \$257,460 \text{ per Year}$$

3. Emissions for the Reciprocating Compressor Provision

Emissions were determined using the reciprocating compressor leak rate data provided by industry. According to the data, the average leak rate for all compressors is about 0.9 scfm per cylinder during pressurized operation, and about 0.45 during pressurized idle and unpressurized states. Data from our Oil and Gas Industry Survey indicates that compressors over 250 hp have an average of 3.45 cylinders and operate an average of 6,546 hours per year. Assuming this gas is 78.8% methane, the total emissions for all reciprocating compressors is estimated to be about 7,000 MT of CH₄, or about 504,000 MT CO₂e using a GWP of 72.

According to the same data from industry, the average leak rate for those compressors emitting more than 2 scfm was about 3 scfm during pressurized operation, and less than 2 scfm during pressurized idle and unpressurized states. This requires the reduction of 1 scfm for the time in pressurized operation to comply with the proposed standard, and calculating reductions

in the same fashion as overall emissions, the reduction from this measure is expected to be about 942 MT of CH₄, or about 68,000 MT CO₂e using a GWP of 72.

Total Volume of Leaked Gas (scfm)
= *Volume Leaked During Pressurized Operation*
+ *Volume Leaked During Pressurized Idle and Unpressurized States*

Volume Leaked
= *Number of Compressors X Cylinders per Compressor X Leak Rate per Cylinder*

Where,

Number of Compressors = 325 (ARB, 2013)

Cylinders per Compressor = 3.45 (ARB, 2013)

Leak Rate per Cylinder in Pressurized Operation = 0.9 scfm

Leak Rate per Cylinder in Pressurized Idle and Unpressurized State = 0.45 scfm

Therefore,

| |
|---|
| <i>Volume Leaked During Pressurized Operation = 325 X 3.45 X 0.9 = 1,009 scfm</i> |
|---|

| |
|---|
| <i>Volume Leaked During Pressurized Idle and Unpressurized State = 325 X 3.45 X 0.45 = 505 scfm</i> |
|---|

Volume of Leaked Gas per Year
= *Volume of Leaked Gas X Minutes per Hour X Hours of Operation per Year*

Where,

Minutes per Hour = 60

Hours of Pressurized Operation per Year = 6,546 (ARB, 2013)

Hours of Pressurized Idle and Unpressurized State per Year = 2,214 (ARB, 2013)

Therefore,

Volume of Leaked Gas per Year during Pressurized Operation (scfm) = 1,009 scfm X 60 minutes/hour X 6,546 hours = 396,343,935 scf per Year

Volume of Leaked Gas per Year during Pressurized Idle and Unpressurized States = 505 scfm X 60 minutes/hour X 2,214 hours = 67,026,082.5 scf per Year

$$\text{Total Volume of Leaked Gas per Year} = 397,615,433 \text{ scf} + 67,026,082.5 \text{ scf} = 463,370,018 \text{ scf}$$

$$\text{Mass of Methane (kg)} = \frac{\text{Volume of Leaked Gas X Composition of Gas X Molar Mass of Methane}}{\text{Conversion Factor}}$$

Where,

Molar Mass of Methane = 16.04 (API, 2009)

Composition of Gas = 78.8% (API, 2009)

Conversion Factor = 836.2 scf/kg mol (API, 2009)

Therefore,

$$\text{Mass of Methane} = 463,370,018 \text{ scf} \times 0.788 \times 16.04 / 836.2 = 7,004,036 \text{ kg CH}_4$$

$$\text{Emissions MT CO}_2\text{e} = \frac{\text{Mass of Methane (kg)} \times \text{GWP}}{1,000 \text{ kg/MT}}$$

Where,

Conversion Factor = 1000 kg / MT

GWP = 72

Therefore,

$$\text{Emissions MT CO}_2\text{e} = \frac{7,004,036 \text{ kg CH}_4 \times 72}{1,000 \text{ kg/MT}} = 504,291 \text{ MT CO}_2\text{e}$$

4. Reductions

The reductions from the provision for reciprocating compressors is estimated to be about 68,000 MT CO₂e. According to our data, the compressors over the proposed standard of 2.0 scfm would only exceed this during pressurized operation, and reductions from pressurized idle or unpressurized states are not accounted for.

Volume Leaked (scfm)

= Number of Compressors X Cylinders per Compressor X Leak Rate per Cylinder

Where,

Number of Compressors = 46

Cylinders per Compressor = 3.45 (ARB, 2013)

Leak Rate per Cylinder Above Standard = 3.0 scfm (PG&E, 2015; Sempra, 2015)

Reduction in Leak Rate to Meet Standard = 1.0 scfm

Therefore,

| |
|--|
| <i>Volume Reduced to Comply with Standard = 46 X 3.45 X 1 = 158.7 scfm</i> |
|--|

Volume of Leaked Gas per Year

= Volume of Leaked Gas X Minutes per Hour X Hours of Operation per Year

Where,

Minutes per Hour = 60

Hours of Pressurized Operation per Year = 6,546 (ARB, 2013)

Therefore,

| |
|---|
| <i>Volume of Leaked Gas per Year = 158.7 scfm X 60 minutes/hour X 6,546 hours = 62,331,012 scf per Year</i> |
|---|

Mass of Methane (kg)

*=
$$\frac{\text{Volume of Leaked Gas X Composition of Gas X Molar Mass of Methane}}{\text{Conversion Factor}}$$*

Where,

Molar Mass of Methane = 16.04 (API, 2009)

Composition of Gas = 78.8% (API, 2009)

Conversion Factor = 836.2 scf/kg mol (API, 2009)

Therefore,

$$\text{Mass of Methane (kg)} = 62,331,012 \text{ scf} \times .788 \times 16.04 / 836.2 = 942,160 \text{ kg CH}_4$$

$$\text{Reductions MT CO}_2\text{e} = \frac{\text{Mass of Methane (kg)} \times \text{GWP}}{1,000 \text{ kg/MT}}$$

Where,

$$\text{Conversion Factor} = 1000 \text{ kg / MT}$$

$$\text{GWP} = 72$$

Therefore,

$$\text{Reductions MT CO}_2\text{e} = \frac{942,160 \text{ kg CH}_4 \times 72}{1,000 \text{ kg/MT}} = 67,836 \text{ MT CO}_2\text{e}$$

5. Savings from the Reciprocating Compressor Provision

The reduction of 68,000 MT CO₂e translates to about 52 million scfm of wholesale quality gas. Reduction in leaks from rod packings directly impact losses from production, and we assume all reductions will count towards savings. Based on data from the U.S. Energy Information Administration (EIA, 2016), we estimate the value of this savings to be \$3.44 per mscf, or about \$178,000.

$$\text{Volume of Gas (scf)} = \frac{\text{Mass of CH}_4 \text{ (MT)} \times \text{Conversion Factor}}{\text{Molar Mass of CH}_4 \times .949 \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}$$

Where,

$$\text{Mass of CH}_4 = 942 \text{ MT}$$

$$\text{Conversion Factor} = 836.2 \text{ kg / k mol}$$

$$\text{Molar Mass of Methane} = 16.04 \text{ (API, 2009)}$$

Therefore,

$$\begin{aligned} \text{Volume of Gas (scf)} &= \frac{942 \text{ MT CH}_4 \times 836.2 \left(\frac{\text{kg}}{\text{k}} \text{ mol}\right) \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}{16.04 \times .949} \\ &= 51,756,415 \text{ scf} \end{aligned}$$

Value of Gas Saved = Volume of Gas X Cost per mscf

Where,

Cost per mscf = \$3.44 (EIA, 2015)

1 mscf = 1,000 scf

Therefore,

$$\text{Value of Gas Saved} = \frac{51,756,415 \text{ scf} \times \$3.44}{1000 \text{ scf/mscf}} = \$178,042$$

6. Cost per Ton of the Reciprocating Compressor Provision

Dividing the cost by the emission reductions results in a cost per ton of about \$3.80 per MT CO₂e reduced. By including savings, the total annual cost of \$257,657 is reduced by \$178,042, for a net cost of about \$80,000 per year. The cost per ton with savings is estimated to be about \$1.17 per MT CO₂e.

$$\text{Cost Per Ton} = \frac{\text{Total Cost per Year (\$)}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

$$\text{Cost Per Ton with Savings} = \frac{\text{Total Cost per Year (\$)} - \text{Savings per Year}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

Therefore,

$$\text{Cost Per Ton} = \frac{\$257,657}{67,836 \text{ MT CO}_2\text{e}} = \$3.80 \text{ per MT CO}_2\text{e}$$

$$\text{Cost Per Ton with Savings} = \frac{\$257,657 - \$178,042}{67,836 \text{ MT CO}_2\text{e}} = \$1.17 \text{ per MT CO}_2\text{e}$$

H. Leak Detection and Repair Provision

The proposed regulation requires facilities to implement a Leak Detection and Repair program (LDAR) on their high-methane use components, and conduct inspections on a quarterly basis. To determine the cost of this segment of the measure, staff estimated the number of components that would be inspected, and estimated the cost of performing these inspections.

To determine emissions and cost for LDAR, staff relied on a number of sources for information. Staff used the ARB's 2009 Survey for the number of components and discussions with LDAR contractors for cost information. Estimates for emissions from this segment are derived from emission factors and 'super leaker' data from CAPCOA's Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities (CAPCOA, 1999). According to ARB's Survey (ARB, 2013), there are about 1,307,831 components that will be affected by our proposed regulation. This includes components for facilities involved in natural gas processing, onshore natural gas production, natural gas transmission compressor stations, and natural gas storage. In addition to these components, reciprocating compressors are also part of the LDAR program for our proposed regulation. This represents 979 compressors according to data from our survey. Additionally, there are 20,485 well casings at heavy oil facilities that will be subject to LDAR inspection. Staff assumed there would be 11 components per compressor subject to the LDAR program and that each well casing would count as a component, so the total amount of components becomes about 1,339,185.

1. Costs of the Leak Detection and Repair Provision

The cost to inspect LDAR components was based on discussions with contractors that perform LDAR inspections and repairs. The per hour cost estimates from contractors for LDAR inspections are summarized in Table B-8. This cost is estimated to be \$60 per hour for labor, and \$1,500 per facility to account for setup costs. In order to derive an annual cost, staff needed to estimate the number of components that could be inspected in an hour. Staff contacted a number of contractors who perform LDAR work and estimated that, on average, about 34 components per hour can be inspected during an eight hour day, when travel and preparation time is accounted for. This also takes into account making a first attempt at a repair if a leak is detected. If accounting only for measurement time, approximately 50 components could be inspected per hour. Following the methodology from the ICF report, the capital cost of larger repairs is not included based upon the assumption that these repairs would need to be made regardless of an LDAR program; because the operator would repair these parts regardless of the LDAR program, the program serves to identify equipment failures sooner, benefiting the operator above and beyond the business as usual.

Table B-8. Estimated Cost from Contractors

| | Estimated Cost per Hour (\$ per hour) |
|--------------|---------------------------------------|
| Contractor 1 | 55 |
| Contractor 3 | 70 |
| Contractor 4 | 62 |

| | |
|----------------|-----------|
| Contractor 5 | 55 |
| Contractor 6 | 50 |
| Average | 60 |

Combining the average inspection rate of 34 components per hour with 2080 work hours per year yields a result of 68,250 components that can be inspected during a person year (PY). Dividing the total number of components, 1,339,185, by the number of components that are able to be inspected in a year, 68,250, yields 19.6, the number of person years needed by our proposed regulation. The total cost is estimated to be \$10 million, and is summarized below.

Cost of LDAR Program

$$= (\text{Number of PY} \times \text{Cost of PY}) + \text{Setup Cost} + \text{Recordkeeping Cost}$$

$$PY = \text{Number of Components} / \text{Components Inspected by One PY}$$

$$\text{Components Inspected by One PY} = \text{Hours per Year} \times \text{Inspection Rate per Hour}$$

Where,

$$\text{Inspection Rate per Hour} = 34$$

$$\text{Labor Hours per Year} = 2,080$$

Therefore,

$$\text{Components Inspected by One PY} = 2,080 \text{ Hours per Year} \times 34 \text{ Components per Hour} = 68,250 \text{ Components per Year}$$

Where,

$$\text{Number of Components} = 1,339,185 \text{ (ARB, 2013)}$$

$$PY = 1,339,185 / 68,250 = 19.6 \text{ PY}$$

$$\text{Annual Cost for a PY} = 2,080 \text{ Hours} \times \text{Hourly Rate}$$

Where,

Hourly Rate = \$60

Annual Cost for a Quarterly Inspection = 2,080 Hours X \$60 per Hour X 4 = \$499,200

Setup Cost = Facilities X Setup Cost X Capital Recovery Factor

Where,

Setup Cost = \$1,500

Capital Recovery Factor = 0.130

Setup Cost = 799 X \$1,500 X 0.130 = \$155,805

2. Recordkeeping, reporting, and testing costs are estimated as follows:

Recordkeeping and Reporting Cost = Cost of Businesses Making an Annual Report + Cost of Recordkeeping for Inspections

Businesses Impacted by LDAR Provision = 201 (ARB, 2013)

Facilities Impacted by LDAR Provision, Including Well Casing Facilities = 1,054 (ARB, 2013)

Cost of Annual Report = \$144

Cost of Recordkeeping = \$48 X 4 = \$192

Therefore,

Recordkeeping and Reporting Cost = (201 X \$144) + (1,054 X \$192) = \$231,505

Therefore,

*Cost of LDAR Program
= (Number of PY X Cost of PY) + Setup Cost
+ Recordkeeping Cost*

Cost of LDAR Program = (19.6 X \$499,200) + \$155,805 + \$231,505 = \$10,181,892

3. Emissions from the LDAR Provision

Emissions were estimated using emission factors from CAPCOA guidelines (CAPCOA, 1999), which also accounted for 'super leaker' components. These are components that leak at a rate several times the rate of what is

expected from a typical component, and make up the majority of emissions^{9,10,11,12}. Several studies that have reported measurements of CH₄ emissions from natural gas production sites share a common observation—the existence of skewed emissions distributions, where a small number of sites or facilities account for a large proportion of emissions. Such skewed distributions can make estimating and attributing emissions more difficult and in turn can impact the effectiveness of emission reduction policies.

Emissions are estimated to be 13,650 MT CH₄ per year, or about 982,827 MT CO₂e using a GWP of 72. According to the ICF report, a quarterly inspection program is expected to reduce emissions by 60%. Reductions for this LDAR program are estimated to be 8,190 MT CH₄ per year, or about 589,680 MT CO₂e per year using a GWP of 72.

Table B-9. Emissions from LDAR Components

| Fugitive source | | | | |
|------------------------------------|-----------------------------|-------------------------------------|------------------------|-------------------------|
| Components <10,000 ppmv | Number of Components | g CH4 per Component per Year | MT CH4 per Year | MT CO2e Per Year |
| Valves | 236,131 | 307 | 72.49 | 5,219.4 |
| Connectors | 870,766 | 105 | 91.43 | 6,583.0 |
| Flanges | 158,486 | 245 | 38.83 | 2,795.7 |
| Open end lines | 692 | 1,288 | 0.89 | 64.2 |
| Pump seals | 2,312 | 1,288 | 2.98 | 214.4 |
| Others (compressors, hatches, etc) | 21,008 | 1,288 | 27.06 | 1,948.2 |

| Components >=10,000 ppmv | | | | |
|------------------------------------|------------------|-----------|---------------|----------------|
| Valves | 5,367 | 1,217,645 | 6,534.64 | 470,494.1 |
| Connectors | 19,790 | 226,884 | 4,490.06 | 323,284.7 |
| Flanges | 3,602 | 480,924 | 1,732.27 | 124,723.2 |
| Open end lines | 16 | 1,208,880 | 19.02 | 1,369.4 |
| Pump seals | 53 | 1,208,880 | 63.53 | 4,574.4 |
| Others (compressors, hatches, etc) | 477 | 1,208,880 | 577.17 | 41,556.5 |
| Total | 1,318,700 | | 13,650 | 982,827 |

Data from ARB's 2009 Survey, and CAPCOA's California Implementation Guide for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities, and API's Fugitive Hydrocarbon Emissions from Oil and Gas Operations. (ARB, 2013¹³; CAPCOA, ARB, 1999¹⁴)

4. Savings from the LDAR Provision

Since gas that is emitted from a leaking component comes directly from the process of production, transmission, processing, or storage, all reductions are counted as savings. Assuming this gas is 94.9 % CH₄, staff estimates that about 450 million cubic feet of gas will be saved with the LDAR program of our proposed regulation. Using a price of \$3.44 per mscf of gas, this results in a savings of about \$1,550,000.

$$Volume\ of\ Gas\ (scf) = \frac{Mass\ of\ CH_4\ (MT) \times Conversion\ Factor}{Molar\ Mass\ of\ CH_4 \times .949 \times 1,000 \left(\frac{mscf}{scf}\right)}$$

Where,

¹³ ARB. 2013. ARB 2007 Oil and Gas Industry Survey Results, Final Report, revised in October 2013.

¹⁴ CAPCOA, ARB. 1999. The California Air Resources Board Staff California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities.

Mass of CH4 = 8,190 MT

Conversion Factor = 836.2 kg / k mol

Molar Mass of Methane = 16.04 (API, 2009)

Therefore,

$$\text{Volume of Gas (scf)} = \frac{8,190 \text{ MT CH}_4 \times 836.2 \left(\frac{\text{kg}}{\text{k}} \text{ mol}\right) \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}{16.04 \times .949}$$
$$= 449,907,765 \text{ scf}$$

Value of Gas Saved = Volume of Gas X Cost per mscf

Where,

Cost per mscf = \$3.44 (EIA, 2015)

1 mscf = 1,000 scf

Therefore,

$$\text{Value of Gas Saved} = \frac{449,907,765 \text{ scf} \times \$3.44}{1000 \text{ scf/mscf}} = \$1,547,683$$

5. Cost per Ton of the LDAR Provision

Cost per Ton is estimated to be about \$17.27, or about \$14.44 per MT CO₂e reduced with savings.

$$\text{Cost Per Ton} = \frac{\text{Total Cost per Year (\$)}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

$$\text{Cost Per Ton with Savings} = \frac{\text{Total Cost per Year (\$)} - \text{Savings per Year}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

Therefore,

$$\text{Cost Per Ton} = \frac{\$10,181,892}{589,680 \text{ MT CO}_2\text{e}} = \$17.27 \text{ per MT CO}_2\text{e}$$

$$\text{Cost Per Ton with Savings} = \frac{\$10,181,892 - \$1,547,683}{589,680 \text{ MT CO}_2\text{e}} = \$14.44 \text{ per MT CO}_2\text{e}$$

I. Pneumatic Devices Provision

The proposed regulation requires continuous bleed pneumatic devices to be replaced by no bleed pneumatic devices, and to replace pneumatic pumps with electronic pumps. Staff relied on information from the ICF report, ARB's Survey, API's "Compendium of Greenhouse Gas Emissions Methodologies for the Oil and Gas Industry" (API, 2004) and EPA's "Methane Emissions from the Natural Gas Industry" (EPA, 1996) to determine the number of affected devices, cost, and emissions.

According to ARB's 2009 Survey, there were 1,701 pneumatic devices relating to production, processing, and storage, and 145 pneumatic pumps. 1151 of pneumatic devices were reported to be continuous bleed devices, 405 were intermittent bleed, and 50 were low bleed. Additionally, 31 continuous bleed devices were reported in transmission and distribution, for a total of 1182 continuous bleed devices.

1. Cost of the Pneumatic Devices Provision

EPA's gas star document entitled "Convert Pneumatics to Mechanical Controls" (EPA, 2011) estimates the cost of a no bleed mechanical device to be \$3,000 per device. According to the ICF report, the cost of replacing a pneumatic pump is \$10,000 with an operating cost of \$2,000 per year. These costs were amortized over seven years to reflect the lifetime of the equipment as noted in the ICF report. The total cost to replace these devices is estimated to be about \$1.2 million per year, and is summarized below.

Cost of Pneumatic Devices

$$= \text{Number of Devices} \times \text{Cost per Device} \times \text{Capital Recovery Factor}$$

Where,

Number of Devices = 1,182 Continuous Bleed Pneumatic Devices (ARB, 2013)

Cost per Device = \$3,000 per No Bleed Pneumatic Device (EPA, 2011)

Capital Recovery Factor = .173 from Table B-3

Therefore,

$$\text{Cost of Pneumatic Devices} = 1,182 \times \$3,000 \times 0.173 = \$612,749 \text{ per Year}$$

Cost of Pneumatic Devices
= *Number of Devices X (Cost per Device X Capital Recovery Factor*
+ *Ongoing Cost per Device*

Where,

Number of Devices = 145 Pneumatic Pumps (ARB, 2013)

Cost per Device = \$10,000 per Pneumatic Pump Replacement (ICF, 2015)

Ongoing Cost per Device = \$2,000 per Year (ICF, 2015)

Capital Recovery Factor = .173 from Table B-3

Therefore,

$$\boxed{\text{Cost of Pneumatic Pumps} = 145 \times (\$3,000 \times 0.173 + \$2,000)} \\ \boxed{= \$540,560 \text{ per Year}}$$

Total Annual Cost = Cost of Pneumatic Devices + Cost of Pneumatic Pumps

$$\boxed{\text{Total Annual Cost} = \$612,749 + \$540,560 = \$1,153,309 \text{ per Year}}$$

2. Emissions from the Pneumatic Devices Provision

Emissions were calculated using emission factors used in ARB's 2009 Survey, which included factors from API's "Compendium of Greenhouse Gas Emissions Methodologies for the Oil and Gas Industry" and EPA's "Methane Emissions from the Natural Gas Industry" (EPA, 1996) .

These emission factors are 3.599 tons CH₄ per year per device for a continuous bleed device (API, 2004), and 992 scf per million gallons pumped for pneumatic pumps (EPA, 2014). Using these emission factors for the 1182 continuous bleed devices and 145 pneumatic pumps in the production and transmission and distribution segments, the total emissions are 4,437 MT of CH₄ or 319,473 MT CO₂e using a GWP of 72.

Emissions for Pneumatic Devices (MT CH₄)
= *Number of Devices X Emission Factor*

Where,

Emission Factor = 3.599 MT CH₄/Year/Device (API, 2004)

$$\text{Emissions MT CH}_4 = 1,182 \times 3.599 \text{ MT CH}_4/\text{Year/Device} = 4,207 \text{ MT CH}_4$$

Emissions for Pneumatic Pumps (MT CH₄)

$$= \frac{\text{Emission Factor} \times \text{Volume Pumped} \times \text{Molar Mass of CH}_4}{\text{Conversion Factor} \times 1,000 \text{ kg/MT}}$$

Where,

Emission Factor = 992 scf CH₄ per million gallons pumped (EPA, 2014)

Volume Pumped = 11,802,226,472 Gallons (ARB, 2013)

Molar Mass of CH₄ = 16.04 (API, 2009)

Conversion Factor = 836.2 kg/k mol (API, 2009)

Therefore,

$$\begin{aligned} \text{Emissions MT CH}_4 &= \frac{992 \frac{\text{scf CH}_4}{1,000,000 \text{ Gallons}} \times 11,802,226,472 \text{ Gallons} \times 16.04}{836.2 \times 1,000 \text{ kg/MT}} \\ &= 224.6 \text{ MT CH}_4 \end{aligned}$$

and,

$$\text{Emissions MT CO}_2\text{e} = (4,207 \text{ MT CH}_4 + 224.6 \text{ MT CH}_4) \times 72 = 319,055 \text{ MT CO}_2\text{e}$$

3. Savings from the Pneumatic Devices Provision

Since these devices are no longer operated by gas, all emissions are reduced. Savings for this segment of the proposed regulation is estimated to be 243 million scf of gas. At a cost of \$3.44 per mscf (EIA, 2016), this represents a savings of about \$840,000.

$$\text{Volume of Gas (scf)} = \frac{\text{Mass of CH}_4 \text{ (MT)} \times \text{Conversion Factor}}{\text{Molar Mass of CH}_4 \times .949 \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}$$

Where,

Mass of CH₄ = 4,431 MT

Conversion Factor = 836.2 kg / k mol

Molar Mass of Methane = 16.04 (API, 2009)

Therefore,

$$\begin{aligned} \text{Volume of Gas (scf)} &= \frac{4,431 \text{ MT CH}_4 \times 836.2 \left(\frac{\text{kg}}{\text{k}} \text{ mol}\right) \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}{16.04 \times .949} \\ &= 243,429,070 \text{ scf} \end{aligned}$$

Value of Gas Saved = Volume of Gas X Cost per mscf

Where,

Cost per mscf = \$3.44 (EIA, 2015)

1 mscf = 1,000 scf

Therefore,

$$\text{Value of Gas Saved} = \frac{243,429,070 \text{ scf} \times \$3.44}{1000 \text{ scf/mscf}} = \$837,396$$

4. Cost per ton of the Pneumatic Devices Provision

Cost per ton is estimated to be \$3.61 per MT CO₂e reduced, or \$0.99 per MT CO₂e reduced with savings.

$$\text{Cost Per Ton} = \frac{\text{Total Cost per Year (\$)}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

$$\text{Cost Per Ton with Savings} = \frac{\text{Total Cost per Year (\$)} - \text{Savings per Year}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

Therefore,

$$\text{Cost Per Ton} = \frac{\$1,153,309}{319,055 \text{ MT CO}_2\text{e}} = \$3.61 \text{ per MT CO}_2\text{e}$$

$$\text{Cost Per Ton with Savings} = \frac{\$1,153,309 - \$837,396}{319,055 \text{ MT CO}_2\text{e}} = \$0.99 \text{ per MT CO}_2\text{e}$$

J. Well Stimulation Provision

For well stimulation circulation tanks, staff relied on industry information and DOGGR data. Based on data from the DOGGR website (DOGGR, 2016), we estimated there would be about 1,200 well stimulation activities during a typical year.

1. Cost of the Well Stimulation Provision

Options to mitigate emissions from a well stimulation activity include using a gas separator plus a low NOx incinerator, which was estimated to cost about \$290,000 (Voyager, 2015) and \$160,000 (Aereon, 2015a), respectively. Staff estimated that six systems would be needed for well stimulation activities throughout the state, which could be a mix of gas separators, and vapor collection systems. Existing incinerators or a bladder collection system could also be used. For this analysis, six control systems consisting of a gas separator and an incinerator are used, which represents greater cost than other alternatives.

Cost of Well Stimulation Treatment
= Number of Devices X (Capital Costs X Capital Recovery Factor)

Where,

Number of Devices = 6 Gas Separators with 6 Low NOx Incinerators

Cost per Gas Separator = \$290,000

Cost per Low NOx Incinerator = \$160,000

Installation Cost for Low NOx Incinerator = \$80,000

Capital Recovery Factor for Incinerator and Gas Separator = 0.130 from Table B-3

Therefore,

| |
|--|
| $\begin{aligned} \text{Cost of Well Stimulation Treatment} \\ &= 6 \times ((\$290,000 \times 0.130) + (\$160,000 + \$80,000) \times 0.130) \\ &= \$463,350 \text{ per Year} \end{aligned}$ |
|--|

2. Emissions from the Well Stimulation Provision

WSPA provided staff a report on emissions from well stimulation recirculation tanks (WSPA, 2015). Given the limited data set and variability within that data set, staff used the high end of the emissions estimates: 1.26 MT CO₂e

per event, based on a GWP of 21. Using a GWP of 72, this translates to emissions of about 4.32 MT CO₂e per well stimulation. Based on 1,200 well stimulation activities, total emissions are estimated to be about 5,184 MT CO₂e per year. Assuming controls are 95% effective, this translates to a reduction of 4,925 MT CO₂e per year.

$$\text{Emissions MT CO}_2\text{e} = \text{Well Stimulation Activities} \times \text{Emissions per Well Stimulation}$$

Where,

$$\text{Well Stimulation Activities} = 1,200 \text{ (DOGGR, 2016)}$$

$$\text{Emissions per Well Stimulation} = 4.32 \text{ MT CO}_2\text{e} \text{ (WSPA, 2015)}$$

Therefore,

| |
|--|
| $\text{Emissions MT CO}_2\text{e} = 1,200 \times 4.32 \text{ MT CO}_2\text{e} = 5,184 \text{ MT CO}_2\text{e}$ |
|--|

3. Savings from the Well Stimulation Provision

Although gas controlled from well stimulation activities may be used or become additional product, for the purposes of this analysis they do not count towards savings.

4. Cost per ton of the Well Stimulation Provision

Using these figures, we estimated the cost of controls for well stimulations. Cost effectiveness is estimated be \$90.93 per MT CO₂e reduced. The calculation is shown below.

$$\text{Cost Per Ton} = \frac{\text{Total Cost per Year (\$)}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

Therefore,

| |
|---|
| $\text{Cost Per Ton} = \frac{\$463,350}{4,925 \text{ MT CO}_2\text{e}} = \$90.93 \text{ per MT CO}_2\text{e}$ |
|---|

K. Centrifugal Compressor Provision

The proposed regulation requires centrifugal compressors that currently use a wet seal to either convert to using a dry seal, or collect the vented gas emissions with a vapor recovery system. Staff estimated the number of centrifugal compressors with wet seals that would need a vapor recovery system or conversion to a dry seal, and relied on data supplied to us by the operator to determine the cost.

According to ARB's 2009 survey (ARB, 2013), there are 48 centrifugal compressors in California, and 28 of these are equipped with a wet seal. Staff contacted these facilities and found that 27 of these centrifugal compressors had been replaced by a compressor using a dry seal, had installed a vapor recovery system, are no longer in use, reported the wet seal in error, or were operated by a company that is no longer in business. Twenty six centrifugal compressors were reported in ARB's transmission and distribution survey, all of which had dry seals. Based on this information, staff estimated there is only one centrifugal compressor that needs to comply with the proposed regulation.

1. Cost of the Centrifugal Compressor Provision

According to the ICF report, the cost to install a vapor recovery system on a centrifugal compressor is estimated to be about \$50,000. Industry provided estimates that confirmed this figure. The cost is amortized over a period of 10 years, which matches the methodology used by ICF. The total cost of installing a vapor recovery system on this centrifugal compressor is estimated to be \$6,475 per year.

2. Emissions of the Centrifugal Compressor Provision

To determine the emissions from this compressor, staff again relied on data supplied to us by the operator of the compressor. According to the operator, the emissions measured from this compressor are 1700 scfh or about 28.4 scfm, and operates about 2,000 hours per year.

At an average of 2000 hours per year, 1700 scfh is equivalent to 3,203,520 scf of methane. Total emissions are 51.5 MT CH₄, or about 3,700 MT CO_{2e} based on a GWP of 72. According to the ICF report, a reduction of 95% is expected from a vapor recovery unit. This translates to a reduction of 48.9 MT CH₄, or about 3,500 MT CO_{2e}.

Where,

Leak Measurement = 1,700 scf per Hour

Hours of Pressurized Operation per Year = 2,000

Total Volume of Leaked Gas per Year = 2,000 Hours X 1,700 scf per Hour = 340,000 scf

Mass of Methane (kg)

$$= \frac{\text{Volume of Leaked Gas} \times \text{Composition of Gas} \times \text{Molar Mass of Methane}}{\text{Conversion Factor}}$$

Where,

Molar Mass of Methane = 16.04 (API, 2009)

Composition of Gas = 78.8% (API, 2009)

Conversion Factor = 836.2 scf/kg mol (API, 2009)

Therefore,

$$\text{Mass of Methane} = \frac{340,000 \text{ scf} \times .788 \times 16.04}{836.2 \times 1,000} = 51.5 \text{ MT CH}_4$$

$$\text{Emissions MT CO}_2\text{e} = \frac{\text{Mass of Methane (kg)} \times \text{GWP}}{1,000 \text{ kg/MT}}$$

Where,

Conversion Factor = 1000 kg / MT

GWP = 72

Therefore,

$$\text{Emissions MT CO}_2\text{e} = 51.5 \text{ MT CH}_4 \times 72 = 3,709 \text{ MT CO}_2\text{e}$$

3. Savings of the Centrifugal Compressor Provision

Since the gas collected from the vapor recovery system is expected to be used or rerouted through their production line, all of the 3.4 million cubic feet of gas that is reduced will count towards savings. Based on data from the U.S. Energy Information Administration (US EIA, 2016), we estimate the value of this savings to be \$3.44 per mscf, or about \$9,000.

$$\text{Volume of Gas (scf)} = \frac{\text{Mass of CH}_4 \text{ (MT)} \times \text{Conversion Factor}}{\text{Molar Mass of CH}_4 \times .949 \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}$$

Where,

Mass of CH₄ = 48.9 MT

Conversion Factor = 836.2 kg / k mol

Molar Mass of Methane = 16.04 (API, 2009)

Therefore,

$$\begin{aligned} \text{Volume of Gas (scf)} &= \frac{48.9 \text{ MT CH}_4 \times 836.2 \left(\frac{\text{kg}}{\text{k}} \text{ mol}\right) \times 1,000 \left(\frac{\text{mscf}}{\text{scf}}\right)}{16.04 \times .949} \\ &= 2,689,090 \text{ scf} \end{aligned}$$

Value of Gas Saved = Volume of Gas X Cost per mscf

Where,

Cost per mscf = \$3.44 (EIA, 2015)

1 mscf = 1,000 scf

Therefore,

$$\text{Value of Gas Saved} = \frac{2,689,090 \text{ scf} \times \$3.44}{1000 \text{ scf/mscf}} = \$9,250$$

4. Cost per ton of the Centrifugal Compressor Provision

Cost effectiveness is estimated to be about \$1.84 per MT CO₂e reduced, or a benefit of \$0.79 per MT CO₂e reduced with savings. The calculation is shown below.

$$\text{Cost Per Ton} = \frac{\text{Total Cost per Year (\$)}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

$$\text{Cost Per Ton with Savings} = \frac{\text{Total Cost per Year (\$)} - \text{Savings per Year}}{\text{Total Emission Reductions per Year (MT CO}_2\text{e)}}$$

Therefore,

$$\text{Cost Per Ton} = \frac{\$6,475}{3,524 \text{ MT CO}_2\text{e}} = \$1.84 \text{ per MT CO}_2\text{e}$$

$$\text{Cost Per Ton with Savings} = \frac{\$6,475 - \$9,250}{3,524 \text{ MT CO}_2\text{e}} = -\$0.79 \text{ per MT CO}_2\text{e}$$

L. Monitoring Plan

Under the proposed regulation, operators of underground natural gas storage facilities will be required to submit a plan for approval that includes daily monitoring of storage wells, and ambient air monitoring. There are a total of 14 underground natural gas storage facilities operated by six businesses that will be impacted by the provision.

There are several options available to operators of these facilities to comply with the proposed regulation. Compliance with the daily monitoring requirement can be accomplished with manual inspection using optical imaging devices, or other leak detecting equipment. Given the cost of this option, it is expected that most operators will choose to use a method of inspecting wells that involves autonomous detection of leaks, which would significantly reduce labor costs.

The cost of these devices was determined through conversations with two businesses that are expected to provide this service. According to the DOGGR website, there are 408 active natural gas storage wells located at the 14 facilities (DOGGR, 2016b). The cost was estimated from a combination of two scenarios; the first using optical imaging cameras mounted on a permanent fixture, and the second using ultrasound monitors in conjunction with optical monitors.

1. Scenario 1

Each facility would need to purchase an OGI camera, and another device capable of detecting leaks. This cost for this equipment was estimated to be \$95,000 (ARB, 2016). To conduct daily monitoring, this scenario assumed that wells are not checked manually, but rather with an automated system consisting of two ultrasonic monitors at a cost of \$18,500 each, and four IR detectors at a cost of \$11,500 each (Caltrol, 2016). These costs are amortized over 10 years.

Cost of Scenario 1 = Annual Cost of Detection Equipment + Annual Cost of Monitoring Equipment + Cost of Manual Inspections + Cost of Ambient Air Monitoring

Annual Cost of Detection Equipment = Number of Facilities X Cost of Equipment X Capital Recovery Factor

Where,

Number of Facilities = 14

Cost of Equipment = \$95,000 (ARB, 2016)
Capital Recovery Factor = 0.130

$$\text{Annual Cost of Detection Equipment} = 14 \times \$95,000 \times 0.130 = \$172,900$$

Annual Cost of Monitoring Equipment = Wells X Cost per Well X Capital Recovery Factor

Where,

Wells = 408
Cost per Well = \$83,000
Capital Recovery Factor = 0.130

Thus,

$$\text{Annual Cost of Monitoring Equipment} = 408 \times \$83,000 \times 0.130 = \$4,402,320$$

The cost of ambient air monitoring for the Monitoring Plan was based on cost estimates from ARB's Monitoring and Laboratory Division for similar applications. This was estimated to be \$84,630 in initial capital cost and \$89,500 ongoing cost for each of the 14 affected facilities (ARB, 2016b).

Cost of Ambient Air Monitoring = Number of Facilities X (Amortized Capital Cost + Ongoing Cost)

$$\text{Cost of Ambient Air Monitoring} = 14 \times ((\$84,630 \times 0.130) + \$89,500) = \$1,407,026$$

$$\text{Cost of Scenario 1} = \$172,900 + \$4,402,320 + \$1,407,026 = \$6,592,207$$

2. Scenario 2

Each facility would need to purchase an OGI camera, and another device capable of detecting leaks. This cost for this equipment was estimated to be \$95,000 (ARB, 2016). To conduct daily monitoring, this scenario assumed that wells are not checked manually, but rather with an automated system consisting of a mounted camera monitor capable of optically detecting leaks. Staff assumed one of these monitors could detect leaks at three wells, and this solution is assumed to be valid for 90% of the wells, with the remaining 10% of the wells still requiring a manual inspection. The cost of this system is estimated at \$90,000 per unit, based on conversations with the manufacturer. This cost of manual inspections is estimated at \$350 per well

per day, and is based on EPA's estimate for inspecting wells using OGI technology (EPA, 2011b). All costs are amortized over 10 years.

Cost of Scenario 2 = Annual Cost of Detection Equipment + Annual Cost of Monitoring Equipment + Ongoing Cost of Equipment + Cost of Manual Inspections + Cost of Ambient Air Monitoring

Annual Cost of Detection Equipment = Number of Facilities X Cost of Equipment X Capital Recovery Factor

Where,

Number of Facilities = 14

Cost of Equipment = \$90,000

Capital Recovery Factor = 0.130

$$\text{Annual Cost of Detection Equipment} = 14 \times \$90,000 \times 0.130 = \$172,900$$

Annual Cost of Monitoring Equipment = Wells X Cost per Well X Percentage of Applicable Wells X Capital Recovery Factor

Where,

Wells = 408

Cost per Well = \$54,000

Percentage of Applicable Wells = 90%

Capital Recovery Factor = 0.130

Thus,

$$\begin{aligned} \text{Annual Cost of Monitoring Equipment} &= \frac{408 \times \$54,000 \times 90\% \times 0.130}{3} \\ &= \$1,432,080 \end{aligned}$$

$$\text{Ongoing Cost for Equipment} = \frac{\text{Wells X Ongoing Cost X 90\%}}{3}$$

Where,

Wells = 408

Ongoing Cost = \$18,000

$$\text{Ongoing Cost for Equipment} = \frac{408 \times \$18,000 \times 90\%}{3} = 2,203,200$$

Cost of Manual Inspections
 = Wells X Cost per Well X Percentage of Applicable Wells X Frequency of Inspection

Where,
 Wells = 408
 Cost per Well = \$350
 Percentage of Applicable Wells = 10%
 Frequency of Inspection = 365 times per year

$$\text{Cost of Manual Inspections} = 408 \times \$285 \times 10\% \times 365 = \$5,212,200$$

The cost of ambient air monitoring for the Monitoring Plan was based on cost estimates from ARB's Monitoring and Laboratory Division for similar applications. This was estimated to be \$84,630 in initial capital cost and \$89,500 ongoing cost for each of the 14 affected facilities (ARB, 2016a, ARB, 2016b).

Cost of Ambient Air Monitoring = Number of Facilities X (Amortized Capital Cost + Ongoing Cost)

$$\text{Cost of Ambient Air Monitoring} = 14 \times ((\$84,630 \times 0.130) + \$89,500) = \$1,306,525$$

$$\text{Cost of Scenario 2} = \$172,900 + \$1,432,080 + \$2,203,200 + \$5,212,200 + 1,306,525 = \$10,831,367$$

Recordkeeping and Reporting Cost = Cost of Businesses Making an Quarterly Report

Businesses Impacted by Monitoring Plan = 6

Cost of Quarterly Report per Year = \$576

Therefore,

$$\text{Recordkeeping} = 6 \times \$576 = \$3,459$$

The total cost of the Monitoring Plan was estimated to be a combination of scenario 1 and scenario 2. Taking the average of the two costs yields an annual cost of about \$8,723,290.

$$\text{Cost of Monitoring Plan} = \frac{\text{Cost of Scenario 1} + \text{Cost of Scenario 2}}{2}$$

| |
|--|
| Cost of Monitoring Plan = (\$6,592,207 + \$10,831,367) / 2 + \$3,459 = \$8,723,290 |
|--|

Table B-2 summarizes the costs and reductions associated with the provisions of the proposed regulation.

M. Indirect Costs

While the direct regulatory costs of the proposed regulation can be estimated using the anticipated cost of each control strategy multiplied by the number of units that will be affected, the indirect costs and economic impacts are modeled using a computational general equilibrium model of the California economy known as Regional Economic Models, Inc. (REMI). This analysis was performed and discussed as part of the SRIA (Attachment E). Although the proposed regulation is different than the SRIA analysis, the results and conclusions of the analysis are still relevant given that the anticipated overall cost of the proposed regulation not only remains similar in magnitude to the cost used in the SRIA analysis, but the magnitude of the direct impacts of the proposed regulation as well as the SRIA are small compared to the overall size of the California economy.

N. Alternatives

Staff considered four alternatives to the proposed regulation that would be less burdensome to the affected industry. These alternatives are not the same as the alternatives in the Environmental Analysis, since those alternatives address reducing the environmental impacts of the proposed regulation while these alternatives address Administrative Procedure Act considerations. It is important to note that these alternatives are in addition to those that staff considered at the SRIA phase of this regulation, which are identified in that document. ARB staff conducted a detailed economic analysis only of options 1 and 2, since these were the most viable of the potential alternatives. The clear policy limitations and uncertain costs associated with alternatives 3 and 4 (given their flexible and unknown implementation paths) precluded a more detailed economic evaluation of those options.

1. Alternative 1: No Action. The Oil and Gas Regulation is Not Enacted

The first alternative is to not propose the regulation. Obviously, this would be less burdensome to the industry. However, this alternative does not achieve the goal of reducing methane emissions from the oil and natural gas production, processing, and storage sector. Accordingly, this alternative was rejected.

a) Costs and Benefits

Alternative 1 would impose no additional costs on consumers or manufacturers. In this scenario the impacted sectors would fall under the federal EPA guidelines of 40 C.F.R. Part 60, Subpart OOOO (Quad O).

b) Economic Impacts

Since Alternative 1 does not impose any additional costs to industries or consumers, there would be no economic impacts relative to the current conditions. Compared to the proposed regulation, there would be no changes in GSP, personal income, private investment, or other economic indicators. There would be no reduction of GHG emissions, VOCs, or other airborne toxics.

c) Cost per ton

Alternative 1 has no cost as it does not impose any fiscal costs or regulatory costs that may be associated with the development and enforcement of the proposed amendment.

d) Reason for Rejection

Alternative 1 does not sufficiently meet the goals of the proposed regulation, which is to reduce GHG emissions from the oil and gas industry. Therefore, it is not a viable alternative to the proposed amendment.

2. Alternative 2: Implement the Oil and Gas Regulation Without the LDAR Provision

The second alternative is to not propose the LDAR requirement in the regulation. This provision of the proposed regulation affects the most facilities and can be a labor intensive control measure. However, it also is the provision that achieves the largest amount of emission reductions, accounting for more than a third of the anticipated methane emission reductions. LDAR is also at the heart of catching small leaks before they become larger leaks. In addition, LDAR is key to making sure that other provisions of the regulation are operating properly, such as vapor recovery on separator and tank systems, thereby ensuring that the anticipated emission reductions from those provisions are achieved in practice. For these reasons, this alternative was rejected.

a) Costs and Benefits

If the proposal was adopted with the provisions in the SRIA, the total cost would be about \$13.8 million per year, and reduce emissions by about 0.9 million MT CO₂e. This includes savings of about \$1.5 million per year due to mitigated emissions. Benefits to businesses and individuals would be negligible and commensurate with the current proposed regulation.

b) Economic Impacts

The economic impacts are described in detail in Appendix E, which contains the SRIA and the provisions of the Proposed Regulation. Although this alternative does not include LDAR, the conclusions of the SRIA are still valid, that the proposed regulation was unlikely to significantly impact California's economy, including the growth of employment, investment, personal income, output, and GSP does not represent a significant change from the BAU scenario.

c) Cost per ton

The cost per ton of Alternative 2 is estimated to be about \$15 per MT CO₂e reduced, using a GWP of 72. Although this is similar to the cost per ton of the current proposal, alternative 2 does not include LDAR.

d) Reason for Rejection

In addition to being a significant source of reductions, LDAR is also at the heart of catching small leaks before they become larger leaks. Also, LDAR is key to making sure that other provisions of the regulation are operating properly, such as vapor recovery on separator and tank systems, thereby ensuring that the anticipated emission reductions from those provisions are achieved in practice. For these reasons, this alternative was rejected.

3. Alternative 3: Performance-based Standard

Staff considered a performance-standard based alternative for the proposed regulation. Specifically, staff considered a performance-based mandate to regulated entities to reduce the vented and fugitive emissions from regulated sources, as of a date certain, by an amount commensurate with the expected reductions the proposed regulation is expected to produce. Staff rejected this alternative for several reasons, but worked to incorporate flexibilities into the proposed regulation where possible to support legislative direction to avoid prescriptive regulations where possible.

Reasons for rejecting a wholesale performance standard alternative include the following points. This proposed regulation is designed to reduce venting and fugitive emissions from the sector. These emissions are, by their nature, difficult to quantify in many cases, and come from a wide range of potential sources. A flat reduction mandate would be very difficult to enforce without more accurate baseline data on current emissions from these sources, at the facility and component level, than is now available – it is, in other words, far more effective to enforce a requirement to replace a certain piece of equipment, or follow a particular LDAR procedure, than a performance-based reduction requirement from an uncertain baseline. To ensure reductions occur, therefore, staff focused on providing uniform, clear standards for equipment and processes that could reliably be measured, implemented, and enforced. Further, because emission controls focusing solely on methane reduction could have contributed to criteria pollutant emissions if poorly implemented, or failed to secure maximum co-benefits of criteria and toxic pollutants, it was important to specify particular implementation requirements to produce better results on this metric as well.

But though staff rejected a performance standard alternative as a complete option, staff made significant efforts to provide options within the rule's directive framework to provide compliance flexibilities. For instance, regulated entities have several options as to how to implement vapor control device provisions, to conduct LDAR inspections, and to address equipment replacement or retrofit decisions. These embedded options within the proposed regulation help reduce compliance burdens, thereby fulfilling the legislative intent driving consideration of performance-based alternatives, while ensuring that emission reductions happen in an enforceable and environmentally appropriate manner.

4. Alternative 4: Emission Reduction Provision

Staff also considered including an emission reduction provision that would require operators to mitigate climate impacts of large methane leaks. In evaluating whether an emission reduction provision would be appropriate, staff considered several options, including increased penalties for operators of facilities where the leak occurred and an emission reduction plan providing ton-for-ton reductions or stricter monitoring requirements. Staff concluded that stiffer monitoring requirements were the most appropriate. Increased penalties were not an effective option since all prohibited leaks violate the proposed regulation and thus every violation is potentially subject to the maximum penalties statutorily allowed. A plan for reductions was deemed inappropriate at this time, for the following reasons: first, developing generally applicable requirements for such a plan – though somewhat specified in the mitigation plan developed for the Aliso Canyon leak – is a difficult regulatory task when generalized to any potential facility, and so would likely delay the regulation and associated methane reductions.

Furthermore, ARB has considerable authority to drive appropriate mitigation via its existing enforcement authorities and settlement authority. Therefore, rigorous monitoring provisions, rigorously enforced, were deemed appropriate for this proposed regulation. ARB will continue to consider the issue, however, and may revisit this decision in future rulemakings.

O. Fiscal Impacts

The proposed regulation's enforcement and implementation provisions recognize that California's local air districts already play an important role in regulating the oil and gas sector, and are intended to build on their efforts. The provisions make clear that ARB can directly enforce the proposed regulation, but also offer paths for local air districts to integrate its requirements into their existing programs to support efficient and effective enforcement.

ARB's proposed regulation can be implemented and enforced by both ARB and the districts. ARB staff assumes most local air districts will choose to take the lead in implementing and enforcing the regulation, with ARB playing a backstop role, and it is our preference for the local air districts to do so. However, ARB will take a lead role in districts that choose not to. The local air districts are more familiar with operators, conduct inspections nearby or at the same sites, and in many instances have been regulating such sources for decades. This is why the regulation allows local districts to enter into MOUs with ARB in order to define implementation and enforcement responsibilities, as well as for information sharing. The regulation also allows for districts to incorporate this regulation into their local rules. To ensure uniform enforcement, however, districts may not waive or reduce the stringency of the state rules, which remain state law, enforceable as necessary by ARB.

ARB staff estimates that the regulation will require 6 PYs to implement depending on the mix of district and ARB implementation. In addition to PYs, ARB will need to purchase equipment including three IR cameras at \$85,000 each, and three toxic vapor analyzers at \$10,000 each. The costs are higher with ARB enforcement than with district enforcement due to the need to travel, train new staff, and set-up programs including a registration program. The total cost to ARB is estimated to be \$285,000 in initial costs ((3 X \$85,000) + (3 X \$10,000)), and about \$870,000 in ongoing costs (6 X \$145,000). These costs are anticipated to be imposed during the 2017/2018 fiscal year.

1. Other State Agencies

The proposed regulation does not affect other state agencies.

2. Air Districts

A local air district may decide – but is not obligated -- to be the primary agency responsible for enforcing the provisions of the Proposed

Regulation. This includes issuing permits for new control equipment, registration and inspection of equipment, and enforcing the LDAR portion of the regulation. The individual district cost estimates range from amounts some districts feel could be absorbed by them without additional funding, to over \$300,000 per year in recurring costs and almost \$1,000,000 in one-time costs, primarily for permitting. Even if the districts do decide to implement and enforce this regulation, there is an annual cost for ARB to manage the reporting requirements in the regulation. The costs to districts are estimated to be approximately \$1,300,000 in initial costs, and approximately \$660,000 in ongoing costs.

Although local agencies (air districts) may choose to implement this regulation, and certain aspects of it may be incorporated in permits as a matter of preexisting law, resulting in some fiscal impacts, the regulation imposes no reimbursable mandates. Air districts face no new legal requirements specific to them under this regulation. As to implementation tasks they may take on or any other costs that may result by operation of statute, air districts have legal authority under Health and Safety Code sections 40510 and 42311 to recover related costs by imposing fees. The Proposed Regulation also specifies that local air districts that choose to enforce the regulation may retain any penalty monies that result. ARB also may make arrangements to further support air districts as a voluntary matter. Thus, because the regulation applies generally to all entities operating affected sources, not the air districts, and so does not impose unique new requirements on local agencies, this is not a reimbursable mandate. (*County of Los Angeles v. State of California*, 42 Cal. 3d 46 (1987)).

The proposed regulation's enforcement and implementation provisions recognize that California's local air districts already play an important role in regulating the oil and gas sector, and are intended to build on their efforts. The provisions make clear that ARB can directly enforce the proposed regulation, but also offer paths for local air districts to integrate its requirements into their existing programs to support efficient and effective enforcement. ARB's proposed regulation can be implemented and enforced by both ARB and the districts. ARB staff assumes most local air districts will choose to take the lead in implementing and enforcing the regulation, with ARB playing a backstop role, and it is our preference for the local air districts to do so. However, ARB will take a lead role in districts that choose not to. The local air districts are more familiar with operators, conduct inspections nearby or at the same sites, and in many instances have been regulating such sources for decades. This is why the regulation allows local districts to enter into MOUs with ARB in order to define implementation and enforcement responsibilities, as well as for information sharing. The regulation also allows for districts to incorporate this regulation into their local rules. To ensure uniform enforcement, however, districts may not waive or

reduce the stringency of the state rules, which remain state law, enforceable as necessary by ARB.

EDMUND G. BROWN JR. ■ GOVERNOR

915 L STREET ■ SACRAMENTO CA ■ 95814-3706 ■ WWW.DDF.CA.GOV

May 28, 2015

Ms. Emily Wimberger
Air Resources Board
1001 I Street
Sacramento, CA 95814

Dear Ms. Wimberger:

Thank you for submitting the standardized regulatory impact assessment (SRIA) and the summary (Form DF-131) for the proposed regulations on reducing greenhouse gas emissions from crude oil and natural gas operations, as required in California Code of Regulations, title 1, section 2002(a)(1).

Based on the April 22, 2015 draft regulations, sources at oil and natural gas production, processing, and storage facilities would be required to reduce methane in support of AB 32—Global Warming Solutions Act of 2006. Affected facilities are expected to achieve compliance through installations of equipment by 2018. Other requirements such as periodic testing, reporting, and recordkeeping of methane and hydrocarbon emissions; and timely repair of leaking components would take effect by 2017. Requirements at each facility would depend on existing equipment and local air district requirements on the same sources. While local authorities would have some flexibility, these proposed regulations are an attempt to bring all facilities up to a minimum standard.

In addition to the health and environmental benefits to individuals, industries that supply control devices benefit when the regulated facilities purchase equipment to comply with the new standards. According to the SRIA, the annualized cost of the proposed regulations peaks at \$18.8 million in 2017, assuming the affected facilities can amortize the costs. This, together with equipment spending, would result in an increase of \$54.3 million in gross state product, thus meeting the major regulations threshold of \$50 million a year. There would, however, be small reductions overall in growth rates of gross state product thereafter.

Finance, in general, concurs with the methodology used to assess the economic impact of the proposed regulation. The SRIA was particularly well constructed in relating the direct impacts of the proposed regulation to the overall impacts. However, it would be helpful to include the magnitude of the unit and total costs of devices and the geographical distribution of the affected facilities. Since the majority of retrofit costs are expected to occur in 2018, the highest direct cost and economic impact should occur in 2018, not in 2017 as described in the SRIA. While the SRIA does comply with the requirement to discuss alternatives, it would be helpful to include the direct cost of each alternative in the SRIA, rather than just the overall impacts. Finally, ARB may want to discuss how an individual facility's characteristics, such as emission rates and existing control devices, may affect the calculation of direct costs, and thus economic impacts of the proposed regulations. These existing efforts also determine the amount of emissions reductions that would be achieved.

These comments are intended to provide sufficient guidance outlining revisions to the SRIA. The SRIA, a summary of Finance's comments, and any responses must be included in the rulemaking file that is available for public comment. Finance understands that the proposed regulations may change during the notice of proposed action, after the public comment period, and following the ARB Board hearing. If any significant changes to the proposed regulations result in economic impacts not discussed in the SRIA, please note that the revised economic impacts must be reflected on the Standard Form 399 for the rulemaking file submittal to the Office of Administrative Law. Please let us know if you have any questions regarding our comments.

Sincerely,

Irena Asmundson
Chief Economist

Response to DOF Comments

Comment #1

It would be helpful to include the magnitude of unit and total costs of devices, and the geographical distribution of the affected facilities.

Most of the affected facilities are in the San Joaquin Air Pollution Control District. According to ARB's 2009 survey, over 60% of the affected LDAR components are located in the San Joaquin APCD. Other districts with a significant amount of affected facilities include Santa Barbara APCD, South Coast APCD, Feather River APCD, and Glen County APCD. The magnitude of unit and total costs of devices is described in detail in the cost analysis section of this Appendix.

Comment #2

Since the majority of retrofit costs are expected to occur in 2018, the highest direct cost and economic impact should occur in 2018, not in 2017.

The standards were set to be effective January 1, 2018 and it was anticipated that the capital costs would occur prior to that, in 2017. Since the effective date of the standards requiring the purchase of capital equipment has been changed to 2019, the majority of retrofit and other capital equipment is estimated to take place in 2018.

Comment #3

Include the direct cost of each alternative in the SRIA, rather than just the overall impacts.

At the time of the SRIA, the first alternative included a requirement that existing continuous-bleed pneumatic devices to be replaced with no-bleed devices. It also required an LDAR inspection program with quarterly inspections. These alternatives were eventually incorporated into the existing proposed regulation. The direct costs for this alternative were estimated to be about \$28 million per year with an emissions reduction of about 500,000 MT CO₂e. The second alternative eliminated the LDAR provision, the centrifugal compressor provision, and added a leak standard for rod packing replacement. This alternative was estimated to cost about \$20 million per year with an emissions reduction of about 450,000 MT CO₂e. Since the SRIA, better data has become available and through development of the regulation, several of the provisions have changed, and incorporated parts of each alternative. Due to these changes, a direct comparison of the costs and emissions is difficult to make.

Comment #4

Discuss how an individual facility's characteristics, such as emission rates and existing control devices, may affect the calculation of direct costs, and thus economic impacts of the Proposed Regulations.

Generally, the emission rates and number of affected devices are proportional to the estimated cost of compliance. Some facilities, which may not be subject to an existing LDAR program, may exhibit greater emissions than those that are under an existing LDAR program for VOC. These facilities may have a greater amount of emissions, or super leaking components. This would increase the cost minimally, but would be more cost effective.

Some facilities may also have an existing flare connected to a separator and tank system. In these cases, the flare would need to be removed to install a low NO_x incinerator. This would be an additional cost for these facilities. The impact is expected to be minimal. Facilities with a tank and separator system with emissions under 10 tons per year of CH₄ emissions would not be required to install vapor recovery and would have less overall cost than facilities with greater than 10 tons per year of CH₄ emissions.

State of California
AIR RESOURCES BOARD

**PUBLIC HEARING TO CONSIDER THE PROPOSED REGULATION FOR
GREENHOUSE GAS EMISSION STANDARDS FOR
CRUDE OIL AND NATURAL GAS FACILITIES**

STAFF REPORT: INITIAL STATEMENT OF REASONS

DATE OF RELEASE: May 31, 2016
SCHEDULED FOR CONSIDERATION: July 21, 2016

Location:

California Environmental Protection Agency
Air Resources Board
Byron Sher Auditorium
1001 I Street
Sacramento, California 95814

This report has been reviewed by the staff of the California Air Resources Board and approved for publication. Approval does not signify that the contents necessarily reflect the views and policies of the Air Resources Board, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

ACKNOWLEDGEMENTS

This report was prepared with the assistance and support from many individuals within the Air Resources Board. Staff would like to acknowledge the cooperation from numerous State and local governmental agencies that have provided invaluable assistance throughout the rulemaking process. Staff would also like to acknowledge the contributions from our key stakeholders.

EXECUTIVE SUMMARY

Background

Climate change is one of the most serious environmental threats facing the world today, and California is already feeling the effects. California has committed to take action to address the threat. Under AB 32, the California Global Warming Solutions Act of 2006, ARB was identified as the state agency charged with monitoring and regulating sources of greenhouse gas emissions that cause climate change. Methane emissions control is critical to fulfilling this mandate because these emissions are not yet declining, putting continued pressure on the GHG emissions limit, as well as on any efforts to achieve deeper reductions. Both the 2008 Climate Change Scoping Plan and the subsequent First Update to the Climate Change Scoping Plan identified the oil and gas sector as a large source of GHG emissions and include the regulation of oil and gas operations covered in the proposed regulation as a potential GHG mitigation measure to help achieve the statute's goals.

Short-lived climate pollutants (SLCP), including methane (CH₄), are among the most harmful to both human health and global climate. They are powerful climate forcers that remain in the atmosphere for a much shorter period of time than longer lived climate pollutants such as carbon dioxide (CO₂). Their relative climate forcing (or impact), when measured in terms of how effectively they heat the atmosphere, can be tens, hundreds, or even thousands of times greater than that of CO₂.¹ While reducing CO₂ emissions impacts climate change over the long term, reducing emissions of SLCPs will effectively slow the rate of climate change in the near-term; therefore, reducing these emissions can have an immediate beneficial impact on climate change.

Methane is a particularly effective SLCP and is the second largest man-made contributor to GHG emissions globally. Methane is 72 times more potent than CO₂ as a GHG when considered on a twenty year time frame. Methane is responsible for about 20 percent of current global warming and is emitted from a wide range of sources with emissions increasing globally as a result of human activities related to agriculture, waste handling and treatment.² Oil and gas systems are responsible for approximately 15 percent of methane emissions in the state. The recently proposed SLCP strategy includes a forty percent reduction of methane by 2030 with a 40-45% reduction from the oil and gas sector as a whole by 2025.

The proposed regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities (proposed regulation) is designed to reduce emissions from both upstream (production, gathering and boosting stations, and processing) and some downstream facilities (natural gas storage and transmission compressor

¹ IPCC. 2007. Direct Global Warming Potentials. Chapter 2, 10.2.

² Kirschke, S. et al. 2013. Three Decades of Global Methane Sources and Sinks. Nature Geoscience.vol. 6, 813-823.

stations), which account for about four percent of statewide methane emissions.³ GHG emissions from oil and gas pipelines and related facilities are being addressed in a separate regulatory effort in partnership with the California Public Utilities Commission (CPUC)⁴.

What are we proposing?

The proposed regulation will reduce methane emissions from oil and gas production, processing, storage, and transmission compressor stations by requiring regulated entities to take actions to limit intentional (vented) and unintentional (leaked or fugitive) emissions from active and idle equipment and operations. Some methane reductions are already achieved as co-benefits of local air district regulations governing emissions of volatile organic compounds (VOC); methane is not considered to be a VOC but can be captured along with VOCs. The goal of the proposed regulation is to obtain the maximum GHG emission reductions from the sector in a technically feasible and cost-effective manner, building upon the existing regulations already being implemented by the air districts. The source categories covered under the proposed regulation currently emit approximately two and a half million metric tonnes (MMT) of CO₂e. The proposed regulation will reduce those emissions by over fifty percent. The proposal is also expected to reduce both VOC and toxic air contaminant (TAC) emissions and provide an essentially neutral NO_x impact statewide.

The provisions of the proposed regulation are:

1. Collection and use (or destruction) of methane and associated gases from uncontrolled oil and water separators and storage tanks with emissions above a set methane standard;
2. Collection and use (or destruction) of methane and associated gases from all uncontrolled well stimulation circulation tanks;
3. Leak Detection and Repair (LDAR) requirements for components, such as valves, flanges, and connectors, currently not covered by local air district rules;
4. Methane emission standards for large reciprocating compressors in addition to LDAR for the other large compressor components and smaller compressors;

³ Upstream emissions cover emissions from production, processing, and gathering and boosting stations. Covered downstream emissions include natural gas storage and transmission compressor stations.

⁴ More information on the CPUC effort can be found at: California Public Utilities Commission (CPUC). 2015. Order Instituting Rulemaking to Adopt Rules and Procedures Governing Commission-Regulated Natural Gas Pipelines and Facilities to Reduce Natural Gas Leakage Consistent with Senate Bill 1371 <http://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M144/K999/144999228.PDF>

5. Collection and use (or destruction) of methane and associated gases from specified centrifugal compressors, or replacement of higher emitting “wet seals” with lower emitting “dry seals”;
6. Use of “No bleed” pneumatic pumps and “no bleed” continuous bleed pneumatic devices with limited exemptions and restrictions on intermittent bleed pneumatic devices; and
7. Enhanced monitoring for underground natural gas storage facilities including leak detection and ambient air monitoring.
8. Reporting requirements for liquids unloading and well casing vents

Why are we proposing this action?

Methane emissions from the oil and gas industry contribute to California’s greenhouse GHG emissions and cost-effective reduction opportunities already exist and are available for use in the sector. In addition, reducing methane emissions from this sector will help slow the rate of climate change in the near-term and have an immediate beneficial impact on climate change because methane is a powerful SLCP.

Who will be subject to the proposed regulation?

Owners and operators of equipment used in the following operations will be subject to the proposed regulation:

- Onshore and offshore crude oil or natural gas production, including well stimulation activities;
- Crude oil, condensate, and produced water separation and storage;
- Natural gas underground storage;
- Natural gas gathering and boosting stations;
- Natural gas processing plants;
- Natural gas transmission compressor stations.

Oil and gas companies, public utilities, and engineering service providers are among the largest companies that would be directly impacted.

Who will enforce the regulation?

Because stationary sources in this sector have historically been regulated by local air districts, ARB staff worked with the California Air Pollution Control Officers Association (CAPCOA) and individual air districts to design the proposal so it can be implemented and enforced by both ARB and the districts. ARB staff expects that most local air districts will choose to take the lead in implementing and

enforcing the regulation, with ARB serving as the backup agency, and it is our preference that the rule is implemented and enforced in this manner. However, ARB is prepared to take a lead implementation role in the event that the air district elects to let ARB serve in that role. The local air districts are more familiar with operators, conduct inspections nearby or at the same sites, and in many instances have been regulating such sources for decades. As a result, the proposal was designed to allow local districts to enter into MOUs with ARB to define implementation and enforcement responsibilities, and to share information. The proposed regulation also provides for districts to incorporate the proposed regulation into their local rules. Upon its adoption, the proposal becomes a State regulation enforceable by ARB. This limits the ability of air districts to implement less stringent requirements. ARB anticipates continuing to work closely with local air districts to ensure adequate support for the proposed regulation's implementation and enforcement.

What are the costs of the proposed regulation?

The proposed regulation would increase costs on the complying industries, which are primarily involved with oil and gas extraction. These industries pay for control equipment and services from secondary industries but may also achieve operational cost savings through recovery of natural gas captured by the proposed control strategies. ARB staff estimates the proposed regulation will cost about \$22 million dollars per year including enhanced natural gas storage monitoring. The proposed regulation is expected to reduce GHG emissions by about 1.5 MMT CO₂e per year based on a 20-year horizon global warming potential (GWP). The cost per ton of CO₂e reduction is estimated to be about \$17 without considering savings and \$15 after savings, based on a 20-year GWP. Considering the size and diversity of the California economy, the economic impacts of the proposed regulation on the California economy are negligible, including the impact on growth of employment, investment, personal income, and production.

What are the benefits of the proposed regulation, including for Environmental Justice and Disadvantaged Communities?

Communities located in close proximity to oil and gas operations experience impacts related to these operations. Additionally, these communities are at risk for exposure to a variety of volatile organic compounds and toxics air contaminants, which are associated with oil and gas operations. Local air districts currently implement a variety of rules that reduce volatile organic compounds from the oil and gas industry with a co-benefit of methane reductions.

The proposed regulation would provide additional benefits in reductions of air pollutants including about 1.5 million metric tons of CO₂e, over 3,600 tons of VOCs, and over 100 tons of toxic air contaminants annually. The majority of all these reductions will occur in the San Joaquin Valley. Although the purpose of the regulation is to reduce methane emissions, the proposed regulation was designed

to provide co-benefits and minimize or eliminate any other potential air quality impacts. While there is an essentially neutral impact on NOx emissions statewide, there is expected to be a slight decrease in NOx emissions in the San Joaquin Valley from current conditions. The San Joaquin Valley Air Pollution Control District (SJVAPCD) has notified ARB that they are considering adopting a flare minimization rule that would achieve NOx reductions from similar sources. ARB will continue to work closely with the district to monitor the development of regulations from the plan and address any remaining NOx concerns.

I. INTRODUCTION

A. BACKGROUND CLIMATE CHANGE PROGRAMS

1. AB 32

On September 27, 2006, Governor Schwarzenegger signed Assembly Bill 32 (AB 32), The California Global Warming Solutions Act of 2006 (Health & Safety Code §§38500-38599). AB 32 requires a reduction of greenhouse gas (GHG) emissions to 1990 levels by 2020 and designates the California Air Resources Board (ARB) as the lead agency for implementing AB 32. AB 32 provided direction and broad authority to create a comprehensive multi-year program to limit California's GHG emissions and initiate the transformations required to achieve the State's long-range climate objectives.

AB 32 charges ARB with achieving statewide GHG emissions targets by 2020, with maintaining that target, and with continuing the maximum technologically feasible and cost-effective GHG reductions going forward. As part of the strategy to reach and maintain the 2020 emission target, and secure continued reductions, ARB identified the oil and gas sector as a large source of GHG emissions – primarily methane. Both the 2008 Climate Change Scoping Plan and the subsequent First Update to the Climate Change Scoping Plan include the regulation of oil and gas operations covered in the proposed regulation as a potential GHG mitigation measure. Unless methane emissions, which now continue at high levels, are controlled, they will put continued pressure on the statewide GHG limit, as well as complicate any efforts to achieve deeper emissions reductions in the future. Steps therefore must be taken to control these emissions in order to fulfill AB 32's mandates.

Accordingly, this regulation covers upstream emissions (production, gathering and boosting stations, and processing) as well as natural gas storage and transmission compressor stations (collectively "oil and gas"). This regulation does not cover the petroleum refining sector. Further, GHG emissions from oil and gas pipelines and related facilities are being addressed in a separate regulatory effort in partnership with the California Public Utilities Commission (CPUC).

In 2009, ARB initiated a survey of the oil and gas industry, collecting information on sources such as compressor seals, storage tanks, valves, flanges, and connectors. The survey included combustion related emissions from equipment (equipment burning fuel for energy) as well as vented and fugitive sources, which are intentional and unintentional releases of gases to the atmosphere, respectively. The survey is the most comprehensive dataset that exists for California's oil and gas industry. No other dataset, federal or statewide, contains as much detailed information about the industry in the state. The findings from this survey provide the basis for the proposed

regulation, which reduces vented and fugitive emissions from oil and gas production, processing, storage, and transmission compressor stations. ARB has incorporated additional or supplemental data where appropriate.

2. Short Lived Climate Pollutants

Short-lived climate pollutants (SLCP), including methane (CH₄), black carbon (soot), and fluorinated gases (F-gases, including hydro-fluorocarbons, or HFCs), are among the most harmful to both human health and global climate. They are powerful climate forcers that remain in the atmosphere for a much shorter period of time than longer lived climate pollutants such as carbon dioxide (CO₂). Their relative climate forcing (or impact), when measured in terms of how they heat the atmosphere, (see explanation of global warming potential in footnote 10) can be tens, hundreds, or even thousands of times greater than that of CO₂.⁵ While reducing CO₂ emissions limits climate change over the long term, reducing emissions of SLCPs will help slow the rate of climate change in the near-term; therefore, reducing these emissions can have an immediate beneficial impact on climate change.

Methane has a global warming potential 72 times that of CO₂, on a 20-year timeframe, and is the principal component of natural gas⁶. Methane emissions also contribute to background ozone in the lower atmosphere. Such ground-level ozone not only contributes to ground level “smog” but ozone is also a powerful GHG.

Methane, the second largest anthropogenic, or man-made contributor to GHG emissions globally, is emitted from a wide range of fugitive sources and biological processes. Methane emissions are increasing globally as a result of human activities related to agriculture, waste handling and treatment, and oil and gas production, and are responsible for about 20 percent of current global warming.⁷ Agriculture represents the largest methane source in California, accounting for nearly 60 percent of methane emissions (Figure 1). Landfills are the next largest source of methane at 20 percent of statewide methane emissions. Oil and gas systems contribute approximately 13 percent of statewide methane emissions, with wastewater treatment and other industrial and miscellaneous sources comprising the remainder of emissions. The proposed regulation is designed to reduce methane emissions from upstream and some downstream oil and gas activities within

⁵ See footnote 1.

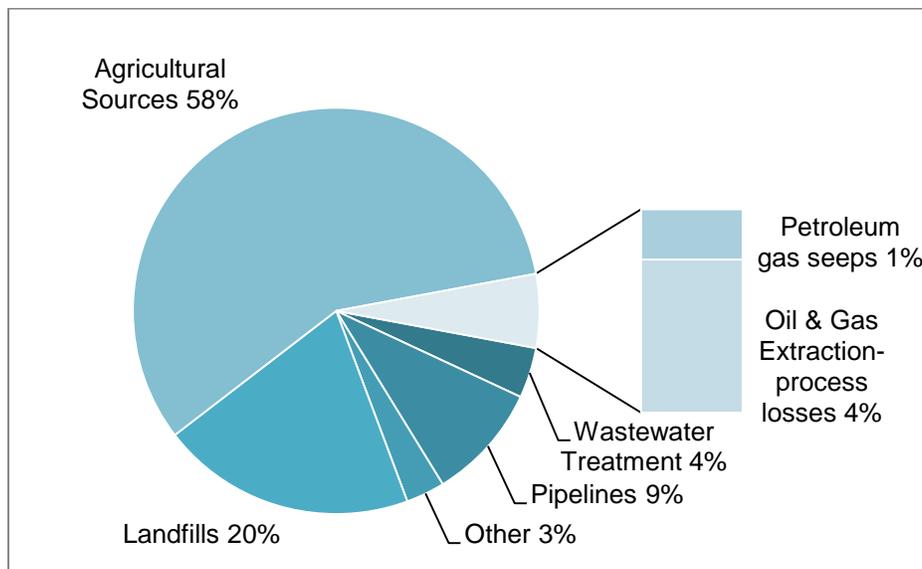

⁶ Staff used the 20 year global warming potential from the Fourth Assessment Report, which is 72. The Fifth Assessment report estimates methane is at least 84 times as potent as carbon dioxide on a 20 year timeframe. IPCC. 2008. Climate Change 2007. Synthesis Report. IPCC Fourth Assessment Report: Climate Change 2007. http://www.ipcc.ch/pdf/assessment-report/ar4/syr/ar4_syr_full_report.pdf And IPCC. 2015. Climate Change 2014. Synthesis Report. IPCC Fifth Assessment Report: Climate Change 2014. http://ar5-syr.ipcc.ch/ipcc/resources/pdf/IPCC_SynthesisReport.pdf

⁷ See footnote 2.

California, which accounts for about four percent of statewide methane emissions⁸.

The regulation supports a larger, on-going, effort to reduce short-lived climate pollutants. Pursuant to Senate Bill 605 (SB 605) (Health & Safety Code § 39730), ARB is proposing a comprehensive approach to reduce methane through the proposed Short-lived Climate Pollutant Reduction Strategy.⁹ As noted in that report, ARB is proposing to reduce methane emissions from oil and gas systems (oil and gas production, processing, storage, and natural gas transmission and distribution) by 40-45 percent in 2025, matching federal commitments. Thus, the proposed regulation helps to achieve the goals identified in the proposed SLCP Reduction Strategy.

Figure 1: California 2013 Methane Emission Sources (118 MMTCO₂e)¹⁰

⁸ Upstream emissions cover emissions from production, processing, and gathering and boosting stations. Covered downstream emissions include natural gas storage and transmission compressor stations. In Figures 6 and 7, Oil and Gas Extraction process losses includes all the upstream emissions, not just production.

⁹ ARB. 2016. Proposed Short-Lived Climate Pollutant Reduction Strategy in California.

¹⁰ See footnote 9. Using the 20-yr global warming potential from the IPCC's Fourth Assessment Report (AR4) for methane. The Intergovernmental Panel on Climate Change (IPCC) developed the concept of global warming potential (GWP) as an index to evaluate the climate impacts of different GHGs, including SLCPs. This metric provides a comparison of the ability of each GHG to trap heat in the atmosphere relative to CO₂ over a specified time horizon. Current practice in most of the world for developing GHG emission inventories, including California's GHG inventory, is to use GWP values from the 4th Assessment Report of the IPCC (AR4), which was released in 2007. California's inventory generally uses GWPs over a 100-yr timeframe. However, the use of GWPs with a time horizon of 20 years better captures the importance of the SLCPs and gives a better perspective on the speed at which SLCP emission controls will impact the atmosphere relative to CO₂ emission controls. Thus, the emission inventory and estimated reductions presented later in this ISOR are calculated using 20-year GWP for methane.

B. BACKGROUND – AIR DISTRICTS

Under State law, ARB and local air districts operate within a cooperative legal framework for controlling air pollution from a variety of sources. There are 35 air districts as shown in Figure 2. Each jurisdiction's authority is based on the type of air pollutants and sources involved.

For smog-forming pollutants including volatile organic compounds, or VOCs, ARB has authority over mobile and area wide sources, such as vehicles, fuels, and consumer products, while the local districts have responsibility over stationary sources, including oil and gas operations. For portable equipment, the State shares jurisdiction with the air districts.

There are two significant exceptions to this general framework. First, with regard to greenhouse gases, AB 32 gives ARB broad authority to regulate GHGs from both mobile, stationary, and area wide sources. This regulation would be implemented under AB 32 as mentioned earlier. The other major area where ARB has authority over stationary sources involves toxic air contaminants, where the regulation of toxic air contaminants is a responsibility shared by ARB and the local districts.

For air districts with significant oil production, each district has rules aimed to reduce particulate matter less than 2.5 microns in diameter (PM_{2.5}) as well as oxides of nitrogen (NO_x) and volatile organic compound (VOC) emissions specifically from the oil and gas sector. These rules do not regulate methane directly from the sector, so the proposed regulation is designed to address those sources that are not controlled by existing district rules. ARB has used the district rules as a starting point, particularly for leak detection and repair, where districts have been implementing programs for decades.

C. CALIFORNIA'S OIL AND NATURAL GAS RESOURCES

Methane emissions from California's oil and gas sector are substantial in part because the state is a large oil and gas producer. The top crude oil producing states are Texas, North Dakota, California, Alaska, New Mexico, and Colorado, representing a combined two-thirds of the total crude oil production in the U.S in September 2015.¹¹ Texas is also the largest natural gas producer in the U.S.;¹² California is at number fifteen on the natural gas producer list, based on 2014 data. According to the U.S. Energy Information Administration (EIA), California ranked third in the nation in crude oil production in 2014, despite an overall decline in production rates in California since the mid-1980s (excluding Federal offshore areas).

¹¹ U. S. EIA. 2015. Rankings: Crude Oil Production, December 2015 (thousand barrels).

¹² U. S. EIA. 2014. Rankings: Natural Gas Marketed Production, 2014 (million cu ft).

California has nine main petroleum systems,¹³ named for the rock where the resource has been generated (source rock) that produce crude oil and natural gas (Table 1). The most prolific oil-producing area in California is the San Joaquin Basin¹⁴ in the southern half of the Central Valley; natural gas reserves and production are located primarily in geologic basins in the Central Valley, the coastal basins onshore in Northern California and offshore along the Southern California Coast. The Monterey Formation, which stretches across the lower part of the state, is the primary source of oil and gas resources in California.

Table 1: California’s main petroleum systems

| Name | Type | General Location |
|-------------|-------------|--|
| Monterey | oil | Los Angeles, Ventura, Santa Maria, and San Joaquin Basins, and Point Arena, Mendocino County |
| Eel River | gas | Humboldt Basin |
| Kreyenhagen | oil | San Joaquin Basin |
| Miocene | oil | Los Angeles, Santa Barbara, Ventura, and Santa Maria Basins Offshore |
| Moreno | oil | San Joaquin Basin |
| Forbes | gas | Sacramento Basin |
| Starkey | gas | Sacramento Basin |
| Hornbrook | gas | Sacramento Valley |
| Domengine | gas | Sacramento and San Joaquin Valleys |

Oil production in California has been occurring since before 1900, and much of the remaining reserves require additional effort to produce including enhanced oil production techniques such as steam-enhanced production, and well stimulation treatments such as acid fracturing, acid matrix and hydraulic fracturing. Oil production in California generally produces large volumes of water and may contain “associated gas” (gas dissolved in oil and produced as a byproduct of crude oil production). California also produces gas not associated with oil production, referred to as both non-associated gas and dry gas. Non-associated gas may produce some natural gas condensate, which is a gaseous hydrocarbon mixture that condenses out of the natural gas when the pressure is sufficiently reduced. The condensate includes butane, propane, and other substances.

¹³ A petroleum system includes all those geologic elements and processes that are essential for an oil and gas deposit to exist in nature. These basic elements include a petroleum source rock, migration path, reservoir rock, seal, and trap; and the geologic processes that create each of these basic elements. (USGS. 1988. Petroleum Systems of the United States.)

¹⁴ A basin is a low area in the Earth's crust, of tectonic origin, in which sediments have accumulated (USGS. 1980. Definitions for the Geologic Provinces.). Hydrocarbon generation can occur within the basin if the source rocks are rich hydrocarbon and occur at an appropriate depth, temperature, and pressure.

California has a large oil and gas industry with more than 50,000 oil and 1,500 gas wells, including offshore platforms. Figure 2 depicts the above-noted oil and natural gas producing regions of California. Each dot on the map represents a currently permitted well in operation as of February 2016. The majority of the oil wells are located in Central and Southern California with most of the gas fields located in Northern California. An extensive network of oil and gas pipelines within the State transports California’s natural gas and crude oil throughout the State.

The San Joaquin Valley Air Pollution Control District (APCD) is home to seven of the top ten largest oil fields in California. Combined, these seven oil fields produced 60 percent of the State’s total oil production in 2014.¹⁵ In addition, five fields in Kern County produced nearly 70 percent of the state’s associated gas in 2014.

California’s remaining top oil producing fields are in the South Coast Air Quality Management District (AQMD), Monterey Bay Unified APCD, and Ventura County APCD and produce 11 percent of the state’s total oil production. The top producing non-associated gas fields are located in northern California are in Yolo-Solano, Glenn, Colusa, and Feather River air districts, and produce almost 60 percent of the state’s total non-associated gas.¹⁶ The air districts and the oil and gas facility types within each district are depicted in Figure 2.

Below are the preliminary 2014 state totals for oil and gas production in California, both onshore and offshore.

Table 2: Preliminary 2014 California oil and gas production levels ¹⁷

Figure 3: California Non-Associated Natural Gas Wells & Oil and Associated Gas Wells

D. OVERVIEW OF EMISSIONS AND REDUCTIONS

GHG emissions occur throughout the oil and gas sector, from production through processing and transmission and distribution. Emissions occur from intentional emissions (venting) that is part of normal operations including open tanks and equipment venting for safety or operational reasons. Emissions can also be due to unintentional leaks that occur at covered tanks, valves, or other components throughout the system. The details on the emissions covered under the proposal are outlined in the Technical Assessment chapter, as well as Appendix D.

As noted, the local air districts have rules and regulations to limit VOC and NO_x emissions because they are precursors of ground-level ozone. Many of the VOC controls also reduce methane as a co-benefit, since both VOCs and methane are found in the raw oil and gas and controlling VOCs will also reduce methane emissions. However, the district rules do not apply once the gas has been processed to the point that not many VOCs remain in the gas (generally less than 10%). For remaining gas streams that have fewer VOCs, the proposed regulation will reduce methane with a co-benefit of reducing the remaining VOCs as well. In 2015, U.S. EPA proposed additional federal measures that could address methane primarily at new oil and natural gas sources, with coverage at some existing sources, finalizing these measures in 2016. These additional actions to reduce methane from the oil and gas sector should also reduce VOC and toxic air contaminant emissions. In 2016, U.S. EPA announced efforts to consider similar measures for existing sources but that measure is in the information gathering stage.¹⁸

In recent years, there has been a significant amount of literature published on emissions from the oil and gas sector. Several studies have suggested that methane emissions are underestimated from this sector based on atmospheric studies.^{19,20} However, some recent literature supports U.S. EPA's oil and gas emissions estimates and at least one sector specific study focused on distribution pipelines found lower emissions than expected.²¹ In April 2016, U.S.EPA adjusted their GHG emission estimates for the sector with significant increases in the production sector and decrease for transmission and distribution.²² ARB staff has reviewed this recent information at a high level and believes that the proposed regulation is consistent with the revised numbers, and there is a sufficiently robust and defensible basis for this proposal. ARB's in-depth industry survey provided much more information than is available at the federal level, and U.S.EPA's estimates were similar or larger for most of the

sectors controlled to be under this proposed regulation, which would result in similar or more cost-effective measures.

Implementing the measures in the proposed regulation would reduce methane emissions by 40-45 percent in 2025. Additional opportunities may emerge to further reduce emissions and will be considered when they do.

1. Super Emitters

Emissions from components are not distributed uniformly throughout the sector, recent studies of natural gas facilities have shown a significant fraction of methane emissions can be attributed to a small fraction of sites or sources.^{23 24 25 26 27 28} The emissions associated with these “super-emitters” are thus important to detect and repair. Figure 4 below, illustrates one production sector example where, according to Allen et al, the top 19% of emitting pneumatic devices accounts for 95% of the emissions from pneumatics. Studies investigating methane emissions from super emitters in the natural gas system have most recently been conducted outside of California. Efforts by ARB and the California Energy Commission (CEC) are underway to investigate such emissions by using aircraft to conduct a survey of methane sources in California, including oil and gas.

Figure 4: Methane Emission by Component, Oil and Natural Gas Systems.²⁹

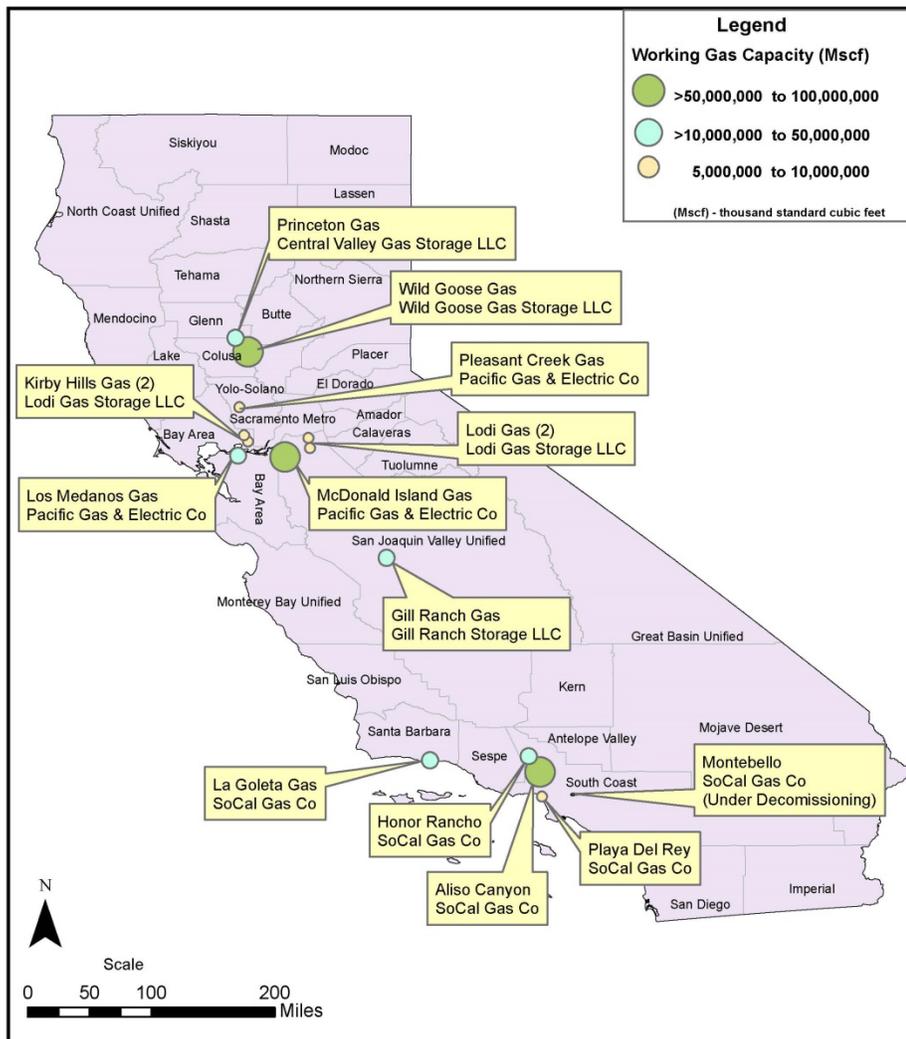

2. Aliso Canyon

In addition to super-emitters, very large unusual and unexpected leaks can occur. One recent example is the incident at Aliso Canyon. On October 23, 2015, Southern California Gas (SoCal Gas) informed the State of a natural gas leak at its Aliso Canyon natural gas storage facility. After several attempts to stop the leak, on February 11, 2016, SoCalGas temporarily controlled the leak by injecting mud from a relief well intersecting the bottom of the leaking well. February 18, 2016, state officials, including the Department of Conservation, Division of Oil, Gas, and Geothermal Resources (DOGGR), confirmed the well has been permanently sealed. However, preliminary measurements suggest a total of 94,500 tons of methane was released.³⁰ Because of this incident, ARB has clarified requirements and added an additional provision to the proposed regulation specifying monitoring for the early detection of leaks.

E. DEVELOPMENT PROCESS FOR THE PROPOSED REGULATION

Staff evaluation of methane emissions from the oil and gas sector began with the 2009 Survey, noted earlier, with an acknowledgement of the importance of the oil and gas sector in the original Scoping Plan. Staff conducted a comprehensive, detailed survey of the industry, which provided a basis for regulatory development. During the informal rulemaking process, Staff conducted multiple public workshops and numerous meetings with individual stakeholders. Below is a timeline of the public actions taken leading to this proposal. Each of the meetings below included opportunities for public comment, which were considered when developing the proposed regulation.

Table 3: Dates of Development Meetings and Workshops

| Date | Meeting |
|------------------|--|
| April 11, 2008 | Workshop on Regulatory Concepts |
| 2009 | Conducted Survey |
| December 8, 2009 | Workshop on Survey Results |
| December 2011 | Posted Survey Results Report |
| November 2013 | Posted Revised Survey Results Report |
| August 25, 2014 | Oil and Gas Rulemaking Workshop #1 |
| December 9, 2014 | Oil and Gas Rulemaking Workshop #2 |
| April 27, 2015 | Oil and Gas Rulemaking Workshop #3 with Proposed Draft Regulatory Language (Sacramento) |
| April 29, 2015 | Oil and Gas Rulemaking Workshop #4 with Proposed Draft Regulatory Language (Bakersfield) |
| February 4, 2016 | Oil and Gas Rulemaking Workshop #5 with Proposed Draft Regulatory Language (Sacramento) |

For each of the rulemaking meetings, over 4000 individuals or companies were notified and invited to participate. Each of these meetings was well attended by a variety of stakeholders, representing oil and gas production and processing companies, natural gas storage facilities, public utilities, non-governmental organizations (NGOs), and other State agencies. Notices for the workshops and associated materials, were posted to ARB's Oil and Gas webpage at: <http://www.arb.ca.gov/cc/oil-gas/oil-gas.htm>, and emailed to subscribers of our "oil and gas" listserve. All rulemaking workshops were streamed to remote attendees by webcast.

In addition to the public meetings, staff held many meetings with stakeholders, attended relevant meetings; conducted district, industry, and NGO working group meetings, and exchanged technical information with various parties on a regular basis. The proposal benefitted from the extensive feedback based upon these communication.

Staff also conducted a Standardized Regulatory Impact Assessment (SRIA). As required by Senate Bill 617 (Chapter 496, Status of 2011), ARB conducted a

SRIA and received public feedback and comments from the Department of Finance.

As part of the SRIA process, ARB solicited public input on alternative approaches, including any approach that may yield the same or greater benefits than those associated with the proposed regulation, or that may achieve the goals at lower cost. The SRIA summary is included as Attachment E and posted at:

http://www.dof.ca.gov/research/economic_research_unit/SB617_regulation/Major_Regulations/documents/Oil_and_Gas_SRIA.PDF

F. ORGANIZATION OF THIS REPORT

The remainder of this report is organized into 11 chapters with 5 appendices. It begins with a background chapter followed by a description of the proposed regulation with the summary and rationale, description of the implementation and funding, description of other related mandates, a technology assessment, an environmental assessment, and an economic assessment. The appendices include the proposed regulation order, economic analysis, environmental analysis, emission estimate calculations, and the standardized regulatory impact analysis (SRIA).

II. STATEMENT OF REASONS

A. DESCRIPTION OF PROBLEM PROPOSAL IS INTENDED TO ADDRESS

ARB has identified the oil and gas sector as a large source of GHG emissions. Both the 2008 Scoping Plan and the subsequent First Update to the Scoping Plan include the regulation of oil and gas operations covered as a potential GHG mitigation measure. Unless emissions from the sector are controlled, they will continue to be substantial, making it more difficult to maintain the state GHG emission limit imposed by AB 32, and will also complicate efforts to further reduce emissions, as AB 32 and multiple executive orders require. Emissions of fluorinated gases are projected to grow rapidly through 2030. Similarly, current projections indicate methane will not decline in the absence of successful methane control measures. If ARB does not take near-term action to stop methane emissions growth, it will be increasingly difficult to maintain the 2020 greenhouse gas limit, much less continue progress. Accordingly, methane emissions from the sector must be reduced. This regulation covers upstream emissions (production, gathering and boosting stations, and processing) as well as natural gas storage and transmission compressor stations. GHG emissions from petroleum refineries are not covered under this proposal, and oil and gas pipelines and related facilities are being addressed in a separate regulatory effort conducted by the California Public Utilities Commission (CPUC) in partnership with ARB.

Methane, the second largest man-made contributor to GHG emissions globally, is emitted from a wide range of fugitive sources and biological processes. Methane emissions are increasing globally because of human activities related to agriculture, waste handling and treatment, and oil and gas production. Cumulatively, methane emissions are responsible for about 20 percent of current global warming.³¹

In California, oil and gas systems are responsible for approximately 15 percent of methane emissions in the State. The proposed regulation is designed to reduce methane emissions from upstream and some downstream oil and gas activities within California, which accounts for about four percent of statewide methane emissions³².

B. PROPOSED SOLUTIONS TO THE PROBLEM – BACKGROUND

The following sections illustrate and describe, in plain English, various aspects of the oil and gas sector in California.

³¹ See footnote 2.

³² Upstream emissions cover emissions from production, processing, and gathering and boosting stations. Covered downstream emissions include natural gas storage and transmission compressor stations.

1. Oil and Gas Processes Addressed by the Proposed Regulation

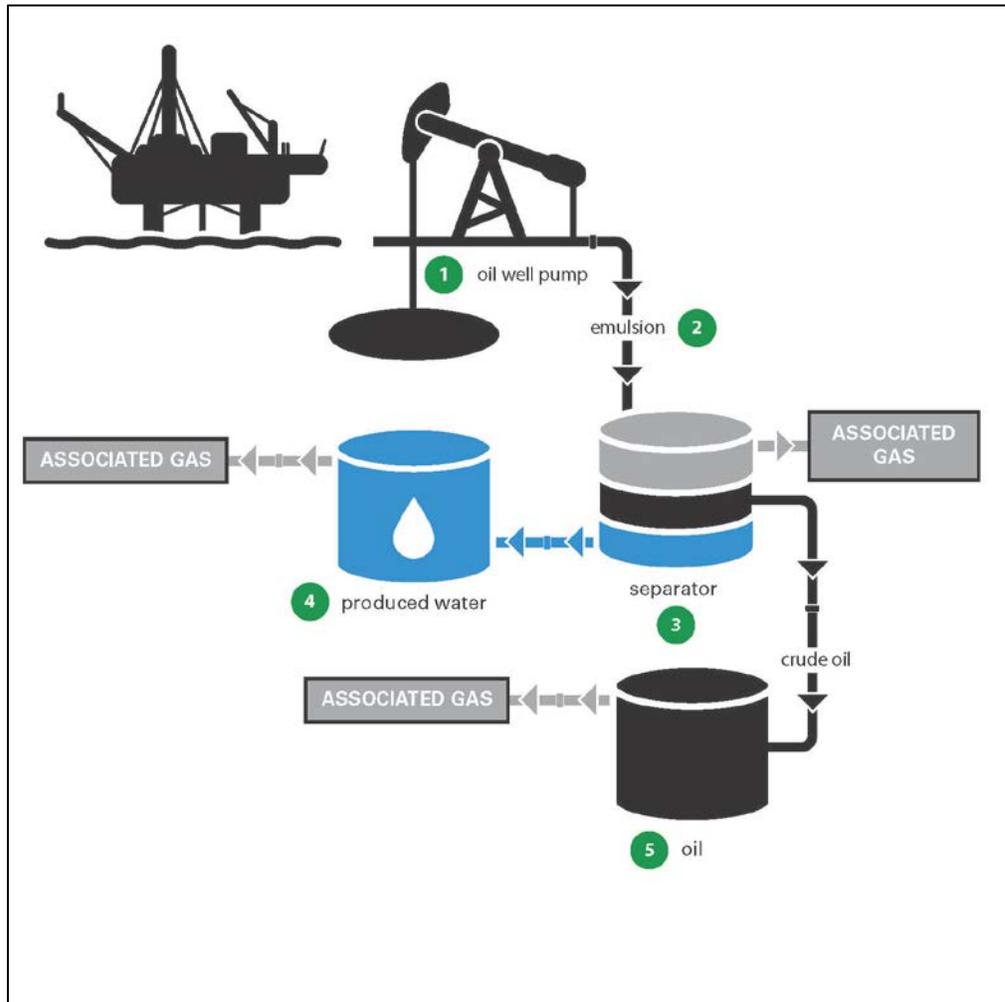

The proposed regulation addresses vented and fugitive emissions generated by processes at facilities in the following sectors:

- Onshore and offshore crude oil or natural gas production,
- Crude oil, condensate and produced water separation and storage;
- Natural gas gathering and boosting stations;
- Natural gas processing plants;
- Natural gas transmission compressor stations; and
- Natural gas underground storage.

The proposed regulation establishes emission standards for active and idle equipment and components at these facilities. Depending on the equipment or component, control mechanisms include vapor recovery, leak detection and repair (LDAR), and equipment replacement. Additionally, the proposed regulation includes monitoring at underground natural gas storage facilities for the early detection of large leaks or well failures. Storage facility monitoring provisions were added to the proposed regulation in response to the catastrophic release that occurred at the Aliso Canyon natural gas storage facility in late 2015-early 2016.

The following sections describe the crude oil and natural gas systems that are addressed in the proposed regulation and identify the equipment and components at each facility covered under the proposed regulation. These systems are further illustrated in Figures 6 through 9. Parenthetical numbers in the text refer to the figure and associated number. For example: (6, 1) refers to component 1 on Figure 6 (oil well pump), while 8-3 refers to component 3 on Figure 8 (water/condensate tank).

Figure 6: Diagram of a Crude Oil System

a) Oil and Gas Production

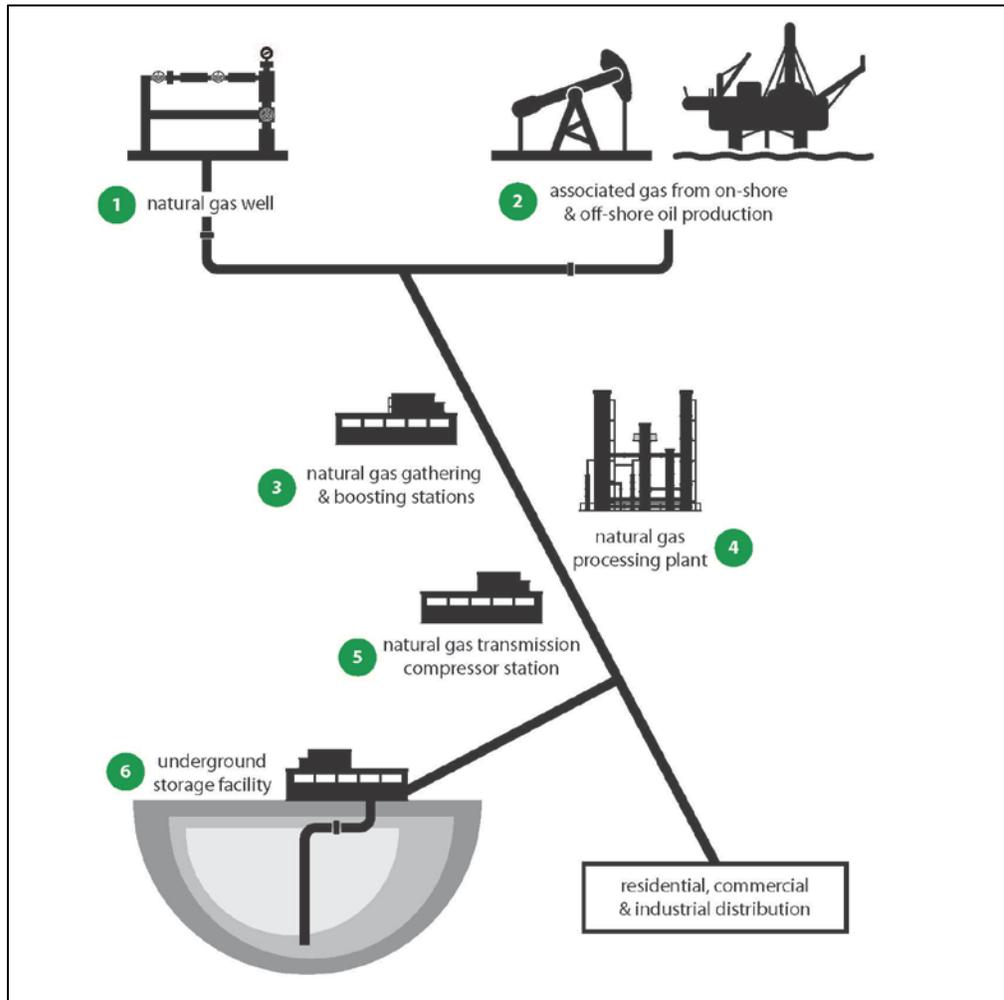

Onshore wells are drilled on a prepared surface known as a drill or production pad (6, 1). During well drilling, tanks are most commonly used to temporarily collect drilling fluids; however, a temporary pit or sump may be constructed to contain drilling fluids. Once a well has been drilled and cemented, the well completion phase begins. Well completions on a new well include casing, cementing, perforating, gravel packing, and installing a production tree. Once the casing is perforated, well stimulations such as acid fracturing, acid matrix, or hydraulic fracturing may be conducted. Well stimulation operations are performed on hydrocarbon producing wells for purposes of enhancing production by increasing the permeability of the geologic formation. These operations include the use of well stimulation fluids which can include acids such as hydrofluoric acid or a variety of other chemicals. If well stimulation occurs, a flush of the well and reservoir may recover

fluids (Figure 9) that include reservoir emulsion, well stimulation treatment fluid, additives, and produced water. Recently adopted regulations, California Code of Regulations Section 1786 (a)(4), prohibit the storage of well stimulation treatment fluid, additives, and produced water from a well that has had a well stimulation treatment in sumps or pits; all such fluids, must be stored in containers.

The most common well stimulation treatment used in California is hydraulic fracturing. The proposed regulation would require controls on “circulation tanks” (8, 2), which are tanks or portable tanks used to circulate, store, or hold liquids or solids from a crude oil or natural gas well during or following a well stimulation treatment. They are used to clean out sand from the system after hydraulic fracturing. The potential control methods required in the proposed regulation include a vapor recovery system, which would be subject to leak detection and repair (LDAR). Well stimulation treatments occur primarily on new crude oil production wells in California.

An oil well is completed with a pumping unit (unless it is free flowing), and connected by piping (flow lines and gathering lines) (6, 2) to production facilities that may include separators (6, 3), tanks (6, 4-5), and testing and shipping facilities. Depending on the type of recovery method used, there may also be facilities for generating and distributing steam, and injection wells for injecting steam and/or water. After an oil or gas well is put into production, an emulsion is brought to the surface. The emulsion primarily includes oil, water, and often associated gas. Flow lines or a bulk header carries the emulsion from the wellhead to a central processing facility or production platform. This combination of components is referred to as the gathering system; it will be subject to LDAR under the proposed regulation. The gathering system feeds into the oil and gas separation system.

Figure 7: Diagram of a Natural Gas System

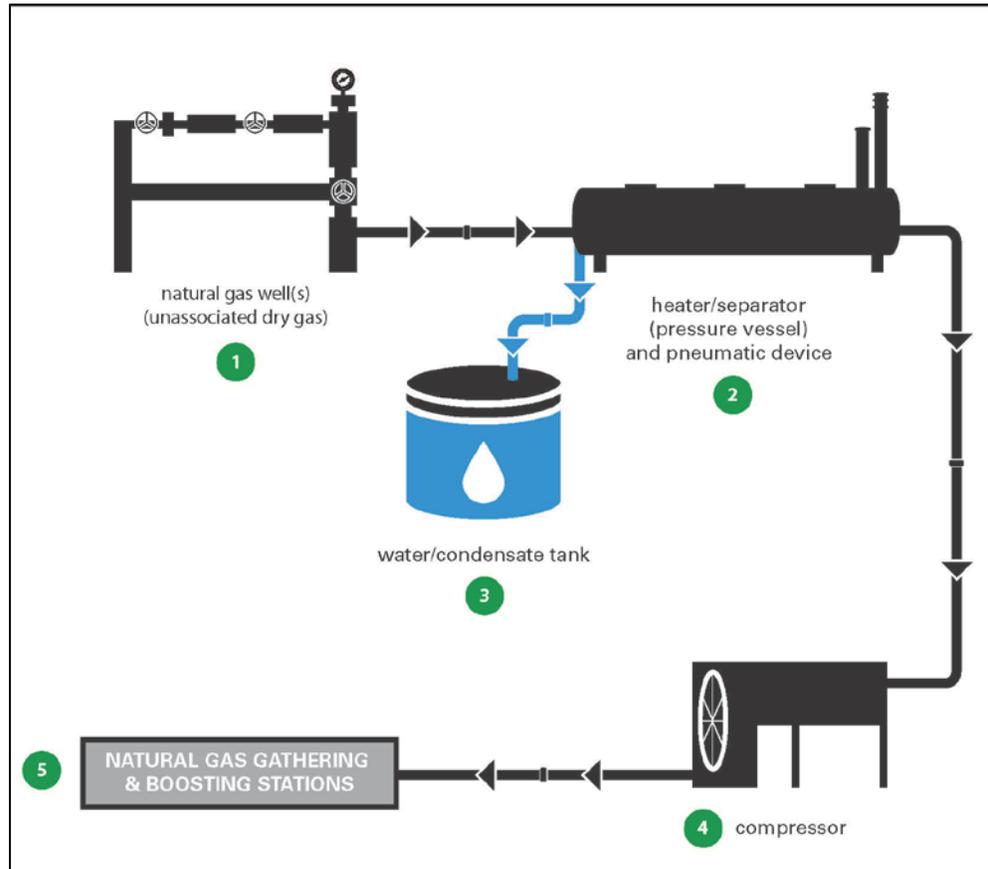

A dry gas well (8, 1) is completed with piping (flow lines and gathering lines) to a heater/separator (pressure vessel) (8, 2). The wellhead, piping and pressure vessel will be subject to LDAR under the proposed regulation. The emulsion produced from the well primarily includes gas, water, and condensate; however, in California condensate is not generally found in large volumes.

The emulsion flows from the wellhead to the heater/separator where water is separated from the gas. Emulsions from dry gas wells are often routed to one heater/separator. Piping moves wastewater to a water storage tank where, if present, residual condensate is separated out by gravity (8, 3). The gas is then routed to a compressor (8, 4) to be moved from the production facility to the gathering and boosting station (7, 3).

The wellhead, piping, pressure vessel, and compressor will be subject to LDAR under the proposed regulation. Pneumatic devices are used

for maintaining a process condition such as liquid level, pressure, pressure differential, and temperature at gas production facilities and will also be subject to LDAR and, in certain circumstances, replacement under the proposed regulation.

Figure 8: Diagram of a Typical Natural Gas Well

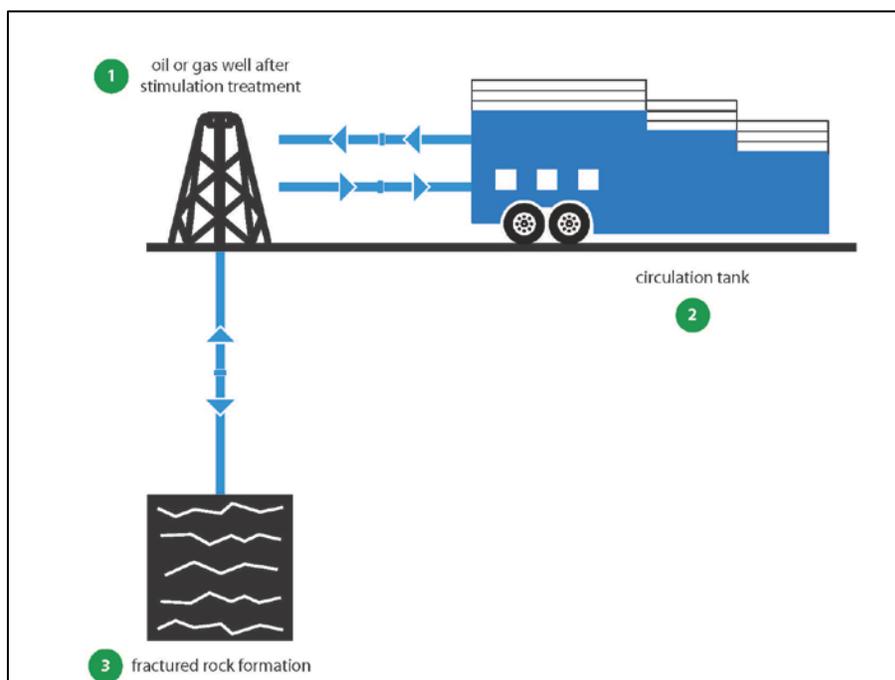

b) Liquids Unloading

Over time, dry gas wells accumulate liquids that can impede and sometimes halt gas production. When the accumulation of liquid results in the slowing or cessation of gas production, removal of fluids (e.g., liquids unloading) is required in order to maintain production. Gas flow is maintained by removing accumulated fluids, through the use of specialized equipment installed in the well such as velocity tubing or a plunger lift system, or with the use of remedial treatments such as swabbing, soaping, or by venting the well to atmospheric pressure (referred to as “blowing down” the well)³³. The proposed regulation would require that vented natural gas from liquids unloading

³³ U. S. EPA. 2006. Installing Plunger Lift Systems in Gas Wells. Office of Air and Radiation: Natural Gas Star Program. Washington, DC.

be measured or calculated and reported, if the liquids unloading operation is not utilizing a 95% effective vapor collection system.

Figure 9: Diagram of a Circulation Tank for Well Stimulation Treatments

c) Crude Oil, Condensate, and Produced Water Separation and Storage

The purpose of the separation system is to process the emulsion into clean marketable products such as oil, natural gas, or condensates, while separating out water and other debris. For example, in crude oil production the separation system (6, 3) allows the emulsion to separate into associated gas, crude oil, and produced water. (6, 4) There are several types of separators that may be used, depending on the type of operations. They include pressure vessels, free water knockouts, gravity separators, and wash tanks.

The crude oil production separator allows for an initial separation that splits the stream into a gas component (associated gas), a liquid crude component, and a water component. This process is generally achieved through a series of vessels where associated gas is allowed to flash, or bubble out, and water to settle at the bottom, with oil taken out from the middle. Potentially large amounts of gas flash off at this point. Once the production separation has been completed, crude oil (6, 5) and associated gas are usually stored briefly onsite in order to stabilize flow between production wells and pipeline or trucking transportation sites. Produced water is either cleaned up and re-used for other purposes or stored for disposal. When stored at the production facility, crude oil, associated gas, and produced water are

kept in storage tanks or sumps (produced water only). The proposed regulation establishes an emissions standard for the separator and tank systems, which includes the separator and first water and first oil tank. The water tank could be sump for produced water.

Separator and tank systems must conduct flash testing to determine emissions levels and if the results show the separator and tank system emissions are above 10 MT of methane per year, two provisions are triggered: (1) the system must employ a vapor collection system, capturing the fugitive emissions at the separator and first water and crude tank. (2) the system is subject to LDAR. Pressure vessels are subject to LDAR regardless of whether the standard is exceeded. More detail on vapor collection systems and LDAR is available in section II.C.1.-2. in this document.

Pneumatic devices and pumps are widespread throughout oil and natural gas operations, including in the separator and tank systems. At crude oil production facilities, pneumatics are generally operated using compressed air or electricity; however, high-pressure natural gas may be used to operate the devices. These devices are used to maintain a process condition such as liquid level, pressure, pressure differential, and temperature. Additionally, compressors and pneumatics are used to move associated gas from the separator system along to the gas pipeline.

Natural gas operated pneumatic devices and pumps will be subject to LDAR under the proposed regulation, and in certain circumstances, may warrant replacement. Compressors will also be subject to LDAR. Pneumatic devices and pumps not operated by natural gas are not subject to the proposed regulation.

d) Natural Gas Gathering and Boosting Stations

Gathering and boosting stations collect gas from multiple wells and move it toward the natural gas processing plant. Equipment and components at these facilities include compressors to increase the pressure of gas in the pipeline from the relatively low pressure coming from the production fields to medium pressure; pneumatic devices and pumps to maintain liquid levels, pressure, and temperature; and water knock out tanks that store water and condensate.

The proposed regulation establishes an emissions standard for compressors and a threshold for controls for any separator or storage tanks at gathering and boosting stations. If compressor flow rates are measured above the standard, in addition to any penalties, the compressor must be repaired, replaced, or the gas must be collected and routed to a vapor collection system in order to meet the standard.

In addition, compressors will be subject to LDAR. Separator and tank systems must conduct flash testing to determine emissions levels and if the results show the separator and tank system emissions are above 10 MT of methane per year, two provisions are triggered: (1) the system must employ a vapor collection system, capturing the fugitive emissions at the separator and first water and crude tank. (2) the system is subject to LDAR. Pressure vessels are subject to LDAR regardless of whether the standard is exceeded.

Natural gas operated pneumatic devices will be subject to LDAR and, in certain circumstances, may warrant replacement under the proposed regulation.

e) Natural Gas Processing Plants

Natural gas processing plants process raw natural gas and separate the various hydrocarbons and fluids from the raw natural gas, to produce what is known as "pipeline quality" dry natural gas. Natural gas used by consumers is composed almost entirely of methane. The raw natural gas commonly exists in mixtures with other hydrocarbons depending on the source of the natural gas (i.e. associated gas from crude oil production or dry gas) and reservoir characteristics, including: ethane, propane, butane, pentanes, the BTEX chemicals (benzene, toluene, ethylbenzene, and xylenes), water vapor, hydrogen sulfide (H₂S), carbon dioxide, helium, nitrogen, and other compounds. This process is analogous to the processing and refining of crude oil but less complicated.

The proposed regulation covers a subset of equipment at these facilities, focusing on large methane sources. The proposed regulation does include requirements for: compressors to move gas; pneumatic devices and pumps to maintain liquid levels, pressure, and temperature; and water knock out tanks that store water and condensate, and other components. The proposed regulation establishes an emissions standard for compressors and a threshold for controls for any separator or storage tanks at natural gas processing plants. If compressor flow rates are measured above the standard, in addition to any penalties, the compressor must be repaired, replaced, or the gas must be collected and routed to a vapor collection system in order to meet the standard. In addition, compressors will be subject to LDAR. Separator and tank systems must conduct flash testing to determine emissions levels and if the results show the separator and tank system emissions are above 10 MT of methane per year, two provisions are triggered: (1) the system must employ a vapor collection system, capturing the fugitive emissions at the separator and first water and crude tank. (2) the system is subject to LDAR. Pressure vessels are subject to LDAR regardless of whether the standard is

exceeded. Natural gas-operated pneumatic devices will be subject to LDAR and, in certain circumstances, replacement under the proposed regulation. Other components are also subject to LDAR.

f) Natural Gas Transmission Compressor Stations

Natural gas-transmission compressor stations, function to move gas further down the pipeline by either increasing the pressure of gas in the pipeline from the medium pressure coming from the gathering and boosting stations to the high pressure of the transmission pipeline or maintaining the high pressure of the transmission pipeline when pipeline flow pressure decreases. Equipment at these facilities include: compressors to increase the pressure of gas; pneumatic devices and pumps to maintain liquid levels, pressure, and temperature; and water knock out tanks that store water and condensate. The proposed regulation establishes an emissions standard for compressors and a threshold for controls for any separator or storage tanks at natural gas transmission compressor stations. If compressor flow rates are measured above the standard, in addition to any penalties, the compressor must be repaired, replaced, or the gas must be collected and routed to a vapor collection system in order to meet the standard. In addition, compressors will be subject to LDAR. Separator and tank systems must conduct flash testing to determine emissions levels and if the results show the separator and tank system emissions are above 10 MT of methane per year, two provisions are triggered: (1) the system must employ a vapor collection system, capturing the fugitive emissions at the separator and first water and crude tank. (2) the system is subject to LDAR. Pressure vessels are subject to LDAR regardless of whether the standard is exceeded. Natural gas-operated pneumatic devices will be subject to LDAR and, in certain circumstances, replacement under the proposed regulation.

g) Natural Gas Underground Storage

Natural gas is most commonly stored underground under pressure in three types of facilities: depleted reservoirs in oil or natural gas fields, aquifers, and salt cavern formations. In 2014, California had 14 active natural gas underground storage sites and one undergoing decommissioning.³⁴ Most of the storage is used for system balancing and as a way to maintain steady and high-utilization of pipeline capacity. The remaining storage facilities are primarily used as depositories for gas produced within the state that is not immediately

³⁴ U. S. EIA. 2015. Underground Natural Gas Storage Capacity.
http://www.eia.gov/dnav/ng/ng_stor_cap_dc_u_sca_a.htm

marketable.³⁵ The wells located at these facilities may function in both a natural gas injection and withdrawal capacity. These wells may be newly constructed or repurposed oil or natural gas production wells. Additionally, abandoned or idle wells may be located at facilities where there was previous oil or natural gas production.

The proposed regulation would require that each underground storage facility be monitored to enable the early detection of well leaks and alert operators of potentially large releases of methane, like at the Aliso Canyon facility. This includes LDAR on components at the wellhead as well as continuous ambient air monitoring at the field. Storage facility monitoring requirements under the proposed regulation built upon the DOGGR's emergency regulation requirements and will replace that leak detection protocol once the plans are fully in place.

Additionally, equipment at these facilities covered under the proposed regulation include: (1) compressors to move gas; (2) pneumatic devices and pumps to maintain liquid levels, pressure, and temperature; and (3) water knock out tanks that store water and condensate. The proposed regulation establishes an emissions standard for compressors and a threshold for controls for any separator or storage tanks at natural gas transmission compressor stations. If compressor flow rates are measured above the standard, in addition to any penalties, the compressor must be repaired, replaced, or the gas must be collected and routed to a vapor collection system in order to meet the standard. In addition, compressors will be subject to LDAR. Separator and tank systems must conduct flash testing to determine emissions levels and if the results show the separator and tank system emissions are above 10 MT of methane per year, two provisions are triggered: (1) the system must employ a vapor collection system, capturing the fugitive emissions at the separator and first water and crude tank. (2) the system is subject to LDAR. Pressure vessels are subject to LDAR regardless of whether the standard is exceeded. Natural gas operated pneumatic devices will be subject to LDAR and, in certain circumstances, replacement under the proposed regulation.

C. PROPOSED SOLUTIONS TO THE PROBLEM – CONTROL MECHANISMS

This section describes the control mechanisms used by the proposed regulation and identifies components that may be part of the control mechanism that are covered under the proposed regulation. The table below serves as a summary of the control mechanisms used in each category, for quick reference.

³⁵ U. S. EIA. 2008. Underground Natural Gas Storage.

1. e.g., piping, flow lines, gathering lines, or bulk header

2. "-" means that there is no threshold for the control mechanisms

3. standard cubic feet per minute

1. Vapor Collection System (VCS)

Vapor collection and recovery is the process of collecting the vapors entrained in produced water from crude oil production, or vapors from produced water from natural gas production, from tanks so they do not escape into the atmosphere. Recovered vapors are sent either to the sales gas or fuel gas system, injected underground, or flared/incinerated.

The proposed regulation specifies that collected vapors be required to go into an existing sales gas system, existing fuel gas system, or an existing underground injection well. If none of these systems is available, the vapors can go to an existing flare, provided it can still meet already permitted emission limits. In absence of existing systems, a new vapor control device is required and must meet the NO_x emission standard in the proposed regulation. This could include a low-NO_x³⁶ vapor control device or other non-destructive device³⁷. In areas classified as in attainment with all state and federal ambient air quality standards, devices would not have to meet the NO_x emission standard.

Vapor collection systems include gathering lines, compressors, and pneumatic devices and pumps; the entire system will be subject to LDAR under the proposed regulation. In addition, the proposed regulation establishes an emissions standard for non-field compressors, which, if exceeded, in addition to any applicable penalties, require the compressor be repaired, replaced, or the gas must be collected and routed into the vapor collection system. Natural gas operated pneumatic devices will be subject to LDAR and, in certain circumstances, replacement under the proposed regulation.

2. Leak Detection and Repair

Leak detection and repair, or LDAR, describes the process of locating and repairing fugitive leaks, which are the unplanned losses of methane from pipes, flanges, seals, or through the moving parts of valves, pumps, compressors, and other types of equipment and components. The air districts within the major oil producing regions of the State have had LDAR programs, or Inspection and Maintenance (I&M) programs, for decades in order to reduce volatile organic compound (VOC) emissions. However, because of the focus on VOCs, current air district I&M programs do not cover components such as valves, flanges, seals, etc., that are primarily used in natural gas service. ARB staff estimates that of all of the components in the oil and gas sector, more than 80 percent are already covered by existing air district I&M programs to prevent the release of VOC emissions, whereas the

³⁶ A device that achieves 95 percent vapor control efficiency and does not generate more than 15 parts per million by volume NO_x when measured at 3% oxygen.

³⁷ A device that achieves 95 percent vapor control efficiency and does not result in emissions of nitrogen oxides (NO_x).

LDAR component of the proposed regulation is aimed at the remaining 20 percent of components.

In addition to requiring LDAR on the major equipment and components described in the previous section (i.e., compressors, pneumatics, storage tanks and separators), the proposed regulation will also require LDAR programs to include additional components. Some examples include:

- Valves used to either restrict or allow the movement of fluids,
- Connectors and fittings used to join piping and process equipment together,
- Sampling connections utilized to obtain samples from within a process, and
- Pressure relief devices designed to protect equipment from exceeding the maximum allowable working pressure.

The LDAR program will require the repair, retrofit, or replacement of leaking equipment and components and would require implementation of improved management practices for reducing vented emissions, such as keeping hatches, or other access point on storage tanks, closed and properly sealed during normal operation, or sealing open-ended lines and valves.

3. Equipment Replacement

The proposed regulation will require some equipment be replaced when it cannot be repaired to meet the established standards. For example, continuous bleed pneumatic devices³⁸ and pumps will likely be replaced with similar devices that meet the leak-free or no venting standard established in the proposed regulation. Existing intermittent pneumatic devices emitting below 6 scfh are exempt from this requirement.

In the event that additional vapors are collected and routed into an existing vapor control system operating a vapor control device (i.e., flare), the proposed regulation will require that the existing vapor control device be replaced with a new vapor control device, (unless the existing device is compliant with the low-NO_x requirements of the proposed regulation). This could include a low-NO_x vapor control device or other non-destructive device, unless the area is classified as in attainment with all state or federal ambient air quality standards in which case any device that achieves a 95 percent vapor control efficiency of total emissions would be allowed.

³⁸ Continuous bleed controllers, used to modulate flow, liquid level, or pressure, for which gas is vented continuously.

D. SUMMARY OF ESTIMATED EMISSION BENEFITS

The proposed regulation is designed to reduce methane emissions from specified oil and gas facilities within California. The proposed regulation would result in slight CO₂ emission increases (i.e., combustion of collected vapors); however, these emissions would be in lieu of the release of methane into the atmosphere, which has a substantially higher global warming potential (GWP) than CO₂. Implementation of the proposed regulation would result in monitoring (e.g., inspections, repairs) and reporting, as well as collection and disposal of methane vapors associated with oil and gas facilities. ARB estimates statewide GHG emission benefits of approximately 1,523,000 metric tons of CO₂ equivalents per year.³⁹

Table 5: Annual Methane Emissions and Reductions using the 20 and 100 year GWP

| | Total annual emissions (MT CO ₂ e, GWP=72) | Annual reductions from proposed regulation (MT CO ₂ e, GWP=72) | Total annual emissions (MT CO ₂ e, GWP=25) | Annual reductions from proposed regulation (MT CO ₂ e, GWP=25) |
|---|---|---|---|---|
| Separators and tanks | 566,000 | 538,000 | 197,000 | 187,000 |
| LDAR | 983,000 | 590,000 | 341,000 | 205,000 |
| Pneumatics | 319,000 | 319,000 | 111,000 | 111,000 |
| Reciprocating compressors | 504,000 | 68,000 | 175,000 | 24,000 |
| Centrifugal compressors | 3,700 | 3,500 | 1,300 | 1,200 |
| Well stimulation circulation tanks | 5,200 | 4,900 | 1,800 | 1,700 |
| TOTAL from sources subject to controls in the proposed regulation | 2,381,000 | 1,523,000 | 827,000 | 529,000 |
| Other upstream oil and gas sources not subject to controls in the proposed regulation ⁴⁰ | 1,047,000 | 0 | 364,000 | 0 |
| TOTAL | 3,428,000 | 1,523,000 | 1,191,000 | 529,000 |

³⁹ Using the 20-yr global warming potential, 72, from the 2007, IPCC Fourth Assessment Report: Climate Change report, for methane. Climate Change 2007. Synthesis Report. IPCC Fourth Assessment Report: Climate Change 2007. http://www.ipcc.ch/pdf/assessment-report/ar4/syr/ar4_syr_full_report.pdf

⁴⁰ The proposed regulation covers a subset of emission sources within the oil and gas upstream sector. Although large in aggregate, these are generally smaller sources. Also includes remaining emissions from sources controlled by districts. For example tank measures are 95% effective so there are 5% of the original emissions remaining.

In addition to the GHG benefits, ARB estimates that the controls and associated compliance responses from the proposed regulation will also provide substantial statewide reductions of several toxic air contaminants and criteria air pollutants, including hydrocarbons, VOC's, and the BTEX suite of chemicals. ARB also estimated the net NO_x emissions impact of the proposed regulation. This analysis is described in detail in Appendix C: Environmental Analysis. The leak detection and repair requirements will result in minor increases in vehicle emissions; however, these are offset statewide by NO_x reductions the proposed regulation is achieving through increased use of low- NO_x vapor control devices. While ARB estimates an essentially neutral impact on NO_x statewide, in the San Joaquin Valley ARB estimates a NO_x benefit of 0.46 tons/year compared to current conditions.

Table 6: Statewide Non-GHG Air Emission Benefits

| Category | Total Hydrocarbons | VOCs | Benzene | Toluene | Ethyl-Benzene | Xylenes | NOx |
|--|---------------------------|-------------|----------------|----------------|----------------------|----------------|------------|
| TOTAL non-GHG benefits from proposed regulation (tons/year) | 27,837 | 3,627 | 62 | 29 | 4.6 | 23 | (<0.1) |

E. SUMMARY AND RATIONALE FOR EACH REGULATORY PROVISION

In this chapter, ARB Staff provides a brief summary of the provisions included in the proposed regulation, explaining the rationale for each requirement.

1. Section 95665. Purpose and Scope.

Summary of Section 95665

This section states that the purpose of the regulation is to establish GHG emission standards for crude oil and natural gas facilities and that the regulation has been designed to serve the purpose of the California Global Warming Solutions Act as codified in Section 38500-38599 of the California Health and Safety Code.

Rationale for Section 95665

This section establishes that the proposed regulation will reduce GHG emissions at crude oil and natural gas facilities and provide reference under applicable ARB authority. The purpose of the proposed regulation is to set emissions standards and establish requirements to control fugitive and vented GHG emissions from oil and gas facilities. Controlled emissions are composed primarily of methane. Methane is a powerful GHG with a GWP 72 times that of carbon dioxide (on a 20-year timeframe), and is found in significant quantities at oil and gas facilities.

2. Section 95666. Applicability.

Summary of Section 95666

This section specifies the types of crude oil and natural gas facilities covered by the proposed regulation. The affected facilities include (1) Onshore and offshore crude oil or natural gas production facilities; (2) Crude oil and produced water separation and storage facilities; (3) Natural gas underground storage facilities; (4) Natural gas gathering and boosting stations; (5) Natural gas processing plants; and (6) Natural gas transmission compressor stations. The section specifies that owners and operators of these facilities must ensure that their facilities, equipment, and components are in compliance with the requirements of the proposed regulation at all times, and are jointly and severally liable for doing so.

Rationale for Section 95666

This section ensures that the proposed regulation will apply to all new and existing oil and gas facilities located within California and California waters, regardless of emissions level. This section also clarifies that owners and operators are jointly and severally liable if they do not comply, and that they

must maintain compliance continuously, which is necessary to ensure compliance with the regulations.

3. Section 95667. Definitions.

Summary of Section 95667

This section establishes definitions for the terms used in the proposed regulation. Establishing definitions for key terms provides clarity and specificity in the proposed regulation.

Rationale for Section 95667

It is necessary that ARB define its terms as they apply to the proposed regulation.

4. Section 95668. Standards.

Summary of Section 95668

This section specifies that the standards apply to all facilities listed in section 95666, and that exemptions to one standard do not provide an exemption to other required standards.

Rationale for Section 95668

This section is necessary to clarify that the standards in this section apply to all listed facilities, and to make clear that any available exemptions apply narrowly, and do not compromise emission reductions required by other applicable standards.

5. Section 95668(a). Separator and Tank Systems.

Summary of Section 95668 (a)(1)

This section indicates that the flash analysis testing and vapor collection system requirements in the following section apply to separator and tank systems located at facilities listed in section 95666.

Rationale for Section 95668 (a)(1)

This section is necessary to define the types of equipment systems to which the section applies.

Summary of Section 95668 (a)(2)(A)

This section specifies that separator and tank systems that receive less than 50 barrels of crude oil and less than 200 barrels of produced water per day are exempt from the requirements of this section.

Rationale for Section 95668 (a)(2)(A)

Methane is emitted from the production of crude oil, condensate, and produced water when the fluids are produced from an underground reservoir and separated or stored on the surface. The emissions are primarily a result of depressurizing the liquids from reservoir pressure to a lower surface pressure and subjecting the liquids to changes in temperature. The analysis showed that separator and tank systems with a production level of than 50 barrels of crude oil per day and less than 200 barrels of produced water do not produce enough liquids to meet the proposed emissions standard and therefore do not warrant flash emissions testing, or a permanent vapor collection system. For more information, see Appendix D.

Summary of Section 95668 (a)(2)(B)

This section specifies that the requirements of this section do not apply to separator and tank systems that are already controlled with the use of a vapor collection system.

Rationale for Section 95668 (a)(2)(B)

Separator and tank systems that are controlled with a vapor collection system in accordance with local air district requirements are already in compliance with this regulation.

Summary of Section 95668 (a)(2)(C)

This section specifies that the requirements of this section do not apply to separators, tanks, and sumps that have not contained crude oil, condensate or produced water for at least 30 calendar days.

Rationale for Section 95668 (a)(2)(C)

Staff's analysis shows that separators, tanks, and sumps that have not contained crude oil, condensate, or produced water for at least 30 calendar days do not contain sufficient quantities of natural gas to warrant emissions control.

Summary of Section 95668 (a)(2)(D)

This section specifies that the requirements of this section do not apply to tanks used for temporarily separating, storing, or holding emulsion, crude oil, condensate, or produced water from a newly constructed well for up to 90 calendar days following initial production from that well, provided the tank is not used to circulate liquids from a well that has undergone well stimulation.

Rationale for Section 95668 (a)(2)(D)

This exemption is necessary to provide a regulated party with the necessary time required to complete the construction of a newly drilled well using temporary tanks to store drilling fluids, emulsion, or other liquids prior to diverting production liquids into a separator and tank system. During this time period, an owner or operator will evaluate a number of characteristics, including well production rate and annual methane emissions from the produced liquids. If the annual methane emission rate is above the specified standard, the information can be used to design and construct an appropriate vapor collection system.

Summary of Section 95668 (a)(2)(E)

This section specifies that the requirements of this section do not apply to tanks used for temporarily separating, storing, or holding emulsion, crude oil, condensate, or produced water from wells undergoing rework or inspection, for up to 90 calendar days following completion, provided the tank is not used to circulate liquids from a well that has undergone well stimulation.

Rationale for Section 95668 (a)(2)(E)

This exception is necessary to inform a regulated party that tanks used in conjunction with temporary well rework and inspection are not subject to the proposed regulation requirements. These tanks are used to hold small amounts of liquids that are expelled from a well while removing or replacing tubing or flushing small quantities of liquids from the well bore. Because the tanks are neither used in a production capacity nor used in conjunction with a well stimulation treatment, they do not warrant flash emissions testing or a permanent vapor collection system.

Summary of Section 95668 (a)(2)(F)

This section specifies that the requirements of this section do not apply to tanks that recover less than 10 gallons per day of any petroleum product from equipment, provided that the owner or operator maintains a list of the amount of liquid recovered.

Rationale for Section 95668 (a)(2)(F)

This exemption is necessary to specify that tanks used to store small quantities of waste fluids from equipment are different from tanks used in crude oil and natural gas production. These tanks are often used to clean out liquid knockout traps from large compressors or equipment but are not used in the production of crude oil or natural gas. A maximum throughput limit is specified as well as daily record keeping requirements to ensure that the tanks are used within the parameters specified.

Summary of Section 95668(a)(3)

This section specifies that existing separator and tank systems not already controlled with a vapor collection system must conduct flash analysis testing of the crude oil, condensate, or produced water processed, stored, or held in the system by the effective date.

Rationale for Section 95668(a)(3)

This section ensures that, beginning on the effective date, existing separators and tank systems are controlled with a vapor collection system.

Summary of Section 95668(a)(4)

This section specifies that new separator and tank systems not already controlled with a vapor collection system must conduct flash analysis testing of the crude oil, condensate, or produced water processed, stored, or held in the system within 90 days of system startup.

Rationale for Section 95668(a)(4)

This section ensures that, beginning on the effective date, new separator and tank systems have 90 days from initial startup, to conduct flash analysis testing and reporting, which is used to determine if the new separator and tank system is above the proposed methane emissions standard and requires the installation of a vapor collection system.

Summary of Section 95668(a)(5)(A)

This section specifies that flash analysis testing must be conducted in accordance with the ARB Test Procedure for Determining Annual Flash Emission Rate of Methane from Crude Oil, Condensate, and Produced Water as described in Appendix C to the regulation.

Rationale for Section 95668(a)(5)(A)

This section ensures that the approved method flash analysis testing will be followed by every regulated party.

Summary of Section 95668(a)(5)(B)

This section specifies that that no crude oil, condensate, or produced water may be diverted through a gauge tank that is open to the atmosphere and located upstream of the separation and system while testing is conducted.

Rationale for Section 95668(a)(5)(B)

This requirement is necessary to ensure that all flash analysis testing is facilitated in the same manner, preventing potential testing bias in facilities that might otherwise allow the products to be open to the atmosphere, before the point at which flash testing takes place.

Summary of Section 95668(a)(5)(C-D)

These sections specify that the owner or operator use the flash analysis test results provided by the laboratory to calculate the annual methane emissions for the crude oil, condensate, and produced water, adding the emissions together.

Rationale for Section 95668(a)(5)(C-D)

These requirements are necessary to ensure that each facility owner or operator is calculating the emissions and adding them together, in a consistent manner across all facilities in the state.

Summary of Section 95668(a)(5)(E-F)

These sections require that owners or operators maintain a record of flash analysis testing and report the results to ARB, per sections 95671 and 95672, respectively. Additionally, it provides for ARB to request further information or testing, if it is determined that test results are not representative of similar systems or wells.

Rationale for Section 95668(a)(5)(E-F)

These sections are necessary to provide recordkeeping requirements for flash analysis tests at a particular location or facility. Additionally, it gives ARB the ability to inquire about atypical flash analysis test results.

Summary of Section 95668(a)(6)

This section specifies that by the effective date, owners or operators of a separator and tank system with an annual emission rate greater than or equal to 10 metric tons per year of methane must control the emissions from the system as well as uncontrolled gauge tanks upstream, with a vapor collection system as specified in section 95668.

Rationale for Section 95668(a)(6)

This section is necessary to inform a regulated party with a separation and tank system with an annual emission rate greater than 10 metric tons per year of methane that the system and all uncontrolled upstream gauge tanks are subject to the vapor collection system requirement. This requirement is

necessary to ensure the separator and tank system is controlled as intended and tested while accounting for uncontrolled upstream gauge tanks that have the potential to vent emissions prior to the separator and tank system.

Summary of Section 95668(a)(7)

This section specifies that new separator and tank systems installed after January 1, 2018 with emissions that exceed the proposed regulation standard must be controlled with the use of a vapor collection system within 180 days from the date that flash analysis testing was conducted.

Rationale of Section 95668(a)(7)

This section is necessary to specify the proposed timeframe for controlling emissions from new separator and tank systems that exceed the proposed regulation standard. The proposed timeframe is intended to provide a regulated party with time necessary to design and construct a system as well as obtain the necessary local air district permits.

Summary of Section 95668(a)(8)

This section specifies that a regulated party with a separator and tank system with methane emissions measured below the proposed standard must conduct annual flash emissions testing for at least three years. If the results of three consecutive years of testing are below 10 metric tons of methane per year, the annual testing requirement may be reduced to once every five years.

Rationale for Section 95668(a)(8)

This requirement ensures that the results of flash analysis testing are accurate and then eliminates the need to conduct repetitive testing. Due to fluctuations in the liquids produced from a well or group of wells, methane emissions from each system may change slightly throughout the year. This is usually due to changes in the amount of oil or water produced. In order to provide a consistent emission baseline for each system, and to avoid the need for testing each time the system fluctuates, staff is proposing an annual testing requirement. The proposed testing requirement may be reduced to once every five years if previous results show that the emissions are consistently below the proposed standard.

Summary of Section 95668(a)(8)(A)

This section requires that the annual methane emissions must be recalculated if the crude oil, condensate, or produced water throughput increases by more than 20 percent per calendar year, after the third consecutive year of testing.

Rationale for Section 95668(a)(8)(A)

Due to the variability of fluids produced from a well or group of wells, this requirement is necessary to determine the annual methane emissions from a well with increased throughput. Methane emissions are directly related to the production rate of liquids, so an increase in the production of liquids will affect the annual methane emissions. To address daily fluctuations in volume with constant liquid composition, staff proposes that annual emissions be recalculated if there is an increase in production of crude oil, condensate, or produced water by more 20 percent per calendar year. The new methane emission rate is to be recalculated using the gas composition analysis provided during the previous year of testing along with the new volume of liquid. This will ensure that each facility maintains a current record of methane emissions for separator and tank systems while eliminating the need for extra testing.

Summary of Section 95668(a)(8)(B)

This section requires that owners or operators required to recalculate emissions with prior flash analysis testing, keep a record of the recalculations as specified. Additionally, it provides for ARB to request further information or testing, if it is determined that test results are not representative of similar systems or wells.

Rationale for Section 95668(a)(8)(B)

This section is necessary to provide recordkeeping requirements for emissions recalculation using prior flash analysis tests at a particular location or facility. Additionally, it gives ARB the ability to inquire about non-typical flash analysis test results

6. Section 95668(b). Circulation Tanks for Well Stimulation Treatments.

Summary of Section 95668(b)(1)

This section requires owners or operators of circulation tanks used in conjunction with well stimulation treatments to submit a best practices management plan designed to reduce methane emissions from circulation tanks, by the effective date listed in the regulation. Additionally, ARB's Executive Officer may approve or disapprove the plan, in whole or in part.

Rationale for Section 95668(b)(1)

This section is necessary to inform a regulated party that uses circulation tanks that they must submit a best practices management plan to ARB by the effective date specified. This requirement is necessary to ensure that a regulated party operates the uncontrolled tanks using the best practices that are available to limit the volume of emissions from the tanks while emission control equipment is designed and tested. Some best management practices that are available include using minimal amounts of water necessary to remove sand from a wellbore and minimizing the duration of circulation activity. All best practices management plans require ARB Executive Officer approval and may require modification prior to final approval, which is necessary to ensure that the plans achieve their intended purpose.

Summary of Section 95668(b)(2) and (b)(2)(A)

This section requires facilities that use circulation tanks in conjunction with well stimulation treatments to submit a written report to ARB that details the results of a technical evaluation of equipment used to control emissions from circulation tanks. The report must be provided, in writing, to ARB's Executive Officer by the effective date. The report must include testing results conducted by the owner or operator or equipment manufacturers.

Rationale for Section 95668(b)(2) and (b)(2)(A)

This section is required to inform a regulated party that uses circulation tanks that they must perform emissions testing of vapor control equipment used on a circulation tank and submit a written report of the results to ARB by the effective date specified. This requirement is necessary to provide a regulated party with time to work with circulation tank and vapor collection system equipment manufacturers to design and test emission control equipment. Examples of equipment that may be used to control emissions include a portable gas separator and a portable low-NOx incinerator to combust the collected vapors. We encourage owners or operators as well as equipment manufacturers to work with ARB during the development of the technical demonstration.

Summary of Section 95668(b)(3)

This section requires that all owners and operators of facilities that use circulation tanks during well stimulation treatments must control the methane emission with 95 percent control efficiency.

Rationale for Section 95668(b)(3)

This section is required to inform a regulated party that circulation tanks used in conjunction with well stimulation treatments by the effective date specified. This requirement is necessary to provide a regulated party with time to purchase and install vapor control equipment following the results of a successful technical demonstration specified in section 95668(b)(2).

7. Section 95668(c). Vapor Collection Systems and Vapor Control Devices.

Summary of Section 95668(c)(1)

This section specifies the types of equipment subject to the vapor collection system and control device requirements and the effective date on which the requirements apply.

Rationale for Section 95668(c)(1)

This requirement is necessary to define the types of equipment subject to the vapor collection system and control requirements and the date on which the requirements apply.

Summary of Section 95668(c)(2)

This section specifies that the vapor collection system must direct the collected vapors to one of following: (A) Existing sales gas system, (B) Existing fuel gas system, or (C) Existing gas disposal well.

Rationale for Section 95668(c)(2)

This section is required to ensure that any newly collected vapors are controlled using equipment that is already available at the facility and to minimize or eliminate ambient air quality impacts. Staff's analysis show that some oil and gas facilities have at least one of these options currently available, minimizing the cost of controlling emissions and preventing the need to install additional combustion equipment⁴¹.

⁴¹ ARB. 2013. Oil and Gas Survey. _ARB 2007 Oil and Gas Industry Survey Results, Final Report, revised in October 2013.

Summary of Section 95668(c)(3)

This section specifies that if no existing sales gas system, fuel gas system, or gas disposal well is available to accept newly collected vapors, the regulated party must install a new vapor control device. New and replacement devices must meet the proposed regulation standards.

Rationale for Section 95668(c)(3)

This section is necessary to complement, and avoid interfering with, ambient air quality standards by ensuring that the installation of new combustion equipment used to reduce methane emissions avoids criteria pollutant or toxic impacts.

Summary of Section 95668(c)(3)(A)

This section specifies that a regulated party must install a new vapor control device to control newly collected vapors in the event that there is no existing vapor control device already installed at the facility.

Rationale for Section 95668(c)(3)(A)

This requirement is necessary to clarify that any existing facility without a vapor control device must install a new vapor control device in order to control the newly collected methane vapors. This alternative is only available when no existing sales gas system, fuel gas system, or underground injection well is available, and when no existing vapor control device is installed at the facility. This section is necessary to comply with the intent of the proposed regulation to control emissions of methane.

Summary of Section 95668(c)(3)(B)

This section specifies that if an existing device does not meet the standard in section 95668(c)(4), the regulated party currently operating an existing vapor control device that is subject to the proposed vapor collection system requirement must replace that existing vapor control device with a new vapor control device that meets the proposed regulation standards.

Rationale for Section 95668(c)(3)(B)

This requirement is necessary to ensure that any incremental increase in combusted methane vapors does not result in an increase of emissions that may affect attainment or local ambient air quality standards. If the existing device does not meet the standard, this alternative must be used when no existing sales gas system, fuel gas system, or gas disposal well is available, and when the facility currently operates an existing vapor control device. This section is necessary to comply with the intent of the proposed regulation to control emissions of methane without impacting local air quality.

Summary of Section 95668(c)(4)(A)

This section specifies that if a new vapor control device is to be installed in an area classified as in attainment with state or federal ambient air quality standards, the device must achieve at least 95% control efficiency and meet all applicable federal, state, and local air district requirements.

Rationale for Section 95668(c)(4)(A)

This section allows a regulated party to install any type of vapor control device that meets the specified control efficiency in a region classified as in attainment with ambient air quality standards, as long as it meets all applicable requirements. This section ensures emission controls required by the proposed regulation complements, and avoids interfering with applicable requirements for air quality.

Summary of Section 95668(c)(4)(B)

This section specifies that if a new vapor control device is to be installed in an area classified as non-attainment with state or federal ambient air quality standards the device must meet certain requirements. This requirement provides flexibility by clarifying that more than one type of vapor control device can fulfill the requirement.

Rationale for Section 95668(c)(4)(B)

This requirement is necessary to ensure that any incremental increase in combusted methane vapors does not result in an increase of emissions that may affect attainment or local ambient air quality standards.

Summary of Section 95668(c)(4)(B)1

This section specifies that a non-destructive vapor control device may be installed in an area classified as non-attainment with ambient air quality standards provided the device is at least 95% efficient in controlling emissions of methane and does not result in emissions of NO_x.

Rationale for Section 95668(c)(4)(B)1

Non-destructive control devices process collected vapors without a need for combustion. An example of such a device chills vapors to an extremely cold temperature which to turn converts the gas into liquid. The liquid may be used on-site or sold as a useable product. Although the technology is not currently employed within the oil and gas sector, manufacturers of the equipment are aware of a need for a system that can be used in this application, and ARB staff believes that the technology can be adapted for use in the oil and gas sector. This requirement is necessary to provide

flexibility in the event that the technology becomes available for future oil and gas applications.

Summary of Section 95668(c)(4)(B)2

This section specifies that a vapor control device may be installed in an area classified as non-attainment with ambient air quality standards provided it is at least 95% efficient in controlling emissions of methane and does not generate more than 15 parts per million volume of NO_x when measured at 3% oxygen and does not require the use of supplemental fuel gas, other than gas required for a pilot burner, to operate.

Rationale for Section 95668(c)(4)(B)2

This section is necessary to ensure that newly collected vapors are controlled in areas classified as non-attainment with state or federal ambient air quality standards using a device that minimizes or reduces ambient air quality impacts. Examples of such devices that can be used to meet the proposed standards include low-NO_x incinerators and microturbines. Low-NO_x incinerators use proprietary technology to efficiently burn, and otherwise destroy, all of the collected vapors. Microturbines are used to generate electricity and create a beneficial use for waste gas, which is otherwise destroyed. This requirement is necessary to provide an emissions standard that reduces emissions affecting ambient air quality while controlling newly collected vapors and allowing the regulated party to continue oil and gas production.

Summary of Section 95668(c)(5)

This section specifies that if any newly collected vapors cannot be controlled using any of the alternative options specified in section 95668(c), then any equipment subject to the proposed regulation vapor collection system requirements must be removed from service by the date specified.

Rationale of Section 95668(c)(5)

This section is necessary to inform a regulated party that they cannot operate equipment that does not meet the proposed regulation vapor collection system requirements after the effective date specified in the proposed regulation. This requirement is necessary to comply with the intent of the proposed regulation to control emissions of methane in a manner that is consistent with state and federal ambient air quality standards.

Summary of Section 95668(c)(6)

This section specifies that vapor collection systems and control devices are allowed to be out of service for a certain number of calendar days each year

for maintenance or utility power outages. Additionally, there is flexibility when replacing compliant devices, and during power outages.

Rationale of Section 95668(c)(6)

This section is required to provide a regulated party with a set amount of time, to take the vapor collection systems and control devices out of service, or to use an alternative method, to perform scheduled maintenance and to make an allowance for utility power outages.

8. Section 95668(d). Reciprocating Natural Gas Compressors.

Summary of Section 95668(d)(1)

This section specifies that reciprocating natural gas compressors used at crude oil and natural gas production facilities must comply with the proposed regulation standards.

Rationale of Section 95668(d)(1)

This section is necessary to inform a regulated party that reciprocating natural gas compressors located at the facilities listed are subject to the proposed regulation standards.

Summary of Section 95668(d)(2)

This section specifies that reciprocating compressors that operate less than 200 hours per year are exempt from the requirements of 95668(d), provided that the owner or operator keep a written record of operating hours, and can demonstrate it to ARB's Executive Officer, upon request.

Rationale of Section 95668(d)(2)

This exemption is necessary to prevent the unnecessary startup and running of a compressor in order to perform annual emissions testing. The unnecessary generation of emissions to perform emissions measurements conflicts with the proposed intent of the regulation to reduce annual methane emissions.

Summary of Sections 95668(d)(3)(A-B)

These sections are necessary to specify that components on the compressor must be tested and repaired during each inspection period according to the proposed LDAR requirements. Additionally, the rod packing or seal must also be tested in accordance with the proposed LDAR test procedure.

Rationale of Sections 95668(d)(3)(A-B)

These sections are necessary to inform a regulated party that regular emissions monitoring is required for the rod packing or seal in addition to other engine and compressor components.

Summary of Section 95668(d)(3)(C-D)

This section specifies that, by the effective date, compressor vent stacks used to vent rod packing or seal emissions shall either be controlled with the use of a vapor collection system as specified in section 95688(c) or shall be subject to measurement and, if above the minimum threshold in 95669, repaired within 30 days of the initial emissions flow rate measurement.

Rationale of Section 95668(d)(3)(C-D)

This section is necessary to specify that owners or operators have the option to control rod packing or seal emissions with the use of a vapor collection system. This section is also necessary to specify that compressors that control the rod packing or seal vent gas with the use of a vapor collection system are not required to conduct LDAR testing of the rod packing or seal. This section is also necessary to specify the repair timeframe for a rod packing or seal, which is different from other repair timeframes listed in LDAR. Due to the complexity of repairing these components, additional time is provided to allow the owner or operator to take the compressor out of service, order parts, and make all of the necessary repairs.

Summary of Section 95668(d)(3)(E)

This section specifies that the owner or operator of the reciprocating compressor shall maintain a record of rod packing leak concentration measurements that are measured above the minimum leak threshold as specified in Appendix A, Table 5. The owner or operator must also report a record of the measurements to ARB once per calendar year as specified in section 95672.

Rationale of Section 95668(d)(3)(E)

This requirement is necessary for an owner or operator to demonstrate to the ARB Executive Officer that emissions testing was conducted as specified in the proposed regulation and for ARB to maintain accurate records of emissions from these components.

Summary of Section 95668(d)(3)(F)

This section specifies that any compressor, which has been approved as a critical component, must be repaired by the end of the next process shutdown

or within 12 months from the date of the initial flow rate measurement, whichever is sooner.

Rationale of Section 95668(d)(3)(F)

This section is necessary to prevent the shutdown of a critical process unit that has the potential to emit more emissions of methane than those from the defective component. Critical components are allowed additional time to make repairs, but must be repaired during the next process unit shutdown or within 12 months from the date of the initial leak concentration measurement, whichever is sooner. All critical components must be pre-approved by the ARB Executive Officer to receive this special designation.

Summary of Section 95668(d)(4)

This section applies to reciprocating natural gas compressors at natural gas gathering and boosting stations, processing plants, transmission compressor stations, and underground natural gas storage facilities listed in section 95666 and which are not covered under section 95668(d)(3).

Rationale of Section 95668(d)(4)

This section is necessary to differentiate between compressors located at the facilities listed which are subject to different rod packing or seal testing requirements and emissions than compressors located at production facilities.

Summary of Section 95668(d)(4)(A)

This section specifies that components on driver engines and compressors shall comply with the leak detection and repair requirements specified in section 95669.

Rationale of Section 95668(d)(4)(A)

This section is necessary to inform a regulated party that components on driver engines and compressors are subject to the LDAR testing requirements during each leak inspection.

Summary of Section 95668(d)(4)(B)

This section directs owners or operators of facilities to measure the rod packing or seal flow rate annually, and in compliance with the regulation, using one of the following methods: (1) Vent stacks must be equipped with a meter or instrumentation to measure the rod packing or seal emissions flow rate; or (2) Vent stacks must be equipped with a clearly identified access port installed at a height of no more than six (6) feet above ground level or a permanent support surface for making individual or combined rod packing or seal emission flow rate measurements

Rationale of Section 95668(d)(4)(B)

This section is necessary to inform a regulated party that regular rod packing or seal emission testing is required to comply with the proposed regulation, in the event that the vent stack emissions are not controlled with the use of a vapor collection system. The rod packing or seal must be measured annually using an emissions flow rate instrument. This measurement frequency was chosen because normal wear and tear on these compressors is low, and methods to measure the emissions rate are complex. In most applications, reciprocating compressors installed at the facilities specified are used to compress processed natural gas that is relatively free of contaminants that might wear out the rod packing or seal quickly. To provide flexibility with testing, owner or operator may use instrumentation, installed within the vent stack, to continuously measure the emissions flow rate or install an access port in the stack for making annual measurements.

Summary of Section 95668(d)(4)(C-E)

These sections specify that compressor vent stacks must either be controlled with the use of a vapor collection system or the rod packing must be measured annually, and any compressor with a rod packing or seal that exceeds 2 scfm (or 2 scfm times the number of rod packing cylinders), must be repaired within 30 calendar days from the date of the initial flowrate measurement. Additionally, the owner or operator must maintain a record of the flow rate measurements as specified in Appendix A, Table 7 of the proposed regulation and report the measurement result to ARB once per year.

Rationale of Section 95668(d)(4)(C-E)

These sections are necessary to specify that emissions from a rod packing or seal must either be controlled with the use of a vapor collection system or tested annually and repaired within 30 calendar days from the date of the initial flowrate measurement. These sections provide flexibility, giving an operator or operator the option to either control the emissions or perform annual measurements and make repairs as specified. The 30 calendar day repair timeframe provides time for a regulated party to take a compressor out of service, order parts, and make any necessary repairs.

Summary of Section 95668(d)(4)(F)

This section specifies that any compressor, which has been approved as a critical component by the ARB Executive Officer, must be repaired by the end of the next process unit shutdown or within 12 months from the date of the initial flow rate measurement, whichever is sooner.

Rationale of Section 95668(d)(4)(F)

This section is necessary to prevent the shutdown of a critical process unit that has the potential to emit more emissions of methane than those from the defective component. Critical components are allowed additional time to make repairs, but must be repaired during the next process unit shutdown or within 12 months from the date of the initial flow rate measurement, whichever is sooner. All critical components must be pre-approved by ARB to receive this special designation

9. Section 95668(e). Centrifugal Natural Gas.

Summary of Section 95668(e)(1)

With the exception of compressors listed in section 95668(e)(2), this section specifies that centrifugal natural gas compressors must comply with the proposed standards beginning on the date specified.

Rationale of Section 95668(e)(1)

This section is necessary to inform a regulated party that centrifugal natural gas compressors located at the facilities specified are subject to the proposed regulation requirements.

Summary of Section 95668(e)(2)

This section specifies that any centrifugal natural gas powered compressor operating less than 200 hours per calendar year is exempt from this section of the proposed regulation, provided that the owner or operator maintains a record of the operating hours per calendar year, and can provide them to ARB's Executive Officer, upon request.

Rationale of Section 95668(e)(2)

This exemption is necessary to prevent the unnecessary startup and running of a compressor in order to perform annual emissions testing. The unnecessary generation of emissions to perform emissions measurements conflicts with the proposed intent of the regulation to reduce annual methane emissions.

Summary of Sections 95668(e)(3)

This section specifies that centrifugal natural gas compressors that use wet seals or dry seals are subject to the proposed LDAR requirements.

Rationale of Sections 95668(e)(3)

This section is necessary to inform a regulated party that regular emissions testing is required for all components found on centrifugal natural gas compressors that use either a wet seal or dry seal system.

Summary of Sections 95668(e)(4)

This section specifies that centrifugal natural gas compressors with wet seals must be measured annually using one of the following methods: (A) Vent stacks shall be equipped with a meter or instrumentation to measure the wet seal emissions flow rate; or, (B) Vent stacks shall be equipped with a clearly identified access port installed at a height of no more than six (6) feet above ground level or a permanent support surface for making wet seal emission flow rate measurements.

Rationale of Sections 95668(e)(4)

This section is necessary to specify that wet seals must be measured annually to determine compliance with the proposed emission flow rate standard. This measurement frequency was chosen because normal wear and tear on these compressors is low and methods used to measure the emissions flow rate are complex. In most applications, centrifugal natural gas compressors are used to compress processed natural gas that is relatively free of contaminants that might wear out the wet seal quickly. To provide flexibility with testing, owner or operator may use instrumentation installed within the vent stack to continuously measure the emissions flow rate or install an access port in the vent stack for making annual flow rate measurements.

Summary of Section 95668(e)(5-7)

These sections specify that wet seal emissions that exceed 3 scfm (or 3 scfm times the number of seals) must either be controlled with the use of a vapor collection system or repaired within 30 calendar days from the date of the initial flowrate measurement. Additionally, the owner or operator must maintain a record of flow rate measurements as specified in Appendix A, Table 7 of the proposed regulation and report flowrate measurement results to ARB once per year.

Rationale of Section 95668(e)(5-7)

These sections are necessary to specify that owners or operators of compressors with wet seals must either control the emissions with the use of a vapor collection system or perform annual measurements and make repairs to wet seals that are measured above the flow rate standard. These sections provide flexibility, giving an operator or operator the option to either control wet seal emissions or perform annual measurements and make repairs as

specified. The 30 calendar day repair timeframe provides time for a regulated party to take a compressor out of service, order parts, and make any necessary repairs. This also provides additional time to evaluate the possibility of controlling the wet seals with the use of a vapor collection system.

Summary of Section 95668(e)(8)

This section specifies that the owner or operator of any centrifugal compressor must maintain a record of the flow rate measurements as described in Appendix A, Table 7 of the proposed regulation and report it to ARB once per year.

Rationale of Section 95668(e)(8)

This requirement is necessary for an owner or operator to demonstrate to the ARB Executive Officer that emissions testing has been conducted as specified in the proposed regulation and for ARB to maintain accurate records of emissions from these components.

Summary of Section 95668(e)(9)

This section specifies that any compressor approved as a critical component must be successfully repaired by the end of the next process unit shutdown or within 12 months of the date of the initial flow rate measurement, whichever is sooner.

Rationale of Section 95668(e)(9)

This section is necessary to prevent the shutdown of a critical process unit that has the potential to emit more emissions of methane than those from the defective component. Critical components are allowed additional time to make repairs, but must be repaired during the next process unit shutdown or within 12 months from the date of the initial flow rate measurement, whichever is sooner. All critical components must be pre-approved by the ARB Executive Officer to receive this special designation.

10. Section 95668(f). Natural Gas Powered Pneumatic Devices and Pumps.

Summary of Section 95668(f)(1)

This section specifies that natural gas powered pneumatic devices and pneumatic pumps are subject to the proposed regulation standards.

Rationale of Section 95668(f)(1)

This section is necessary to inform a regulated party that both natural gas powered pneumatic devices and natural gas powered pneumatic pumps are subject to the proposed regulation.

Summary of Section 95668(f)(2)

This section specifies that continuous bleed pneumatic devices shall not vent natural gas after the effective date specified and must comply with the leak detection and repair standards..

Rationale of Section 95668(f)(2)

This requirement is necessary to prevent the venting of methane from continuous bleed pneumatic devices. By design, continuous bleed devices continuously vent natural gas into the atmosphere. Other types of non-venting pneumatic devices are available and continuous bleed devices may also be retrofitted to use compressed air or electricity to eliminate the vented emissions.

Summary of Section 95668(f)(2)(A)1-5

These sections specify that continuous bleed pneumatic devices installed prior to January 1, 2016 that do not vent natural gas at a rate greater than 6 standard cubic feet per hour (scfh) may remain in service provided that the devices are clearly identified with a permanent tag to identify these particular devices, and the devices are tested annually using a flow rate measurement method.

Rationale of Section 95668(f)(2)(A)1-5

This section is necessary to identify a subcategory of existing continuous bleed pneumatic devices that vent small amounts of methane and were previously installed in order to comply with ARB Mandatory Reporting Regulation requirements, which required either replacing high-bleed devices with low bleed devices or metering the gas flow rate. . The requirements listed specify how an owner or operator must identify the devices for identification by inspectors, and how the devices must be tested annually to ensure that they do not vent emissions at a rate greater than 6 scfh. Similar to other devices that require emission flow rate testing, the annual measurement frequency was chosen due to the complexity of performing flow rate measurements.

Summary of Section 95668(f)(3)

This section specifies that intermittent bleed pneumatic devices must comply with the leak detection and repair requirements when they are not controlling.

Rationale of Section 95668(f)(3)

This requirement is necessary to ensure that intermittent bleed pneumatic devices do not leak or vent natural gas when they are not controlling, a state that is also known as “idle”. By design, intermittent bleed devices are designed to be sealed, and do not vent natural gas when idle. However, they may vent a predetermined volume of natural gas when controlling a process or equipment. This requirement is designed to ensure that the devices are tested consistently by an owner or operator or inspector and to ensure that the device is sealed when idle.

Summary of Section 95668(f)(4)

This section specifies that pneumatic pumps shall not vent natural gas to the atmosphere and must be tested and repaired during each inspection period according to the proposed LDAR requirements.

Rationale of Section 95668(f)(4)

This requirement is necessary to eliminate emissions of methane from pneumatic pumps that vent natural gas into the atmosphere. Other types of non-venting pneumatic pumps are available and these pumps may be retrofitted to use compressed air or electricity to eliminate the vented emissions.

Summary of Section 95668(f)(5)

This section specifies that natural gas powered pneumatic devices and pumps must be replaced or retrofitted with the use of a vapor collection system, compressed air, or electricity to prevent the venting of natural gas emissions into the atmosphere.

Rationale of Section 95668(f)(5)

This section is necessary to inform a regulated party that the proposed regulation would require the replacement of pneumatic devices or require the devices to be retrofitted. The control strategies include controlling devices with use of a vapor collection system or modifying devices to use compressed air or electricity to operate. These options are designed to provide a regulated party with flexibility to control emissions of methane from a variety of devices and pumps.

11. Section 95668(g). Liquids Unloading of Natural Gas Wells.

Summary of Section 95668(g)

This section specifies that a regulated party who vents natural gas to the atmosphere for the purpose of liquids unloading must either control the

vented natural gas with the use of a vapor collection system or measure or calculate the volume of vented gas. Regulated parties must also maintain records and report volumes of vented natural gas from liquids unloading operations and equipment installed to automatically perform liquids unloading.

Rationale of Section 95668(g)

This section is required to either (1) control emissions of natural gas that is vented as a result of liquids unloading or (2) quantify the emissions and gather information on the activity and automation equipment used to perform the operation automatically. If a regulated party chooses to control the vented natural gas, they must use a vapor collection system as specified in section 95668(c). If a regulated party chooses to measure the volume of gas that is vented they are permitted to choose from several measurement methods. A regulated party may also choose to calculate the volume of gas that is vented by using one of the specified calculation methods. If a regulated party chooses to use either one of the measurement or calculation methods, they must report the results to ARB annually. This information is necessary for ARB to accurately quantify emissions and determine the performance of automation equipment. The results will be used to determine if future modifications to the proposed regulation are necessary.

12. Section 95668(h). Well Casing Vents.

Summary of Section 95668(h)

This section specifies that by the effective date, owners or operators of wells located at facilities listed in section 95666, with a well casing vent that is open to the atmosphere shall measure the natural gas flow rate from the well casing vent annually, and according to the methods listed in the regulation. Additionally, a record of each well casing vent flow rate measurement according to Appendix A, Table 7 of the proposed regulation, should be maintained and made available to ARB's Executive Officer, annually.

Rationale of Section 95668(h)

This section is required for ARB to quantify emissions and gather information from well casing vents that are open to the atmosphere. This section is also required to notify inspectors that well casing vents that are open to the atmosphere are not subject to the LDAR standards. Each year, the owner operator must measure the volume of natural gas that is vented from each well casing vent and report the results to ARB. The results will be used to determine if future modifications to the proposed regulation are necessary.

13. Section 95668(i). Natural Gas Underground Storage Facility Monitoring Requirements.

Summary of Section 95668(i)

This section details the monitoring requirements for natural gas underground storage facilities. Operators must comply with leak detection protocols that are already in place at the effective date of this subarticle. Operators must then submit an air monitoring plan and a leak detection protocol to ARB's Executive Officer for approval. The leak detection protocol may include the daily use of Method 21, Optical Gas Imaging, or other screening instruments; or a continuous monitoring alarm system. Recordkeeping and quarterly reporting requirements are also detailed. The ambient air monitoring plan requires the use of a continuous air monitoring network. All leaks discovered must be repaired within the repair timeframes detailed in section 95669.

Rationale of Section 95668(i)

The purpose of this section is to prevent leaks in underground storage facilities from going unnoticed, neglected, or unchecked. A variety of methods to detect leaks are included in the protocol, to provide flexibility to operators in meeting requirements. Continuous ambient air monitoring is required to provide the public agencies and the public accurate exposure information.

14. Section 95669. Leak Detection and Repair.

Summary of Section 95669(a)

This section specifies the facilities that are subject to the proposed leak detection and repair requirements.

Rationale of Section 95669(a)

This section is required to inform a regulated party of the types of facilities that are subject to the proposed leak detection and repair requirements.

Summary of Section 95669(b)

This section specifies the types of equipment that are not covered by the proposed leak detection and repair requirements.

Rationale of Section 95669(b)

This section is necessary to specify components that are not subject to the proposed leak detection and testing requirements.

Summary of Section 95669(b)(1)

This section specifies that any components that are subject to local air district leak detection and repair requirements prior to January 1, 2018 are not subject to the proposed leak detection and repair requirements.

Rationale of Section 95669(b)(1)

This section is necessary to specify that, for the purposes of this proposed regulation, all components that are already tested and repaired in accordance with local air district requirements are already in compliance with this proposed regulation.

Summary of Section 95669(b)(2)

This section specifies that components, including components found on tanks, separators, and pressure vessels used exclusively with the crude oil with API gravity less than 20 are not subject to the proposed leak detection and repair requirements.

Rationale of Section 95669(b)(2)

This section is necessary to specify that the proposed leak detection and repair testing requirements do not apply to heavy oil components. Staff's analysis of published emission factors⁴² to date show that components associated with heavy oil emit less total hydrocarbons, and therefore less methane, than other components found in gas or other liquid service.

Summary of Section 95669(b)(3)

This section specifies that components incorporated into produced water lines located downstream of a separator and tank system are not subject the proposed leak detection and repair requirements.

Rationale of Section 95669(b)(3)

The section is necessary to specify that components used in conjunction with produced water and which are located downstream of a separator and tank system are not subject to the proposed requirements. Staff was not able to locate any published emission factors for these components which are located downstream from the point of where flashing occurs.

⁴² CAPCOA. 1999. California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities

Summary of Section 95669(b)(4)

This section specifies that natural gas distribution lines used to deliver commercial quality natural gas to a facility, and which are not owned or operated by the facility, are not subject to the proposed leak detection and repair requirements.

Rationale of Section 95669(b)(4)

This section is necessary to specify that an owner or operator is not responsible for testing or repairing components that are not owned or operated by the facility.

Summary of Section 95669(b)(5)

This section specifies that components that are buried below ground are not subject to the proposed leak detection and testing requirements and that the portion of well casing that is visible above the ground is not considered a buried component.

Rationale of Section 95669(b)(5)

This section is necessary to specify that testing is not required for buried components and prevents the need for owners or operators to uncover and test components. However, testing is required for well casing components, including the portion of well casing that is visible on the surface. In some cases it's possible for an underground well casing leak to permeate up the surface along the exterior portion of well casing. These types of leaks can be detected at well head casing on the surface and are subject to the proposed leak detection and repair requirements.

Summary of Section 95669(b)(6)

This section specifies that stainless tube fittings used in conjunction with compressed air are not subject to the proposed requirements.

Rationale of Section 95669(b)(6)

This section is necessary to prevent the need for testing components that do not contain any emissions of methane or other hydrocarbons.

Summary of Section 95669(b)(7)

This section specifies that stainless tube fittings used in conjunction with natural gas that have been tested in accordance with Method 21 do not require additional testing.

Rationale of Section 95669(b)(7)

This section is necessary to prevent the need re-testing stainless-steel tube fittings that have been previously testing. These fittings are designed with the use of a nut and ferrule locking system and are designed to not loosen or leak once tightened.

Summary of Section 95669(b)(8)

This section specifies that components operating under negative gauge pressure or below atmospheric pressure are not subject the proposed leak detection and repair requirements.

Rationale of Section 95669(b)(8)

This section is necessary to prevent the need for testing components that do not have the ability to emit methane or hydrocarbon emissions.

Summary of Section 95669(b)(9)

This section specifies that components located downstream of a custody transfer meter and are not owned by the production facility are not subject to the proposed leak detection and repair requirements.

Rationale of Section 95669(b)(9)

This section is necessary to specify that an owner or operator is not responsible for testing or repairing components that are not owned or operated by the facility.

Summary of Section 95669(b)(10)

This section specifies that components used for general maintenance and used less than 300 hours per year are not subject to the proposed leak detection and repair requirements if the owner or operator maintains a record of the components and can provide a copy of the record at the request of the ARB.

Rationale of Section 95669(b)(10)

This section is necessary to specify that temporary components are not subject to the proposed regulation requirements. These components are used to temporarily divert liquid or gases while equipment is being constructed or modified. This requirement prevents the need to perform counting and measurements on components that are only used temporarily.

Summary of Section 95669(b)(11)

This section specifies that well casing vents that are open to the atmosphere are not subject to the proposed leak detection and repair requirements.

Rationale of Section 95669(b)(11)

This section is necessary to specify that well casing vents that are open to the atmosphere are not subject to the proposed leak detection and repair requirements. However, these components are subject to the proposed annual flow rate testing and reporting requirements. This section is necessary to prevent owners or operators or inspectors from testing these components during regular leak inspections.

Summary of Section 95669(c)

This section specifies that all components not identified in the exemptions section are subject to the proposed leak detection and repair requirements beginning on January 1, 2018.

Rationale of Section 95669(c)

This section is necessary to inform a regulated party that components located at facilities which are not identified in the exemption's section are subject to the proposed regulation requirements.

Summary of Section 95669(d)

This section specifies that the ARB Executive Officer may perform inspections at facilities at any time in order to determine compliance with the proposed leak detection and repair requirements.

Rationale of Section 95669(d)

This section is necessary to inform a regulated party that ARB may perform routine inspections at facilities at any time throughout the calendar year. These inspections may be in addition to local air district inspections. This requirement is necessary for ARB to determine compliance with the proposed regulation.

Summary of Section 95669(e)

This section specifies that owners or operators must perform daily audio-visual inspections on hatches, pressure-relief valves, well casings, stuffing boxes, and operating pump seals to look for the presence of leaks. The daily inspection frequency is reduced to weekly for unmanned facilities.

Rationale of Section 95669(e)

This section is necessary to inform a regulated party that audio-visual inspections are required for specified components. This requirement is similar to current requirements used by local air districts in major oil and gas producing regions. Each of the components listed have the potential to emit large amounts of methane so this requirement is necessary to ensure that these components do not leak for extended periods of time, or continue to leak in between routine instrument inspections. The list of components was shortened to only the most critical components so that an owner or operator has the ability to perform simple audio-visual checks when they visit the facilities.

Summary of Section 95669(e)(1)

This section specifies that all pipes installed at a facility must be audio-visually checked at least once every 12 months.

Rationale for Section 95669(e)(1)

This section is necessary to inform a regulated party that audio-visual inspections are required for all pipes located at a facility at least once every twelve months. This requirement is similar to current requirements used by local air districts in major oil and gas producing regions. This requirement is necessary to ensure that all gathering pipes used at a facility are inspected. Although pipes are designed not to leak emissions, they are also not routinely inspected with the use of Method 21 which is primary used for measuring connections. This requirement is necessary to ensure that pipes are checked for damage and repaired within 24 hours or tested with the use of Method 21 and repaired within the specified timeframes.

Summary of Section 95669(f)

This section specifies that any audio-visual inspection that indicates a leak that cannot be repaired within 24 hours must be measured with the use of Method 21 and then repaired within the timeframe specified for the resulting leak concentration measurement. Provisions have been made to clarify the testing requirement for leaks discovered over weekends or holidays.

Rationale for Section 95669(f)

This section is necessary to specify resulting actions that are required by an owner or operator if a leak is discovered during an audio-visual inspection. In many cases leaks can be repaired immediately, but some leaks require more complex repairs. The measurement requirement is necessary to identify the leak concentration which is used to determine the repair timeframe.

Summary of Section 95669(g)(1)

This section specifies that components must be tested in accordance with EPA Reference Method 21 at least once each calendar quarter and that the quarterly inspections may be reduced to annual inspections if a facility maintains compliance for five consecutive calendar quarters. The annual inspection frequency will revert back to quarterly if the facility fails to maintain compliance with the proposed requirements.

Rationale of Section 95669(g)(1)

This section is necessary to specify the proposed test method and the proposed leak inspection frequency. The EPA Reference Method 21 provides a reliable means of quantifying leaks and is currently in use by local air districts in major oil and gas producing regions. Accurately quantifying leaks is critical to determining compliance with the specified leak thresholds and repair timeframes. This section is also necessary to specify criteria that determine the leak inspection frequency after five consecutive calendar quarters. The proposed option for compliant facilities to conduct annual inspections is similar to current requirements used by local air districts in major oil and gas producing regions. This option provides an incentive for facilities to find and repair leaks quickly and also prevents the need for unnecessary instrument-based inspections at compliant facilities. In the event that a facility is determined to be out of compliance with the proposed requirements, either by way of an ARB or local air district inspection or by way of an inspection conducted by the owner or operator, the facility must revert back to quarterly inspections.

Summary of Section 95669(g)(2)

This section specifies that Optical Gas Imaging (OGI) instruments may be used to screen for leaks at a facility if they are approved for use by the local air district and used by a technician with minimum Level II Thermographer training. All leaks detected with these instruments must be measured with the use of Method 21 within the timeframes specified in order to quantify the leak concentration and determine the appropriate repair timeframes.

Rationale of Section 95669(g)(2)

This section is necessary to specify that OGI instruments may be used as a screening device to locate leaks if all of the specified conditions are met. Some owners or operators may find it useful to use these instruments in order to assist with leak inspections or to locate leaks in hard to reach places. Special provisions have been included that require local district approval and the need for specialized OGI instrument training. The training requirement is necessary because there are special conditions required for using OGI instruments and reading the images that they create. This section is also

necessary to specify that all leaks detected with the use of an OGI instrument must be tested with the use of Method 21. This requirement is necessary to accurately determine the component leak concentration and repair timeframe.

Summary of Section 95669(h) and (i)

These sections specify the proposed leak thresholds and repair timeframes that apply to regulated facilities subject to the proposed regulation. Under this proposal, leaks that are measured with a total hydrocarbon concentration above the leak threshold are required to be repaired within the designated timeframe. Two different minimum leak threshold standards are required under this regulation proposal. Beginning January 1, 2018, the minimum leak threshold is greater than or equal to 10,000 parts per million by volume (ppmv), and beginning January 1, 2020, the minimum leak threshold is greater than or equal to 1,000 ppmv. The proposed repair time periods are the same for each minimum leak threshold providing 14 calendar days for a regulated party to make repairs. These proposed repair time periods do not apply to critical components which are provided additional time to make repairs.

Rationale of Section 95669(h) and (i)

These requirements are necessary to eliminate methane emissions from components such as valves, flanges, and fittings. Emissions from these components may occur from the effects of weathering when bolts may naturally loosen or when components wear out. The proposed leak thresholds and repair timeframes are similar to those used by local air districts for oil and gas facilities in major oil and gas producing regions. The minimum leak threshold between the 2018 and 2020 calendar years are intended to provide owners or operators with time to repair any large leaks found at their facilities. These minimum leak thresholds are higher than similar leak thresholds used by local air districts. After January 1, 2020, facilities must comply with lower leak thresholds which resemble those currently used by local air districts.

Summary of Section 95669(j)

This section specifies how a leaking component must be identified with a weatherproof tag, which identifies the date that the inspection was conducted and the leak concentration measurement. The tag must remain affixed to the component until it has been repaired and retested to verify that it is no longer leaking above the minimum leak threshold standard.

Rationale of Section 95669(j)

This section is required so that a regulated party and inspectors can track component leaks measured above leak concentration thresholds, and reduces the possibility that a leaking component will be double-counted

during any inspection period. Each tag is required to remain affixed to the component until it has been fully repaired and tested to demonstrate it does not leak above the proposed minimum leak threshold.

Summary of Section 95669(k)

This section specifies that a regulated party must maintain a record of each leak detection and repair inspection including the leak concentration measurement and repair date(s) or components. It also requires that regulated parties must report this information to ARB once per calendar year, as well as making records available to the Executive Officer upon request.

Rationale of Section 95669(k)

This section is necessary to document the results of the leak detection and repair inspections and components awaiting repairs. This allows both the regulated party and inspectors to verify compliance with the proposed regulation and to ensure that all components are repaired within the timeframes.

Summary of Section 95669(l)

This section specifies that hatches must be closed at all times except during sampling, process material, or attended maintenance operations.

Rationale of Section 95669(l)

This requirement is necessary to ensure that unattended pressure vessels, separators, and tanks do not emit methane emissions. The emissions may occur as a result of an automated process, such as when liquids are automatically transferred to a tank or vessel, or when liquids are stored for an extended period. The requirement allows for hatches to be open during routine activities so that a regulated party may enter a vessel to perform routine maintenance or sampling.

Summary of Section 95669(m)

This section specifies requirements for open-ended lines or valves located at the end of lines used at facilities subject to the proposed regulation requirements.

Rationale of Section 95669(m)

This requirement is necessary to prevent the release of methane from open ended lines or valves that have one side of a valve seat open to the atmosphere. This requirement is designed to ensure that all valves are sealed as intended and do not solely rely on the valve seat to prevent the release of

emissions. Provisions are included to allow the owner or operator to use the valve as intended, but the valve must be sealed when not being used.

Summary of Section 95669(n)

This section specifies that components or component parts that incur five repair actions within a continuous 12 month period must be replaced.

Rationale of Section 95669(n)

This section is necessary to ensure that documented faulty or defective components are replaced to eliminate methane emissions. In some cases, these components may emit methane in between regular leak detection and repair inspections. This requirement is necessary to address faulty components that cannot be repaired by simple adjustment, such as tightening bolts that have loosened due to weathering.

Summary of Section 95669(o)

This section specifies that a regulated party must comply with all of the proposed leak detection requirements specified in the proposed regulation, and specifies the beginning compliance dates, leak thresholds, and percentage of leaks that are allowed during each compliance period. Failure to meet the requirements shall constitute a violation of the proposed regulation requirements.

Rationale of Section 95669(o)

This section is necessary to specify the leak detection and repair standards and to notify a regulated party that failure to meet any of the requirements constitutes a violation of the proposed regulation. Table 3 identifies the proposed compliance requirements for the first year of leak detection and testing, and Table 4 identifies the requirements beginning January 1, 2019 and thereafter.

15. Section 95670. Critical Components.

Summary of Section 95670(a)

This section specifies that by the proposed date, or within 180 days from installation, critical components must be pre-approved by ARB.

Rationale of Section 95670(a)

This section is necessary to inform a regulated party that all critical components must be pre-approved by ARB. Critical components are those that receive additional time to make repairs, which can be up to 12 months

from the date of initial leak detection or the next time that the equipment is shut down or removed from service.

Summary of Section 95670(b)

This section specifies that a regulated party must provide sufficient documentation demonstrating that a critical component is part of critical process unit and that removing the component within the proposed repair timeframes would result in excessive methane emissions or would impact the safety or reliability of the system.

Rationale of Section 95670(b)

This requirement is necessary so that a regulated party can adequately demonstrate that a critical component is part of a critical process unit.

Summary of Section 95670(c)

This section specifies that requests for critical components are made by submitting records and documentation to ARB as specified.

Rationale of Section 95670(c)

This section is necessary to provide a regulated party with instructions for submitting a request for a critical component designation.

Summary of Section 95670(d)

This section specifies that a regulated party must maintain a record of all critical components installed at the facility and must be able to make the record available upon request by the ARB or local air district inspector.

Rationale for Section 95670(d)

This section is necessary to inform a regulated party that records of critical components must be maintained at the facility and made available upon request by ARB or the local air district inspector. These records are necessary to provide documentation for use in determining compliance with the proposed leak repair timeframes.

Summary of Section 95670(e)

This section specifies that all critical components must be identified with a weatherproof, readily visible tag, indicating that they are pre-approved ARB critical components.

Rationale of Section 95670(e)

This section is necessary to inform a regulated party that all critical components must be clearly identified. This requirement is necessary so that ARB or local air district inspectors can easily verify these components during routine inspections and determine compliance with the proposed leak repair timeframes.

Summary of Section 95670(f)

This section specifies that approval of critical components may be granted if all of the requirements listed in Section 95670 are met, and that ARB reserves discretion to deny a critical component approval.

Rationale of Section 95670(f)

This section is necessary to inform a regulated party that ARB may deny a request for critical component approval. This requirement is needed to provide ARB with the discretion to evaluate, and re-evaluate if needed, all critical components to ensure that they are the part of a critical process unit and that repairing such component within the proposed repair timeframes would result in excessive methane emissions or would impact the safety or reliability of the system.

16. Section 95671. Record Keeping Requirements.

Summary of Section 95671(a)(1)

This section specifies that a record of flash analysis testing, including a sketch or drawing of the separator and tank system, laboratory reports, calculations, and field testing forms must be maintained for five years.

Rationale of Section 95671(a)(1)

This section is necessary to list all of the information required to adequately document the results of flash analysis testing and to document any changes in the system configuration or annual methane emissions. This information is also used by ARB or a local air district inspector to determine compliance with the proposed regulation standard.

Summary of Section 95671(a)(2)

This section specifies that a record of each leak concentration measurement for a reciprocating compressor rod packing or seal that is measured above the minimum leak threshold is recorded as specified in Appendix A, Table A5 of the proposed regulation and maintained for at least five years.

Rationale of Section 95671(a)(2)

This requirement is necessary to list information that is required to adequately document the results of emissions testing. This information is required by ARB to maintain accurate records of leak concentration measurements from these particular components and is also used by ARB or local air district inspectors to verify compliance with the proposed regulation requirements.

Summary of Section 95671(a)(3)

This section specifies that a record of each reciprocating compressor rod packing or seal emission flow rate measurement must be recorded as specified in Appendix A, Table A7 of the proposed regulation and maintained for at least five years.

Rationale of Section 95671(a)(3)

This requirement is necessary to list information that is required to adequately document the results of emissions flow rate testing. This information is required by ARB to maintain accurate records of emission flow rate measurements from these particular components and is also used by ARB or local air district inspectors to verify compliance with the proposed regulation requirements.

Summary of Section 95671(a)(4)

This section specifies that a record of each centrifugal compressor wet seal emission flow rate measurement must be recorded as specified in Appendix A, Table A7 of the proposed regulation and maintained for at least five years.

Rationale of Section 95671(a)(4)

This requirement is necessary to list information that is required to adequately document the results of emissions flow rate testing. This information is required by ARB to maintain accurate records of emission flow rate measurements from these particular components and is also used by ARB or local air district inspectors to verify compliance with the proposed regulation requirements.

Summary of Section 95671(a)(5)

This section specifies that a record of each pneumatic device emission flow measurement must be recorded as specified in Appendix A, Table A7 of the proposed regulation and maintained for at least five years.

Rationale of Section 95671(a)(5)

This requirement is necessary to list information that is required to adequately document the results of emissions flow rate testing. This information is required by ARB to maintain accurate records of emission flow rate measurements from these particular components and is also used by ARB or local air district inspectors to verify compliance with the proposed regulation requirements.

Summary of Section 95671(a)(6)

This section specifies that each liquids unloading measurement or calculation must be recorded as specified in Appendix A, Table A7 of the proposed regulation and maintained for at least five years.

Rationale of Section 95671(a)(6)

This requirement is necessary to list information that is required to adequately document the results of liquids unloading activities. This information is required by ARB to maintain accurate records of liquids unloading activities and is also used by ARB or local air district inspectors to verify compliance with the proposed regulation requirements.

Summary of Section 95671(a)(7)

This section specifies that a record of each well casing flow measurement must be recorded as specified in Appendix A, Table A7 of the proposed regulation and maintained for at least five years.

Rationale of Section 95671(a)(7)

This requirement is necessary to list information that is required to adequately document the results of emissions flow rate testing. This information is required by ARB to maintain accurate records of emission flow rate measurements from these particular components and is also used by ARB or local air district inspectors to verify compliance with the proposed regulation requirements.

Summary of Section 95671(a)(8)

This section specifies that a record of each leak concentration measurement for leaks identified during daily inspections or identified by a continuous leak monitoring system and subsequently measured above the minimum leak threshold is recorded as specified in Appendix A, Table A5 of the proposed regulation and maintained for at least five years.

Rationale of Section 95671(a)(8)

This requirement is necessary to document leaks that have been identified during daily inspections or identified by a continuous monitoring system and demonstrate that they have been tested and repaired within the proposed repair timeframes. This information is required by ARB to maintain accurate records of leak concentration measurements and is also used by ARB or local air district inspectors to verify compliance with the proposed regulation requirements.

Summary of Section 95671(a)(9)

This section specifies that a record of the number of leaks identified during inspections for each leak threshold category is recorded as specified in Appendix A, Table A4 of the proposed regulation and maintained for at least five years.

Rationale of Section 95671(a)(9)

This requirement is necessary to document the number of leaks identified during a leak inspection for each leak threshold category in order to determine compliance with the proposed regulation requirements,

Summary of Section 95671(a)(10)

This section specifies that a record of each leak initial and final leak concentration and repair date is recorded as specified in Appendix A, Table A5 of the proposed regulation and maintained for at least five years.

Rationale of Section 95671(a)(10)

This requirement is necessary to document all components that have been measured above the minimum leak threshold. This information is required by ARB to maintain accurate records of leak concentration measurements and is also used by ARB or local air district inspectors to verify compliance with the proposed regulation requirements.

17. Section 95672. Reporting Requirements

Summary of Section 95672(a)(1)

This section specifies that within 90 days of performing flash analysis testing or recalculating annual methane emissions, the results must be reported to ARB as specified in Appendix A, Table A1 of the proposed regulation.

Rationale for Section 95672(a)(1)

This information is required by ARB to maintain accurate records of these activities and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(a)(2)

This section specifies that a record of each rod packing or seal leak concentration measurement that is above the minimum allowable leak threshold must be reported to ARB annually as specified in Appendix A, Table A5 of the proposed regulation.

Rationale for Section 95672(a)(2)

This information is required by ARB to maintain accurate records of these activities and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(a)(3)

This section specifies that a record of each rod packing or seal emission flow rate measurement must be reported to ARB annually as specified in Appendix A, Table A7 of the proposed regulation.

Rationale for Section 95672(a)(3)

This information is required by ARB to maintain accurate records of these activities and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(a)(4)

This section specifies that a record of each centrifugal compressor wet seal emission flow rate measurement must be reported to ARB annually as specified in Appendix A, Table A7 of the proposed regulation.

Rationale for Section 95672(a)(4)

This information is required by ARB to maintain accurate records of these activities and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(a)(5)

This section specifies that a record of each pneumatic device emission flow rate measurement for devices with a designed flow rate of less than 6

standard cubic feet per hour must be reported to ARB annually as specified in Appendix A, Table A7 of the proposed regulation.

Rationale for Section 95672(a)(5)

This information is required by ARB to maintain accurate records of these activities and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(a)(6)

This section specifies that the measured or calculated volume of natural gas that is vented to perform liquids unloading must be reported to ARB annually as specified in Appendix A, Table A3 of the proposed regulation.

Rationale for Section 95672(a)(6)

This information is required by ARB to maintain accurate records of these activities and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(a)(7)

This section specifies that a record of each well casing emission flow rate measurement must be reported to ARB annually as specified in Appendix A, Table A7 of the proposed regulation.

Rationale for Section 95672(a)(7)

This information is required by ARB to maintain accurate records of these activities and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(a)(8)

This section specifies that within 24 hours of identifying a leak that is measured above the maximum allowable leak threshold at each underground injection/withdrawal well wellhead assembly, attached pipelines, and the surrounding area within a 200 foot radius of the wellhead, the regulated party must contact ARB, the Department of Oil, Gas, and Geothermal Resources, and the local air district to report the leak concentration measurement.

Rationale for Section 95672(a)(8)

This requirement is necessary to notify ARB and other appropriate agencies of a leak concentration measurement found at or near a wellhead assembly that exceeds the maximum allowable standard and potentially signals a well

failure. This requirement is necessary to ensure that all appropriate agencies are notified promptly so that appropriate action may be taken.

Summary of Section 95672(a)(9)

This section specifies that within 24 hours of receiving an alarm signaled by an air monitoring system that detects levels of natural gas that exceed more than 10 percent of baseline conditions that the regulated party must contact ARB, the Department of Oil, Gas, and Geothermal Resources, and the local air district to report the leak concentration measurement.

Rationale for Section 95672(a)(9)

This requirement is necessary to notify ARB and other appropriate agencies of an alarm that exceeds baseline conditions and potentially signals a well failure. This requirement is necessary to ensure that all appropriate agencies are notified promptly so that appropriate action may be taken.

Summary of Section 95672(a)(10)

This section specifies that a record of all leaks identified during daily inspections or identified by a continuous leak monitoring systems and that are measured above the minimum leak threshold must be reported to ARB quarterly as specified in Appendix A, Table A5 of the proposed regulation.

Rationale for Section 95672(a)(10)

This information is required by ARB to maintain accurate records of leaks identified at or near an underground injection/withdrawal well wellhead assembly and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(a)(11)

This section specifies that the results of leak detection and repair inspections conducted during each calendar quarter must be reported to ARB annually as specific in Appendix A, Table A4 of the proposed regulation.

Rationale for Section 95672(a)(11)

This information is required by ARB to maintain accurate records of these activities and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(a)(12)

This section specifies that the initial and final leak concentration measurement for each leak measured above the minimum allowable leak

threshold must be reported to ARB annually as specific in Appendix A, Table A5 of the proposed regulation.

Rationale for Section 95672(a)(12)

This information is required by ARB to maintain accurate records leak inspection activities and is also used by ARB or a local air district to determine compliance with the proposed requirements.

Summary of Section 95672(b)

This section specifies the mailing address and electronic mailing address for ARB.

Rationale for Section 95672(b)

This section is necessary to provide contact information so that reports can be submitted to ARB.

18. Section 95673. Implementation.

Summary of Section 95673(a)(1)

This section specifies that the requirements of the proposed regulation are provisions of state law that are enforceable by both ARB and local air districts, and that a regulated party must pay fees required by a local air district to implement and enforce the proposed requirements, including fees associated with enforcement penalties. Enforcement action penalties secured by local air districts may be retained by the district.

Rationale for Section 95673(a)(1)

This section is necessary to clarify that the proposed regulation is enforceable by both ARB and the local air districts, and that a local air district may charge fees associated with implementing or enforcing the requirements, that regulated parties are responsible for paying the fees, and that local air districts may retain the funds.

Summary of Section 95673(a)(2)

This section specifies that the ARB Executive Officer may enter into an agreement with a local air district to further define implementation and enforcement requirements or to establish formal information sharing procedures.

Rationale for Section 95673(a)(2)

This section is necessary to make clear that ARB and local air districts may enter into formal written agreements, such a Memorandum of Understanding or Agreement, which may further define the implementation or enforcement procedures. Providing for such agreements is necessary to implementing the regulation in a flexible and cost-effective manner, and supports efficient use of ARB and air district resources. These agreements can be developed to provide a formal process for sharing confidential information such as registration or permit records, inspection or enforcement records, or collected test data.

Summary of Section 95673(a)(3)

This section specifies that implementation and enforcement by a local air district may not result in a standard, requirement, or prohibition that is less stringent than any of the requirements listed in the proposed regulation.

Rationale for Section 95673(a)(3)

This section is necessary to specify that the proposed regulation sets the minimum standards and requirements for regulated parties. In no instance may a local air district issue a registration or permit used on less stringent standards or requirements or adopt rules that result in less stringent standards or requirements, which are less stringent than the proposed requirements. This is necessary to ensure that this statewide regulation is implemented in a uniform manner, ensuring consistent emissions benefits and costs for regulated entities.

Summary of Section 95673(a)(4)

This section specifies that implementation and enforcement of the proposed regulation by a local air district does not waive or limit ARB's authority to implement or enforce any of the requirements specified. It further specifies that a facility's permitting or registration status does not otherwise limit the ability of a local air district to enforce applicable requirements.

Rationale for Section 95673(a)(4)

This section is necessary to clarify that both ARB has the ability to implement and enforce each of the provisions specified in this proposed regulation. It is also necessary to clarify that facilities subject to compliance with this article may be subject to local air district enforcement regardless of permitting or registration status.

Summary of Section 95673(b)(1)

This section specifies that a regulated party currently required to maintain a local air district permit for a facility or equipment due to federal, state, or local requirements must apply for these permits to be amended to include the terms specified in the proposed regulation and that future local air district requirements do not alter these provisions.

Rationale for Section 95673(b)(1)

This section is necessary so that a regulated party, as well as other federal, state, and local entities, understand that the terms and conditions of this proposed regulation must be included in any existing permit that covers affected facilities or equipment and that future changes to those permits do not alter the proposed regulation requirements.

Summary of Section 95673(b)(2)

This section specifies the registration requirements for facilities or equipment covered by the proposed regulation, which include registration with ARB, unless a local air district collects the required information and enters into an agreement to share it with ARB.

Rationale for Section 95673(b)(2)

This section is necessary to specify that facilities or equipment covered by the proposed registration must register equipment with ARB. This section specifies all required information. This section is also necessary to make clear that air districts may take on the registration program, obviating the need for separate registration with ARB.

Summary of Section 95673(b)(3)

This section specifies that owners and operators subject to the proposed regulation must comply with all of its requirements, even if they have not complied with any of the permitting and registration requirements of section 95673.

Rationale for Section 95673(b)(3)

This section is necessary to make clear that even if permitting and registration requirements are not fulfilled, the substantive standards and requirements of the proposed regulation still apply. This will ensure that any confusion over these compliance requirements does not act as an excuse to compromise emission reductions.

19. Section 95674. Enforcement.

Summary of Section 95674

This section specifies the types of violations that may occur under this proposed regulation. Subsection (a) specifies that each violation at each individual piece of equipment constitutes a separately enforceable violation. Subsection (b) specifies that each day or portion of a day that compliance is not maintained is a separate violation. Subsection (c) specifies that each metric ton of methane emitted in violation of the proposed regulation will constitute a separately enforceable violation. Subsection (d) specifies that failure to submit any required report will constitute a violation, and that each day a report is late will constitute a violation. Subsection (e) specifies that failures to retain required records and failures to produce records will constitute violations for each record, and for each day production is late. Subsection (f) specifies that producing inaccurate information is a violation of the proposed regulation. Subsection (g) specifies that submitting or producing false information is a violation of the proposed regulation.

Rationale for Section 95674

This section is required to specify that failure to comply with any of the proposed requirements is subject to enforcement action. Each enforcement provision is clearly specified so the proposed regulation is not interpreted in such a way to mean that a regulated party is not subject to enforcement action.

20. Section 95675. No Preemption for More Stringent Air District or Federal Requirements.

Summary of Section 95675

This section specifies that the proposed regulation does not preempt more stringent federal or local requirements.

Rationale for Section 95675

This section is required so that the proposed regulation is not interpreted in such a way to mean that any more stringent federal or local requirement do not apply to an entity subject to this proposed regulation.

21. Section 95676. Severability.

Summary of Section 95676

This section specifies that each part of the proposed regulation is severable.

Rationale for Section 95676

This section is necessary so that the proposed regulation is not interpreted in such a way to mean that a future determination, which invalidates any part of the proposed regulation, does not invalidate any of the other requirements.

22. Appendix A.

Summary of Appendix A, Table A1

This table specifies data that must be recorded at the time each flash analysis test is conducted.

Rationale for Appendix A, Table A1

This table is required to document the results of flash analysis testing and to adequately describe the separator and tank system at the time of testing. This table is also used to report results to ARB as specified and to determine compliance with the proposed regulation requirements.

Summary of Appendix A, Table A2

This table specifies data that must be recorded each time a liquids unloading activity is conducted.

Rationale of Appendix A, Table A2

This table is required to document the results of liquids unloading activities. This table is also used to report results to ARB as specified and to determine compliance with the proposed regulation requirements.

Summary of Appendix A, Table A3

This table specifies the minimum amount of information that must be provided to ARB each time an owner or operator makes a request for a critical component designation.

Rationale of Appendix A, Table A3

This table is required to submit information to ARB for critical component approval request. This table is used by a regulated party and ARB or local air district inspectors to maintain records of all critical components located at a facility and verify component repair timeframes.

Summary of Appendix A, Table A4

This table specifies test data that must be recorded during each leak detection and repair inspection.

Rationale of Appendix A, Table A4

This table is required to list the number of leaks found in each leak threshold category in order to determine compliance with the proposed leak detection and repair requirements.

Summary of Appendix A, Table A5

This table specifies the initial and final leak concentration measurements of each component that is found leaking above the minimum leak threshold.

Rationale of Appendix A, Table A5

This table is necessary to document components that are found leaking above the minimum leak threshold and to verify that the leak is either awaiting repairs or has been repaired and re-tested to verify that the component is not leaking above the minimum leak threshold.

Summary of Appendix A, Table A6

This table specifies the data that is required to register equipment at facilities with ARB.

Rationale of Appendix A, Table A6

This table is required to provide the ARB with adequate information to maintain records of equipment installed at facilities. This information will be used to assist ARB with conducting routine inspections and provide AB with accurate records of equipment installed at facilities.

Summary of Appendix A, Table A7

This table specifies the data that is required when conducting emission flow rate measurements.

Rationale of Appendix A, Table A7

This data is required to adequately document the results of emission flow rate measurements. This table is also used to report results to ARB as specified and to determine compliance with the proposed regulation requirements.

23. Appendix B.

Summary of Appendix B

This section specifies the approved methodology for determining vented natural gas volume from liquids unloading of natural gas wells.

Rationale for Appendix B

This appendix is necessary to provide owners and operators with the calculation specified in the proposed regulation.

24. Appendix C.

Test Procedure for Determining Annual Flash Emission Rate of Methane from Crude Oil, Condensate, and Produced Water

Summary of Section 1

This section specifies that the intended purpose of the test procedure is to quantify emissions from crude oil, condensate, and produced water and that it is applicable for use on separator and tank systems.

Rationale of Section 1

This section is required to inform a regulated party of the intended purpose and applicability of the test procedure.

Summary of Section 2

This section describes the test procedure and specifies that testing is conducted by gathering pressurized liquid samples upstream of a separator and tank system. The intent of the test procedure is to replicate flashing inside of a separator and tank system. Therefore, samples must be gathered upstream of the system before emissions can flash from the liquid. After the samples are gathered, they are taken to a laboratory for conducting liquid and gas analyses in accordance with specified test methods and procedures. After the laboratory completes the analyses, the annual methane emissions are calculated using the laboratory results and a calculation methodology.

Rationale of Section 2

This section is required to provide a summary of the test procedure so that a regulated party can understand the test procedure concept.

Summary of Section 3

This section proposes definitions to the terms used in the test procedure.

Rationale of Section 3

It is necessary that ARB defines its terms as they apply to the test procedure.

Summary of Section 4

This section provides a list of each item that may create a bias, or errors, in the final reported results. A bias in the reported results can be introduced by using an incorrect sampling method, gathering samples from the wrong location or type of vessel, using the wrong type of sampling cylinder, or using un-calibrated equipment.

Rationale of Section 4

This section is necessary to inform a regulated party with a list of each bias that has been identified with the procedure so they can avoid errors that will affect the final reported results.

Summary of Section 5

This section provides a list of minimum equipment specifications for equipment that is used to take measurements from liquid that is collected from a pressurized separator.

Rationale of Section 5

This section is required so that all field measurements are performed using instruments that provide a minimum degree of accuracy and provide consistency in the final reported results.

Summary of Section 6

This section specifies the minimum equipment specifications required to gather liquid samples from a pressurized separator. The equipment includes pressure and temperature gauges, sampling cylinders, and high pressure rated fittings. This section also specifies the need for a portable pressurized separator in the event that no pressurized separator is installed within the separator and tank system. The portable pressurized separator is optional if a pressurized separator is installed and located immediately upstream of the separator and tank system.

Rationale of Section 6

This section is required so that a regulated party can obtain all equipment necessary to conduct the liquid sampling procedure.

Summary of Section 7

This section specifies that a sampling technician must be provided with specific information by the owner or operator at the time of liquid sampling. A list of the required information is provided which includes a system

identification number, the daily crude oil and produced water throughput, number of wells in the system, and the days of operation per year.

Rationale of Section 7

This section is required to inform a regulated party that information must be provided to the sampling technician at the time of liquid sampling. The information is required at the time of sampling because the characteristics of a separator and tank system can change daily, and any change in the parameters will affect the final reported results. Failure to provide the technician with the required information at the time of sampling will prevent the laboratory from conducting its analysis and will not provide the information necessary to calculate the annual methane emissions and report the final results.

Summary of Section 8

This section specifies procedures for using a Double Valve sampling cylinder to collect samples of crude oil or produced water. Depending on the liquid gathered, the cylinder is pre-filled with the specified liquid and sample liquid is introduced in the orientation as shown. Prior to gathering a sample, liquid must be purged through the sampling train into a suitable waste container to prevent filling the cylinder with air or other containments and to ensure that representative liquid is gathered.

Rationale of Section 8

This section is required to instruct a sampling technician on the proper method used for collecting crude oil or produced water using a Double Valve cylinder. This section is intended to provide detailed instructions to prevent sample collection bias and to prevent errors in final the reported results.

Summary of Section 9

This section specifies procedures for using a Piston Cylinder to collect samples of condensate or produced water. The Piston Cylinder may only be used to collect light hydrocarbon liquids or water because heavy crude oil can solidify and damage the cylinder, which will also prevent the laboratory from extracting the liquid. Prior to gathering a sample, liquid must be purged through the sampling line into a suitable waste container to prevent filling the cylinder with air or containments, and to ensure that representative liquid is gathered.

Rationale of Section 9

This section is required to instruct a sampling technician on the proper method used for collecting condensate or produced water using a Piston

Cylinder. This section is intended to provide detailed instructions to prevent sample collection bias and to prevent errors in final the reported results.

Summary of Section 10.1

This section specifies the laboratory quality control and quality assurance requirements required to conduct the test procedure. Each day of sampling, the laboratory must gather at least one sample duplicate. This way the lab can ensure consistency with their instruments and ensure that samples are collected in accordance with the test procedure. All deviations in measurements must be documented by the laboratory to provide a record of the deviation and explain discrepancies in reported results. Each laboratory must train its technicians on the sampling methods contained in the test procedure and must maintain records associated with sampling.

Rationale of Section 10.1

This section is required to maintain consistency in reported results from each of the separator and tank systems measured and to maintain consistency amongst the different laboratories performing the test procedure.

Summary of Section 10.2

This section lists the equipment specifications and practices required to conduct the flash analysis procedure. The minimum reporting limit for a gas chromatograph system is 100ppm for hydrocarbon and fixed gases. This provides for sufficient accuracy when reporting annual methane emissions. The equipment must be able to heat samples to the same temperature of the separator and tank system and have the ability to measure gas volume, temperature, and pressure.

Rationale of Section 10.2

This section is required to provide consistency amongst laboratories performing the laboratory flash analysis procedure. These specifications can accommodate different instruments, system configurations, and procedures used by different laboratories while ensuring consistency in final reported results

Summary of Section 10.3

This section specifies how a laboratory conducts the flash analysis procedure required to calculate the gas to oil or gas to water ratio. This includes procedures for how to heat and depressurize a sampling cylinder, collect flash gas, and analyze the gas for methane and other gaseous compounds. The procedure also includes a requirement that at least 0.20 cubic feet of gas is required to conduct test methods specified in the test procedure. After a flash analysis procedure is completed, the laboratory

must completely drain the cylinder and measure the volume of liquid to calculate the gas to oil or gas to water ratio.

Summary of Section 10.3

This section is required to ensure consistency among different laboratories conducting the flash analysis procedure. A minimum gas volume is required so that all of the instruments can be purged of air or contaminants and eliminates error in the final reported results. The minimum gas volume requirement is listed in this section because this is the point when a laboratory will discover how much gas is entrained in the liquid.

Summary of Section 10.4

This section specifies the calculation methodology used by the laboratory to calculate a gas to oil or gas to water ratio.

Rationale of Section 10.4

This section is necessary to specify the calculations that must be used by a laboratory to calculate a gas to oil or gas to water ratio. This section is required to ensure consistency in reported results.

Summary of Section 10.5

This section specifies the laboratory methods required to conduct the test procedure.

Rationale of Section 10.5

This section is necessary to specify laboratory methods required to conduct the test procedure and to ensure consistency in reported results.

Summary of Section 11

This section specifies the calculation methodology required to calculate the annual methane emissions using a gas to oil or gas to water ratio and a gas composition analysis provided by a laboratory in conjunction with the separator and tank system throughput obtained at the time of liquid sampling.

Rationale of Section 11

This section is necessary to specify the calculations required to calculate the annual methane emissions and ensure consistency in reported results.

Summary of Section 12

This section specifies records that must be compiled and maintained by a laboratory conducting the test procedure. These records include a field data collection form for each sample gathered, a sketch or diagram of the separator and tank systems, laboratory reports, and other information necessary to support the reported results.

Rationale of Section 12

This section is necessary to properly document all records associated with conducting the test procedure. In the event that the reported results do not represent the results of similar systems, the ARB Executive Officer or the owner or operator can contact the laboratory to evaluate the reported results and investigate possible sources of discrepancy.

Summary of Section 13

This section specifies that the test procedure must be conducted as specified and that alternative test procedures or laboratory methods used to report annual methane emissions must receive ARB Executive Officer approval. Any alternative procedures or methods will be evaluated by ARB on a case-by-case basis and a record of any approval will be maintained by ARB and made available upon request.

Rationale of Section 13

This section is necessary to specify that the test procedure must be conducted as specified and that alternative procedures or methods cannot be used without prior ARB Executive Officer approval. This section is required to ensure consistency in reported results.

Summary of Form 1

This section specifies the laboratory methods or procedures required to conduct the test procedure.

Rationale of Form 1

This section is necessary to document all applicable test methods and procedures used to conduct the test procedure and to ensure consistency in reported results.

III. ALTERNATIVES TO THE PROPOSED SOLUTION

Staff considered four alternatives to the proposed regulation that would be less burdensome to the affected industry. These alternatives are not the same as the alternatives in the Environmental Analysis, since those alternatives address reducing the environmental impacts of the proposed regulation while these alternatives address Administrative Procedure Act considerations. It is important to note that these alternatives are in addition to those that staff considered at the SRIA phase of this regulation, which are identified in that document.

A. ALTERNATIVE 1 – No Action

The first alternative is to not propose the regulation. Obviously, this would be less burdensome to the industry. However, this alternative does not achieve the goal of reducing methane emissions from the oil and natural gas production, processing, and storage sector. Accordingly, this alternative was rejected.

B. ALTERNATIVE 2 – Implement the Regulation without the LDAR Provision

The second alternative is to not propose the LDAR requirement in the regulation. This provision of the proposed regulation affects the most facilities and can be a labor intensive control measure. However, it also is the provision that achieves the largest amount of emission reductions, accounting for more than a third of the anticipated methane emission reductions. LDAR is also at the heart of catching small leaks before they become larger leaks. In addition, LDAR is key to making sure that other provisions of the regulation are operating properly, such as vapor recovery on separator and tank systems, thereby ensuring that they anticipated emission reductions from those provisions are achieved in practice. For these reasons, this alternative was rejected.

C. ALTERNATIVE 3 – Performance-based Standard

Staff considered a performance-standard based alternative for the proposed regulation. Specifically, staff considered a performance-based mandate to regulated entities to reduce the vented and fugitive emissions from regulated sources, as of a date certain, by an amount commensurate with the expected reductions the proposed regulation is expected to produce. Staff rejected this alternative for several reasons, but worked to incorporate flexibilities into the proposed regulation where possible to support legislative direction to avoid prescriptive regulations where possible.

Reasons for rejecting a wholesale performance standard alternative include the following points. This proposed regulation is designed to reduce venting and fugitive emissions from the sector. These emissions are, by their nature, difficult to quantify in many cases, and come from a wide range of potential sources. A flat reduction mandate would be very difficult to enforce without more accurate baseline data on current emissions from these sources, at the

facility and component level, than is now available – it is, in other words, far more effective to enforce a requirement to replace a certain piece of equipment, or follow a particular LDAR procedure, than a performance-based reduction requirement from an uncertain baseline. To ensure reductions occur, therefore, staff focused on providing uniform, clear standards for equipment and processes that could reliably be measured, implemented, and enforced. Further, because emission controls focusing solely on methane reduction could have contributed to criteria pollutant emissions if poorly implemented, or failed to secure maximum co-benefits of criteria and toxic pollutants, it was important to specify particular implementation requirements to produce better results on this metric as well.

But though staff rejected a performance standard alternative as a complete option, staff made significant efforts to provide options within the rule's directive framework to provide compliance flexibilities. For instance, regulated entities have several options as to how to implement vapor control device provisions, to conduct LDAR inspections, and to address equipment replacement or retrofit decisions. These embedded options within the proposed regulation help reduce compliance burdens, thereby fulfilling the legislative intent driving consideration of performance-based alternatives, while ensuring that emission reductions happen in an enforceable and environmentally appropriate manner.

D. ALTERNATIVE 4 - Emission Reduction Provision

Staff also considered including an emission reduction provision that would require operators to mitigate climate impacts of large methane leaks. In evaluating whether an emission reduction provision would be appropriate, staff considered several options, including increased penalties for operators of facilities where the leak occurred and an emission reduction plan providing ton-for-ton reductions or stricter monitoring requirements. Staff concluded that stiffer monitoring requirements were the most appropriate. Increased penalties were not an effective option since all prohibited leaks violate the proposed regulation and thus every violation is potentially subject to the maximum penalties statutorily allowed. A plan for reductions was deemed inappropriate at this time, for the following reasons: first, developing generally applicable requirements for such a plan – though somewhat specified in the mitigation plan developed for the Aliso Canyon leak – is a difficult regulatory task when generalized to any potential facility, and so would likely delay the regulation and associated methane reductions. Furthermore, ARB has considerable authority to drive appropriate mitigation via its existing enforcement authorities and settlement authority. Therefore, rigorous monitoring provisions, rigorously enforced, were deemed appropriate for this proposed regulation. ARB will continue to consider the issue, however, and may revisit this decision in future rulemakings.

IV. FUNDING, IMPLEMENTATION, PERMITTING AND ENFORCEMENT

The proposed regulation's enforcement and implementation provisions recognize that California's local air districts already play an important role in regulating the oil and gas sector, and are interested in building on their efforts. The provisions make clear that ARB can directly enforce the proposed regulation, but also offer paths for local air districts to integrate its requirements into their existing programs to support efficient and effective enforcement.

A. FUNDING FOR IMPLEMENTING AND ENFORCING ARB'S PROPOSED OIL AND GAS REGULATION

ARB's proposed regulation can be implemented and enforced by both ARB and the districts. ARB staff assumes most local air districts will choose to take the lead in implementing and enforcing the regulation, with ARB playing a backstop role, and it is our preference for the local air districts to do so. However, ARB will take a lead role in districts that choose not to. The local air districts are more familiar with operators, conduct inspections nearby or at the same sites, and in many instances have been regulating such sources for decades. This is why the regulation provides for the local districts to enter into MOUs with ARB in order to define implementation and enforcement responsibilities, as well as for information sharing. The regulation also allows for districts to incorporate this regulation into their local rules. To ensure uniform enforcement, however, districts may not waive or reduce the stringency of the state rules, which remain state law, enforceable as necessary by ARB.

To aid enforcement, operators must register their facilities with ARB (unless the district takes on this task via MOU) and update relevant permits for permitted facilities. Permit updates can occur on whatever frequency now in use at a district; registration with ARB (or the district) is required by January 1, 2018.

Implementing and enforcing this regulation does not come without costs. Local air districts have the legal authority to raise fees paid by the regulated community to support additional programs such as this regulation, which will help to address these costs, but likely need board approval, which is uncertain. The rule also makes clear that districts may retain penalties secured from rule enforcement. ARB continues to explore opportunities to further assist the air districts.

ARB staff, with district input, estimate that the regulation will require on the order of 5-6 PYs to implement depending on the mix of district and ARB implementation. The costs are going to be higher with ARB enforcement than with district enforcement due to the need to travel, train new staff, and set-up programs including a registration program. The individual district cost estimates range from amounts some districts feel could be absorbed by them without additional funding, to over \$300,000 per year in recurring costs and almost \$1,000,000 in one-time costs, primarily for permitting. Even if the districts

decide to implement and enforce this regulation, there is an annual cost for ARB to manage the reporting requirements in the regulation.

B. PERMITTING AND ENFORCEMENT

The proposed regulation addresses enforcement, permitting, and registration requirements for covered equipment and facilities in several ways:

- Operators with equipment and facilities that are already covered by local air district permitting programs must include the proposed regulation requirements as part of their submission, ensuring compliance with the proposed regulation. This submission will aid enforcement by ensuring that applicable requirements are gathered in operating and construction permits, but limits local air district workload because it does not require that any new permits be issued to otherwise unpermitted facilities or equipment. In addition, permits can be updated upon scheduled renewal timelines, to avoid unduly increasing district workload. New covered equipment and facilities (including wells) must include this in their submission at the time they are permitted.
- All equipment and facilities covered by this proposed regulation would also be required, by January 1, 2019, to be registered with ARB, to ensure that ARB enforcement personnel have the information necessary to effectively enforce the regulation. However, if the local air district is also collecting this information, and has entered into an MOU with ARB to share the information with ARB, then this requirement may not apply, depending on the MOU details.

In sum, the proposed regulation is designed so that its requirements can be folded into existing permitting programs, where they exist, and to ensure that critical enforcement and compliance information reaches ARB, with minimum duplication of local air district efforts. Local air districts are free to expand or establish permitting or registration programs to support enforcement, but are not required to do so.

ARB anticipates working closely with the local air districts to support implementation and enforcement. The proposed regulation thus contains several provisions to support further ARB/air district cooperation on enforcement and implementation. It makes clear, first, that both ARB and local air districts may enforce and inspect to ensure compliance. ARB anticipates entering into MOUs with interested local air districts to ensure that these shared responsibilities are undertaken in a coordinated way. To further support local air districts in their efforts, the proposed regulation also provides that districts may incorporate the terms of the regulations into their local rule, that owners and operators must be subject to fee increases imposed by air districts to implement the proposed regulation, and that local air districts may retain penalties they collect enforcing the regulation.

To support statewide uniformity and rigorous enforcement, the proposed regulation is clear that no local air district may implement or enforce it in ways that reduce its stringency; similarly, local air district decisions, and permitting and registration decisions, do not in any way waive or limit ARB's own enforcement authority. Conversely, the proposed regulation is also clear that it does not preempt any local air district requirements that are more stringent, or substitute for compliance any applicable federal requirements.

Finally, the proposed regulation defines potential violations to provide clarity. Individual violations for which enforcement consequences may result include: (1) failure to comply with its requirements with regard to each individual piece of covered equipment, (2) each day or portion thereof out of compliance, (3) each metric ton of methane emitted in violation, (4) failure to submit any required report and each day or portion thereof the report is late, (5) failure to retain and failure to produce any record required by the regulation, (6) falsifying any information or record, and (7) producing inaccurate records or information.

V. TECHNICAL ASSESSMENT

A. DEVELOPMENT OF METHANE EMISSION STANDARDS

In developing the proposed regulation, Staff analyzed the impact of applying control measures to the different components affected by the regulation's provisions.

1. Crude Oil and Produced Water Separator and Tank Systems

Separator and tank systems are used to separate and store crude oil, condensate, and produced water. Based on ARB site visits to production facilities and conversations with industry, Staff identified several types of separator and tank system configurations. In crude oil production, the most common system consists of a separator, which allows emulsion to gravimetrically separate, and two tanks, one of which is used to hold the separated crude oil and one which is used to hold the produced water. There may be further oil tanks and produced water tanks downstream of these first two for further separation and treatment of the oil and produced water. However, for purposes of the proposed regulation, "separator and tank system" means the first separator in a crude oil or natural gas production system and only the tanks directly connected to the separator, which typically is no more than two – one for oil and one for produced water.

In dry natural gas production, the most common system consists of a heated separator used to heat the gas to remove liquids, and a single tank used to store produced water and small amounts of condensate, which is typically a mixture of very light hydrocarbons.

Each of the system configurations vary slightly due to factors such as the number of wells in the system, type of oil produced, and the amount of gas entrained in the crude oil or produced water.

Staff evaluated emissions from separator and tank systems based on the results of flash analysis testing. Emissions from flashing are primarily a result of depressurizing liquids from underground reservoir pressure to atmospheric pressure at the tanks. Staff used test data to derive average emission factors for crude oil and produced water, and then applied the factors to counts of separators and tanks and to oil and produced water throughputs, both obtained from the ARB Oil and Gas Industry Survey, to estimate annual methane emissions⁴³. The results of the analysis and test data are provided in Appendix D.

The flash emission test data show that methane is emitted in varying quantities from each well or group of wells that serve each separator and tank system. The amount of methane emitted is a function of the percentage of

⁴³ See footnote 41. ARB. 2013. Oil and Gas Survey. ARB 2007 Oil and Gas Industry Survey Results

methane contained in the gas, the volume of gas entrained in the liquid (the Gas Oil Ratio or the Gas Water Ratio), and the total oil and water throughput. This means that emissions can be different for each separator and tank system. As shown in the data in Appendix D, both heavy oil and light oil contain methane and may have similar volumes of gas entrained in the liquid. In some case, the only difference in methane emissions is due to the oil and water throughput.

a) Limited Throughput Exemption

Staff is proposing a limited exemption from flash analysis testing and vapor collection system requirements for small producers of oil and natural gas. The proposed exemption is based on an analysis of the flash test data as outlined in Appendix D to determine if there are production levels below which no systems are expected to exceed the proposed methane standard. The analysis shows that a separation and tank system will not exceed the proposed standard if both the crude oil production is below 50 barrels per day and the produced water production is below 200 barrels per day. This exemption applies to both crude oil and natural gas separator and tank systems. Owners or operators with systems meeting both of these requirements will not need to conduct flash analysis testing or control a separator and tank system with the use of a vapor collection system. ARB Staff estimates this will exempt approximately 1,500 smaller separator and tank systems from the proposed regulation requirements, resulting in lower costs for smaller producers without an expected impact on emission reductions.

b) Methane Standard

To develop the proposed emission standard, Staff analyzed impacts for a range of methane standards between 0 and 40 MTCH₄/Year for uncontrolled separator and tank systems. The proposed 10 MTCH₄/Year standard was chosen to achieve approximately 90% annual methane. Standards of 0 or 5 MTCH₄/Year were also considered, although those standards would have required vapor controls on significantly more systems while achieving only limited additional methane reductions. The results of the analysis are shown below in Table 7.

Table 7: Impact of Different Annual Methane Standards on Uncontrolled Systems⁴⁴

| Category | O&G System Threshold | | | | | | | | |
|---|----------------------|-------|-------|-------|-------|-------|-------|-------|-------|
| | 0 MT | 5 MT | 10 MT | 15 MT | 20 MT | 25 MT | 30 MT | 35 MT | 40 MT |
| # of Systems Controlled | 1,072 | 38 | 29 | 29 | 26 | 7 | 5 | 4 | 4 |
| # of Water Tanks Controlled | 1,432 | 303 | 294 | 289 | 281 | 252 | 224 | 168 | 99 |
| System CH ₄ Emission Reductions (MT) | 1,217 | 929 | 871 | 871 | 821 | 408 | 350 | 316 | 316 |
| Water Tank CH ₄ Emission Reductions (MT) | 8,132 | 7,445 | 7,424 | 7,390 | 7,344 | 7,116 | 6,744 | 5,897 | 4,631 |
| Total CH ₄ Emission Reductions (MT) | 9,349 | 8,374 | 8,295 | 8,261 | 8,165 | 7,524 | 7,094 | 6,213 | 4,947 |
| % of Total Emissions Captured | 100.00% | 90% | 89% | 88% | 87% | 80% | 76% | 66% | 53% |

While evaluating different methane standards, Staff also considered the US EPA New Source Performance Standards (NSPS) Subpart OOOO⁴⁵ for new or modified tank systems used at crude oil and natural gas production facilities. The NSPS sets an emissions limit of 6 tons of VOC per year for new or modified systems to require vapor recovery. This analysis was conducted to ensure that the proposed methane standard would be at least as stringent as the standard required by EPA. As described in Appendix D, the analysis shows that 6 tons per year of VOC is equivalent to approximately 36 metric tons per year of methane, which means that the proposed methane standard is more stringent than the current US EPA NSPS as it relates to VOCs. Therefore, the proposed methane standard will not result in emissions that exceed the current US EPA NSPS requirements and will provide significant reductions.

2. Circulation Tanks for Well Stimulation Treatments

Well stimulation treatments (WSTs) are performed on crude oil or natural gas wells to increase the production of gas or fluids. The different types of well stimulation treatments used at crude oil and natural gas production facilities

⁴⁴ Does not include emissions from tanks currently controlled under district rules.

⁴⁵ U. S. EPA. 2012. 77 FR 49542 Oil and Natural Gas Sector: New Source Performance Standards and National Emission Standards for Hazardous Air Pollutants Reviews, August 16, 2012.

include hydraulic fracturing, acid fracturing, and acid matrix stimulation. A WST is performed after a drilling operation has been completed, but before the well is put into final production. After a WST has been completed, the surface equipment used to conduct the operation is removed from the well pad and replaced with a circulation tank (see Figure 8) and other support equipment to remove drilling plugs and excess sand from the wellbore. During the circulation process, water is injected into the wellbore where it mixes with other hydrocarbon liquids found in the reservoir. The sand, contained within the water and hydrocarbon mixture, is then forced back up to the surface where it is transported to the circulation tank to remove the sand from the liquid mixture. This process is conducted to prevent sand from entering the separator and tank system where it can clog or damage equipment. Staff visited several different WST operations that used a circulation tank to circulate sand from a wellbore. In all cases, the tanks were open to the atmosphere. This allows methane to vent to the atmosphere during the circulation process.

Staff initially relied on US EPA estimates for emissions from hydraulically fractured oil wells⁴⁶; however, industry conducted additional testing on wells located in California⁴⁷. Although the industry testing is limited, Staff believes it is more representative of California data since WST is very different in other parts of the country. Due to the limited number of tests, Staff chose the upper limit of the range for the estimates. The data did not include information on other constituents in the vapor coming from the tanks other than methane. However, since the well stimulation process uses a variety of chemicals, there is potential for reductions in other pollutants such as toxic air contaminants.⁴⁸ A recent meta-analysis showed 87 percent of studies on unconventional natural gas development indicated increased air emissions compared to conventional natural gas development⁴⁹. For this reason, and due to the fact that both the US EPA and California industry studies show that uncontrolled emissions of methane are associated with hydraulically fractured oil and gas wells, Staff is proposing emissions controls for all circulation tanks used in conjunction with well stimulation treatments.

During the development of the proposed regulation, Staff received feedback from industry⁵⁰ indicating that it may be difficult to collect small volumes of natural gas from some hydraulically fractured oil wells, or that although the

⁵⁰ WSPA. 2016. Meetings, Attachment 2. http://www.arb.ca.gov/cc/oil-gas/meetings/WSPA_attachment2_03042016.pdf

gas may be able to be collected, it may not be feasible to inject the gas into an existing vapor collection system. Staff contacted one manufacturer of circulation tanks to inquire about using their equipment to recover both small and large quantities of natural gas from circulated liquids. Through subsequent discussion, the manufacturer reported that their equipment is commonly used in other states outside of California for collecting gas from wells that are subject to US EPA NSPS requirements, and that their equipment can be used to collect any volume of natural gas liquids, including low volumes as used in circulation tanks⁵¹.

Additional discussions with industry suggested that even if gas is collected from circulation tanks, it would be difficult to route the gas to an existing vapor collection system and that the gas may be of unsuitable quality for use in on-site equipment. Staff contacted one manufacturer of Low-NOx incinerators to determine if such a device could be used in this type of application^{52 53}. The manufacture reported that their devices are used for destroying low quality waste gas, and for situations where only a small amount of gas is collected, they may be able to temporarily store gas in what is called a “bladder” until a volume is large enough volume of gas is collected for incineration.

Based on initial discussions with industry and equipment manufacturers, Staff is proposing that facilities using circulation tanks in conjunction with WSTs develop a best management practices plan to reduce emissions from the tanks and provide ARB with the results of a technical demonstration of vapor control equipment by the date specified in the proposed regulation. This will provide time for industry and equipment manufacturers to work together to develop and test all necessary equipment, and help to ensure that industry is taking steps to reduce emissions while the equipment is being designed and tested.

For the purposes of estimating costs and emissions associated with controlling circulation tank emissions, Staff relied on cost estimates provided by manufactures of Low-NOx incinerators and costs to install a vapor collection system as described in Appendix B. To estimate the number of tanks that would be subject to the vapor control requirements, Staff estimated that 6 circulation tanks would be subject to the proposed requirements. This estimate is based the assumptions that only a limited number of circulation tanks are used in California. In practice, circulation tanks are portable and frequently moved from one job site to another, and the duration of a circulation job typically lasts no more than 48 hours. The calculations used to estimate the costs and emissions can found in Appendix B.

⁵³ Aeron. 2015. Phone conversations.

3. Vapor Collection Systems and Control Devices

Vapor collection systems are used to control emissions for separator and tank systems, circulation tanks, and other types of equipment. The systems are used to collect and route vapors to equipment for use as a fuel source or underground injection, or to send the vapors to a control device that may thermally or non-thermally destroy the collected vapors. The collection systems are typically comprised of vapor collection piping and a compressor, although some systems operate without a compressor by using natural gas pressure.

Currently, vapor collection systems are used at crude oil and natural gas facilities for controlling VOC emissions from pressure vessels, tanks, separators, and other types of equipment such as natural gas compressors. After vapor is collected, it must be controlled with 95% efficiency. This level was chosen to align with the U.S. EPA NSPS requirements. The vapors are often sent to a sales gas or fuel gas system, but they may also be re-injected into an injection well or combusted with the use of a vapor control device. Vapor control devices, such as a flare or incinerator, are used to destroy collected vapors. However, destroying vapors with the use of these devices can also result in the formation of nitrogen oxides or NO_x emissions, which also contribute to the formation of ozone and particulate matter⁵⁴.

To develop the proposed vapor control device standards, Staff considered NO_x emission impacts in regions classified as nonattainment for federal and State ambient air quality standards. Staff is concerned with NO_x because it is an ozone precursor, and creating more of it in ozone impacted areas would have a negative effect on the air quality in those regions. These nonattainment areas are California air basins described in the Environmental Analysis, Appendix C to this document. Staff focused on designing methane emission controls that would complement and avoid interfering with efforts to address these important criteria pollutants, while protecting communities (including low-income and disadvantaged communities) living in these areas. Staff is proposing a systematic approach for handling any newly collected vapors, which results in reduced NO_x emission from business as usual.

The proposal is designed to take a tiered approach with regard to collecting and disposing of methane vapors. The first tier of the proposal requires any newly collected vapors to be directed to an existing sales gas system, fuel gas system (where they are combusted as fuel in equipment), or sent to an existing gas disposal well for underground injection. This systematic approach to handling newly collected methane vapors is designed to use existing systems that have no impact on NO_x, since even the newly collected vapors used in a fuel gas system will displace natural gas that would have been purchased.

⁵⁴ U. S. EPA. 1999. Nitrogen Oxides (NO_x), Why and How They Are Controlled.

If the facility does not have these options, the second tier is to use a new non-combustion vapor control device. During the regulatory development process, Staff contacted one non-combustion technology manufacturer that uses this type of equipment to reduce VOC emissions to determine if the technology could be used in oil and gas applications⁵⁵. This type of technology rapidly cools and condenses vapors into a liquid. The manufacturer reported that condensing gaseous carbon dioxide along with methane can cause equipment problems and is not currently feasible. However, Staff has included an option to use a non-combustion technology if they become feasible in the future.

If the facility cannot use an existing sales gas, fuel gas, or injection system, or a non-combustion vapor control device, the facility can consider a newly installed or existing vapor control device. A new vapor control device must meet the proposed NO_x standard of 15 ppmv and must not use supplemental fuel gas to operate, aside from gas required to run a pilot. Table 8 compares average values of NO_x emissions from different types of combustion equipment. As shown, a low- NO_x incinerator and microturbine provide the lowest NO_x emission rates compared to other types of combustion equipment, including regular flares and rich burn internal combustion engines.

If a facility has newly collected vapors and an existing flare, and needs to use a combustion control device due to this proposed regulation, then the facility will have to replace an existing higher-NO_x flare with a low-NO_x incinerator or other device that meets the 15 ppmv NO_x standard. As shown in Appendix D, replacing existing flares with low-NO_x incinerators will more than make up for the resulting new NO_x emissions from the combustion of newly collected vapors, resulting in a NO_x benefit of approximately 1.6 tons per year of NO_x.

Table 8: NO_x Emission Comparison of Equipment

| Equipment Type | NO _x Emissions (lb/MMBtu Input) |
|---------------------------------|---|

4. Reciprocating Natural Gas Compressors

Reciprocating compressors are used to compress natural gas by using a piston driven by crankshaft, connected to an engine or electric motor. Rod packing systems are the mechanism used to create a seal around a moving crankshaft, to contain the gas inside of the compressor. Due to the design of these systems, a rod packing or seal may leak a small amount of natural gas during normal operation, and have the potential to vent large amounts of gas if the rod packing or seal becomes damaged or wears out.

In order to develop the proposed emissions standard for reciprocating compressors, Staff reviewed the most current local air district rules for compressors, (see LDAR section below), the US EPA NSPS, information provided by rod packing manufacturers, and owners and operators of reciprocating compressors.

The current US EPA NSPS requires new or modified compressors used at gathering and boosting stations and natural gas processing plants to replace rod packing systems within 26,000 hours or 36 months of operation, regardless of the condition of the rod packing⁵⁹. There are no other requirements for compressors installed at the other types of facilities. ARB Staff reviewed current local air district rules for requirements pertaining to natural gas compressors. They found that some compressors installed within major oil and gas producing regions are subject to regular leak inspection requirements over and above the NSPS standards. These requirements are included within the local air district leak detection and repair programs and require owners and operators to measure concentration from the vent area around the rod packing or seal and other compressor components on a regular basis.

In addition to evaluating the current federal and local requirements, ARB Staff also contacted a manufacturer of reciprocating compressors to gather information and manufacturer guidelines for replacing faulty or defective rod packing systems. The guidelines provided below, are described in terms of a natural gas flow rate of emissions from the vent near the piston rod-packing on the reciprocating compressor. Table 9 identifies the manufacturer's recommended guidelines for repairing or replacing rod packing systems. These guidelines apply to one compressor manufacturer that produces compressors for use at natural gas transmission and underground storage facilities where the compressor uses a driver engine or motor with greater than 250 rated horsepower.

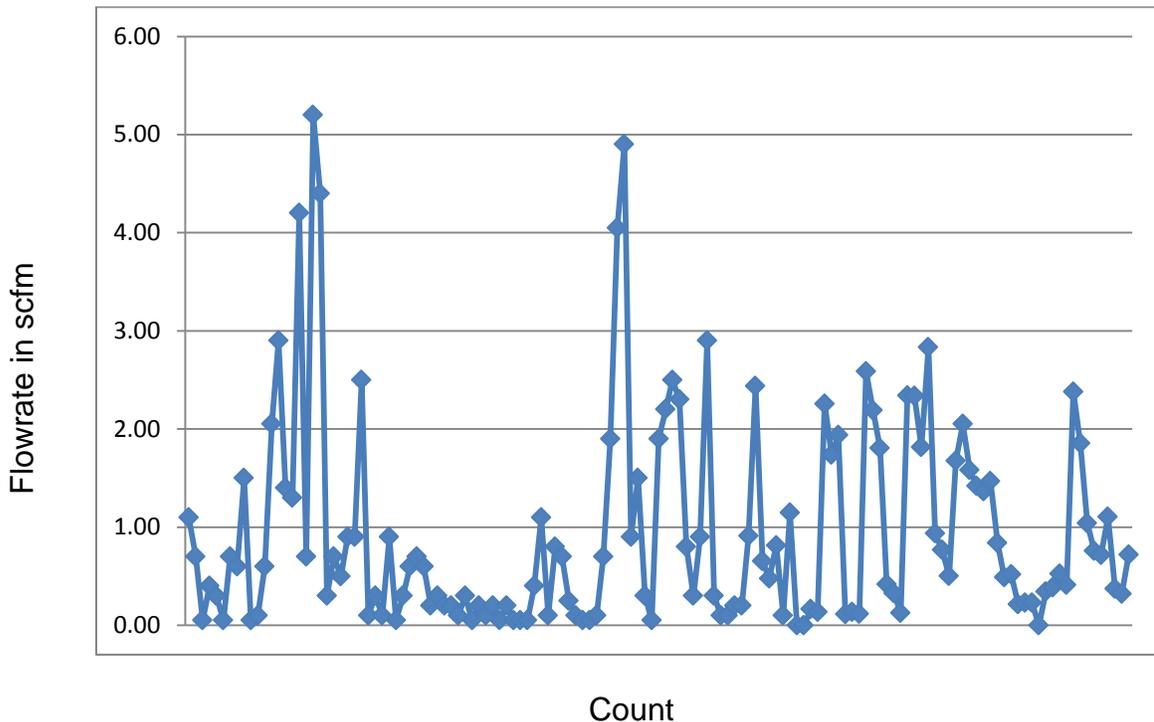

⁵⁹ U.S. EPA. 2012. 77 FR 49542 Oil and Natural Gas Sector: New Source Performance Standards and National Emission Standards for Hazardous Air Pollutants Reviews, August 16, 2012

Table 9: Manufacturer Rod Packing Guidelines⁶⁰.

| Condition | Rod Packing Flow Rate measured in standard cubic feet per minute (scfm) | Rod Packing Flow Rate measured in standard cubic feet per hour (scfh) |
|--------------|---|---|
| Excellent | 0.02 | 1.2 |
| Good | 0.05 | 3.0 |
| Normal | 0.10 | 6.0 |
| Fair | 0.50 | 30.0 |
| Poor (Alarm) | 2.00 | 120.0 |
| Very bad | 3.00 | 180.0 |
| Dangerous | 4.00 | 240.0 |
| Failure | 100.00 | 6000.0 |

Staff also used natural gas emission flow rate data provided by industry. The industry provided data included measurements from 55 reciprocating compressors taken over a four year period. According to the data, about 14% of the measurements indicated a leak rate of over 2 scfm per cylinder. Figure 10 below depicts the industry provided flow rate measurements.

Figure 10: Measured Rod Packing Flow Rate (scfm)

Most of the measurements in Figure 10 are below 2 standard cubic feet per minute (scfm), or 120 scfh, which is below the manufacturer’s “poor” guideline

⁶⁰ Dresser-Rand. 2014. Email from Matt Gilbert of Dresser Rand to Christian Hurley of ARB. December 17, 2014.

rating. However, several were measured above 2 scfm, and would be considered dangerous or as a rod packing failure according to the manufacturer's guidelines shown in Table 9.

Using the manufacturer's and industry data, Staff is proposing a 2 scfm standard for rod packing emissions from compressors used at natural gas transmission compressor stations, underground storage facilities, gathering and boosting stations, and processing plants. This standard was designed to correspond with the manufacturer's recommended guidelines for heavy duty compressors used at these types of facilities, regardless of the amount of time the compressor has been in use. Because many of these compressors use elevated vents stacks, ARB Staff also proposes that each compressor is outfitted with an access port installed at ground level to ensure that both the operators and inspectors can make regular flow rate measurements without specialized equipment. In addition, these compressors are subject to the LDAR requirement for all components other than the rod packing. Any newly installed or modified compressor must still comply with the NSPS as well as the proposed regulation.

Staff believes that the NSPS standards do not conflict with ARB's proposed emissions standards. In the event that a rod packing is measured in accordance with the proposed testing requirements prior to the EPA NSPS timeframe, the rod packing may not require repair or replacement, which does not interfere with the NSPS standards. However, in the event that a rod packing is measured above the proposed emissions standards, the rod packing would require repair or replacement sooner than the NSPS timeframe, which will result in fewer methane emissions. In addition, the NSPS only applies to compressors found at gathering and boosting stations and natural gas processing plants, whereas this proposed regulation's rod packing standard also applies to compressors at underground natural gas storage facilities and transmission compressor stations.

The remaining compressors identified in the ARB survey are located at oil and natural gas production facilities. ARB proposes that compressors used at production facilities undergo LDAR testing to check the rod packing or seal in order to provide for a simple leak concentration measurement. ARB is also proposing that all other components on production compressors be subject to LDAR. Staff considered using the same flow rate measurement standard as proposed for compressors used at other types of facilities, as well as the simpler LDAR test method and emission standard. During site visits, Staff found that nearly all production facility compressors are uncovered and can be reached from ground level. Further, many of the production facility compressors are already subject to local air district LDAR requirements, which is an effective, easier test method to perform. In order to integrate with local air district programs and provide a simpler form of testing for the majority of compressors located in California, staff is proposing to use the Method 21 test method (detailed further in the LDAR section) combined with a 30-day

repair timeframe for a rod packing or seal that is measured above the minimum LDAR leak threshold. The 30 calendar day repair timeframe is intended to provide time for the owner or operator to remove the compressor from service and make the necessary repairs.

3. Centrifugal Natural Gas Compressors

Centrifugal compressors use a rotating disk or impeller to pressurize natural gas for use in a transmission pipeline or underground storage applications. Similar to reciprocating compressors, centrifugal compressors also use a mechanism, referred to as either a wet seal or a dry seal, to create a seal around a moving crankshaft, which contains the gas inside of the compressor. Wet seals use pressurized oil circulated around the moving shaft to form a barrier and contain the natural gas inside of the compressor. Unlike wet seals, dry seals do not use high pressure oil to create the sealing barrier. Instead, dry seals use a very tight tolerance fit to contain the gas inside of the compressor. Methane emissions from wet seals are higher than the emissions from dry seals because normal operation causes natural gas to become entrained into the seal oil, which is circulated through the oil pump system, and emitted.

To develop the proposed wet seal emissions standard, Staff reviewed the current NSPS⁶¹, the EPA Natural Gas STAR recommended technologies and practices⁶², and data collected as part of the ARB survey⁶³. Staff also conducted several site visits to natural gas transmission and underground storage facilities and visited a centrifugal compressor manufacturing facility to verify wet seal and dry emissions rates, and learn about compressors and common maintenance practices, including retrofitting.

Current NSPS requirements state that all new or modified compressors installed at oil and gas production facilities must control 95% of the wet seal emissions. There are no NSPS requirements for compressors installed at transmission compressor stations or underground storage facilities. Staff contacted each of the facilities reporting centrifugal compressors in the 2007 ARB survey. Staff confirmed that there is only one uncontrolled wet seal centrifugal natural gas compressor currently operating in California. The compressor is not subject to EPA NSPS requirements.

To develop the proposed emission standard, Staff referred to the US EPA Natural Gas STAR recommended technologies and practices. The Gas STAR program is a voluntary partnership that encourages oil and natural gas companies to adopt cost-effective emission reduction technologies. According to the Gas STAR data, wet seals are estimated to emit 50 scfm

⁶¹ U. S. EPA. 2012. 77 FR 49542 Oil and Natural Gas Sector: New Source Performance Standards and National Emission Standards for Hazardous Air Pollutants Reviews, August 16, 2012.

⁶² U. S. EPA. 2014. Natural Gas Star. Wet Seal Degassing Recovery System for Centrifugal Compressors.

⁶³ See footnote 41.

(3000 scfh) per seal while dry seals emit 3 scfm (180 scfh) per seal. Because both the wet seal and dry seal emission estimates are provided in terms of flow rate, Staff concluded that measuring the wet seal emission flow rate is feasible, as long as the operator or inspector has access to the wet seal vent stack for making measurements.

Staff developed the 3 scfm emission standard because this is the equivalent of an average dry seal emission rate and similar to a 95% vapor control for the average wet seal emission rate. Staff also proposes that an access port for making flow rate measurement be installed at ground level.

Two alternative means to meet this standard are also proposed. One option is for the operator to control the emissions from wet seals with at least 95% control efficiency using a vapor collection system. It is identical to the NSPS for centrifugal compressors installed at production facilities. The second alternative allows the operator to replace the wet seals with dry seals by January 1, 2020. This provides additional time for the operator to modify California's only wet-seal reciprocating compressor due to the high cost of replacing a wet seal compressor with a dry seal compressor, if controlling the emissions with the use of a vapor collection system is not possible.

4. Natural Gas Powered Pneumatic Devices and Pumps

Pneumatic devices are used for maintaining a process at an oil or natural gas facility such as liquid level, pressure, or temperature. While pneumatic devices are commonly used at crude oil production facilities, most devices use compressed air or electricity to operate and therefore do not vent natural gas or methane emissions. However, gas powered pneumatic devices are commonly found at natural gas production and midstream facilities such as natural gas transmission compressor stations or underground storage facilities where natural gas is readily available. These devices use pressurized natural gas to operate and can be classified into three primary types;

- Continuous bleed devices vent natural gas to the atmosphere on a continuous basis.
- Intermittent bleed devices also vent natural gas to the atmosphere but only do so when they control a process, or more specifically, when the actuators spin to open or close or control a process; and
- No bleed devices do not vent natural gas while idle or when they actuate.

a) Continuous Bleed Devices

Continuous bleed devices, as the name implies, are designed to continuously vent natural gas into the atmosphere in order to operate.

The devices are commonly referred to as either high bleed or low bleed depending on the volume of gas that is vented,

- High Bleed devices vent more than 6 scfh;
- Low Bleed devices are those that vent less than 6 scfh;

Due to advances in technology, the use of electronic control instrumentation has been increasing. These systems use small electrical motors to operate valves and therefore do not bleed natural gas into the atmosphere. Mechanical devices are another alternative to high bleed pneumatic devices that are widely used in the natural gas and petroleum industry. They operate using a combination of springs, levers, flow channels and hand wheels. However, use of the mechanical devices is limited because they need to be in close proximity to the process measurement⁶⁴.

Staff contacted one manufacturer of continuous bleed pneumatic devices to discuss retrofitting existing high bleed devices with electric or mechanical devices⁶⁵. The manufacturer reported that they provide retrofit kits for a number of their units for converting the devices to use electricity, and they also supply retrofit kits to convert units to low bleed⁶⁶.

Staff also considered recently installed low bleed devices as several operators recently choose to change out high bleed devices with low bleed devices instead of installing metering in order to be compliant with ARB's Mandatory Reporting Regulation. Requiring these low bleed devices to be changed to no bleed devices would place a burden on facilities, but the amount of methane emissions reduced by replacing those previously installed low bleed devices is small when compared to the total methane emissions from continuous high bleed natural gas powered pneumatic devices.

Accordingly, Staff is proposing that continuous bleed pneumatic devices be converted to no bleed devices, except where high bleed devices have been recently changed out to low-bleed devices pursuant to ARB's Mandatory Reporting Regulation.

⁶⁶ Emerson Process Management. 2016. Electro-Pneumatic Transducers.

<http://www2.emersonprocess.com/en-US/brands/fisher/FieldInstrumentation/valveaccessories/Electro-PneumaticTransducer/Pages/FisherElectro-PneumTrans.aspx>

b) Intermittent Bleed Devices

Intermittent bleed devices vent natural gas only when they control a process, and the frequency of the controlling depends upon the size of the device and the particular operation. Since intermittent bleed devices are designed to prevent natural gas from venting while idle, Staff proposes for these devices to be subject to LDAR and should be tested while idle to ensure no unintended leakage. This ensures that industry, ARB, and local air district inspectors conduct consistent testing among all of the different devices.

c) Pneumatic Pumps

Pneumatic pumps, commonly referred to as “Kimray” pumps, are often found at natural gas production well sites and used in conjunction with glycol dehydrators. There are two types of gas powered pumps: piston and diaphragm. Both types have two major components, a driver side and a motive side, which operate in the same manner but with different reciprocating mechanisms. Pressurized gas provides energy to the driver side of the pump, which operates a piston or flexible diaphragm in order to draw liquid into the pump. The natural gas leaving the exhaust port of the pump is either directly discharged into the atmosphere or is recovered using a vapor collection system⁶⁷.

In contrast to gas powered pumps, electric motor driven pumps do not use pressurized gas to operate and therefore do not vent emissions to the atmosphere. Using electric pumps as an alternative to gas powered pumps provides significant benefits. First, electric powered pumps provide a financial return on the gas that is otherwise vented into the atmosphere. Second, worn O-rings in gas powered pumps can cause contamination of lean glycol in the dehydrator, reducing system efficiency and requiring an increase in the glycol circulation rate, compounding the methane emissions. Finally, replacing gas powered pumps often results in lower annual maintenance costs because the O-rings in gas powered pumps must be replaced when they begin to leak, typically every 3 to 6 months. The need for this replacement is eliminated when electric pumps are employed⁶⁸.

Staff has provided several options that owners or operators can use to comply with the proposed regulation standard of not venting gas, including replacing gas powered pumps with electric pumps, collecting the vented gas with the use of a vapor collection system, or using compressed air to operate. Staff performed the cost analysis assuming that all pumps would be replaced with electric powered

⁶⁷ U. S. EPA. 2014: Oil and Natural Gas Sector Pneumatic Devices.

⁶⁸ U. S. EPA. 2006. Replacing Gas-Assisted Glycol Pumps with Electric Pumps.

pumps as described in Appendix B. However, it is possible that some owners or operators may use one of the other available options.

5. Liquids Unloading of Natural Gas Wells

Staff proposes to require that owners or operators of natural gas wells vented to the atmosphere for the purpose of liquids unloading, collect the vented gas using a vapor collection system; measure the volume of vented gas by direct measurement; or calculate the volume of vented gas. There are currently no rules that apply to the unloading of liquids from natural gas wells and the purpose of this provision is to gather data about liquids unloading activity in California. This data will inform ARB Staff, in modifying these rules for additional emission reductions.

6. Well Casing Vents

Staff is proposing that owners or operators of crude oil or natural gas wells with well casing vents that are open to atmosphere perform annual flow rate emissions testing of each casing vent and submit the results to ARB annually. The purpose of this provision is to gather equipment and emissions data which will inform ARB Staff if future emissions controls are necessary.

7. Natural Gas Underground Storage Facility Monitoring Requirements

A large natural gas leak was discovered at a natural gas storage facility in Southern California on October 23, 2015 (Aliso Canyon). Numerous initial attempts to stop the leak failed, and on January 6, 2016, Governor Brown issued a state of emergency. The leak was plugged on February 18, 2016. This event highlighted the need to require monitoring at all natural gas storage facilities. The Division of Oil and Gas and Geothermal Resources (DOGGR) responded by adopting an emergency regulation for gas storage facilities (Cal. Code Regs., tit. 14, s 1724.9, subd. (e)) that requires operators of storage facilities to submit an inspection and leak detection protocol to DOGGR for review and approval.⁶⁹ The protocol is required to include inspection of the wellhead, attached pipelines, and area within a 100 foot radius of the wellhead at least daily. The operator is required to select and use gas leak detection technology such as infrared imaging that takes into consideration detection limits, remote detection of difficult to access locations, response time, reproducibility, accuracy, data transfer capabilities, distance from source, background lighting conditions, geography, and meteorology. DOGGR staff is currently working with operators to finalize and approve leak detection protocol for each facility.

⁶⁹ DOGGR. 2016. Requirements for Underground Gas Storage Projects. Final Text of Emergency Regulations.

DOGGR anticipated including the leak detection protocol requirements in their final regulation expected to be adopted in early 2017. As DOGGR and ARB have agreed that the monitoring requirements are more appropriately located in ARB's Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities, staff has included them in the proposed regulation.

Storage facility monitoring requirements under the proposed regulation will replace the leak detection protocol under DOGGR's regulation. In developing the requirements, ARB staff was cognizant of investments facility operators may have made to acquire leak detection instruments and systems and to assure that they would qualify for use under the proposed regulation. The area around the wellhead to be included in leak screening has been expanded under the proposed regulation to 300 feet in response to the detection of leaking gas in this area at Aliso Canyon.⁷⁰

The proposed regulation requires natural gas storage facility owners and operators to develop and submit to ARB a plan to provide continuous ambient air monitoring at the facility and to screen for surface leaks at least daily. Continuous air monitoring is included in response to community concern with exposure to pollutants that resulted from the leak at Aliso Canyon. To provide data transparency to the public, the monitoring system is required to be accessible remotely by the ARB and other state or local agencies specified by the ARB Executive Officer.

8. Leak Detection and Repair

The proposed leak detection and repair (LDAR) requirements are used to locate and measure leaks at facilities. Local air districts in the major oil producing regions of California currently implement LDAR programs at crude oil production facilities. These programs, as originally designed and intended, reduce emissions of VOC gases but do not cover components used in natural gas service including those found in dry natural gas production, underground storage, or transmission compressor facilities. This is because methane is not considered a major contributor to ground level ozone, so it has not been counted as a VOC. Using ARB's 2007 Survey data, ARB Staff estimates that current local air district programs cover about 80% of all components used at crude oil and natural gas facilities throughout California⁷¹. Implementing LDAR will be used to prevent the release of powerful greenhouse gas emissions found at these facilities. It could also reduce product losses, increase safety for workers, and decrease the exposure of the surrounding community. In the following sections Staff details the development of the three major provisions of ARB's proposed LDAR requirement.

⁷⁰ South Coast Air Quality Management District. 2016. SCAQMD/DOGGR Joint Inspection. <http://www.aqmd.gov/home/regulations/compliance/aliso-canyon-update/air-sampling/scaqmd-doggr-joint-inspection>

⁷¹ See footnote 41.

a) Test Method Requirement

To develop the proposed LDAR requirement, Staff evaluated current local air district rules and the US EPA Method 21⁷² test method, and Optical Gas Imaging (OGI) technologies. Each of the local air districts that currently have LDAR programs require Method 21 in combination with specified leak concentration thresholds^{73 74 75 76 77}. The leak measurement is then used to determine the timeframe in which a facility must make repairs to fix the leaking component. Method 21 is the only test procedure currently in use by the local districts at oil and gas facilities. This method is favored because it has the ability to quantify leak concentrations. Quantifying the concentration of leaks gives air districts the ability to define leak thresholds and thereby specify repair timeframes, with the largest leaks having the shortest repair timeframe. This approach provides the districts with the ability to enforce the leak standards if measured concentrations exceed specified thresholds.

OGI is an alternative to Method 21 measurements, but is used to view leaks from various sources including hard-to-reach and unsafe locations. While traditional OGI cannot measure leak concentrations and there are no US EPA adopted test methods available for using these instruments, Staff discovered that there are new OGI technologies that are evolving and are being designed to quantify emissions. This technology is currently untested; however ARB is open to future testing for use of this new type of OGI measurement technology, including comparative testing with Method 21 instrumentation.

For this rulemaking, ARB proposes the use of Method 21 to implement a US EPA-approved test method along with a set of leak thresholds and repair timeframes that are similar to current local air districts. Both the local air districts and facility operators can use their existing instruments to implement the same or similar standards at facilities that are not currently subject to a LDAR program. Although Staff proposes

⁷² CFR. 2016. Method 21 - Determination of Volatile Organic Compound Leaks. http://www.ecfr.gov/cgi-bin/text-idx?c=ecfr&tpl=/ecfrbrowse/Title40/40cfr60_main_02.tpl

⁷³ San Joaquin Valley Air Pollution Control District. 2011. Rule 4401: Steam-Enhanced Crude Oil Production Wells.

⁷⁴ San Joaquin Valley Air Pollution Control District. 2005. Rule 4409: Components at Light Crude Oil Production Facilities, Natural Gas Production Facilities, and Natural Gas Processing Facilities.

⁷⁵ Ventura County Air Pollution Control District. 1998. Rule 74.10: Components at Crude Oil and Natural Gas Production and Processing Facilities.

⁷⁶ Santa Barbara Air Pollution Control District. 1991. Rule 331: Fugitive Emissions Inspection and Maintenance.

⁷⁷ South Coast Air Quality Management District. 2009. Rule 1173: Control of Volatile Organic Compound Leaks and Releases From Components at Petroleum Facilities and Chemical Plants.

Method 21 as the required test method, the proposed regulation will not prohibit the use of OGI technologies. Some local air districts and oil and natural gas facilities currently use OGI as a means to perform leak screening surveys, with Method 21 used to determine compliance with the leak thresholds and repair timeframes. Staff believes the same type of work practice will continue with the adoption of the proposed LDAR program, and ARB encourages the use of alternative leak detection instruments including the use of OGI technologies. ARB has a contract nearing completion to compare different LDAR technologies and determine correlation equations, if feasible, but results are not currently available for evaluation.

b) Leak Threshold and Repair Times

This proposed rule includes requirements for leak thresholds and repair time periods for components at oil and natural gas facilities. Detected leaks must be repaired within a specific time period depending on the leak concentration, with larger leaks requiring the quickest repair times. Staff developed a phased in approach with higher concentration thresholds in the first two years. The final thresholds and repair times are as follows:

Table 10: Repair Time Periods on or after January 1, 2020

| Leak Threshold | Repair Time Period |
|------------------------|-----------------------------------|
| 1,000-9,999 ppmv | 14 calendar days |
| 10,000-49,999 ppmv | 5 calendar days |
| 50,000 ppmv or greater | 2 calendar days |
| Critical Components | Next shutdown or within 12 months |

In the proposed regulation, 1,000 ppmv is the lowest leak threshold defined. Staff chose this threshold to be consistent with the majority of districts with oil and gas LDAR regulations. District regulations vary on the threshold but 1,000 ppmv is the most common across the districts. In addition, staff chose to lower the threshold from 10,000 ppmv after two years to 1,000 ppmv simply to ensure that more leaks are being detected. The thresholds and repair times assure that leaks are repaired once found and that the largest emitting sources are prioritized. The quickest leak repair time period is 2 calendar days for leaks measuring 50,000 ppmv or greater.

c) Leak Inspection Frequency

To develop the proposed leak inspection frequency, Staff reviewed existing LDAR programs currently in use by California local air districts, then contacted enforcement Staff and management at the Santa Barbara, Ventura, South Coast, and San Joaquin Valley air districts to further discuss the minimum inspection frequency requirements in detail. The districts require daily inspections for specific types of components that have the potential for substantial emissions, such as pressure relief valves. These inspections are audio or visual based and do not require instrument testing. Each district also has provisions for unmanned or remote facilities that allow operators to inspect those facilities on a less than daily basis. ARB believes these are appropriate and in line with recent findings that open tank hatches can be a significant source of methane.⁷⁸

The Method 21 instrument-based inspection frequency is also similar among each of the different air districts. For example, in South Coast, Santa Barbara, Ventura, and the San Joaquin Valley (for gas and light crude oil), the minimum inspection frequency is quarterly for a minimum number of inspection quarters. If a facility meets a specified set of criteria, they may convert to annual inspections. The criteria for converting from a quarterly to annual inspection frequency is based upon the number of leaks found during each inspection period and does not prevent the district from conducting random leak inspections. At any time during a calendar year, the local district may enter a facility and conduct random leak inspections in order to determine if the facility is in compliance with district LDAR rules. If at any time a district discovers leaks that exceed the LDAR requirements, or finds leaks that may exceed a maximum leak threshold, the annual inspection frequency reverts to quarterly. This approach is similar to the approach currently used by several local air districts.

Quarterly LDAR achieves approximately a 60 percent reduction in methane emissions from leaking components, whereas annual LDAR achieves only about a 40 percent reduction.⁷⁹ In addition, quarterly inspections will result in more opportunities to detect “super-emitting” components, the source of the majority of component emissions, according to several studies.^{80 81 82 83 84 85}

⁷⁸ ACS Publications. 2016. Aerial Surveys of Elevated Hydrocarbon Emissions from Oil and Gas Production Sites. Environmental Science & Technology. Publication Date (Web): 05 Apr 2016.

⁷⁹ ICF International. 2014. Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries.

⁸⁰ See footnote 19.

⁸¹ See footnote 21.

⁸² See footnote 25.

⁸³ See footnote 26.

Based on the information gathered, ARB Staff proposes a quarterly instrument-based inspection frequency with an option for compliant facilities to convert to annual inspections after passing a minimum of five quarterly inspections. In addition, ARB's regulation will require a daily audio-visual inspection requirement for facilities that are visited on daily basis, and weekly audio-visual inspection requirement for unmanned or remote facilities. The audio-visual based inspections are required for all accessible pumps, compressors, and automatic pressure relief valves located at each facility. These requirements are designed to integrate with the proposed Method 21 test method, leak thresholds, and repair timeframes, and to integrate with existing local air district rules.

⁸⁴ See footnote 27.

⁸⁵ See footnote 28.

VI. JUSTIFICATION FOR ADOPTION OF REGULATIONS DIFFERENT FROM FEDERAL REGULATIONS CONTAINED IN THE CODE OF REGULATIONS

Oil and gas operations are also subject to the federal Clean Air Act, including its permitting requirements. They are subject to U.S. EPA performance standards for oil and gas operations. These regulations, 40 C.F.R. Part 60, Subpart OOOO (Quad O), limit emissions of volatile organic compounds from new equipment installed at crude oil and natural gas operations. Corresponding air toxics standards for certain pieces of oil and gas equipment are also codified in 40 C.F.R Part 63. In 2015, EPA committed to reduce methane emissions in the U.S. by 40 percent below 2012 levels by 2025 from the oil and gas sector. As part of this effort, EPA has proposed additional NSPS requirements for new and modified sources in the oil and gas sector and suggested Control Technology Guidance for existing sources in non-attainment areas. EPA finalized its rules in May 2016. On March 10, 2016, President Obama announced steps to reduce emissions from all existing oil and gas facilities but that process is in the information gathering stage. ARB staff anticipate that controls proposed in this regulation would aid in (and may suffice entirely for) compliance with any federal standards developed.

California has authority to set its own standards to reduce emissions further to meet federal and state ambient air quality standards and climate change requirements and goals, and to require additional and separate reporting. The proposed regulation addresses existing facilities and equipment where Quad O does not, and is more restrictive. The differing state requirements proposed are authorized by law (AB 32, as discussed above) and are necessary to achieve additional benefits for human health, public welfare, and the environment, and are justified by these benefits, as envisioned by authorizing legislation, as this section explains.

ARB's proposed regulation covers more facilities in California compared to EPA's NSPS, because it will apply to existing and new facilities, including offshore oil and natural gas production facilities. EPA's New Source Performance Standards (NSPS) applies to onshore oil and gas facilities newly constructed, reconstructed, or modified after August 23, 2011 (or after September 2015, in certain cases to which the May 2016 final federal rule applies). The types of facilities subject to the NSPS, are natural gas well sites, oil well sites, production gathering and boosting stations, natural gas processing plants, and natural gas compressor stations (transmission and storage).

The Bureau of Land Management (BLM) has also recently proposed new regulations to reduce the waste of natural gas from venting, flaring, and leaks during oil and gas operations on federal and tribal lands. (43 CFR 3162 and 3179) These proposed regulations are consistent with EPA's NSPS rules and would apply to sources not covered in those rules. ARB's proposed regulation does not apply to tribal lands; it does apply to federal lands, in which case ARB may develop an MOU with BLM to coordinate enforcement.

In addition to direct federal regulations, many air districts with significant oil production have rules aimed to reduce PM_{2.5} as well as NO_x and VOC emissions specifically from the oil and gas sector in order to meet federal ambient air quality requirements. The district rules do not cover methane specific sources and the proposed regulation generally addresses emissions from equipment and processes not already controlled by those existing district rules. ARB has used the district rules as a starting point, particularly for leak detection and repair, where districts have been implementing programs for decades.

ARB staff carefully reviewed existing and proposed regulations as this proposed regulation was developed. Because EPA's rule was finalized as this proposed regulation was being issued, review of modifications made to that rule during finalization is ongoing. However, because that rule covers only new sources, and follows the basic structure of EPA's proposal, it does not obviate the need for more rigorous, and far broader, source coverage in this proposed regulation. Indeed, EPA makes clear that its final rules are intended to complement state efforts, rather than supplant them. The proposal is designed to be as strong as, or stronger than, existing rules in other jurisdictions and in certain California air districts, and to extend strong elements of those rules. The proposal is also designed to integrate well with regulatory efforts for other aspects of the sector, as well as to provide a complementary basis for compliance with potential proposed federal rules.

VII. AIR QUALITY

A. OVERVIEW

This chapter describes the expected emissions, air quality, and health impacts associated with the proposed regulation. Furthermore, this chapter reports on the potential effects of the proposed regulation on environmental justice and local communities. The purpose of the proposed regulation is to establish GHG, primarily methane, emission standards for the oil and gas operations and facilities covered under the proposed regulation. Additionally, the Draft Environmental Analysis in Appendix C identifies the reduction of volatile organic compounds and toxic air contaminants as a co-benefit of the proposed control strategies.

1. Air Quality

ARB's Draft Environmental Analysis (Draft EA) in Appendix C, describes the long-term operations resulting from compliance with the proposed regulation. These operations could include the combustion of methane vapors as a management option for captured methane gas and increased vehicle use as a result of inspections, equipment replacement and repairs, and transporting compressed vapor. These compliance responses, if not properly constrained as they have been in the proposed regulation, have the potential to increase emissions from the pollutants for which national and state ambient air quality standards have been established.

The proposed regulation is designed to require the cleanest combustion devices, consequently reducing any potential additional air quality emission impacts to below significance in nonattainment areas and would not affect areas currently in attainment. Specifically, though some newly-collected vapors may be combusted, the proposed regulation requires that inefficient combustion devices already in use be replaced with cleaner devices before they can be used for compliance. The result of this design ensures that no significant emission increases would occur in nonattainment areas, and could result in a net reduction of emissions for some areas and pollutants.

Table 11 displays the estimated statewide GHG emission benefits from the proposed regulation by category. These benefits are described in further detail in Chapter 4.8 of the Draft EA, Appendix C. In addition to the benefits identified in Table 12, the proposed regulation would also provide a reduction in risk of large, catastrophic methane releases (similar to the events at Aliso Canyon) from the proposed enhanced monitoring at natural gas underground storage facilities.

Table 11: Estimated Statewide GHG Emission Reductions (MT CO₂e/year).*

| Category | Reductions |
|---|-------------------|
| Vapor collection on uncontrolled oil and water separators, tanks, and sumps with emissions above a set methane standard | 538,000 |
| Control of vapors from uncontrolled well stimulation circulation tanks | 4,900 |
| Leak Detection and Repair (LDAR) on components, such as valves, flanges, and connectors currently not covered by local air district rules | 590,000 |
| Inspection and repair requirements for reciprocating natural gas compressors | 68,000 |
| Vapor collection of centrifugal compressor wet seal vent gas, or replacement of higher emitting “wet seals” with lower emitting “dry seals” | 3,500 |
| Replacement of pneumatic pumps, and replacement or retrofitting of pneumatic devices under certain circumstances | 319,000 |
| TOTAL from proposed regulation | 1,523,000 |

*Using 20 year GWP, AR4

Table 12 displays ARB’s estimated statewide emissions reductions of toxic air contaminants and criteria air pollutants from implementation of the proposed regulation. ARB’s detailed description on the emissions calculations is found in Appendix D of this ISOR. Generally, the emissions were calculated from a combination of emission factors, survey data, and other data provided by stakeholders based on likely compliance responses to each of the provisions in the proposed regulation. ARB’s detailed description of the air quality impacts of the proposed regulation is found in the Draft EA in Appendix C, Chapter 4.3 of this ISOR.

Reductions in emissions from vapor collection on uncontrolled oil and water separators, tanks, and sumps all occur in the San Joaquin Valley Air Basin, since ARB’s analysis showed that facilities in other oil and gas production regions would either not exceed the methane standard or already have vapor collection installed. As noted in Table 12, ARB estimates statewide NO_x benefits of approximately 1.6 tons per year from vapor collection tanks, separators and sumps. This is a result of the design of the proposed regulation which requires the use of a complaint vapor control device (e.g., low-NO_x combustion device). However, ARB’s analysis of vehicle emissions associated with LDAR results in an estimated statewide increase in NO_x of approximately 1.6 tons per year. Therefore the proposed regulation results in

an estimated statewide net increase in NOx of less than 0.1 tons per year. A detailed description of these emissions can be found in the Draft EA.

Table 12: Estimated Statewide Emission Reductions of Toxic Air Contaminants and Criteria Air Pollutants (tons/year)

| Category | Total Hydrocarbons | VOCs | Benzene | Toluene | Ethyl-Benzene | Xylenes | NOx |
|--|--------------------|--------------|-----------|-----------|---------------|-----------|--------------------|
| Vapor collection on uncontrolled oil and water separators, tanks, and sumps with emissions above a set methane standard ¹ | 10,458 | 1,362 | 23 | 11 | 1.7 | 8.5 | 1.6 |
| Control of vapors from uncontrolled well stimulation circulation tanks | 96 | 12 | 0.2 | 0.1 | <0.1 | <0.1 | <0.1 |
| Leak Detection and Repair (LDAR) on components, such as valves, flanges, and connectors currently not covered by local air district rules | 9,698 | 1,264 | 22 | 10 | 1.5 | 7.9 | (1.6) ² |
| Inspection and repair requirements for reciprocating natural gas compressors | 1,318 | 172 | 3.0 | 1.4 | 0.21 | 1.1 | NA |
| Vapor collection of centrifugal compressor wet seal vent gas, or replacement of higher emitting "wet seals" with lower emitting "dry seals" | 68 | 9 | 0.2 | <0.1 | <0.1 | <0.1 | NA |
| Replacement of pneumatic pumps, and replacement or retrofitting of pneumatic devices under certain circumstances | 6,199 | 808 | 14 | 6.5 | 1.0 | 5.0 | NA |
| TOTAL (benefits from proposed regulation) | 27,837 | 3,627 | 62 | 29 | 4.6 | 23 | (<0.1) |
| ¹ All estimated emission reductions from this category are occurring in the San Joaquin Valley Air Basin. ² ARB estimates that increased LDAR will result in increased NOx from vehicle emissions by 1.6 tons/year. | | | | | | | |

In addition to the statewide emission benefit evaluation, ARB completed an emissions impacts analysis at the district level as part of the Draft EA in

Appendix C. ARB staff completed this analysis for the following districts: Bay Area AQMD, Butte County AQMD, Colusa County APCD, Feather River AQMD, Glenn County APCD, Monterey Bay Unified APCD, North Coast Unified AQMD, Santa Barbara County APCD, South Coast AQMD, SJVAPCD, Sacramento Metropolitan AQMD, Tehama County APCD, Ventura County APCD, and Yolo-Solano AQMD. ARB's analysis identified negligible emission impacts (less than 0.1 tons per year) for ROG, TOG, CO, NOx, PM10, PM2.5, and SOx for all air districts evaluated except for SJVAPCD. ARB reports these emission impacts as negligible since the analysis contains too much uncertainty in the analysis to accurately quantify such small increases. For SJVAPCD, ARB staff estimates net reductions of 0.5 tons per year of NOx and 30.1 tons per year of CO, and negligible reductions in SOx. Conversely, ARB has identified emission increases of 0.9 tons per year of PM10 and 0.3 tons per year of PM 2.5 in the SJVAPCD. The design of the proposed regulation ensures that emission impacts are well below any applicable CEQA significance thresholds for direct and cumulative impacts. The regulation decreases NOx emissions below existing levels in the San Joaquin Valley and provides substantial emission benefits of VOCs as well as smaller benefits of the BTEX suite of chemicals.

As previously stated, ARB's analysis shows a net NOx decrease of 0.5 tons per year and net increases of PM10 and PM2.5 of 0.9 and 0.3 tons per year, respectively, in the SJVAPCD. ARB's analysis uses the current baseline (i.e., emissions from current vapor control devices). The SJVAPCD has published a study of the potential to reduce NOx from existing flaring, as required by a commitment in the 2015 State Implementation Plan (SIP) for the 1997 PM2.5 Standard. In an update to the SJVAPCD Governing Board (SJVAPCD 2016), district staff state that the low-NOx vapor control devices, as required under the Proposed Regulation, will be required under the district's upcoming SIP therefore ARB must not "take credit" for NOx reductions from these devices.

Pursuant to CEQA, the baseline to be used in an environmental analysis is the physical environmental conditions as they exist at the time environmental review is commenced. ARB staff disagree that undeveloped future rules are properly considered part of the CEQA baseline. However, in an effort to fully address SJVAPCD's concerns, ARB has conducted a further analysis against a hypothetical future baseline where all existing vapor control devices are already low-NOx vapor control devices. In such a scenario, there would be no NOx benefit attributed to the Proposed Regulation for replacing current vapor control devices with low-NOx vapor control devices. Under that scenario, the Proposed Regulation would result in a NOx emissions increase in the SJVAPCD of 4.1 tons per year, CO emissions increases of 1.6 tons per year, and a negligible SOx emissions increase. PM10 and PM2.5 emissions would not change. All estimated emissions increases under this alternative scenario are below the CEQA significance threshold for the SJVAPCD of 10 tons per year for NOx, 5 tons per year for PM10, and 15 tons per year for PM 2.5. The SJVAPCD does not define CEQA significance thresholds for CO and SOx.

However, as noted above, the proper CEQA baseline for this project is existing environmental conditions, as analyzed above.

The change in NO_x emissions that might occur as a result of the proposed regulation was estimated separately by staff of the SJVAPCD. The SJVAPCD analysis was limited to emissions from tanks only. For context, when comparing against this hypothetical future baseline, ARB staff estimates an additional 2.9 tpy NO_x from the tank measure only. SJVAPCD staff estimates an additional 20.2 tpy NO_x, an order of magnitude greater than the ARB staff estimates.

ARB staff believes these high estimates are not accurate for several reasons. SJVAPCD made assumptions on tank coverage, assumed all gas at a lease would go into one large system, assumed all recovered gas would go to a flare, and included supplemental fuel (which is not allowed in the current version of the regulation). ARB used the robust data contained within the oil and gas survey results to determine the amount of gas going to each tank system (not each facility), the number of systems above our standard, which systems were already controlled, the disposal method for each system, and did not assume supplemental fuel use since low NO_x incinerators can handle waste gas. More detailed information can be found in the Draft EA.

Although the regulation decreases NO_x compared to current levels, ARB staff recognizes some of the ARB's proposed NO_x reduction approaches in this rule may be required in the future by the district and ARB is committed to spurring innovation in, and application of, NO_x control strategies. Staff suggests following the development of the related SJVAPCD rules and exploring options to address any remaining concerns through, among other options, consideration of innovative NO_x technologies or funding or implementation of NO_x reduction projects.

Additionally, implementation of the proposed regulation would consist of modifications to existing facilities such as installation of vapor collection systems, and replacement or repair of leaking equipment resulting in the installation or replacement of gathering lines and piping, flanges, valves, low NO_x combustion devices pneumatic devices and pumps, and other components. Any proposed modifications to facilities would require having local or State land use approvals secured prior to their implementation. Part of the development review and approval process for projects located in California requires environmental review consistent with California environmental laws (e.g., CEQA) and other applicable local requirements (e.g., local air quality district rules and regulations). The environmental review process would include an assessment of whether or not implementation of such projects could result in air quality impacts. As described in ARB's Draft EA in Appendix C, ARB expects any construction-related impacts to air quality to be less-than-significant due to the limited nature of the modifications and upgrades to oil and gas facilities that could be

required under the Proposed Regulation, consisting of activities such as installation of piping, gathering lines, tanks, valves, and hatches.

VIII. ENVIRONMENTAL ANALYSIS

The Air Resources Board (ARB), as the lead agency for the proposed regulation, has prepared an environmental analysis under its certified regulatory program (17 CCR 60000 – 60008) to comply with the requirements of the California Environmental Quality Act (CEQA). ARB's regulatory program, which involves the adoption, approval, amendment, or repeal of standards, rules, regulations, or plans for the protection and enhancement of the State's ambient air quality has been certified by the California Secretary for Natural Resources under Public Resources Code section 21080.5 of CEQA (14 CCR 15251(d)). ARB, as a lead agency, prepares a substitute environmental document (referred to as an "Environmental Analysis" or "EA") as part of the Staff Report to comply with CEQA (17 CCR 60005).

The Draft Environmental Analysis (Draft EA) for the proposed regulation is included in Appendix C to this Staff Report. The Draft EA provides an environmental analysis, which focuses on reasonably foreseeable potentially significant adverse and beneficial impacts on the physical environment resulting from reasonably foreseeable compliance responses taken in response to implementation of the proposed actions within the proposed regulation. The Draft EA is intended to disclose potential adverse impacts and identify potential mitigation specific to the proposed regulation.

Implementation of the proposed regulation would require regulated entities to take actions to limit vented and fugitive methane emissions from equipment and operations. The Draft EA states that implementation of the proposed regulations would result in beneficial impacts to GHGs through reductions in methane emissions from oil and gas operations in California. The Draft EA states that the proposed regulation would result in less-than-significant long term impacts to air quality but with reductions in VOCs. The Draft EA also states the proposed regulations could result in less-than-significant or no impacts to aesthetics, agriculture resources, air quality, biological resources (long term), energy demand, greenhouse gases (short term), geology and soils (long term), hazards and hazardous materials, hydrology and water quality (long term), land use planning, transportation and traffic, mineral resources, noise, population and housing, public services, recreation, and utilities and service systems; and potentially significant and unavoidable adverse impacts due to short term construction related impacts to biological resources (short term), cultural resources (short term), geology and soils (short term), and hydrology and water quality (short term) that are reasonably foreseeable as a result of the proposed regulation.

Written comments on the Draft EA will be accepted starting June 3, 2016 through 5 p.m. on July 18, 2016. The Board will consider the Final EA and responses to comments received on the Draft EA before considering adoption of the proposed regulation.

| Long-Term Operational Impacts | Less-than-significant |

A. HEALTH IMPACTS

California experiences some of the highest concentrations of PM_{2.5} in the nation.⁸⁶ The majority of California’s population lives in areas that exceed the national and state PM_{2.5} air quality standards.^{87 88} These standards are set based upon assessments of scientific studies that link exposure to PM_{2.5} to health effects, including hospitalization due to respiratory and cardiovascular illness, and premature death from cardiopulmonary disease.^{89 90} The U.S. EPA has determined that exposure to PM_{2.5} plays a “causal” role in premature death, meaning that a substantial body of scientific evidence shows a relationship between PM_{2.5} exposure and increased mortality, a relationship that persists when other risk factors such as smoking rates and socioeconomic factors are taken into account.⁹¹ NO_x emissions impact human health because photochemical reactions convert some NO_x into ammonium nitrate aerosol, a

component of PM_{2.5}, and convert some NO_x to ozone, a major constituent of smog and a potent lung irritant.

There are no expected associated health impacts.

IX. ENVIRONMENTAL JUSTICE

Government Code section 65040.12(e) defines environmental justice as the fair treatment of people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies. ARB is committed to supporting the achievement of environmental justice. In 2001, the Board adopted a framework for incorporating environmental justice into the ARB's programs consistent with the directives of State law.⁹² Although ARB's environmental justice policies apply to all communities in California, they recognize that environmental justice issues have been raised more often in the context of low-income and minority communities.

As a result of ARB's work with the public, the business sector, local government, and air districts, California's ambient air is the cleanest since air quality measurements have been recorded.⁹³ However, large numbers of Californians live in areas that continue to experience episodes of unhealthy concentrations of ozone and PM_{2.5}.

Communities located in close proximity to oil and gas operations are already experiencing the impacts of those operations including, but not limited to, odors, noise, and vehicle traffic. Additionally, these communities are at risk for exposure to a variety of volatile organic compounds and toxics, including the BTEX suite of chemicals, which are associated with oil and gas operations. Local air districts currently implement a variety of rules that reduce volatile organic compounds from the oil and gas industry. The purpose of the proposed regulation is to reduce methane emissions from the covered oil and gas operations and facilities covered with the reduction of additional volatile organic compounds and toxic air contaminants as a co-benefit of the proposed control strategies. The proposed regulation was designed to minimize or eliminate any potential air quality emission impacts in nonattainment areas and minimize potential emissions well below significance levels in attainment areas. Specifically, though some newly-collected vapors may be combusted, the proposed regulation requires that inefficient combustion devices already in use be replaced with cleaner devices before they can be used for compliance. The surrounding communities will benefit from the proposed regulation to the extent that the proposed control strategies provide reductions in emissions of volatile organic compounds and toxic air contaminants. There will be no adverse impact to the surrounding communities due to the oil and gas regulation.

X. ECONOMIC IMPACTS

A. SUMMARY OF PROPOSED COSTS AND IMPACTS

The proposed Regulation for the Reduction of Greenhouse Gas (GHG) Emissions from Crude Oil and Natural Gas Operations (proposed regulation) is intended to reduce GHG emissions from oil and gas production, processing, storage and transmission compressor stations. The economic impacts of the proposed regulation are discussed in this section, and include impacts and benefits to businesses, individuals, and government agencies. This section also includes a discussion of the estimated cost of the proposed regulation.

B. MAJOR REGULATIONS

For a major regulation proposed on or after January 1, 2014, a Standardized Regulatory Impact Assessment (SRIA) is required. A major regulation is one “that will have an economic impact on California business enterprises and individuals in an amount exceeding fifty million dollars (\$50,000,000), as estimated by the agency.” (Govt. Code Section 11342.548) Further, the Health and Safety Code Section 57005(b) defines a “major regulation” as any regulation that will have an economic impact on the state’s business enterprises in an amount exceeding ten million dollars (\$10,000,000), as estimated by the board, department, or office within the agency proposing to adopt the regulation in the assessment required by subdivision (a) of Section 11346.3 of the Govt. Code.

When amortized, the proposed regulation will cost \$23 million with the enhanced underground storage monitoring plan and \$14 million per year without that provision; however, the largest expenditures will be in 2018 when most of the capital equipment is expected to be purchased. This upfront cost is estimated to be over \$40 million in direct costs, and over \$50 million in overall economic impact. Due to the estimated economic impact of compliance exceeding \$50 million in a 12 month period during 2018, the proposed regulation was determined to be a major regulation and required a SRIA. A SRIA was submitted to the Department of Finance (DOF) on February 20, 2015 and a revised version on April 29, 2015. On May 28, 2015, ARB received a letter from the DOF acknowledging the status of a major regulation, and commenting on the information presented in the SRIA. These comments are addressed in Appendix B to this document.

Since the submittal of the SRIA, the proposed regulation has undergone several changes. In addition to changes in the standards, there have been changes to the methodology of estimating the cost and emissions for provisions of the proposed regulation due to the availability of updated data and feedback from industry representatives and other stakeholders. Although these changes have been made after the submittal of the SRIA, staff believes the conclusions of the

SRIA continue to be accurate, since the overall annual cost, emission, reductions, and impacted industries are similar.

In addition to changes made to the standards of the proposed regulation, ARB is now using the 20 year AR4 value (72) of GWP instead of the 100 year AR4 value (25) to determine the reductions in CO₂e. Also, the value assigned to gas saved changed from \$4.10 per mscf to \$3.44 per mscf. This value was changed to reflect the most recently available data and is the average wholesale price that is specific to California over the last 12 months of available data, from November 2014 to October 2015.⁹⁴ Also, the compliance dates for the regulation have changed from starting January 1, 2017, to starting January 1, 2018.

In addition to the changes discussed above, some of the methodologies of estimating the potential costs and emission have changed. This is due to the availability of better data, stakeholder comments, as well as the continued development of the proposed regulation. These changes are described in detail below. All SRIA emissions use a GWP of 25, and all current emissions use a GWP of 72 in the descriptions.

1. Changes from SRIA

a) Reciprocating Compressors

In the SRIA version of the proposed regulation, all reciprocating compressors would need to replace a rod packing after three years of use. In the current version of the proposed regulation, compressors at production facilities are no longer subject to a rod packing leak standard, but instead are required to meet an LDAR standard. Many of the compressors at production facilities are smaller, may be portable, and handle a different composition of gas than compressors at processing, storage or transmission facilities. In addition, most of the available data concerning leak rates and rod packing cost and performance are from larger compressors that are typically not found at production facilities. The provision to exclude production type compressors eliminated over 600 of almost 1000 compressors from this segment, for determining cost and emissions. In addition, industry provided data on the leak rate by compressor for a large subset of the remaining compressors. This new data was used in place of the emission factors previously used. With the reduction in number of compressors, the change from a time based standard to a performance based standard, and using measurement data instead of emission factors, the estimated reduction of emissions has changed from 143,000 MT CO₂e to about 68,000 MT CO₂e. Based on the

⁹⁴ U. S. EIA. 2016. U.S. Natural Gas Citygate Price (Dollars per Thousand Cubic Feet).

decrease of compressors potentially impacted by the standard for rod packing leaks, the estimated cost of compliance has decreased from about \$600,000 per year to about \$260,000 per year.

b) Centrifugal Compressors

In the SRIA version of the proposed regulation, 25 centrifugal compressors with wet seals were anticipated to need a vapor recovery system or to be converted to a dry seal. In an effort to verify this data from ARB's 2009 Survey, staff contacted the facilities that would be impacted by this provision in the proposed regulation. All centrifugal compressors, except for one, were reported with wet seals in error, are no longer in use, have been replaced with a compressor with a dry seal, or now have a vapor recovery system installed to control emissions. In addition, measurement data taken directly from this single compressor was used in place of the emission factors used to generate the emissions and reductions for the SRIA. Due to the updated number of impacted units, the emissions dropped from about 20,000 MT CO₂e to about 3,700 MT CO₂e and the reduction estimates dropped from about 10,000 MT CO₂e to about 3,500 MT CO₂e. The associated cost of compliance decreased from about \$375,000 per year to about \$6,000 per year.

c) LDAR

In the SRIA version of the proposed regulation, the emissions did not include a small percentage of super emitter components, which are responsible for the majority of emissions. In addition, the LDAR program was changed from an annual inspection to a quarterly inspection requirement. These changes were made to address stakeholder comments, and ensure emissions were determined with the best available data. The estimated emissions reduction has changed from about 1,200 MT CO₂e to about 590,000 MT CO₂e, and the estimated cost has changed from about \$2 million per year to about \$10 million per year.

d) Pneumatic Devices

At the time of the SRIA, all continuous bleed pneumatic devices were required to change to a low bleed pneumatic device. Based on stakeholder feedback, this has been changed to require a no bleed pneumatic device in the current proposed regulation to maximize emission reductions with no increased cost. Also, after a review of the data, the count of continuous bleed devices was overestimated by about 170. The anticipated emissions reduction from this segment have changed from about 124,000 MT CO₂e to about 320,000 MT

CO₂e, and the estimated cost has changed from about \$1.3 million per year to about \$1.2 million per year.

e) Tank and Separator Systems

The provisions for tank and separator systems have changed from requiring a vapor recovery system for all uncontrolled systems, to require vapor recovery and comply with a NO_x emission standard, but only for uncontrolled systems that are anticipated to have over 10 MT per year of CH₄ emissions. Due to this change, the estimated number of systems impacted changed from over 600 to about 300. It is now assumed that a low NO_x incinerator will be used to comply with the NO_x emission standard in place of a flare. The emissions are now calculated with the throughput to the separators instead of limited, reported emissions data from the 2009 ARB survey. The estimated emissions reductions have changed from about 252,000 MT CO₂e to about 540,000 MT CO₂e. The estimated cost has changed from about \$16 million per year to about \$4.7 million per year.

f) Well Stimulations

The current proposal uses emission factors from WSPA⁹⁵ to estimate emissions from well stimulations. These emission factors became available after the submittal of the SRIA when the best available data projected much greater emissions. The estimated emissions reduction from this segment of the proposed regulation has changed from about 24,400 MT CO₂e to about 5,000 MT CO₂e. The estimated cost has changed from about \$200,000 per year to about \$460,000 per year due better cost data becoming available and inclusion of additional compliance equipment.

g) Liquids Unloading

The requirement for controls for liquids unloading were removed for the proposed regulation, and replaced with a reporting requirement. The estimated reductions of about 350 MT CO₂e have been eliminated, and the expected cost of \$450,000 per year has been replaced with a cost of about \$6,000 for reporting and recordkeeping.

h) Monitoring Plan

The proposed regulation now includes a monitoring plan, which requires operators of natural gas storage facilities to monitor gas wells on a daily basis, and install a system for ambient air monitoring. This was not included in the SRIA. The cost of this provision is estimated to be about \$8.7 million per year.

⁹⁵ WSPA. 2015. Recirculation Tank Emissions Testing, Source Test Report.

C. ECONOMIC IMPACTS ASSESSMENT

The proposed regulation encourages the use of more efficient and potentially cost-saving technology to ensure maximum production of natural gas. Much of the capital equipment purchased, such as vapor recovery for tanks, have lifetimes that far exceed the pay-off period. Though at some point the primary industries no longer are making payments for the capital required for compliance, they continue to enjoy the natural gas savings that are provided by that capital. Therefore, the primary industries oil and gas extraction and natural gas distribution, are required to make minor changes to their production facilities, these modifications include increases in efficiency that may result in net benefits to regulated parties in the long run. Secondary industries face increased product demand, resulting in increased output and employment in those industries.

The proposed regulation was analyzed using generally high estimates and GHG emission reduction estimates; thus, the analysis may serve as an upper bound of anticipated impacts. To the extent there are greater cost savings due to increased product capture, the economic impacts of the proposed regulation would be less negative in all years, and likely show a benefit to the economy. This result would persist in later years and the primary industries, having made a large initial investment in the capital necessary to prevent substantive leaks, would continue to see savings long after the payments for the capital are finished.

The proposed regulation is unlikely to significantly impact California's economy, including the growth of employment, investment, personal income, output, and GSP does not represent a significant change from Business as Usual (BAU).

D. COST EFFECTIVENESS

1. Cost Analysis and Costs per Ton

This section describes the sources and general methodology to determine the emissions, cost, and cost per ton of the proposed regulation. In general, for each segment of the regulation, staff identified the number of devices affected, estimated the cost to comply with the regulatory provisions, estimated emissions and reductions, and accounted for any savings to be included in the cost per ton. Cost per ton is the dollars spent to reduce a unit mass of a specified pollutant, in this case methane. The general methodology to determine these items for each segment of the regulation is described below and is described in more detail in Appendix B. Costs are based on best estimates at the time of preparation.

The indirect costs and economic impacts were modeled using a computational general equilibrium model of the California economy known as Regional Economic Models, Inc. (REMI). The REMI model generates year-

by-year estimates of the total regional effects of a policy or set of policies. These results and analysis are included with the SRIA in Attachment C. The results helped evaluate the impact of the proposed regulation on California's economy, including business impacts, job creating, and impacts to individuals. Finally, alternatives to the proposed regulation were evaluated and fiscal impacts to ARB and local air districts were estimated. The cost estimate of the proposed regulation follows guidelines recommended by the California Environmental Protection Agency (Cal/EPA), and is consistent with the methodologies used in previous cost analyses for ARB regulations (ARB, 1999; ARB, 2000; ARB, 2004; ARB, 2005; ARB, 2007). The segments analyzed for this proposed regulation include control strategies for reciprocating compressors, centrifugal compressors, oil and water separators and storage tanks, pneumatic devices, circulation tanks for well stimulations, and a leak detection and repair (LDAR) program. Information from this survey, of which parts were later updated by staff to account for changes since 2009, was used to form the basis of the number and types of facilities potentially impacted, number and types of equipment, and estimated emissions reduction from the standards in the proposed regulation. After the number and types of equipment impacted were identified, the direct cost to industry was estimated for each component of the regulation. Sources of data include ARB's 2009 Survey, ICF's Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries (ICF Report), EPA documents including their Gas Star Program, industry groups, and communications with operators of potential control equipment, and other stakeholders. Appendix B details the methodology and calculations by sector.

Table 14: Summary of Cost, Emissions, and Cost per Ton using the 20 year and 100 year GWP respectively

| Provision | Annual Cost | Annual Savings | Reductions using 20 year GWP (MT CO ₂ e) | Cost per Ton using 20 year GWP (\$ / MT CO ₂ e reduced) | Cost per Ton using 20 year GWP with Savings (\$ / MT CO ₂ e reduced) | Cost per Ton Using 100 year GWP (\$ / MT CO ₂ e reduced) | Cost per Ton with Savings Using 100 year GWP (\$ / MT CO ₂ e reduced) |
|---------------------------|--------------|----------------|---|--|---|---|--|
| VRU for Tanks | \$4,700,000 | \$500,000 | 540,000 | \$ 9 | \$ 8 | \$25 | \$23 |
| Reciprocating Compressors | \$260,000 | \$180,000 | 68,000 | \$ 4 | \$ 1 | \$11 | \$3 |
| LDAR | \$10,000,000 | \$1,500,000 | 590,000 | \$ 17 | \$ 14 | \$49 | \$41 |

|--------------|---------------------|--------------------|------------------|-------------|-------------|-------------|-------------|

All Figures are in 2015 dollars

2. Direct Costs

a) Direct Costs on Individuals

For 2017, the baseline projected outputs for oil and gas extraction and natural gas distribution industries are approximately \$25 billion and \$19 billion respectively. The ratio of compliance cost to total output is less than 0.5 percent for both industries, making it likely that pass-through of costs would be unnoticeable. However, to the extent that any potential costs are passed on to individual consumers, minor increases in the price of natural gas and electricity may occur.

b) Direct Costs on Typical Businesses

Any business involved with crude oil or natural gas extraction, natural gas storage, crude oil processing excluding refineries, natural gas processing (including gas plants), crude oil tank farms (excluding tank farms at refineries), or transmission of natural gas will potentially be impacted by the proposed regulation. In February 2009, ARB conducted an Oil and Gas Industry Survey for crude oil and natural gas production, processing, and storage facilities in California.⁹⁶ The survey was completed by 325 companies representing over 1,600 facilities and approximately 97 percent of the 2007 crude oil and natural gas production in California. Out of these companies, 272 companies that responded to the survey are expected to be impacted by the provisions in the proposed regulation.

ARB estimates the direct cost to industry for the proposed regulation to be approximately \$25 million per year. This includes the amortized cost of capital equipment, and annual costs for labor, maintenance, reporting and recordkeeping. ARB generally used high estimates throughout for estimating emissions, costs, and reductions. The average impact each of the 272 businesses is expected to be about \$100,000 per year. The typical businesses are not small because the primary industries are ineligible to be classified as small under government code.⁹⁷ Therefore, the increased costs on industry do not directly impact small businesses.

The proposed regulation will impact some businesses that would have otherwise been classified as a small business. Small businesses with estimated annual revenue of less than \$10 million per year, but greater

⁹⁶ ARB. 2013. ARB 2007 Oil and Gas Industry Survey Results, Final Report, revised in October 2013.

⁹⁷ Government Code Section 11342.610(b). 2016. Small Business Procurement and Contract Act. http://www.leginfo.ca.gov/cgi-bin/displaycode?section=gov&group=14001-15000&file=14835-14843_

than \$2.5 million per year, as estimated by annual gas and oil production from ARB's survey (ARB, 2013) are expected to incur costs of about \$16,000 per year to comply with the provisions in the proposed regulation. These businesses have average revenue of about \$5.2 million, and the estimated costs account for less than 0.5% of the estimated annual revenue. Microbusinesses are businesses with annual revenue of less than \$2.5 million per year. Based on ARB's survey (ARB, 2013), these businesses have an average revenue of about \$780,000 and will incur costs of about \$3,700 annually. This accounts for less than 0.5% of the estimated annual revenue.

3. Cost Analysis

a) Benefits

The proposed regulation is anticipated to deliver environmental benefits that include an estimated annual reduction in GHG emissions, beginning in 2018, of about 1.5 million MT CO₂e per year from oil and gas related operations in California. In addition, the proposed regulation is expected to save primary industries about 800 million standard cubic foot (scf) per year of industrial natural gas through reductions of leaks and vapor recovery systems⁹⁸. This will result in a savings of about \$3 million per year, assuming the value of this gas is \$3.44 per Mscf. The cost per ton of the proposed regulation is estimated to be approximately \$15 per MT CO₂e reduced. These estimates use the 20-year GWP for methane (i.e., 72) from the Intergovernmental Panel on Climate Change's (IPCC) Fourth Assessment Report (AR4).

Using the 20-year GWP shows the impact of reducing methane in the short term when compared to carbon dioxide. Reducing SLCPs, such as methane, can produce near term results that deliver immediate and tangible climate, air quality, economic, and health benefits while longer-term changes are being implemented.

The proposed regulation is also expected to provide co-benefits of reductions in emissions of VOCs and toxic air contaminants that are emitted from uncontrolled oil and water storage tanks and released from well stimulation circulation tanks. The estimated reduction in VOCs is approximately 3,630 tons per year, or about 10 tons per day statewide. There was the potential for NO_x increases for vapor recovery units if the facility used a flare. However, since the proposed regulation would impose a NO_x standard in these cases where none or a less stringent one applied before, the overall impact is a small but

⁹⁸ This assumes gas is 94.9% CH₄.

beneficial with a reduction of about 1.6 metric tons per year, but there are NO_x impacts from LDAR leading to an overall impact that is neutral for the state as a whole. Table 12, above, summarizes reductions of all pollutants, and detailed calculations are in Appendix D.

b) Benefits to Individuals

The proposed regulation will not directly affect individual consumers; however, as a result of the anticipated decrease in methane emissions, VOCs, and other toxic air contaminants, the proposed regulation will provide health and climate benefits.

Like emissions of other GHGs, emissions of methane due to human activities (anthropogenic emissions) have increased markedly since pre-industrial times. Of the GHGs emitted as a result of human activities, methane is the second most important GHG after carbon dioxide (CO₂), accounting for 14 percent of global GHG emissions in 2005. Though methane is emitted into the atmosphere in smaller quantities than CO₂, its global warming potential (i.e., the ability of the gas to trap heat in the atmosphere) is 72 times that of CO₂, resulting in methane's stronger influence on warming during its atmospheric life time.⁹⁹

California experiences some of the highest concentrations of PM_{2.5} in the nation.¹⁰⁰ The majority of California's population lives in areas that exceed the national and state PM_{2.5} air quality standards.^{101 102} These standards are set based upon assessments of scientific studies that link exposure to PM_{2.5} to health effects, including hospitalization due to respiratory and cardiovascular illness, and premature death from cardiopulmonary disease.^{103 104} The U.S. EPA has determined that exposure to PM_{2.5} plays a "causal" role in premature death, meaning that a substantial body of scientific evidence shows a relationship between PM_{2.5} exposure and increased mortality, a relationship that persists when other risk factors such as smoking rates and socioeconomic factors are taken into account.¹⁰⁵ NO_x emissions impact human health because photochemical reactions convert some NO_x into ammonium nitrate aerosol, a component of PM_{2.5}, and

convert some NO_x to ozone, a major constituent of smog and a potent lung irritant.

The PM_{2.5} and NO_x emission changes due to the proposed regulation are expected to be negligible, and so there are no expected associated health impacts.

c) Benefits to California Businesses

The proposed regulation requires the oil and gas industry to purchase, retrofit, and service capital equipment. The requirements of the regulation would increase the demand for these services and increase business opportunities for secondary industries both within and outside of California. Additionally, the proposed regulation is designed to reduce industrial natural gas leakage, which will result in cost savings for the regulated parties. For example, many of the proposed control strategies are designed such that natural gas can be recovered and either used on site as energy or captured for sale. These savings are estimated to be about \$ 3 million per year. While the primary industries are not small businesses, by definition, some of the secondary industries contain small businesses. If these businesses were able to meet the increased demand and provide the capital equipment and services to the primary industries for compliance, small businesses would see increased demand, output and, likely, employment.

ARB estimates that more than \$25 million each year will be spent on control equipment and inspection services. This includes over \$10 million complying with the LDAR provisions in the proposed regulation. Companies involved in LDAR inspections may see an increase in business or expansion. In areas of the state that previously did not have an inspection program, there will be new demand for a previously unneeded service, which may result in new businesses being created.

In areas without existing VOC based regulations for LDAR or higher pressure natural gas systems, LDAR is likely to be more cost effective. Also, staff believes that with the advent of newer technologies, the efficiency of LDAR inspections will improve.

While direct costs to the primary industries exceed \$40 million in the first year of implementation, these industries achieve savings of about \$3 million annually from leakage prevention strategies within the proposed regulation. Secondary industries also achieve benefits, as demand for their equipment, services, or other products such as natural gas increases yielding positive economic benefits.

E. IMPACTS TO CALIFORNIA, STATE, OR LOCAL AGENCIES

1. Fiscal Impacts

a) ARB and Air Districts

The proposed regulation's enforcement and implementation provisions recognize that California's local air districts already play an important role in regulating the oil and gas sector, and are intended to build on their efforts. The provisions make clear that ARB can directly enforce the proposed regulation, but also offer paths for local air districts to integrate its requirements into their existing programs to support efficient and effective enforcement.

ARB's proposed regulation can be implemented and enforced by both ARB and the districts. ARB staff assumes most local air districts will choose to take the lead in implementing and enforcing the regulation, with ARB playing a backstop role, and it is our preference for the local air districts to do so. However, ARB will take a lead role in districts that choose not to. The local air districts are more familiar with operators, conduct inspections nearby or at the same sites, and in many instances have been regulating such sources for decades. This is why the regulation allows local districts to enter into MOUs with ARB in order to define implementation and enforcement responsibilities, as well as for information sharing. The regulation also allows for districts to incorporate this regulation into their local rules. To ensure uniform enforcement, however, districts may not waive or reduce the stringency of the state rules, which remain state law, enforceable as necessary by ARB.

A local air district may decide – but is not obligated -- to be the primary agency responsible for enforcing the provisions of the proposed regulation. This includes issuing permits for new control equipment, registration and inspection of equipment, and enforcing the LDAR portion of the regulation. The individual district cost estimates range from amounts some districts feel could be absorbed by them without additional funding, to over \$300,000 per year in recurring costs and almost \$1,000,000 in one-time costs, primarily for permitting. Even if the districts do decide to implement and enforce this regulation, there is an annual cost for ARB to manage the reporting requirements in the regulation. The costs to districts are estimated to be approximately \$1,300,000 in initial costs, and approximately \$660,000 in ongoing costs.

Although local agencies (air districts) may choose to implement this regulation, and certain aspects of it may be incorporated in permits as a matter of preexisting law, resulting in some fiscal impacts, the

regulation imposes no reimbursable mandates. Air districts face no new legal requirements specific to them under this regulation. As to implementation tasks they may take on or any other costs that may result by operation of statute, air districts have legal authority under Health and Safety Code sections 40510 and 42311 to recover related costs by imposing fees. The Proposed Regulation also specifies that local air districts that choose to enforce the regulation may retain any penalty monies that result. ARB also may make arrangements to further support air districts as a voluntary matter. Thus, because the regulation applies generally to all entities operating affected sources, not the air districts, and so does not impose unique new requirements on local agencies, this is not a reimbursable mandate. (*County of Los Angeles v. State of California*, 42 Cal. 3d 46 (1987)).

The proposed regulation's enforcement and implementation provisions recognize that California's local air districts already play an important role in regulating the oil and gas sector, and are intended to build on their efforts. The provisions make clear that ARB can directly enforce the proposed regulation, but also offer paths for local air districts to integrate its requirements into their existing programs to support efficient and effective enforcement. ARB's proposed regulation can be implemented and enforced by both ARB and the districts. ARB staff assumes most local air districts will choose to take the lead in implementing and enforcing the regulation, with ARB playing a backstop role, and it is our preference for the local air districts to do so. However, ARB will take a lead role in districts that choose not to. The local air districts are more familiar with operators, conduct inspections nearby or at the same sites, and in many instances have been regulating such sources for decades. This is why the regulation allows local districts to enter into MOUs with ARB in order to define implementation and enforcement responsibilities, as well as for information sharing. The regulation also allows for districts to incorporate this regulation into their local rules. To ensure uniform enforcement, however, districts may not waive or reduce the stringency of the state rules, which remain state law, enforceable as necessary by ARB.

ARB staff estimates that the regulation will require 6 PYs to implement depending on the mix of district and ARB implementation. In addition to PYs, ARB will need to purchase equipment including three IR cameras at \$85,000 each, and three toxic vapor analyzers at \$10,000 each. The costs are higher with ARB enforcement than with district enforcement due to the need to travel, train new staff, and set-up programs including a registration program. The total cost to ARB is estimated to be \$285,000 in initial costs ((3 X \$85,000) + (3 X \$10,000)), and about \$870,000 in ongoing costs (6 X

\$145,000). These costs are anticipated to be imposed during the 2017/2018 fiscal year.

b) Other State Agencies

The proposed regulation does not affect other state agencies.

Jim Nyarady
Manager, Oil & Gas Section
California Air Resources Board
1001 I. Street
Sacramento, CA 95814
Jim.nyarady@arb.ca.gov

Dear Mr. Nyarady:

Please accept these comments on behalf of Clean Air Task Force, Environmental Defense Fund, Natural Resources Defense Council and Sierra Club. We greatly appreciate the opportunity to comment on the California Air Resources Board's ("CARB") draft regulation for methane pollution from oil and gas facilities. We commend CARB for proposing a strong draft that, in particular, directly regulates methane from new and existing sources, and applies to a broad suite of facilities across the natural gas supply chain. We are particularly supportive of those provisions that require, or prioritize, the capture of methane, over combustion, and the broad applicability of the leak detection and repair requirement to multiple pieces of equipment and components. That being said we believe there is room for improvement and offer below some suggestions to this end.

A. Leak Detection and Repair

We commend CARB on proposing that operators inspect facilities quarterly. As we have documented in prior comments, frequent inspections are critical to ensuring leaks and emissions are minimized and promptly remediated.¹ They are also highly cost effective.² We do, however, believe the leak detection and repair provisions can and should be improved. Specifically, we strongly recommend the following:

- While maintaining the quarterly inspection frequency in the draft proposal, remove the provisions allowing operators to adjust frequency based on the number or percentage of leaking components identified in prior surveys, which are not rationally tied to the emissions performance of a facility, and misaligns incentives for operators;
- Allow for the use of optical gas imaging and other equally effective advanced technologies to detect leaks. This, coupled with Method 21 compliant devices capable of quantifying methane, will ensure that inspections efficiently detect the full suite of leaking components at a site, while still quantifying emissions from leaking components.
- Remove the exemptions in Section 95669(e)(1), (6) and (4) and narrow the exemption in (8); and
- Decrease the lowest allowable leak threshold from 10,000 ppm to 500 ppm, consistent with other leading states.

¹ May 15 Letter to CARB from EDF; May 15 Letter to CARB from Sierra Club, et al.

1. *Eliminate Provisions Allowing for Reduction in Inspection Frequency*

We strongly advise eliminating provisions allowing operators to adjust frequency based on the number or percentage of leaking components identified in prior surveys, neither of which is rationally tied to the future leak performance of a facility. Moreover, such an approach misaligns incentives for operators.

As we have explained in prior comments, studies suggest that past leak emissions are not a good predictor of future leak emissions given the prominent role that improperly functioning equipment, poorly maintained equipment, and other random events play in overall leak emissions.³ Numerous studies have found that leaks, in particular very large leaks or “super emitters,” are largely unpredictable and shift over time. In particular, a series of studies undertaken in the Barnett Shale found that abnormal operating conditions, such as improperly functioning equipment, could occur at different points in time across facilities.⁴ As a result, one of the study’s authors concluded that inspections need “to be conducted on an ongoing basis” and “across the entire population of production sites.”⁵ Accordingly, we recommend that CARB propose an LDAR standard based on fixed frequencies.

Data from operators collected as part of Colorado’s rulemaking further supports a fixed inspection requirement. Colorado’s recently adopted leak detection and repair program requires that operators inspect for leaks at all but the smallest sites on a continuous annual, quarterly, or monthly basis.⁶ Notably, Encana submitted testimony regarding its own voluntary LDAR program, which requires monthly instrument-based inspections. According to Encana, “Encana’s experience shows leaks continued to be detected well into the established LDAR program.”⁷ Encana’s data shows that while the largest reductions in VOC emissions occur in the first year of an LDAR program, operators continue to find leaks during every subsequent survey because leaks re-occur on an ongoing basis at facilities.⁸ This pattern was independently confirmed in supplementary analysis carried out by Carbon Limits on leak inspection data from a number of

well production facilities and compressor stations.⁹ Carbon Limits found that inspectors continued to find leaks in frequent repeat inspections on the same facility. Additionally, Carbon Limits found that the cost-effectiveness of the leak inspections, expressed in dollars per metric ton of VOC abatement, did not significantly rise over several years after regulations were put in place requiring LDAR at facilities in Alberta.

CARB's proposal creates perverse incentives by rewarding operators for failing to identify harmful leaks. This is not a hypothetical concern. A 2007 report by EPA found "significant widespread non-compliance with [LDAR] regulations" at petroleum refineries and other facilities.¹⁰ EPA observed: "Experience has shown that poor monitoring rather than good performance has allowed facilities to take advantage of the less frequent monitoring provisions."¹¹ The report recommends that "[t]o ensure that leaks are still being identified in a timely manner and that previously unidentified leaks are not worsening over time," companies should monitor more frequently.¹²

We strongly recommend that CARB maintain the quarterly inspection frequency and remove provisions allowing operators to reduce frequency based on the percentage of leaking components identified in prior surveys. However, if CARB retains the provisions that allow for decreased inspections, we urge CARB to strengthen these by adding a provision that explicitly prohibits a decrease in monitoring if the facility is in violation of any aspect of the LDAR provisions, and requires a return to quarterly at those facilities conducting annual surveys upon the finding of a violation of any of the the LDAR provisions. This is the approach taken by Ventura County, San Joaquin Valley, and Santa Barbara air districts, and we maintain this is an important element to ensuring that reductions in frequency only occur at those facilities in compliance with the CARB rule.¹³

2. CARB Should Allow for the Use of OGI and other Emerging Technologies Demonstrated to be Equally or More Effective, yet Less Costly, than Method 21.

Optical gas imaging (OGI) systems have rapidly advanced to the forefront of leak detection technology, primarily because of the speed and comprehensiveness with which these technologies can detect leaks, as well as other important advantages over Method 21 or non-instrument based methods. In addition, the methane leak detection landscape is innovating

rapidly and we urge CARB to include an alternative compliance pathway that allows operators to use methods demonstrated to be equally or more effective at detecting methane leaks as Method 21 or OGI. Importantly, these benefits not only enhance the effectiveness of inspections in detecting leaks, but also reduce costs. Coupled with Method 21, OGI offers an efficient, comprehensive method to detect, quantify and help repair leaks:

- **Speed.** Optical gas imaging can be used to quickly and comprehensively scan an entire facility for leaks, accurately detecting almost any leaking equipment from safe vantage points. The Colorado Air Pollution Control Division estimates operators can scan a facility for leaks twice as quickly using an IR camera as they can using a Method 21 compliant device.¹⁴ Some suggest that this is a conservative estimate of the time savings associated with the use of IR cameras, and that IR camera scans can be performed even more efficiently.¹⁵ BLM estimates OGI can identify up to 2,100 components per hour while portable analyzer can only identify 30-40.¹⁶ A recent presentation by Target Emission Services similarly notes that OGI is capable of surveying 1000-5000 components per day versus only 250-600 using Method 21.¹⁷
- **Comprehensive Inspection.** Moreover, optical gas imaging technology with infrared cameras is proven to enable efficient and accurate site-level assessments, including difficult to access components.¹⁸ A clear illustration of this is that operators can detect leaks atop storage tanks using an IR camera that would otherwise go undetected unless an inspector climbed to the top of the tank.¹⁹ As we have previously noted, thief hatches are a very significant source of leaks, as documented by various EPA Region 8 and Colorado inspections and enforcement actions.²⁰ This allows open thief hatches or other similar leaks to be promptly addressed once detected, without requiring an inspector to climb the tank on every leak survey. OGI allows operators to safely but effectively monitor components and equipment that may be unsafe to monitor with Method 21, and also

²⁰ May 2015 Letter to CARB from EDF.

allows operators to detect leaks such as pinhole corrosion leaks in tanks, which operators are very unlikely to find with Method 21.

- **Accuracy and Efficacy.** Although technologies such as OGI do not currently quantify leaks, detection is of primary importance since most leaks are cost effective to repair once detected.²¹ The quantitative comparisons that exist indicate that OGI is as effective as Method 21 in detecting all but the smallest leaks.²² There is also data indicating that OGI can be more accurate for identifying the source of specific leaks.²³
- **Compliance Monitoring and Enforcement.** OGI technologies allow operators to record and save videos of leaks. These records can help CARB or district inspectors confirm compliance with the LDAR requirements. While we urge CARB to remove the provisions allowing operators to decrease inspection frequency based on past performance, if these provisions remain, records of the leaks detected will become even more important and strict recordkeeping requirements should be adopted.

The use of OGI-based LDAR programs is a central feature of many leading and federal state standards. Five states – Colorado, Pennsylvania, Ohio, Utah and Wyoming – have adopted LDAR requirements for oil and gas facilities that allow the use of OGI instruments as a means of compliance.²⁴ Since 2011, Subpart W of EPA’s Greenhouse Gas Reporting Program has allowed the use of OGI cameras to detect leaking components at above-ground facilities in natural gas processing, transmission, storage, and distribution, as well as LNG import/export facilities.²⁵ EPA and the Bureau of Land Management’s recent proposals to limit pollution from oil and natural gas facilities both propose to allow for the use of OGI as the primary leak detection method.²⁶

Many leading operators have also deployed OGI to help detect and repair leaks. Companies such as Shell, Anadarko Petroleum Corporation, and Noble Energy have indicated that they are utilizing infrared cameras for leak detection and repair purposes.²⁷ More specifically, Jonah

²⁷ EDF, Oil and Natural Gas Sector Leaks Peer Review Responses of Environmental Defense Fund, June 16, 2014 at 9.

Energy's Enhanced Direct Inspection & Maintenance (EDI&M) Program in Wyoming has been ongoing for the last five and a half years, employing a *monthly* leak detection and repair program using instrument-based surveys (IR camera technology). This program has resulted in over 16,000 inspections and thousands of repaired leaks identified by IR camera technology and a reported overall control effectiveness in excess of 75%.²⁸

We are aware that Air Districts with existing inspection and maintenance programs require quantification of leaks. To the extent that CARB retains the requirement in the proposal that operators quantify leaks, we urge allowing operators the flexibility to couple their OGI inspections with a device capable of quantification. This would take advantage of many of the benefits of OGI while also ensuring quantification. Under this approach, operators would be required to first scan the facility with OGI, thus ensuring that difficult or unsafe to monitor components are scanned. Operators would then only be required to measure the leaks detected with the OGI camera. Since OGI operators can conduct OGI inspections more quickly than Method 21, this approach would result in a lower overall inspection time and therefore inspection costs, and still ensure that any detected leaks are quantified. Colorado allows operators to utilize this approach.²⁹

As we have previously indicated, the methane leak detection technology landscape is advancing rapidly and the draft rule should support such innovation. Accordingly, we strongly urge the agency to allow operators to utilize approved devices other than Method 21 and OGI that have been demonstrated to be equally or more effective at detecting methane leaks. This is the approach allowed in Colorado.

3. LDAR Exemptions Should be Removed or Narrowed to Improve the Protectiveness of the Rule and Increase Emission Reductions

The LDAR provisions contain numerous exemptions that undermine the protectiveness of the rule and are not supported by LDAR requirements adopted or proposed in other jurisdictions. To ensure that this LDAR program results in the greatest degree of emission reduction feasible, we suggest removing or narrowing the following exemptions:

- Section 95669(e)(1). This provision exempts “components at a facility upstream of a transfer of custody meter used exclusively for the delivery of commercial quality natural gas to the facility.” We understand that this exemption is intended to exempt the facility receiving commercial quality natural gas from responsibility for conducting LDAR on components that handle gas that does not belong to them. The problem with this approach is that it leaves components with the potential to leak unregulated. Regardless of who owns the gas, all components at facilities listed in Section 95666 should be subject to LDAR if the rule is to achieve the maximum feasible emission reductions. No other state with an LDAR program, nor the local District inspection and maintenance programs in California, contain this exemption. We urge CARB to remove this overly broad exemption, or otherwise clarify what entity is responsible for addressing leaks from the components identified in Section 95669, if it is not the entity receiving the commercial quality natural gas.

²⁸ Jonah Energy LLC, presentation at the WCCA Spring Meeting, May 8, 2015, on file with EDF.

²⁹ 5 C.C.R. § 1001-9 XVII.F.6.e.

- Section 95669(e)(6). This provision exempts “components and piping located downstream from the point where crude oil, condensate, or natural gas transfer custody occurs, including components and piping located outside the facility boundaries of natural gas compressor stations and underground storage facilities.” Like the exemption in Section 95669(e)(1), this exemption is overly broad and threatens to exempt components located at numerous facilities. No other state with an LDAR program, nor the local District inspection and maintenance programs in California, contain this exemption. Custody transfer occurs at numerous points between the production, gathering and boosting, processing, storage and transmission segments, and therefore there are countless components potentially exempt under this provision. We urge CARB to remove this provision, or narrowly cabin it to certain limited, clear instances where CARB explains the basis for this exemption.
- Section 95669(e)(4). This provision exempts “one-half inch and smaller stainless steel tube fitting including those used for instrumentation. No other state LDAR program contains this exemption. Nor does the South Coast Air District inspection and maintenance rule 1173. We are not aware of any data that indicates that these types of fittings do not leak. In fact, to the contrary, other local Air District inspection and maintenance rules require these types of fittings to be included in LDAR unless demonstrated to be leak free.³⁰ We urge CARB to remove this exemption, or at a minimum, only allow it if operators demonstrate such fitting to be leak free.
- Section 95669(e)(8). This provision exempts components that are “unsafe to monitor when conducting Method 21 measurements and as documented in a safety manual or policy approved by the ARB Executive Officer.” First off, we note that if CARB were to allow the use of OGI, the need for and use of this exemption would be significantly lessened, as operators can scan many components that may be unsafe to monitor using Method 21 (see above). Second, while we understand the need for safety exceptions, such exceptions should be narrowly tailored. We thus recommend that CARB require unsafe to monitor components be inspected within a certain timeframe. This is the approach taken by a number of the local Air Districts. Ventura County Air District requires operators inspect unsafe to monitor components at least once a year³¹ and San Joaquin Valley requires such components be inspected “during each turnaround” or within two years of the date when five major leaks within a year have been detected, whichever is sooner.³² We urge CARB to include similar provisions in its rule, specifically requiring inspection of such components at least every 6 months, during each turnaround, or when the component becomes safe to inspect, whichever happens earliest.

³² San Joaquin Valley Air Pollution Control District R.4409.5.3.7.6

4. *CARB Should Require All Leaks of 500 ppm be Repaired Upon Rule Implementation*

The proposal sets the lowest leak threshold at 10,000 ppm for the first year of the rule's implementation, and then lowers this to 1,000 in year two. A 10,000 ppm leak is a large leak, and we are not aware of any technical or other justification for allowing smaller leaks that can be detected to go unmitigated. Method 21 and OGI are both capable of detecting leaks smaller than 10,000 ppm. Moreover, other leading states with LDAR programs that contain quantitative leak thresholds such as Colorado and Pennsylvania require operators repair much smaller leaks of 500 ppm.³³ U.S. EPA uses a leak threshold of 500 ppm for a number LDAR requirements for new facilities under NSPS Subpart OOOO.³⁴ We therefore urge CARB to lower the initial leak threshold to 500 ppm to be consistent with these other states and EPA to reflect what is technically feasible.

B. Pneumatic Devices and Pumps

We believe that CARB intends to regulate pneumatic devices in the following ways:

- Prohibit venting of natural gas from *continuous*-bleed pneumatic devices and pumps after 1 January 2018, as provided for in §§ 95668(f)(3) and (6);
- Include continuous-bleed, intermittent bleed pneumatic devices and pneumatic pumps in LDAR, as provided for in §§ 95668(f)(3)-(5); and
- Prohibit intermittent bleed devices from venting natural gas when not actuating after January 1, 2018, as provided for in § 95668(f)(4).

We commend CARB for proposing these provisions. No other jurisdiction prohibits venting from new continuous bleed devices or pumps located at the suite of facilities subject to this proposal, nor includes all pneumatic devices, including intermittent bleed devices, in leak detection and repair requirements. These provisions will go a long way towards reducing emissions from new continuous-bleed pneumatic devices and pumps, and malfunctioning intermittent and continuous-bleed devices and pumps.

1. CARB Should Phase Out Existing Low-Bleed Continuous Devices

That said, for continuous-bleed pneumatic devices, the draft regulation is significantly weaker than the 22 April 2015 draft regulation. We understand the proposal as allowing for the use of continuous-bleed pneumatic devices installed before 1 January 2015, provided operators adhere to the monitoring provisions in draft § 95668(f)(2), which requires operators to regularly check that these devices are not emitting more than six standard cubic feet per hour (scfh), and to fix or replace them if they do emit over this threshold. This “grandfather” clause that allows for the *indefinite* use of continuous bleed devices is not warranted.

³⁴ See 77 F.R. at 49,498.

As we detailed in our May 2015 comments, there are numerous ways to eliminate emissions from pneumatic devices that bleed natural gas to the atmosphere.³⁵ Compressed air can be used instead of natural gas to drive devices. EPA’s 2012 OOOO NSPS standards require all pneumatic controllers at processing plants to be zero emitting,³⁶ and EPA presumes that most operators will use compressed air systems to comply with this regulation.³⁷ For sites with numerous pneumatic devices, compressed air is a cost-effective and feasible approach to eliminate emissions from pneumatic devices – including any intermittent-bleed devices on site, and also most pneumatic pumps – especially when electric power is readily available. Oil and gas production in California occurs largely in areas with increased access to electric power. Many centralized production sites and compressor stations have numerous pneumatic devices.

Other “zero-bleed” technologies exist beyond compressed air to eliminate emissions from pneumatic devices. These include:

- generating low-cost electric power on-site which can be used to power electrical valve controllers and actuators, or potentially to compress air, including devices which generate electricity from compressor waste heat;
- solar / battery systems which can be used with electric controllers and actuators; and
- “closed-loop” actuator systems which use natural gas to control and actuate valves but capture that gas on the low-pressure side of a system so it is not vented.

These systems are described in more detail and documented in our comments to US EPA on Proposed NSPS Subpart OOOOa.³⁸

In addition to using equipment that is not designed to bleed in the first place, emissions from pneumatic devices can be captured and utilized, sold, or controlled, as CARB’s proposal recognizes. These options apply well to the “low-bleed” continuous-bleed pneumatic devices that CARB’s proposal would grandfather. Since many of these devices are on sites that have, or will have, a vapor collection system, the cost of connecting a device to the vapor collection system is very low.

We thus recommend that CARB remove the provision allowing “low-bleed” continuous-bleed pneumatic devices that were in operation on 1 January 2015 to continue operating. If CARB concludes that such devices must be allowed to continue venting gas into the atmosphere, despite the numerous options operators have to eliminate these emissions, CARB must limit the period over which operators are allowed to continue these harmful emissions to at most a few years. Indefinite grandfathering is not warranted.

2. *Control Emissions from Intermittent-bleed Pneumatic Devices*

CARB has significantly strengthened its proposal for intermittent-bleed pneumatic devices, by adding specific testing requirements to ensure that these devices do not leak gas into the air when

³⁵ May 15, 2015 CATF et al Comments to CARB at 8-9.

not actuating. Draft § 95668(f)(4). However, we reiterate our concern that, beyond this provision, the draft regulation, like the April 2015 draft, does not limit emissions from these devices. These devices are a very significant source of emissions. Oil and gas producers reported over 850,000 metric tons of methane emissions nationwide in 2014 from intermittent-bleed devices to US EPA's GHGRP, far higher than the 161,000 metric tons of methane they reported from continuous-bleed devices (both high-bleed and low-bleed).³⁹ In California, oil and gas producers reported over 4,100 tons of methane in 2014 from intermittent-bleed devices, while reporting no emissions at all from continuous-bleed devices.⁴⁰ Alarming, reported emissions from intermittent-bleed devices are increasing, both nationwide and in California.⁴¹

Similar to continuous-bleed devices, there are numerous options to limit or eliminate emissions from intermittent-bleed pneumatic devices. Many high-emitting intermittent-bleed pneumatic controllers can be replaced with lower emitting, or even zero-emitting, equipment. The zero-emitting technologies described above can all be applied to intermittent-bleed devices, and in the case of compressed air systems, a single system can readily be used to run a mix of continuous-bleed and intermittent-bleed devices. Even where venting natural gas-driven pneumatic devices are used, lower-bleed intermittent pneumatic devices are available. Properly designed intermittent bleed devices can emit below 6 scfh in many applications.⁴² The emissions factor for intermittent bleed pneumatics in natural gas transmission is 2.35 scfh,⁴³ well below 6 scfh. In a recent study of the methane abatement opportunities from oil and gas, ICF International estimated that 25% of high emitting intermittent-bleed controllers in oil and gas production can be replaced with low-emitting devices.⁴⁴ Wyoming requires *all* pneumatic controllers to be low emitting, regardless of whether they are continuous-bleed or intermittent-bleed, at new and modified facilities.⁴⁵

While CARB's proposal would reduce emissions from intermittent-bleed devices by ensuring that devices that leak continuously are fixed or replaced, the emissions from properly operating devices will remain high without additional standards.

It may be useful to consider that not all intermittent-bleed devices actuate frequently – but some actuate very frequently, and therefore emit large amounts of natural gas. For example, Allen *et*

⁴¹ *Id.*

⁴² In their comments on EPA's 2012 oil and gas rules, the American Petroleum Institute stated, "Achieving a bleed rate of < 6 SCF/hr with an intermittent vent pneumatic controller is quite reasonable since you eliminate the continuous bleeding of a controller." In fact, API advocated intermittent-bleed devices to achieve the 6 scfh bleed rate, rather than continuous low-bleed devices. American Petroleum Institute, "Technical Review of Pneumatic Controllers," at 7 (Oct. 14, 2011), available as Attachment K to American Petroleum Institute, Comment on OOOO New Source Performance Standards (Nov. 30, 2011), <http://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2010-0505-4266>.

⁴⁵ This requirement is applied to intermittent-bleed controllers in addition to continuous-bleed controllers (email from Mark Smith, WDEQ, to David McCabe, 22 September 2014), Ex. 2.

al. (2015) observed that controllers for emergency shut-off devices made up 12 percent of the population of controllers that they studied.⁴⁶ These devices will actuate very rarely, if at all. It may be reasonable to exclude some intermittent-bleed devices from control requirements for vent gas, if operators can demonstrate that actuation is very uncommon. (If facilities have instrument air installed, however, the costs of connecting that air supply to every intermittent-bleed controller are very low, and in general that should be required.)

In contrast, some intermittent-bleed devices actuate very frequently. Of the 377 devices studied by Allen *et al.* (2015), 24 were intermittent-bleed devices that actuated at least 10 times during the sampling period, which was typically 15 minutes. Four actuated over fifty times while sampled.⁴⁷ These devices can emit at high levels – five of the forty highest emitting devices studied by Allen *et al.* (2015) are intermittent-bleed devices that were assessed to be operating properly.⁴⁸ Devices with specific functions, such as level controllers on separators, are likely to actuate frequently.

While specific treatment of intermittent-bleed devices that very rarely actuate may be warranted, the fact that some controllers very rarely actuate cannot be used to justify inaction for the entire class of intermittent-bleed controllers.⁴⁹ Since there are available approaches to avoid these emissions, CARB must issue appropriate standards to address emissions from intermittent-bleed controllers that are operating properly (not continuously emitting) and that have high emissions.

We suggest that CARB require emissions from intermittent-bleed devices be routed to a vapor collection system; if such a system is not available or operators can demonstrate that such routing is not feasible, operators must ensure that the intermittent-bleed device does not emit natural gas continuously or emit over six scfh, as is required in Wyoming.⁵⁰

As we discussed and documented in our May 2015 comments, these requirements will produce abatement at a reasonable cost. This is particularly true for California, where most facilities will have vapor collection systems, so the costs of routing emissions from intermittent-bleed devices to these systems should be quite low (like the costs of routing emissions from continuous-bleed controllers to these control devices, as ARB proposes).

Finally, we commend CARB’s proposal to require capture of all emissions from natural gas-driven pneumatic pumps.

C. Compressors

⁴⁶ Allen D.T. *et al.* (2015), “Methane Emissions from Process Equipment at Natural Gas Production Sites in the United States: Pneumatic Controllers,” *Environ. Sci. Technol.* 49, 633–640.

⁴⁷ Derived from analysis of table S4-1 in Allen *et al.* (2015) supplemental information.

⁴⁸ See Allen *et al.* (2015), Supporting Information, section S-8. Temporal profiles of emissions from the 40 highest-emitting controllers sampled in the study are shown. Controllers LB01-PC01, LB07-PC01, LB04-PC01, LB06-PC05, and LB04-PC03 – five of the forty highest emitting controllers – are clearly intermittent devices which were assessed to be “operating as expected.”

⁴⁹ Since some intermittent-bleed devices actuate very rarely, their emissions are low. These devices bring the average emissions factor for intermittent-bleed devices down.

1. *Reciprocating Compressors*

We support CARB's approach to require operators to either capture and control all emissions from rod packing on reciprocating compressors, or to monitor rod packing emissions at the vent point and repair them when they exceed thresholds. We commend CARB's draft proposal for requiring control of rod packing emissions from compressors at wellpads, which EPA has failed to require or propose for even new equipment to date, and for requiring measurement of actual emissions from "midstream" compressors – those at natural gas gathering and boosting stations, processing plants, transmission compressor stations, and underground storage facilities.

However, the draft regulation should be strengthened. Since even new, properly installed rod packing seals allow some natural gas to escape past the seals, emissions from reciprocating compressors – even those that are monitored closely – are inevitable if the natural gas that escapes is not captured and directed to a vapor collection system (VCS). Therefore directing gas to a VCS should be required whenever possible. The alternative approach of monitoring emissions and requiring repair when emissions rise above a threshold should only apply when directing gas to a VCS is somehow not feasible. Even if used to control emissions with a vapor control device as described in draft §95668(c)(3) – (c)(4), instead of directing vapors to a sales, fuel, or reinjection line, collecting vapors with a VCS is superior to monitor and repair. CARB should strengthen the draft by requiring the use of a VCS whenever feasible.

The draft standards magnify this problem by only requiring annual monitoring for midstream compressors, which would be regulated under draft §95668(d)(2), when those compressors do not have vapor collection systems in place. Furthermore, the emissions standard for these compressors – two standard cubic feet per minute (scfm) per cylinder (draft §95668(d)(2)(E)) – is much higher than appropriate, since rod packing replacement can cost-effectively reduce emissions at levels far below 2 scfm per cylinder, as we show below.

We commend CARB for requiring measurement of the volumetric or mass flow rate from rod packing vents for midstream compressors, as opposed to measuring the hydrocarbon concentration at the access port. Measuring the volumetric or mass flow rate from an access port with high volume sampling, bagging, or calibrated flow measuring instruments gives a real value for emissions, while hydrocarbon concentration is only weakly correlated with emissions.⁵¹ Some leak-detection service providers routinely measure emissions from leaks with high volume samplers, indicating that the cost of these measurements is quite reasonable.⁵² The routing of all emissions through an access port will make such measurements particularly accurate and feasible. Therefore, CARB should retain the requirement for measuring actual flow in this manner for midstream reciprocating compressors, but on a quarterly instead of annual basis, as discussed above. If measurements are only required on an annual basis, as in the current draft, two problems arise. First, elevated emissions can and will continue over a longer period than if quarterly measurements are required. Second, the lax annual requirement encourages operators

⁵¹ Clearstone Engineering *et al.* (2006) *Cost-Effective Directed Inspection and Maintenance Control Opportunities at Five Gas Processing Plants and Upstream Gathering Compressor Stations and Well Sites*, at 3. Available at http://www.epa.gov/gasstar/documents/clearstone_II_03_2006.pdf.

⁵² Carbon Limits (2014), *supra* note 21 at 10.

of midstream compressors to monitor emissions rather than direct natural gas from reciprocating compressor seals to a VCS.

Further, CARB must strengthen the proposal by reducing the threshold at which repair of rod packing is required. Draft §95668(d)(2)(E) requires repair or replacement of rod packing when emissions per cylinder reach two scfm. However, since the natural gas that escapes from rod packing and is vented to the air is a salable product, and repair / replacement of rod packing keeps more natural gas in the system and therefore increases revenues for operators, repair / replacement of rod packing is cost-effective when emissions are far lower than 2 scfm. In comments we recently filed on US EPA's 2015 proposed New Source Performance Standard Subpart OOOOa, we used US EPA figures for the costs of rod packing replacement to show that replacement is cost-effective when emissions per cylinder reach 20 to 25 standard cubic feet *per hour*, over a factor of four lower than the 2 scfm threshold in draft §95668(d)(2)(E).⁵³ For example, using cost figures from US EPA documents (converted to 2015 dollars) and a \$4 per MCF price of natural gas, we showed that the net abatement cost of replacing rod packing when emissions per cylinder reach 20 scf per hour is \$538 per short ton of avoided methane pollution; if the threshold were 25 scf per hour, the net cost would drip to \$232 per short ton of abated methane.⁵⁴ Accordingly, CARB must reduce the threshold at which replacement or repair of rod packing is required. It is important to consider that operators have other options for control; specifically, the option of using a vapor collection system. Indeed, commercial systems to direct rod packing emissions to fuel systems for compressors are available,⁵⁵ and in general these emissions can be routed to a VCS which directs gas into a sales line such as a vapor recovery unit on a tank. We also note that the Ohio EPA has released a draft general permit that requires operators to capture all emissions from reciprocating compressor rod packing and direct those emissions to sales, fuel lines, or 98% control.⁵⁶

Finally, CARB should consider requiring measurement of actual flow, in the manner required for midstream compressors, for compressors at wellpads and other oil and gas production sites, as opposed to measuring hydrocarbon concentration as currently required in draft § 95668(d)(1)(B). At a minimum CARB should seek comment and cost data on this approach for these compressors. Wellpad compressors can be large and, given the low cost of actual emissions measurements, it is not appropriate to require the less accurate concentration measurement at all of these compressors.

2. Centrifugal Compressors

We believe that the approach taken by CARB in the previous (22 April 2015) draft of the Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities was more appropriate than the approach taken in the current draft. The April 2015 draft would have required operators of centrifugal compressors with wet seals to “collect the wet seal vent gas with a vapor collection system and route the collected gas to an existing sales gas system, fuel gas system, or vapor control device.” April 2015 Draft at § 95213(f)(1)(B). In contrast, the

⁵³ Joint comments at 101-102.

⁵⁴ *Id* at 102.

⁵⁵ *Id* at 98.

⁵⁶ Ohio EPA, General Permit 17.1 Template, C.(1)(b)(1)(d), available at <http://epa.ohio.gov/dapc/genpermit/permitsec.aspx>

current Draft Proposal allows operators of centrifugal compressors with wet seals to opt out of installing a vapor collection system, and instead to monitor emissions from the wet seals and, if they rise above three scfm, to “minimize” emissions and after several years, to install dry seals. Draft regulation at § 95668(e)(3) – (e)(8). This is an odd approach.

First, it is generally very feasible and cost effective to install vapor collection systems that route wet seal degassing emissions to the suction side of the compressor, another beneficial use, or a control device. EPA has published literature through its Natural Gas STAR program describing how these systems — consisting of seal oil/gas separators, demisters/filters for both high and low-quality gas, and necessary piping and instrumentation — are cost effective and can largely eliminate vented gas from wet seal compressors.⁵⁷ EPA literature presents four different options for using gas that is captured through these devices: 1) return it to compressor suction; 2) route high-pressure gas to a combustion turbine for electricity generation; 3) route low-pressure gas to a heater or boiler to use as fuel; and 4) send the captured gas to a control device.⁵⁸ EPA notes that at least one operator has configured its system to use all four of these options.⁵⁹ Based on experience from about one hundred installations, BP has reported that systems that return seal gas to compressor suction (the first option) are “simple, broadly flexible, and reliable,” and generate “positive cash flow in less than a month.”⁶⁰ EPA requires that operators of new and modified wet-seal centrifugal compressors at gathering and boosting compressor stations and gas processing plants use these vapor collection systems to capture seal oil degassing vapors and route emissions to a process or 95% control,⁶¹ and has proposed extending this requirement to new and modified transmission and storage segment wet-seal centrifugal compressors.⁶²

Second, according to US EPA, “Methane emissions from wet seals typically range from 40 to 200 standard cubic feet per minute.”⁶³ The minimum of this range is an order of magnitude above the threshold above which CARB would require operators to “minimize” emissions. Draft regulation at § 95668(e)(6) – (e)(7). Simply put, wet seal centrifugal compressors without vapor collection systems in place cannot meet this standard.

Recognizing this, many operators may choose to simply install vapor collection systems, which is a comparatively simple modification, not requiring years of lead time. However, in addition to increasing the complexity of the rule, the option to monitor and “minimize” emissions instead of installing a vapor collection system may be detrimental. First, since the word “minimize” in draft § 95668(e)(7) is not defined, and a wet seal unit operating normally typically emits at least 40 scfm, the provision may be interpreted by some operators as allowing them to operate wet

⁵⁷ See EPA, *Wet Seal Degassing Recovery System for Centrifugal Compressors* (2014), available at <http://www3.epa.gov/gasstar/documents/CaptureMethanefromCentrifugalCompressionSealOilDegassing.pdf>; see also Reid Smith, BP, and Kevin Ritz, BGE, *Centrifugal Compressor Wet Seals Seal Oil De-gassing & Control*, presentation delivered at 2014 Natural Gas STAR Annual Implementation Workshop (May 2014), available at http://www3.epa.gov/gasstar/documents/workshops/2014_AIW/Experiences_Wet_Seal.pdf, at 7—19.

⁶³ See EPA, *Replacing Wet Seals with Dry Seals in Centrifugal Compressors* (2006), at 1. Available at: http://www3.epa.gov/gasstar/documents/ll_wetseals.pdf.

seal compressors uncontrolled, emitting well over three scfm, until January 1, 2020. Second, it is not clear how the critical component provision in draft 95668(e)(8) will operate, and whether operators of designated-critical wet seal centrifugal compressors will enact controls.

As such, CARB should revert to the simpler and clearer approach to wet seal centrifugal compressors in the April 2015 Draft regulation.

Finally, CARB should ensure that components on driver engines and compressors for *dry seal* centrifugal compressors are subject to the LDAR provisions of §95669. We believe that this would reflect CARB's intent. However, since 95668(e)(2) specifically requires this for wet seal compressors but the draft is silent on dry seal compressors in this regard, we are concerned that some operators may misinterpret the draft regulation as not requiring LDAR for dry seal compressors.

D. Crude Oil, Condensate, and Produced Water Separation and Storage

CARB should clarify and tighten deadlines related to both commencement of annual flash analysis testing and installation of vapor collection systems (where the measured annual flash emission rate is greater than 10 metric tons per year).

1. Testing Should Occur Earlier and Controls be Installed Sooner

We remain concerned that the draft rule may allow new vessels to operate without any emission controls for the first year of operation. Section 95668(a)(4) provides that owners and operators of new and existing separators and tank systems that are not controlled for emissions with the use of a vapor collection system must conduct annual flash analysis testing of the crude oil, condensate, or produced water – with no requirement to actually control emissions unless this analysis demonstrates emissions in excess of ten metric tons of methane per year. (Section 95668(a)(2)(B) exempts tanks from the requirements of this subsection entirely if they are “used for temporarily separating, storing, or holding emulsion, crude oil, condensate, or produced water from any newly constructed well for up to 30 calendar days following initial production,” so long as the tank is not used to circulate liquids from a well that has been subject to a well stimulation treatment.)

Section 95668(a)(4) clarifies that this annual flash analysis testing must be conducted “[b]eginning January 1, 2017 and by no later than September 1, 2017.” Though the draft states that this requirement applies to “new and existing” systems, it appears to apply to separator and tanks systems that are in place prior to January 1, 2017 (and possibly to those that become operational between January 1, 2017 and September 1, 2017). For such systems, CARB should require that owners and operators conduct testing by a date certain that is earlier than September 1, 2017. Furthermore, CARB should clarify that this means that the first test must be done prior to that date (as opposed to that date commencing a year-long period during which testing may occur).

For separator and tank systems that start operation between January 1 and September 1, 2017, or after September 1, 2017, it is unclear when flash analysis testing must commence. For example, because the measurement is only required annually, it is possible that an owner or operator of a system that starts operation after September 1, 2017 may choose to conduct testing on the last day of the first year of a tank's operation. Because section 95668(a)(5) only requires control

once methane emissions have been measured to exceed 10 metric tons per year, the draft regulation does not plainly require control within the first year.

CARB should also specify how soon controls must be installed once emissions are measured in excess of 10 metric tons. Section 95668(a)(5) specifies that the requirement to control emissions begins January 1, 2018 (“Beginning January 1, 2018, owners or operators of separator and tank systems with a measured annual flash emission rate greater than 10 metric tons per year of methane shall control the emissions from the separator and tank system with the use of a vapor collection system as specified in section 95668(c)”). It is unclear when vapor collection systems must be installed (i.e., how soon after the measurement greater than 10 metric tons), particularly for systems that exceed the 10 metric tons per year threshold after January 1, 2018. Section 95668(a)(8) further states that flash analysis testing “shall be conducted *within one calendar year* of adding a new well to the separator and tank system since the time of previous flash analysis testing” (emphasis added). With a full year to conduct testing and no firm date to realize control of the vessel, we are concerned that operators may delay installation for long periods of time *after* testing, leading to excessive periods without control.

Other jurisdictions have successfully implemented regulations that require control of tanks in the months after production begins at a well. US EPA requires that emissions from new and modified storage vessels that have potential to emit six tons of VOC or more per year must control emissions from those vessels by 60 days after the vessel goes in service.⁶⁴ As discussed below, Colorado requires operators to assess whether emissions will be significant from tanks – and if so, to control vessels from the date of initial production at the well. In light of these precedents, CARB’s proposal is clearly insufficiently protective.

As noted in our prior comments, a regulation that had the effect of allowing vessels to operate without controls for the first year is problematic because emissions are likely to be highest during the first year. Oil and gas well production generally sharply declines during the first year of operation. Throughput of materials (oil, produced water, and other substances) in vessels tracks production, meaning that potential vessel emissions follow this curve as well. Thus, the draft regulation may not only have the effect of allowing uncontrolled vessel emissions for a year—it could allow emissions without control during the time when those emissions will be highest. This concern is heightened because operators may be incentivized to delay testing until the end of the year, because if production has dropped enough to reduce potential emissions below the 10 metric ton per year threshold, the vessel will not need control.

As noted in our May 2015 comments, in crafting emission control requirements for vessels, the Colorado Air Pollution Control Division expressed concern that even allowing operators to wait *ninety days* after commencement of production to install controls on vessels would allow significant and avoidable air pollution.⁶⁵ Colorado determined that it would be cost effective to

⁶⁴ See 40 C.F.R. §60.5395(d)(1)(i). “For each Group 2 storage vessel affected facility [that is, vessels constructed after 12 April 2013], you must achieve the required emissions reductions by April 15, 2014, **or within 60 days after startup**, whichever is later.” Emphasis added.

⁶⁵ Colorado Air Pollution Control Division, Final Economic Impact Analysis for Proposed Revisions to Colorado Air Quality Control Commission Regulation Number 5 (5 CCR 1001-9), pages 8-9 (Jan 30, 2014), available at [ftp://ft.dphe.state.co.us/apc/aqcc/Oil%20&%20Gas%20021914-022314/REBUTTAL%20STATEMENTS,%20EXHIBITS%20&%20ALT%20PROPOSAL%20REVISIONS/Air%20Pollution%20Control%20Division%20\(APCD\)/APCD%20REB%20R7.finalEIA.pdf](ftp://ft.dphe.state.co.us/apc/aqcc/Oil%20&%20Gas%20021914-022314/REBUTTAL%20STATEMENTS,%20EXHIBITS%20&%20ALT%20PROPOSAL%20REVISIONS/Air%20Pollution%20Control%20Division%20(APCD)/APCD%20REB%20R7.finalEIA.pdf)

require controls to be installed on all crude oil and produced water tanks immediately, allowing operators to remove controls from a tank once testing demonstrated that the tank's uncontrolled emissions would fall below the applicable threshold. A presumption of control has the added benefit of providing operators with an incentive to test emissions promptly. ARB should follow Colorado's lead and assume that vessels require emission controls unless and until operators demonstrate otherwise.

At bare minimum, CARB should clearly indicate 1) when annual flash analysis testing must commence (including for systems that become operational after the dates specified in 95668(a)(4)), and 2) for systems with a measured annual flash emission rate greater than 10 metric tons per year, the mandatory timeline for installing a vapor collection system.

We suggest that testing should be carried out within 30 days of initial production, and that CARB require that controls be in place within 60 days after initial production for tanks that have potential emissions above the threshold, in line with the Federal standards (note that the Federal standards have a different, VOC-based threshold than the draft CARB standard). CARB should also consider requiring control from the day of initial production when emissions from the tank can be anticipated to exceed 10 metric tons per year, in accordance with the Colorado approach.

CARB must also ensure that for new wells, the Test Procedure for Determining Annual Flash Emission Rate of Methane from Crude Oil, Condensate, and Produced Water properly assesses annual emissions. It is critical that operators assess potential emissions rapidly after operation of a tank begins, so that the tank can be controlled if needed. CARB must also ensure that operators do not use a simple extrapolation of low production in the first days after production begins to conclude that potential emissions from the vessel will be less than the 10 metric ton per year threshold. Such extrapolation would be inappropriate because for new wells, particularly wells that were hydraulically fractured, production can rise dramatically over the initial weeks after production begins. CARB thus must ensure that operators use liquid throughput values in Equation 1 of Section 11 of the Test Procedure that are appropriate for yearly averages for new wells.

2. Provisions Requiring Clarification or Strengthening

CARB should also clarify or strengthen the following provisions:

- 95668(a)(4)(D): "Demonstrate that the results of the flash analysis testing are representative of the crude oil, condensate, and produced water processed or stored in the separator and tank system. The ARB Executive Officer may request additional flash analysis testing or information in the event that the test results reported do not reflect representative results of similar systems." It is unclear how the owner or operator would demonstrate that the test results are representative, or how the ARB Executive Officer would determine whether the test results "reflect representative results of similar systems."
- 95668(a)(7): "... If the results of flash analysis testing are less than or equal to 10 metric tons per year of methane using three consecutive years of test results the owner or operator may reduce the frequency of testing and reporting to once every five years."

Testing once every five years is too infrequent to effectively determine if emissions have increased above 10 metric tons per year.

- 95668(a)(9): “Flash emissions shall be recalculated if the annual crude oil, condensate, or produced water throughput increases by more than 10 percent since the time of the previous flash analysis testing” (provided that the increase in throughput is not a result of adding a new well to the separator and tank system which requires additional flash analysis testing as specified in section 95668(a)(8)). This provision should specify how soon after the throughput increase the flash emissions must be recalculated.

3. Comparison of CARB Proposal to Colorado Requirements

The following section compares the requirements and timelines in the CARB draft rule to those in the Colorado methane rule (emphasis added):

XVII.C. (State Only) Emission reduction from storage tanks at oil and gas exploration and production operations, well production facilities, natural gas compressor stations, and natural gas processing plants.

XVII.C.1. Control and monitoring requirements for storage tanks

XVII.C.1.a. Beginning May 1, 2008, owners or operators of all storage tanks storing condensate with uncontrolled actual emissions of VOCs equal to or greater than twenty (20) tons per year based on a rolling twelve-month total must operate air pollution control equipment that has an average control efficiency of at least 95% for VOCs.

*XVII.C.1.b. Owners or operators of storage tanks with uncontrolled actual emissions of VOCs **equal to or greater than six (6) tons per year based on a rolling twelve month total** must operate air pollution control equipment that achieves an average hydrocarbon control efficiency of 95%. If a combustion device is used, it must have a design destruction efficiency of at least 98% for hydrocarbons, except where the combustion device has been authorized by permit prior to May 1, 2014.*

XVII.C.1.b.(i) Control requirements of Section XVII.C.1.b. must be achieved in accordance with the following schedule:

*XVII.C.1.b.(i)(a) A storage tank constructed on or after May 1, 2014, must be in compliance **within ninety (90) days of the date that the storage tank commences operation.***

XVII.C.1.b.(i)(b) A storage tank constructed before May 1, 2014, must be in compliance by May 1, 2015.

*XVII.C.1.b.(i)(c) A storage tank not otherwise subject to Sections XVII.C.1.b.(i)(a) or XVII.C.1.b.(i)(b) that increases uncontrolled actual emissions to six (6) tons per year VOC or more on a rolling twelve month basis after May 1, 2014, must be in compliance **within sixty (60) days of discovery of the emissions increase.***

XVII.C.1.c. Control requirements within ninety (90) days of the date of first production.

*XVII.C.1.c.(i) Beginning May 1, 2014, owners or operators of storage tanks at well production facilities must collect and control emissions by routing emissions to operating air pollution control equipment **during the first ninety (90) calendar days after the date of first production.** The air pollution control equipment must achieve an average hydrocarbon control efficiency of 95%. If a combustion device is used, it must have a design destruction efficiency of at least 98% for hydrocarbons. This control requirement does not apply to storage tanks that are projected to have emissions less than 1.5 tons of VOC during the first ninety (90) days after the date of first production.*

XVII.C.1.c.(ii) The air pollution control equipment and any associated monitoring equipment required pursuant to Section XVII.C.1.c.(i) may be removed at any time after the first ninety (90) calendar days as long as the source can demonstrate that uncontrolled actual emissions from the storage tank will be below the threshold in Section XVII.C.1.b.

...

XVII.C.2. Capture and monitoring requirements for storage tanks that are fitted with air pollution control equipment as required by Sections XII.D. or XVII.C.1.

XVII.C.2.a. Owners or operators of storage tanks must route all hydrocarbon emissions to air pollution control equipment, and must operate without venting hydrocarbon emissions from the thief hatch (or other access point to the tank) or pressure relief device during normal operation, unless venting is reasonably required for maintenance, gauging, or safety of personnel and equipment. Compliance must be achieved in accordance with the schedule in Section XVII.C.2.b.(ii).

...

XVII.C.2.b.(ii) Owners or operators must achieve the requirements of Sections XVII.C.2.a. and XVII.C.2.b. and begin implementing the required approved instrument monitoring method in accordance with the following schedule:

*XVII.C.2.b.(ii)(a) A storage tank constructed on or after May 1, 2014, must comply with the requirements of Section XVII.C.2.a. **by the date the storage tank commences operation.** The storage tank must comply with Section XVII.C.2.b. and implement the approved instrument monitoring method inspections **within ninety (90) days of the date that the storage tank commences operation.***

XVII.C.2.b.(ii)(b) A storage tank constructed before May 1, 2014, must comply with the requirements of Sections XVII.C.2.a. and XVII.C.2.b. by May 1, 2015. Approved instrument monitoring method inspections must begin within ninety (90) days of the Phase-In Schedule in Table 1, or within thirty

(30) days for storage tanks with uncontrolled actual VOC emissions greater than 50 tons per year.

*XVII.C.2.b.(ii)(c) A storage tank not otherwise subject to Sections XVII.C.2.b.(ii)(a) or XVII.C.2.b.(ii)(b) that increases uncontrolled actual emissions to six (6) tons per year VOC or more on a rolling twelve month basis after May 1, 2014, must comply with the requirements of Sections XVII.C.2.a. and XVII.C.2.b. and implement the required approved instrument monitoring method inspections **within sixty (60) days of discovery of the emissions increase***

E. Catastrophic Leaks

We commend CARB for considering this important issue, particularly in light of the disastrous natural gas leak at the Aliso Canyon underground storage facility and the regulatory gap it exposed. Given the current regulatory framework applicable to California's fourteen underground gas storage facilities and the age and condition of the state's oil and gas infrastructure, the potential for large and catastrophic leaks is a critical safety and environmental problem. We also note, however, that this is a complicated new undertaking with many complex topics that must be carefully considered. While we urge CARB to move forward with developing a mitigation framework to address any future major leaks as expeditiously as possible, we request that ARB not delay the current rulemaking schedule in order to do so.

In developing mitigation requirements, we request that CARB consider the following:

- Regulatory Authority. CARB should reserve for itself broad authority to ensure emissions from large and catastrophic leaks are fully mitigated. Criteria for determining which leaks are subject to mitigation requirements should not be narrowly limited to predetermined emissions thresholds. Site-specific conditions should be taken into account when determining whether any particular leak qualifies for regulation under this new program, including but not limited to volume, proximity to sensitive receptors, potential health and environmental threats, leak duration, and others.
- Accounting Framework for Quantifying Leaks. CARB must develop a scientifically rigorous framework for quantifying leak volume. The exact accounting method may vary depending on the nature of the leak and site-specific conditions and CARB should therefore ensure that the framework provides sufficient flexibility to respond to different leak sources and types, while also relying on proven and scientifically defensible measurement and estimation methods.
- Preventative Measures. CARB should prioritize measures that could help prevent large or catastrophic leaks from occurring in the first place, for example requiring facilities to develop an assessment of the threat of such leaks and steps that could be taken to minimize those threats. To the extent that agencies other than ARB have jurisdiction over the sorts of preventative measures that could prevent large or catastrophic leaks from occurring, CARB should coordinate with those agencies to help ensure they have everything they need to put such measures in place.

- Mitigation Requirements. Detailed and specific criteria need to be developed that can serve as the foundation for required mitigation of large and/or catastrophic leaks. At a minimum, the following should be addressed:
 - Stringency. CARB should require that leaks be repaired as expeditiously as possible and that the entire volume of leaked methane be remediated.
 - Accuracy. As discussed above, a site-specific and scientifically rigorous method must be developed to determine the total leak volume.
 - Credibility. CARB itself, in addition to local air districts, should approve and independently verify reductions using scientifically proven methods.
- Penalties and Compensation. CARB should consider options such as fines based, for example, on the volume and duration of the leak, and compensation for people negatively affected by the leak. It should also ensure that costs associated with the leak will not be passed on to ratepayers.
- Emergency Authorization. ARB should also consider including provisions analogous to section 303 of the federal Clean Air Act, 42 U.S.C. § 7603, which authorizes EPA to bring suit in federal court to stop or prevent pollution that poses an imminent and substantial endangerment to the public health and welfare, or to issue enforceable orders where necessary. An analogous provision in CARB's regulations could grant APCDs/AQMDs or any other appropriate agency authority to bring suits against, or issue binding orders to, any source that is responsible for a large or catastrophic leak limited in time and scope to measures that would remove any imminent and substantial endangerment posed by the leak.
- Notification Procedures. The rules should include specific timeframes in which leaks must be reported to CARB, local air districts, other regulatory agencies with jurisdiction over the leaking facility, potentially impacted members of the public, and other relevant stakeholders.
- Emergency Planning. CARB should require facilities to prepare and submit emergency response plans for large and catastrophic leaks. These plans should be reviewed and approved in conjunction with other regulatory agencies with jurisdiction over the facilities, (e.g. DOGGR, CPUC, etc.). Such plans should be periodically reviewed and updated at a fixed frequency and/or when necessitated by material changes in operations at the subject facility.

We greatly appreciate the opportunity to comment on this important proposal and look forward to working with CARB as it develops the next iteration of this regulation.

Re: Pacific Gas and Electric Company's Comments on the Proposed Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities

Dear Ms. Scheehle,

Pacific Gas and Electric Company (PG&E) appreciates the opportunity to provide comments on the Air Resources Board's (ARB) Proposed Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities¹ (Proposed Regulation), which was released on May 31, 2016.

I. GENERAL COMMENTS

PG&E is committed to delivering safe, reliable and affordable natural gas to our 15 million natural gas customers. Spanning 70,000 square miles, the company's system serves one in 20 Americans, provides 970 billion cubic feet per year of volume, and consists of thousands of miles of pipelines in addition to compressor stations, boosting stations, storage facilities, and other supporting infrastructure.

PG&E is also committed to helping California achieve its ambitious climate goals. Many of the improvements that PG&E has made in recent years to increase the safety and reliability of the natural gas system, including implementing one of the nation's most aggressive pipeline modernization programs and adopting the latest innovative leak-detection technologies, also serve to reduce methane emissions. Additionally, PG&E has upgraded its measurement, monitoring, and data management systems to improve the accuracy of greenhouse gas (GHG) data reported to the United States Environmental Protection Agency (EPA) and ARB in support of the Mandatory Reporting Regulation (MRR).

PG&E respectfully submits the following comments on the Proposed Regulation. An overview of PG&E's comments includes:

¹ Air Resources Board, May 2016. Proposed Regulation Order: Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities.

- More time is required for stakeholder analysis and input regarding the new storage requirements.
- Accurate leak measurement is critical to reducing emissions.
- Critical component exemptions can be appropriately considered at the facility level.
- Performance criteria limiting the number of leaks based on component population counts should be eliminated.

B-10-1

II. STORAGE REQUIREMENTS MERIT ADDITIONAL PUBLIC DISCUSSION

The May 31 Proposed Regulation includes substantial new provisions related to natural gas storage.² Unlike the other requirements, the proposed language in 17CCR§95668(h), *Well Casing Vents* and 17CCR§95668(i), *Natural Gas Underground Storage Facility Monitoring Requirements* have not been addressed in public workshops. In light of the fact that the other requirements of this regulation were developed with substantial stakeholder engagement over the course of multiple years, PG&E respectfully requests that the underground storage requirements be excluded from the regulation until more thorough stakeholder review and public discussion can be conducted. Additional public process regarding the storage requirements is also important in light of the Division of Oil, Gas and Geothermal Resources (DOGGR) discussion draft storage regulation and the associated risk for duplicative regulatory requirements.

B-10-2

At this time, PG&E notes that the 200 foot radius well-head monitoring requirement conflicts with the 100 foot radius well-head monitoring requirement contained in the DOGGR discussion draft. PG&E recommends this inconsistency be corrected. Additionally, a well-head radius of 200 feet would include within it components from other types of equipment at certain PG&E facilities. PG&E recommends that the radius be reduced to 100 feet to avoid inadvertently making non-storage components subject to the storage regulations.

III. ACCURATE LEAK MEASUREMENT IS CRITICAL TO REDUCING EMISSIONS

PG&E supports reduction of leak emissions but recommends that further consideration be given to the measurement basis in the Proposed Regulation's Leak Detection and Repair (LDAR) requirements. The LDAR requirements are a key emission reduction provision of the Proposed Regulation, as noted in the Staff Report: Initial Statement of Reasons.³ Leak repair timelines are driven by measurement of leak concentration using EPA Reference Method 21 testing, with higher concentration leaks requiring speedier repair. In this way, "large" leaks would ostensibly be repaired quickly so as to limit emissions.

B-10-3

However, it is well understood that Method 21, as a concentration-based measurement, does not correlate well to volume-based leak rates. This can result in inaccurate characterization

B-10-4

² Air Resources Board. May 2016. Proposed Regulation Order: Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities. 95668(i).

³ California Air Resources Board. May 31, 2016. Staff Report: Initial Statement of Reasons. P 84.

of actual emissions from leaks. Even after strictly following Method 21 procedures, external factors like wind speed, probe orientation, and screening speed introduce measurement uncertainties that can cause any single leak rate estimate to vary by a factor of 1000. ARB's own documentation regarding Method 21 recognizes the issue: "This procedure is intended to locate and classify leaks only, and is not to be used as a direct measure of mass emission rate from individual sources."⁴ The lack of correlation between concentration-based measurements and actual leak emissions can lead to the misclassification of minor leaks as severe.

B-10-4
Cont.

Accurate leak measurement is critical for cost-effective emissions reduction. For one, understanding the true severity of leaks allows for proper repair prioritization. Additionally, making repairs on the timelines mandated by the Proposed Regulations will often require equipment blowdowns, which may result in emissions many times greater than the leak that is being repaired. Accurate leak measurement allows for informed analysis of the tradeoffs between repair and blowdown over a given timeframe.

PG&E recognizes that Method 21 offers practical advantages for local air districts that have historically used concentration-based measurement. These advantages include familiarity of use, and avoided cost of purchasing new equipment and training personnel. However, since the purpose of this regulation is to reduce methane emissions, the language should allow operators to use volume-based measurements, such as high-flow sampler devices to confirm any high concentrations measured prior to initiating leak repairs. These records would be retained and made available for inspection.

Finally, with regard to the LDAR provisions that are driven by concentration-based leak measurement, PG&E reiterates that variance provisions to repair time frames be developed to protect against increased emissions. Due to the scope of this regulation and the variety of equipment and station designs that it covers, it is impossible to give consideration to every repair scenario. This regulation may inadvertently force the repair of a leak that will create a net increase in emissions when the repair blowdown volume is considered. Variance provisions which enforce reasonable repair timelines while allowing operators to bundle repairs will help the regulation achieve its emission reduction goals.

B-10-5

IV. FACILITY LEVEL CRITICAL COMPONENT EXEMPTIONS

PG&E facilities subject to the Proposed Regulation play key roles in the operation of the natural gas system and the provision of safe, affordable, and reliable energy to customers. PG&E supports the critical component exemption included in the Proposed Regulation, which recognizes that LDAR requirements for certain components may need to be delayed in cases where shutting down the component would result in greater emissions, or would impact the safety or reliability of the natural gas system.⁵

B-10-6

PG&E recommends that the regulation specifically allow system or facility level exemptions. A single PG&E compressor may have hundreds of individual components, the

⁴ California Air Resources Board. July 1, 1999. *Method 21 Determination of Volatile Organic Compound Leaks.*

⁵ Air Resources Board. May 2016. *Proposed Regulation Order: Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities.* 95670(b).

majority of which would require taking the compressor out of service to repair. Preparing a critical component exemption for each compressor component would be onerous and require developing a specific naming convention and catalog for each component in a way that could be understood by both the operator and regulators. Since the compressor as a whole unit is critical to safely operating the facility, a system-level exemption would be appropriate for this location.

B-10-6
Cont.

PG&E agrees that the critical component exemption should not be used to avoid routine maintenance and standard repairs that can be conducted without taking a critical component/facility out of service. Requiring tightening, lubrication or adjustment (TLA) repairs on a timeframe consistent with the Proposed Regulation's LDAR requirements (subject to variance provisions) could be a stipulation of critical component status in facility-level cases.

B-10-7

V. PERFORMANCE CRITERIA LIMITING THE ALLOWABILITY OF LEAKS BASED ON COMPONENT POPULATION COUNTS SHOULD BE ELIMINATED

The Proposed Regulation includes criteria specifying the number of allowable leaks based on the number of components at a given facility.⁶ PG&E's natural gas underground storage and transmission compressor facilities operate under varying pressures that can range from <1 psig to 2160 psig. While manufactured components have an estimated service life, system operations, environmental factors, and other variables make it very difficult for operators to predict when a component will fail and leak. PG&E currently implements a condition-based maintenance program to ensure the safety and reliability of equipment and components within a facility. In order to comply with the proposed regulation, PG&E will need to develop and implement a prescriptive, aggressive, and costly component replacement schedule. This would likely yield little emission reduction benefit, as a majority of the components would be replaced prior to their service life.

B-10-8

Additionally, this prescriptive requirement is counter to the objective of the LDAR program which is designed to detect and repair leaks on an on-going basis. Adding punitive performance criteria for the discovery of leaks detected through compliance with the LDAR program is at odds with the broader mission of leak detection, repair, and emissions avoidance.

B-10-9

PG&E also notes that starting in 2020, any leak detected with a concentration measurement of 50,000 ppmv or greater constitutes a violation of the regulation. PG&E interprets this requirement as intending to limit "super-emitting" leak sources; however, as noted in Section III, a high concentration measurement does not necessarily correlate to a high-emission leak. Unless volume-based measurement is instituted and agreement is reached on what constitutes a zero-allowability, super-emitting leak by volume, PG&E recommends this stipulation be removed.

B-10-10

⁶ *Ibid.* 95669(o)

Finally, the Proposed Regulation contains provisions which require the replacement of components which require five repair actions within a 12 month period.⁷ In addition to the quarterly LDAR requirements, this stipulation provides a backstop against operators that may choose to perform minimal repairs. Given the multiple repair requirements prescribed in the Proposed Regulation, PG&E again recommends removing the leak allowability criteria.

B-10-11

VI. CONCLUSION

Thank you for the opportunity to submit these comments on the ARB Proposed Regulation.

Sincerely,

/s/

To: California Air Resources Board
 From: Seth Shonkoff, Executive Director, PSE Healthy Energy
 Date: July 16, 2016
 Re: California Code of Regulations, Title 17, Division 3, Chapter 1, Subchapter 10
 Climate Change, Article 4, Subarticle 13: Greenhouse Gas Emission Standards for
 Crude Oil and Natural Gas Facilities

Thank you for accepting these comments on California Air Resource Board's (CARB) proposed Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities. In light of the recent Aliso Canyon gas leak disaster, the recommendations of the California Council on Science & Technology's (CCST) Independent Scientific Study of Well Stimulation (Long et al. 2015), and the national commitment made by the Obama Administration to reduce methane leakage from the oil and gas sector by 40-45% below 2012 levels by 2025, these regulations are an important step forward to reducing the powerful greenhouse gas pollutant, methane, and working to stabilize the climate.

We submit these comments on behalf of PSE Healthy Energy, a national energy science and policy institute that supports the adoption of responsible evidence-based energy policies that aim to protect the climate, public health, and the environment. Our organization is composed of physicians, scientists, and engineers who work to fill data gaps and promote scientific understanding of modern energy resources and production.

PSE Healthy Energy strongly supports CARB's proposed standards for crude oil and natural gas facilities. We especially appreciate CARB's leadership in proposing standards simultaneously for both new and existing sources. In conjunction with local, state, and federal regulatory requirements, these standards will prevent the waste of hydrocarbon resources and reduce the environmental, social, and economic costs of methane and other co-emitted air pollutant emissions. We encourage swift implementation of these standards to mitigate climate change and protect the health of Californians.

B-11-1

In addition to our support for these new regulations, we submit the following comments as additions and revisions that we would like to see in the final regulations.

California
 1440 Broadway, Ste 205
 Oakland, CA 94612
 Tel: (510) 359-5706

New York

 Tel: (607) 252-6754

General Comments

Overall, we support the adoption of these regulations with minimal additions or deletions. These go a long way toward reducing the leakage of methane pollution into the atmosphere.

CARB should make some improvements to this proposal to ease public participation in the regulatory process, especially with respect to the LDAR program as described below.

First of all, CARB should not take a “step-down” approach to enforcement. CARB should maintain a consistent standard for inspection frequency. Under this proposal, failing to discover leaks can lead to eased requirements and less frequent inspections. This approach is flawed for two reasons. First, the absence of a leak reveals nothing about the probability of a future leak. Second, if failing to detect leaks can result in reduced requirements for inspections, companies are incentivized to encourage less rigorous inspections. Operators may find it in their best interest to not find leaks rather than repair them. This approach also sets a poor regulatory precedent as methane leakage is regulated in other states and at the federal level, and for regulations of other pollutants.

B-11-2

In addition to the draft regulations, we also urge CARB to engage in community-scale air quality monitoring to ensure that community exposures to air toxics attributable to oil and gas development are not elevated beyond thresholds for health.

B-11-3

We also recommend that CARB consider the implementation of minimum surface setbacks as recommended in the California Council on Science & Technology (CCST) Independent Scientific Study of Well Stimulation (Long et al. 2015).

B-11-4

95668(i) Natural Gas Underground Storage Facility Monitoring Requirements

PSE Healthy Energy applauds CARB's attention to underground storage with special monitoring requirements. We are currently in the process of conducting an extensive nationwide review of best practices for underground natural gas storage, and are pleased to see strong requirements in these draft regulations.

We note and are supportive of CARB's taking over LDAR implementation from the Department of Conservation Division of Oil, Gas, and Geothermal Resources (DOGGR). The proposal to have the ability to remotely access readings from the continuous monitoring of ambient air from underground natural gas storage facilities by

2018 will be important in reducing future leakage, and this data will greatly benefit the public.

We are aware that some groups have suggested that CARB augment this remote access monitoring system with a simple function allowing the public to upload monitoring data of its own, submitting citizen complaints with OGI video compliant with 95668(i)(B) that can trigger the 95669 inspection and repairs. As discussed below, a cooperative LDAR approach involving industry, government, and the public will most efficiently reduce emissions, save money, and ease compliance. We would like to see language included that would ensure that the upload of such data would trigger inspection by either a state agency or a certified third-party operator within a short timeframe, such as one week, in order to catch existing leaks not detected by infrequent inspections.

B-11-5

In addition, we support the proposal (95668 (i)(c)(6)) to require operators to maintain and make available records of their monitoring system to CARB upon request. We urge CARB to similarly require operators to also make those records available to the public.

B-11-6

95669. Leak Detection and Repair.

The Optical Gas Imaging (OGI) from the leak at the Aliso Canyon facility helped bring to the national spotlight the dangers associated with methane emissions. The infrared plumes also highlighted the contributions citizen science can bring to the enforcement of this rule. Ultimately, regulations mean nothing without proper enforcement mechanisms like an effective LDAR program.

To ease both compliance and implementation, CARB should create a single publicly accessible and searchable web based portal. This platform will first assist the regulated community by allowing electronic submission of recordkeeping and inspection reports. It will also benefit the public by allowing for online streaming of the continuous monitoring data CARB will receive under 95668(i)(1)(A).

B-11-7

Nothing in this above approach should be construed to replace or supersede the inspection, recordkeeping, and reporting requirements detailed under this proposed regulation.

95669(b)(1) PSE Healthy Energy encourages CARB to collaborate with local air districts on implementing an LDAR program that standardizes inspections, monitoring, recordkeeping, and reporting. Accordingly, local air districts should maintain the flexibility to impose additional LDAR requirements. In no circumstance should some districts have weaker LDAR requirements than CARB.

B-11-8

95669(b)(4) PSE Healthy Energy opposes CARB's proposal to exempt natural gas distribution pipelines not owned by the operator of the crude oil production facility. Pipelines can be a significant source of methane emissions and, regardless of ownership, operators should have LDAR obligations for all components of the system within their sphere of influence.

B-11-9

95669(g)(1) PSE Healthy Energy supports regular inspections of all 95668 components. However, we are concerned about CARB's proposal to reduce the frequency of inspections simply because the operator finds no leaks or only low-level leaks. This approach provides a disincentive to find and repair leaks, by rewarding operators for not detecting them. Furthermore, past leak performance is not indicative of future performance. If anything, older components should receive greater scrutiny.

B-11-10

95672 Reporting Requirements.

95672(a)(8-12) We support CARB's proposals to require operators to report leaks within specified timeframes and to report the results of inspections conducted pursuant to section 95669. Similarly, we urge CARB to require operators to make these reports available to the public upon request; and create a publicly accessible and searchable web based platform where operators must submit these records.

B-11-11

Conclusion

We are pleased to see these draft rules addressing both existing and new infrastructure moving forward in California, and we encourage swift adoption of the final rules. CARB will achieve important public health, economic, safety and climate benefits with the implementation of this rule. But as with all rules, enforcement is key. We look forward to the revision and adoption of this rule, followed by strong and swift implementation of these monitoring programs.

Air Resources Board

PUBLIC MEETING AGENDA July 21, 2016

Agenda Item # - 16-7-2: to tracy.jensen@arb.ca.gov

Testimony detailed content by Elias Tobias, P.Eng. Safety Scan USA (safetyscan.org) on behalf of EDF (environmental defence fund)

- Safety Scan specializes in Gas Leak Detection using state of the art infrared optical gas imaging (OGI). Quantification using hi-flow sampler technology. Emissions management program support for LDAR programs and GHG emissions reporting deployed on an encrypted cloud based system
- There was a study made by Colorado State University and Carnegie Mellon University found out recently that Natural Gas facilities in the US alone lose about 100 billion cubic feet of gas every year. That is 8x the estimates that the EPA uses. Big leakers
 - Compressor Stations (transmission and storage). (Fugitive) 22%
 - Underground pipelines. (Fugitive) 16%
 - Vented accounts for 30%
 - Total just here 68%
 - Facilities inspected = 4,549
- Although OGI costs more per hour because we can inspect a facility usually 20x to 100x faster than the traditional method 21 most of the time. At the end of the day our services will cost less. This sometimes is a paradigm that needs some work. As an

example for a private underground natural gas storage facility in northern California (we visited most after the emergency proclamation was signed by governor Brown) our inspection will take between 1/2 h to 4 h on a starting rate of \$265. At the end of the day our inspection will probably cost less than the regular old method 21

- OGI can be extremely helpful in detecting gas leaks at an early stage. Methane for example has a detection limit at 3 gr / h or 0.1oz / h. Imagine a regular cigarette lighter gas flow, this technology will detect that level of leak at a proper distance
- OGI makes the leak visible to the human eye producing an undeniable proof from a safe distance with encrypted GPS and date stamp
- We can deploy our OGI camera from the ground, helicopter, airplane or a military / industrial grade drone if necessary
- Porter Ranch leak videos from almost 3 miles showed the seriousness of that event and we have produced over 20 optical gas imaging videos with very "dramatic" imaging for our own scientific study purposes
- And because gas leaks are unpredictable we support the removal of the ARB step down rule
- There is also a recent very modern technology that uses spectral imaging based on the combination of an infrared spectrometer with a single element detector and a scanner system that can qualify and quantify over 400 types of compounds (methane included).
- Qualify = it can tell what gases are leaking, and the system will identify all of them

- Quantification = with the proper ground installation the gas leak plums information can provide that quantity of gases leaked into the atmosphere. The technology available can be deployed from 2 km or 1.25 miles away from the leak
- Quantification from an airborne helicopter is know to be in development at the present moment
- Many of the technologies presented here can be automated on a 24/7 option connected to a control room and/or scada for automatic alarms as soon as the leaks reach the detection limits that can sometimes be adjusted

For and example if we were to deploy this new technology while the Aliso Canyon leak was happening we could have identified all the compounds that were being emitted into the atmosphere and also had a very strong chance to scientifically quantify the concentration of all gases being leaked into the atmosphere on a 24/7 real time monitoring with spectral images videos as a proof
