 Sacramento, California 95814

Subj: Proposed Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities

Dear California Air Resources Board (CARB):

These comments address California Environmental Protection Agency's efforts to minimize greenhouse gas emissions and volatile organic compounds (VOCs) for oil & natural gas facilities in a technically feasible and cost-effective manner.

CARB states:

The proposed regulation will reduce...emissions by over fifty percent. The proposal is also expected to reduce both volatile organic compounds (VOC) and toxic air contaminant (TAC) emissions and provide an essentially neutral nitrous oxide (NO_x) impact statewide.

B-1-1

If operators capture leak data at specified intervals—not continuously—the regulation suggests this will be sufficient for establishing compressors' emissions' footprints.

M-Squared Products & Services, Inc. manufactures the packing leak detector (PLD[®]), a technology offering inexpensive and accurate emissions' measurements with universal applicability. PLDs are an effective solution for large, reciprocating compressors' methane emission standards in addition to leak detection and repair (LDAR) for other large compressor components and smaller compressors.

Significantly, PLDs operate effectively with and can be retrofitted to any reciprocating compressor capacity.

In reciprocating compressors, emissions result from several possible functional failures. Until the PLD, emissions detection was less a precise science and largely anecdotal.

The evolution of Optical Gas Imaging (OGI) increases operator awareness of leakage, but doesn't provide volume or causal information. Additionally, OGI observations are static. PLDs operate continuously and isolate failure causal factors.

M-Squared Products & Services, Inc.

Features and benefits of a properly installed PLD

- First, real-time baseline indicator of packing gland and packing health. Determines whether packing material is appropriate, leaking, failing, installed correctly, the piston rod is too smooth or assembly is over-lubricated
- Visually indicates packing gland leaks
- Measures leak rates
- Calibrated for varying rates and different gases
- PLD outlets can be redirected for low-pressure gas applications until packing is serviced or replaced

Additionally, transducer-equipped PLDs

- Provide local and remote monitoring
- Coupled to V570 Programmable Logic Control (PLC) panels enable alarm and shutdown capabilities

PLDs are cost-effective tools which can help the California Environmental Protection Agency achieve emissions baselines for used or new compressors.

Of CARB's stated *objectives and benefits of the proposed regulatory action*, PLDs would find appropriate applications for provisions 2, 3, 4 and 7.

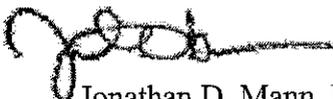

┌ B-1-2

PLDs are the first, unique tools that provide real-time baselines helping operators assess the health & effectiveness of compressor packing. As operators install PLDs broadly, they will enjoy the following direct & indirect benefits:

- Cost effective alternative to determining packing life cycle
- Linear vs. random maintenance
- Capturing profit instead of lost production (when integrated with vapor recovery technologies)
- Flexibility (local & remote data monitoring & alarms)
- Compliance (the ultimate goal of emission regulations)

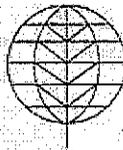

We appreciate the opportunity to contribute to this regulatory forum and would be delighted to provide Packing Leak Detector product and technical information.

Sincerely,

Jonathan D. Mann, President
M-Square Products & Services, Inc.

Bruce Baizel

**California Code of Regulations, Title 17, Division 3, Chapter 1, Subchapter 10
Climate Change, Article 4
Subarticle 13: Greenhouse Gas Emission Standards for Crude Oil and
Natural Gas Facilities**

July 21, 2016

Thank you for the opportunity to comment on the California Air Resources Board (CARB) Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities. Please accept these comments on behalf of Earthworks, a national nonprofit organization dedicated to protecting communities and the environment from the impacts of mineral and energy development while seeking sustainable solutions.

General Comments

Overall, these proposals represent an important step forward in controlling methane emissions from oil and gas facilities. We especially appreciate CARB's leadership in proposing standards simultaneously for both new and existing sources. Other essential components include robust programs for Leak Detection and Repair (LDAR) as well as inspections and replacements.

B-2-1

CARB should make some improvements to this proposal to ease public participation in the regulatory process, especially with respect to the LDAR program as described below.

In addition, CARB should maintain a consistent standard for inspection frequency. Under this proposal, failing to discover leaks can form the basis for less frequent inspections. This approach is flawed for two reasons. First, the absence of a leak reveals nothing about the probability of a future leak. Second, reducing inspections for failure to discover emissions may inadvertently encourage shoddy inspection work. Operators may find it easier not to find leaks rather than repair them. This approach also sets a poor regulatory precedent.

B-2-2

In general, Earthworks supports the implementation of LDAR requirements (95669) to the listed 95668 facilities.

Specific Comments

95668(i) Natural Gas Underground Storage Facility Monitoring Requirements

Earthworks applauds CARB's proposal for special monitoring requirements for underground storage.

B-2-3

To begin, we support CARB's decision to assume LDAR implementation from the

Department of Conservation Division of Oil, Gas, and Geothermal Resources (DOGGR). By 2018, CARB wants the ability to remotely access readings from the continuous monitoring of ambient air from underground natural gas storage facilities. This data will greatly benefit the public.

B-2-3
Cont.

We also suggest CARB augment this remote access monitoring system with a simple function allowing the public to upload monitoring data of our own.¹ As discussed below, a cooperative LDAR approach involving industry, government, and the public will most efficiently reduce emissions, save money, and ease compliance.

B-2-4

In addition, we support CARB's proposal (95668 (i)(c)(6)) to require operators to maintain and make available records of their monitoring system to CARB upon request. We urge CARB to similarly require operators to make those records also available to the public.

B-2-5

95669. Leak Detection and Repair.

The Optical Gas Imaging (OGI) from the leak at the Aliso Canyon facility helped bring to the national spotlight the dangers associated with methane emissions. The infrared plumes also highlighted the contributions citizen science can bring to the enforcement of this rule. Ultimately, regulations mean nothing without proper enforcement mechanisms like an effective LDAR program.

In particular, CARB should encourage voluntary third party verification of the LDAR testing required under this section. This approach will both ease the compliance burden on operators and the oversight burden on CARB. Faster leak identification saves operators money, conserves the resource, and results in fewer fines and penalties. Regulators and the public, in turn, achieve better public health, safety, compliance and climate benefits.

B-2-6

As part of the LDAR program, third party verification will comply with the same requirements placed upon operators pursuant to 95669(g)(2) and (g)(2)(a). These certified OGI Thermographers will also conform to the applicable recordkeeping and reporting provisions of 95671 and 95672.

To ease both compliance and implementation, CARB should create a single publicly accessible and searchable web based portal. This platform will first assist the regulated community by allowing electronic submission of recordkeeping and inspection reports. It will also benefit the public from online streaming of the continuous monitoring data CARB will receive under 95668(i)(1)(A). Finally, this system ought to accommodate citizen complaints- especially a function allowing persons to upload OGI footage directly to CARB for 95669 purposes.

B-2-7

Nothing in this above approach should be construed to replace or supersede the inspection, recordkeeping, and reporting requirements detailed under this proposed regulation.

95669(b)(1) Earthworks encourages CARB to collaborate with local air districts on implementing an LDAR program that standardizes inspections, monitoring, recordkeeping, and reporting. Accordingly, local air districts should maintain the flexibility to impose additional LDAR requirements. In no circumstance should some districts have weaker LDAR requirements than CARB.

B-2-8

95669(b)(4) Earthworks looks forward to the upcoming rulemaking CARB is developing in conjunction with the Public Utility Commission to regulate methane emissions from oil and gas pipelines. Pipelines can be a significant source of methane emissions and operators should have similar LDAR obligations for all components of pipeline systems.

B-2-9

95669(g)(1) Earthworks supports regular inspections of all 95668 components. However, we oppose CARB's proposal to reduce the frequency of inspections simply because the operator finds no leaks or only low-level leaks. This approach provides a disincentive to find and repair leaks, by rewarding operators for not detecting them. Furthermore, past leak performance is not indicative of future performance. If anything, older components should receive greater scrutiny.

B-2-10

95669(g)(2) Earthworks supports CARB's proposal to encourage operators to employ OGI instruments. In particular, we appreciate that CARB provides that only a certified Thermographer may operate the equipment and proscribes specific timeframes for verification of the camera readings.

B-2-11

95671 Record Keeping Requirements.

95671(a)(9 and 10) Earthworks supports CARB's proposal to require operators to maintain records of LDAR inspections for at least 5 years. We also urge CARB to require operators to make these records available to the public upon request; CARB should create a publicly accessible and searchable web based platform where operators must submit these records.

B-2-12

95672 Reporting Requirements.

95672(a)(8-12) Earthworks supports CARB's proposals to require operators to report leaks within specified timeframes and to report the results of inspections conducted pursuant to section 95669. Similarly, Earthworks urges CARB to require operators to make these reports available to the public upon request; and create a publicly accessible and searchable web based platform where operators must submit these records.

B-2-13

Conclusion

CARB achieves important public health, safety and climate benefits from this rule. As with all rules, enforcement is key. CARB should not take a "step-down" approach to enforcement, but instead encourage voluntary third party LDAR verification.

B-2-14

Sunlight also aids enforcement. CARB already proposes remote access monitoring, recordkeeping, reporting, and a robust LDAR program. Allowing a role for citizen science in this rule's implementation will achieve benefits for all stakeholders.

B-2-15

¹ We envision here an opportunity to allow the public to submit citizen complaints with OGI video compliant with 95668(i)(B) that can trigger the 95669 inspection and repairs.

Agenda Item 16-7-2: Comments on Proposed Regulation of Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities

Dear Ms. Scheehle:

Thank you for the opportunity to provide comments on the Proposed Regulation of Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities. Staff from the Butte County Air Quality Management District have been involved with the CAPCOA/ARB working group over the past several months collaborating with ARB staff as the regulation has been developed. We appreciate ARB establishing the working group and seeking input from the air districts early in the process of developing this important measure. Having said that, we have the following comments which should be considered. These are areas which our staff brought forward in the working group meetings.

Idle wells: The regulation is unclear on the requirements for wells not currently in service. Districts have heard terminology describing wells as "idle", "abandoned", "plugged", "dry", "inactive", etc. but the Proposed Regulation and ISOR do not include definitions for these terms and is unclear to what extent wells not currently in service for any reason are to be regulated. The regulation and ISOR limits discussions of "idle" to intermittent bleed pneumatic devices and does not clarify if the control, monitoring and reporting requirement apply to "idle" wells; however, we believe that there are as many or more wells not currently in service than in service that may be subject to this regulation and require district or ARB oversight but are not included in the cost estimates prepared for this ISOR. Regulating wells currently not in service will be a significant challenge for districts, ARB and the regulated community.

B-3-1

Record keeping: Section 95668(i) relating to Natural Gas Underground Storage Facility Monitoring Requirements was a recent inclusion to the proposed regulation. In this section requirement monitoring for these facilities, Section 95668(i)(1)(C) 6 requires facilities with continuous monitoring to keep records but Section 95668(i)(1)(B) does not require facilities opting for daily screening to keep records of this monitoring. We recommend record keeping be required regardless of the type of monitoring system chosen. If the requirements in 95668(i)(1)(C) 6 are supposed to also apply to 95668(i)(1)(B), this is not clear in the regulation or ISOR.

B-3-2

In general, organization of bifurcated compliance methods, requirements, and standards in the proposed rule are problematic. For example, in Section 95668(g), owners and operators with liquid unloading "shall do one of the following:" and below are listed three compliance options and one record keeping requirement. All four elements of the rule are on the same outline level indicating only one of the four is required; however, we believe it the intent of the ARB as clarified in the ISOR which indicates owners or operators must choose a compliance and then records kept of the option. Similar organizational issues exist within many subsections of the proposed regulation and the ISOR does help clarify the intent on some of these sections. We recommend organizing the regulation so that interpretation of the requirements is not an unnecessary issue.

B-3-2
Cont.

Enforcement and permitting: While ARB states in the ISOR that districts may elect to implement and enforce the regulation, Section 95673(b)(1) requires regulated entities to apply to the local district to have conditions added to district permits ensuring compliance with this (sub)article upon the district issuing a new or renewed permit. Based on this language, district participation is not optional. If district participation is optional, it is not evident how permits will be issued if a district does not implement the regulation. Permitting authorities and the implementation needs to be clarified.

B-3-3

Thank you again for the opportunity to comment. We look forward to working with ARB staff on the final regulation. If there are any questions regarding these comments, please contact David Lusk of my staff or me.

Sincerely,

W. James Wagoner
Air Pollution Control Officer

**Comments of the California Independent Petroleum Association
on the Proposed Greenhouse Gas Emission Standards for
Crude Oil and Natural Gas Facilities (May 31, 2016 version)**

Clerk of the Board
California Air Resources Board
1001 I Street
Sacramento, CA 95814

July 21, 2016

Via electronic submittal to: http://www.arb.ca.gov/lispub/comm/bcsubform.php?listname=oilandgas2016&comm_period=A

The California Independent Petroleum Association (CIPA) appreciates this opportunity to officially comment on the proposed new regulation to control methane from oil and gas operations here in California. The Proposed Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities is an entirely new regulation under California's continued push to reduce greenhouse gases (GHGs) and Short-Lived Climate Pollutants (SLCP). This regulation is designed to specifically address a single pollutant (methane) within a single industrial category (Oil and Gas Production) and within a single state, therefore this opportunity to fully address remaining technical issues and evaluate its impacts on that single industry is critical.

The mission of CIPA is to promote greater understanding and awareness of the unique nature of California's independent oil and natural gas producer and the market place in which he or she operates; highlight the economic contributions made by California independents to local, state and national economies; foster the efficient utilization of California's petroleum resources; promote a balanced approach to resource development and environmental protection and improve business conditions for members of our industry.

Over the past year CIPA has actively been working with Air Resources Board (ARB or Board) staff on informal versions of this regulation. Through multiple conversations and comment submittals, CIPA has conveyed concerns about the scope, standards and implementation of this regulation. We would like to recognize the effort ARB staff has made to improve the regulation and work with industry stakeholders. *This version is much improved, but it cannot yet be considered complete.* There are remaining technical, clarity and implementation issues that must be addressed in a subsequent 15-day amendment package. CIPA has not provided an exhaustive list of detailed changes, but rather highlighted the remaining issues that staff and stakeholders need to continue working together to resolve. Those categories of potential changes are the focus of this comment letter.

B-4-1

CIPA's remaining areas of concern are summarized below followed up with additional details:

- Implementation and enforcement
- Consistency with MRR
- Standards and exemptions
- Vapor recovery requirements, including the late addition of "Gauge" tanks

B-4-1
Cont.

Implementation and Enforcement

CIPA understands ARB's desire to have this regulation implemented and enforced at the local level, and believes that doing so may be the most efficient use of resources. But not all local Air Districts (districts) have the resources or desire to take on this responsibility. To date, CIPA has not seen any district MOUs to fully understand what these would look like, who would be the primary enforcement body, and how ARB would handle oversight of the districts. As it is anticipated that more than one local air district will enter into an MOU with ARB, these agreements should be finalized and made public prior to the effective date of the regulation. Knowing who your regulatory lead is, is just as important as the standards themselves.

B-4-2

Historically, air quality regulations have been segregated into either "CARB enforced" or "local enforced". This clear delineation has been well established. A regulated party should only have to answer to one regulatory body for a single regulatory regime. This regulation subjects CIPA members to potential violation at both the State and local level for the same potential offense. This is a significant concern.

B-4-3

Additionally, there are a variety of dates, and response times contained within the regulation that are shorter than those of the existing local district rules. This inconsistency is problematic and should be reconciled to be consistent with the longer timeframes already in use today.

B-4-4

CIPA strongly recommends that prior to final regulatory adoption, these pending implementation and enforcement issues are resolved in the public domain, including the elimination of possible double jeopardy and adoption of any local district MOUs.

B-4-5

MRR Consistency

In reviewing the proposed Regulation, CIPA members have noted several inconsistencies between it and the Mandatory Reporting Regulation (MRR). This may cause uncertainty, confusion, and inconsistency in interpreting the regulation, in defining record keeping and reporting practices, and in agency and public use of the data collected under these regulations. Because definitions are critical to the implementation of the rule and are key to enforcement and compliance efforts it is of paramount importance to ensure they are as tightly written as possible. The definitions of "component" and "facility" are only two examples. CIPA believes these issues can and should be addressed in a subsequent 15-day amendment package, and looks forward to working with staff.

B-4-6

CIPA recommends ARB continue to work with stakeholders and then use a 15-day amendment package to revisit and clarify as needed prior to the final adoption of the rule.

B-4-7

Standards and Exemptions

This regulation is entirely new, but it is also layered with a variety of difference sections each with their own set of standards and exemptions. CIPA has noted that several of these provisions, and exemptions, are either not feasible (timelines for certain required action) or do not take into account the reality of California's oil production system (exemptions based

B-4-8

on an inappropriate “one size fits all” oil/water ratio criteria) and should be revisited in a 15-day amendment package prior to final adoption.

B-4-8
Cont.

An example of a specific technical issue is the requirement to change to dry seals. A number of wet seal compressors cannot be converted to dry seals due to the size of the dry seal cartridge. Also, when using dry seals in the oil fields, they require a gas scrubber and treatment equipment to achieve for their supply system as they need clean dry gas, as well as, additional equipment to ensure the high pressure supply to the dry seal at start up and low flow operations to prevent premature seal failure.

B-4-9

It was also brought to CIPA’s attention that a late staff proposal would eliminate the option to “step down” Leak Detection and Repair frequency from quarterly to annual. This is a significant change which comes with a increase in costs to stakeholders. CIPA is concerned that the costs and impacts of such a change have not be analyzed including that such a change creates local and state testing requirements that are not in sync.

B-4-10

CIPA recommends ARB continue to work with stakeholders on these issues and then use a 15-day amendment package to revisit and clarify as needed prior to the final adoption of the rule.

B-4-11

Vapor Recovery Requirements

The regulation envisions additional vapor control and/or flaring of collected methane emissions, including from heavy oil tanks. However, the ability to permit new flares in California’s non-attainment air districts is still a major question. In fact, some districts have stated that they do not want additional flaring to occur under this regulation. Because increased flaring and/or new flares would not be allowed without air district permitting, CIPA is concerned that new flares may not be a reasonable method of compliance.

B-4-12

CIPA also notes that the inclusion of gauge tanks in this version of the regulation comes without prior stakeholder discussion or notice. This addition is a significant concern as it changes the initial point of regulation under the rule, requiring owners or operators to extend the reach of vapor control, which for a variety of reasons may not be practicable. Prior versions of the regulation did not contain such provisions. CIPA is concerned with the implications of such an addition, including costs and lack of transparency or analysis in the process. There are also significant concerns about the effectiveness of such a requirement due to the intermittent nature of their operations.

B-4-13

CIPA recommends that because the stakeholder process was bypassed, including a robust feasibility and cost analysis, that the newly inserted gauge tank provisions be removed. CIPA recommends that prior to final adoption, ARB demonstrate that there are viable compliance options associated with new vapor recovery requirements.

B-4-14

CIPA has consistently advocated for a fair, cost-effective, and implementable regulation. And while this version is much improved, CIPA respectfully submits these summary comments in an effort to constructively assist ARB in taking the next step to a final adoption that addresses these remaining technical and implementation concerns. The version presented to the Board at the July 21, 2016, hearing cannot be the final version of the rule.

B-4-15

We are ready to continue the dialogue that is needed to bring this process to a successful conclusion. This additional dialogue should result in a subsequent 15-day amendment process. Thank you for your attention to this important matter. Any questions or follow-up comments can be directed to rock@cipa.org.

Sincerely,

A handwritten signature in black ink, appearing to read 'Rock Zierman', with a stylized flourish at the end.

**Testimony on CARB's Proposed Rulemaking for
"PROPOSED REGULATION FOR GREENHOUSE GAS EMISSION STANDARDS FOR
CRUDE OIL AND NATURAL GAS FACILITIES"**

Jaclyn Schroeder
Moms Clean Air Force
July 21, 2016
Sacramento, California

Hello my name is Jaclyn Schroeder, and thank you for taking the time to hear my story.

When I was first invited to come today, I almost quickly declined because it is extremely hard to leave three young children at home. But that's exactly the reason I decided to come because I AM A MOTHER FIRST.

Being a mother first is being a voice for my children. Being a mother first is making sure I provide a HEALTHY and happy environment for my children. I am a mother first by speaking up for my children's health.

Thank you for taking this important step in addressing methane pollution from oil and gas operations and I urge you to move forward with your proposal, while considering TWO important changes:

- 1) Remove the "step-down" provision which would allow operators to shift to less rigorous monitoring requirements, this would create a perverse incentive to avoid finding and reporting leaks, and less of a reason to avoid fixing them quickly. B-5-1
- 2) The current proposal pushes the implementation timeline by a year (from Jan 2017 to Jan 2018). Our families cannot afford to wait until 2018. B-5-2

I currently own a home in Porter Ranch, California where I live with my husband and three children (a 5 year old and twin 2 year olds).

My family, community and I understand the direct impacts of methane pollution especially the exposure to co-pollutants that leak alongside methane pollution from oil and gas development.

I am a local native of the San Fernando Valley. I grew up in Porter Ranch and decided to raise my family in Porter Ranch. However, never did I realized that we lived on top of one of the LARGEST gas storage reserves in the United States, THAT WAS NOT MONITORED PROPERLY and what that could mean to the health of my family.

October 23, 2015, in Porter Ranch, the largest methane gas leak in US history was reported. Ironically, a month earlier, my daughter, Emma (22 months), was sent home from Kaiser with an at home nebulizer (breathing treatment). She began showing signs of asthma, and continued to show signs of asthma over the next few months.

October 31st, Halloween. Unbeknownst to us at time, the leak had been reported a week earlier. My children that evening were sniffing, complaining of headaches and fatigue. There was an odd odor in the air, like rotten eggs. My kids barely lasted 30 minutes trick or treating.

November 5, 2015 we took our daughters to Kaiser again because they were having trouble breathing. Just days later my daughter Grace developed bad eczema on her cheeks.

December 10th, my girls were BACK at Kaiser and diagnosed with asthma with acute exacerbation.

These are the real impacts of oil and gas development and the hazards that can come for the co-pollutants leaked alongside methane pollution. Our most vulnerable are the little lungs and developing bodies of our children.

My twins needed breathing treatments at home, and my son began getting sick (often missing school because of persistent coughing and runny nose). It was time to move. Within days of relocating, the symptoms my kids were experiencing began to fade. My kids were healthy.

The leak was "capped" on February 18 and we moved back. However, within days of returning, the symptoms began to reappear. February 25 my girls needed at home breathing treatments. February 26 my daughter Grace broke out with another eczema rash. All three of my kids were "sick" CONTINUALLY within the month of moving home.

As mothers, we must account for the unaccountable and prepare for the unknown. The health impacts of co-pollutants emitted alongside methane pollution from oil and gas development are real. I urge you to strengthen this proposed rule. Our children's health and safety depends on it.

B-5-3

Thank you for your time.

Loni Russell
16-7-2

**Testimony on CARB’s Proposed Rulemaking for
“PROPOSED REGULATION FOR GREENHOUSE GAS EMISSION STANDARDS FOR
CRUDE OIL AND NATURAL GAS FACILITIES”**

Loni Russell, Deputy Field Manager, Western States

Moms Clean Air Force

July 21, 2016
Sacramento, California

I am Loni Russell, I am here today as a concerned citizen, a daughter and an aunt. I am a member and community organizer for Moms Clean Air Force California, a community of over 80,000 California parents fighting for clean air. On behalf of our members, I want to thank you for the opportunity to testify today.

I thank you for taking this important step in addressing methane pollution from oil and gas operations and respectfully urge you to move forward with your proposal, while considering two important changes:

- 1) The current proposal includes a “step-down” provision which would allow operators to shift to less rigorous monitoring requirements if it fails to find leaks over a specified number of inspections, this would create a perverse incentive to avoid finding and reporting leaks, and less of a reason to avoid fixing them quickly. | B-6-1
- 2) The current proposal pushes the implementation timeline by a year (from Jan 2017 to Jan 2018). Our communities cannot afford to wait until 2018 for the public health benefits. | B-6-2

The scientific record and public health co-benefits demonstrate that cutting methane pollution would provide strong public health protections for Californians and most importantly for our children. | B-6-3

I am no stranger to poor air quality growing up in the San Fernando Valley of Los Angeles, where my family still resides. Many of my relatives suffer from asthma.

Nearly 1 in every 10 schoolchildren in the US has asthma. Asthma being the number one health issue that causes kids to miss school.

Co-pollutants that leak along with methane lead to ozone formation, or smog, which is damaging to health. Numerous studies have found elevated smog in regions with oil and gas development, largely due to emissions of volatile organic compounds (VOC) and nitrogen oxides from these activities. | B-6-4

Standards that reduce methane emissions from oil and gas development will simultaneously reduce emissions and formation of health-damaging air pollutants, including VOC, hazardous air pollutants (HAP), particulate matter (PM2.5), and ozone. | B-6-5

Reducing all of these would reduce the exposure of nearby communities to these pollutants and the subsequent risk of health effects, including respiratory morbidity and premature death.

B-6-5
Cont.

A large body of scientific research indicates that oil and gas development is associated with adverse health impacts. Empirical studies have found evidence for the following:

- 1) Higher reported health symptoms per person among residents who live close to gas wells
- 2) Greater prevalence of adverse birth outcomes, including congenital heart defects, neural tube defects, and low birth weight for infants born to mothers who live in high densities of natural gas development compared to no natural gas development

B-6-6

Children, pregnant women, and the elderly - are most susceptible to experiencing negative health impacts from oil and gas pollution.

Let's keep our most vulnerable safe with a strong standard that helps millions of children breathe easier.

Thank you for this opportunity to testify.

HOW OIL AND GAS OPERATIONS IMPACT YOUR BABY'S HEALTH

Lori Russel 16-7-2

Air pollutants associated with oil and gas

operations are known to cause serious health

impacts in pregnant women, babies, and

children – as well as other adults.

DID YOU KNOW?

- Children's lungs continue to develop after birth.
- Children breathe faster and spend more time outside than adults.
- Other organs like their brains and reproductive systems are also still developing after birth.
- That makes children particularly vulnerable to air pollution.
- Pregnant women also need clean air.
- If the air you breathe is polluted, that can lead to health problems for your baby.
- Companies are not required to monitor or disclose dangerous air pollution, and government air monitors may not be sited close to natural gas activity.
- As a result, it's hard to find out whether you are breathing these pollutants in your community.

LOW BIRTH WEIGHT

A Pennsylvania study found that living near natural gas wells was associated with having lower birth weight babies. Low birth weight babies are at increased risk of early death, infections, and learning disabilities.

PRETERM BIRTH

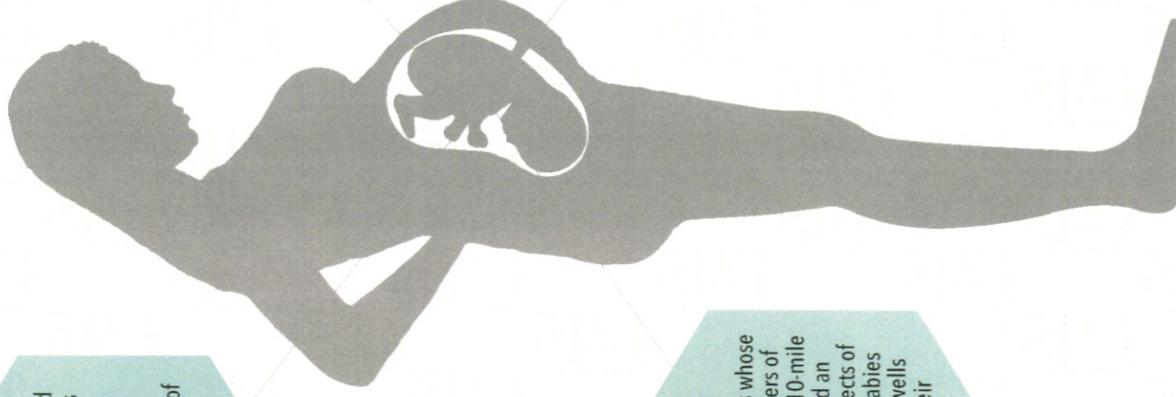

In a Pennsylvania study, babies whose mothers lived close to natural gas wells were more likely to be born preterm (before 37 weeks gestation), compared to babies whose mothers lived farther away from gas wells.

CONGENITAL HEART DEFECTS

In a Colorado study, babies whose mothers had large numbers of natural gas wells within a 10-mile radius of their home had an increased risk of birth defects of the heart, compared to babies whose mothers had no wells within 10 miles of their home.

HIGH-RISK PREGNANCY

Pregnancies in Pennsylvania among mothers who lived close to natural gas operations were more likely to be labeled "high-risk," a designation that can include high blood pressure or excessive weight gain during pregnancy.

MOMS

FIGHTING FOR
OUR KIDS' HEALTH

WHAT IS HAPPENING TO BABIES IN OIL AND GAS REGIONS?

Preliminary studies have found that living near pollution emitted from oil and gas operations may be harmful to your baby's health.

HOW CAN I PROTECT MY BABY?

Because the oil and gas industry does not monitor or disclose air pollution, you should document your family's health by writing down your observations. If you notice health problems, contact your local health department and your state environmental agency. Visit your doctor regularly, and discuss these issues with her.

| AIR POLLUTANT | OIL AND GAS SOURCE | HEALTH IMPACTS |
|---------------------------|--|---|
| BENZENE | Occurs naturally in oil and gas; leaks during routine operations of natural gas wells, pipelines, compressor stations; also released by diesel-powered equipment. | Leukemia, asthma attacks, lung infections, low birth weight, headaches, vomiting, dizziness. |
| DIESEL EMISSIONS | Emitted from generators and trucks associated with oil and gas development. Pumps and compressor stations are often powered by diesel engines. | Asthma attacks, cancer, lung infections, heart disease, premature death. |
| FORMALDEHYDE | Emitted by compressor stations; created in the atmosphere when oil and gas pollutants, such as benzene, combine with heat and sunlight. | Asthma attacks, cancer. |
| METHANE | The main component of natural gas. Leaks at every point along the natural gas life cycle. Sometimes is vented deliberately into the air. | A powerful greenhouse gas that contributes to climate change. Health impacts of climate change include heat illness, asthma attacks, vector-borne infection, and disruptions to the global food supply. |
| PARTICLE POLLUTION | Emitted from generators and trucks used in oil and gas development. Pumps and compressor stations are often powered by diesel engines. Also caused by heavy truck traffic. | Infant death, asthma attacks, low birth weight, heart attacks, stroke, cancer, premature death. |
| SILICA DUST | Sand is used in the process of hydraulic fracturing, or fracking. As sand is transported to well pads and poured into well shafts, silica dust can get into the air. | Cancer, silicosis. |
| SMOG (GROUND LEVEL OZONE) | Created when oil and gas pollutants, such as benzene, combine with heat and sunlight in the air. | Asthma attacks, lung infections, impaired lung development. |

Join other families in your community to demand protections from pollution.

**Testimony on CARB's Proposed Rulemaking for
"PROPOSED REGULATION FOR GREENHOUSE GAS EMISSION STANDARDS FOR
CRUDE OIL AND NATURAL GAS FACILITIES"**

Jennifer Moeller, Los Angeles Field Organizer, CA

Moms Clean Air Force

July 21, 2016

Sacramento, California

Good Morning, my name is Jennifer Moeller and I come before you today as a mother and concerned citizen. Thank you in advance for allowing me a few brief minutes to tell my story.

I am the mother of three beautiful children five and under. My son Mason is 5.5, Madison 2.5 and Miles 9 months old. I can remember October 2015 like it was yesterday, it was two weeks after I had given birth to our third child, Miles, I returned home from a much needed outdoors walk when I noticed a letter taped to my front door, on Southern California Gas Company letterhead, notifying me of the biggest gas leak known to date. Naturally, I panicked, was horrified and stricken with more questions than I could fathom. Baffled and looking for answers, I immediately relocated our family to a distant city away from our current, dangerous and hazardous living environment. Prioritizing my family's health was of utmost importance and this momma bear was not taking any chances of jeopardizing my children's health or potential to developing future illnesses.

Because of this catastrophe, I urge you to address high levels of methane pollutions and efforts to controlling oil and gas operations by considering the following options:

1. Fixed frequency inspections: remove incentives to shift to loose annual inspections. A substantial portion of methane emissions across the supply chain come from leaks. That's why a leak detection and repair (LDAR) program that requires operators to regularly find and fix leaks is a straightforward, cost-effective way to reduce oil and gas methane emissions. CARB's proposed rule initially requires quarterly monitoring of facilities, but allows for a step-down to annual depending on whether operators find leaks. A program that allows operators to meet less rigorous inspection requirements creates a disincentive to find and report leaks and sets a bad precedent for other programs.

B-7-1

2. The implementation timetable needs to be faster. Recent amendments pushed back the implementation of the rule by a year – California communities need reductions sooner than that.

B-7-2

Did you know, that children's lungs continue to develop after birth? Children breathe faster and spend more time outside than adults. That children are especially more vulnerable to air pollution, and organs much like a child's brain and reproductive system still continue to develop post birth? You can see why my sense of urgency to immediately relocate my family to safer and cleaner breathing grounds was nothing less but my main priority when high levels of methane

along with other cancer causing chemicals such as benzene were being emitted into the air due to a lack of regularly regulated aging infrastructure in a oil/gas storage facility.

Living in a dense and overly populated city such as Los Angeles where driving vehicles is a commonality, smog and air pollution is already a heavy and weighted ongoing issue, let alone allowing for the release of high levels of methane into the air.

Lets work together to make a difference, for us, for our children.

Thank you allowing me to share my story with you.

**Testimony on CARB's Proposed Rulemaking for
"PROPOSED REGULATION FOR GREENHOUSE GAS EMISSION STANDARDS
FOR CRUDE OIL AND NATURAL GAS FACILITIES"**

Jason Hector

July 21, 2016
Sacramento, California

It is an honor and pleasure to speak before the CA Air Resources Board and I want to thank the ARB for proposing comprehensive regulation of fugitive emissions especially in light of Aliso Canyon. My name is Jason Hector and I have been a longtime resident of Porter Ranch, husband, father of an amazingly bright 3 ½ year old daughter and have taken care of my elderly grandmother for the last decade all in Porter Ranch. My daughter, when I would watch the webcast of the Porter Ranch Community Advisory Committee she would point at my computer and say "Is that the Gas Leak Meeting?"

I urge you to move forward with your proposal, while considering two important changes:

Removing the "step-down" provision which would allow operators to shift to less rigorous monitoring requirements, this would create a perverse incentive to avoid finding and reporting leaks, and less of a reason to avoid fixing them quickly.

B-8-1

The proposal pushes the implementation timeline by a year (from Jan 2017 to Jan 2018). Our families and communities cannot wait until 2018.

B-8-2

My family and my community understand the direct impacts of pollution from these facilities and the impacts of the co-pollutants that leak alongside oil and gas development.

Increasingly, scientific research indicates that oil and gas development is associated with adverse health impacts. During the massive gas blowout, I personally experienced severe headaches, nosebleeds, blood in my phlem, lethargy, sick feeling, and extreme allergy like symptoms.

My daughter had difficulty breathing and other sickness symptoms for a long time even after we relocated. My first severe symptoms started after being outside and exposed to the methane blowout for several hours. I suffered from a severe headache and my wife felt very dizzy. After speaking with public health officials, we left our home and checked into a hotel. My 98 year old grandmother was relocated as well. Unfortunately, when we would return to work or pick up clothes or mail, we would get sick again.

I remember just before our vacation, I started having the worst allergy-type symptoms like extreme thirst, non-stop runny nose, uncontrollable sneezing and headache.

I am very concerned about the health effects of the children who live, go to school and play near oil and gas facilities like Aliso Canyon. I support the ARB standards because they help reduce methane emissions from oil and gas facilities and formation of health damaging air pollutants, including volatile organice compounds, and other hazardous air pollutants. An example are the children attending attending the two schools in Porter Ranch. We still don't know all the chemicals that we may have been exposed to since that information has been deemed confidential or proprietary. Once moving back, oily residue was found in our park and since we have not returned out of fear of unknown. I am very concerned about how this might impact our groundwater aquifer.

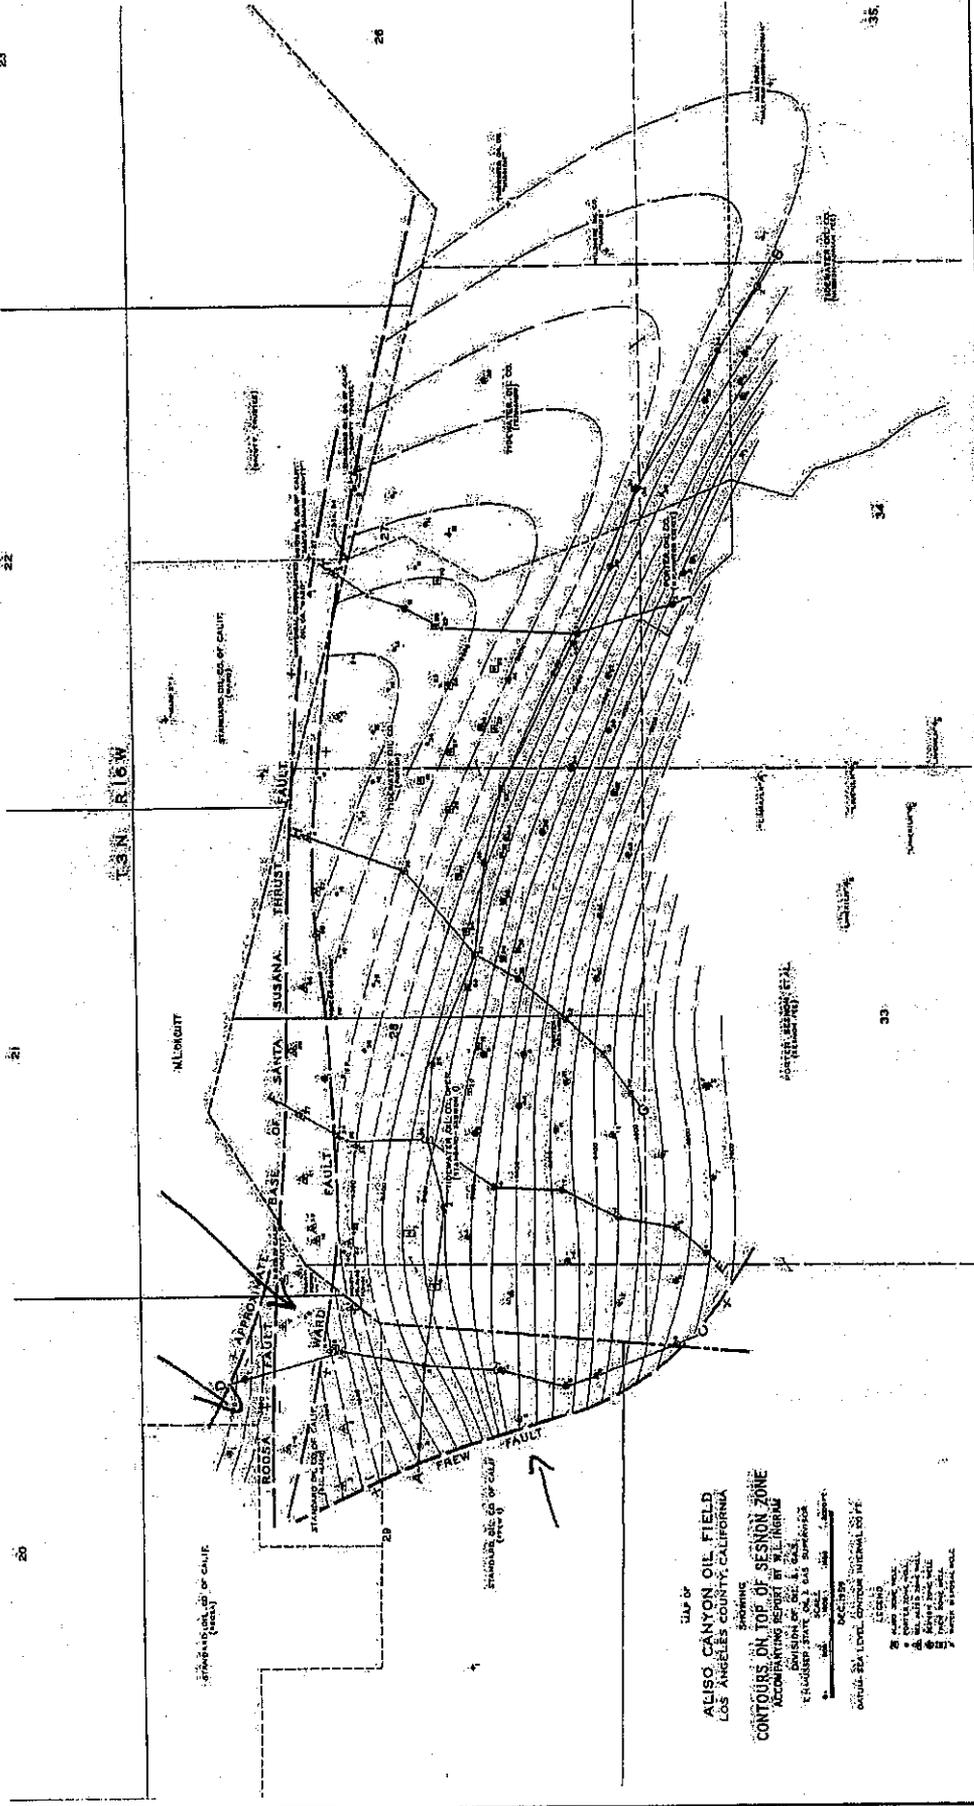

B-8-3

(over)

I am also very concerned about the concept of storing gas underground. There is not a steel SCUBA tank underground to ensure containment of the very high pressure reservoir. Also, how can we confirm if there are leaks coming up from the reservoir. We are talking about geologic formations here and Aliso Canyon sits on a fault line. How can we be sure that the gas is not moving up from the reservoir through the ground and through the water before it reaches the surface?

B-8-4

I want to thank the ARB for continuing California's leadership on climate change and taking this important step to address methane pollution and the opportunity to testify. Let's make to not let this happen to California families again.

Castlebay Lane, Porter Ranch Schools to Relocate Due to Aliso Canyon Natural Gas Leak

S F E C

Schools will share space with two other campuses for second semester

LOS ANGELES (Nov. 17, 2015) - The Board of Education took action today to expedite the temporary relocation of Castlebay Lane Charter and Porter Ranch Community School, where teaching and learning have been disrupted by a natural-gas leak in nearby Aliso Canyon.

When classes resume after the winter break, the 770 students in grades K-5 who attend Castlebay Lane will be relocated to Sunny Brae Avenue Elementary in Winnetka. Porter Ranch Community School, which has 1,100 students in grades K-8, will relocate to Northridge Middle School. Portable classrooms and available space at the host-schools will be used to house the Castlebay Lane and Porter Ranch students, teachers and staff.

To minimize disruption, the relocation will be in effect for the rest of the 2015-16 school year. Details are being finalized, and parents will be notified as decisions are made.

The board's unanimous approval will allow the District to make alterations or improvements at the Sunny Brae and Northridge campuses over the three-week winter break, without having to go through the time-consuming competitive-bidding process.

"This has been a difficult decision because it will impact the lives of so many families," said school board member Scott Schmerelson, who represents the West San Fernando Valley. "I believe this is the right decision to protect the health of our students and employees and to stabilize the learning environment."

The leak was discovered Oct. 23 in a natural-gas well owned by the Southern California Gas Co. Initial efforts to cap the well were unsuccessful, and the company estimates it will take up to four months to stop the leak.

Since late October, parents, employees and residents at Castlebay and Porter Ranch have been raising concerns about the effects of the odorant that allows natural gas to be detected. To ensure that schools, students and faculty remained safe, the District installed air filters in every classroom, assigned additional nurses and began independent air-quality monitoring at the two campuses.

L.A. Unified also worked with parents that relocated away from the Porter Ranch area to enroll their children in other District schools, and offered an independent study program for families that opted to keep their students at home.

Despite these efforts, absenteeism and visits to the health office increased. As a result, the Los Angeles County Department of Public Health issued a directive on Wednesday, ordering Southern California Gas to work with the District in relocating Castlebay Lane and Porter Ranch

students.

The board resolution adopted Thursday authorizes the District's Office of General Counsel to initiate litigation, if necessary, to recover the cost of temporarily relocating the schools.

AQMD Meeting Notes

Item 8 Leak detection protocol—Include five main components to supplement present inspections and meet proactive requirement of #8.

1. Fence Line real time monitoring system surrounding the perimeter of ALL facilities which have nearby homes, schools, etc nearby.
2. Fixed site ground monitors which can be checked in real time by ARB and online by residents. Locations should be the places where high levels of methane have been found before.
3. Fly over monitoring by ARB using current technology and drones to be used in coordination with NASA Jet Propulsion Labs with a pilot program to be implemented at Aliso Canyon.
<http://www.jpl.nasa.gov/news/news.php?feature=6192>
4. Li Cor vehicle with mobile methane monitoring must be used on a DAILY basis or 6 days a week and results posted online as soon as possible. This mobile monitoring helps keep the community informed and compliments nicely the LiCor mobile methane monitoring vehicle.
5. On site monitoring must include using BOTH the FLIR type camera as well as a TVA. Using one without the other means less of a chance of finding leaks. Also, the TVA is a valuable tool for quantifying the emissions rates.
6. The air monitoring should be with ARB in collaboration with NASA's Jet Propulsion Labs since they have a methane drone combined with the flyovers ARB has been doing to identify and estimate emissions.

With respect to the issue of confirming odor complaints due to "fleeting smells" which was a recurring theme and concern of the board...one idea is to create an application for cell phones. This "I smell something app" would be simple for residents to report odors and GPS locations could be sent in real time to appropriate agencies.

Secondly, I would request the help of local city and county fire/police/haz mat facilities near these natural gas storage sites to be equipped with sensitive detection equipment to aid in confirmation of symptoms, smells, etc. Fire and EMS have training in observing and reporting symptoms but more importantly the ability to respond very quickly, maybe in less than 5 minutes to help document the validity of the complaint.

Health Study—#14 Key requirements needed for a comprehensive symptom based study for impacted residents of Porter Ranch and neighboring communities:

1. Creation of a means for impacted residents to voluntarily submit pictures, logs and sworn statements of health impacts.
2. As requested by board member, testimony from an expert about the AQMD proposed National Academy of Sciences. The public and board should be presented with a summary of the details for public review and comment.
3. Study length to remain open for one decade given the sometimes long period for onset of certain types of cancers.

PORTER RANCH REAL-TIME COMMUNITY AIR MONITORING DATA

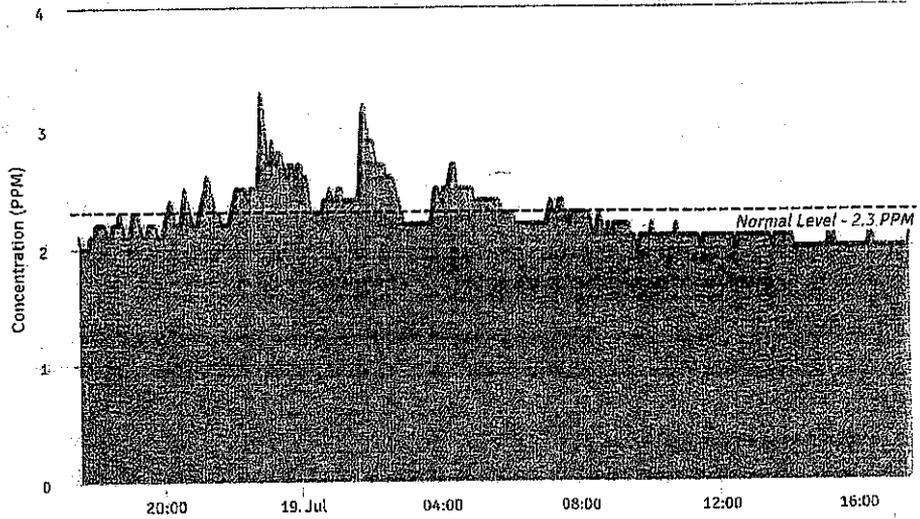

Message Board

06/04/2016 19:10 - We want to let you know we had to do some modification to the Porter Ranch Fence Line website. It turns out the air monitor we were using to detect Benzene, Toluene, and Xylene was a lot sicker than we originally thought. One of the electronic boards needed to operate the system burned out and it will take two months to get a replacement shipped to us. So to help keep the community up to date on what's going on, we're now taking the data from the benzene monitoring systems the Air District operates and are putting it on the website. The methane system continues to provide updated data every five minutes and nothing has changed with respect to that system.

Mini NASA Methane Sensor Makes Successful Flight Test

A JPL mini methane gas sensor is flight tested on a small unmanned aerial system (sUAS) under a project to improve energy pipeline industry safety. The sensor enables methane detection with higher sensitivity than previously available for the industry in hand-carried or sUAS-deployable instruments. Credit: University of California, Merced

[Larger image](#)

As part of a project to improve safety in the energy pipeline industry, researchers have successfully flight-tested a miniature methane gas sensor developed by NASA's Jet Propulsion Laboratory, Pasadena, California, on a Vertical Take-off and Landing small unmanned aerial system (sUAS). The sensor, similar to one developed by JPL for use on Mars, enables detection of methane with much higher sensitivity than previously available for the industry in hand-carried or sUAS-deployable instruments.

The tests were conducted in central California at the Merced Vernal Pools and Grassland Reserve, and were funded by Pipeline Research Council International (PRCI). The jointly conducted test of NASA's Open Path Laser Spectrometer (OPLS) sensor is the latest effort in a methane testing and demonstration program conducted on various platforms since

2014. The ability of the OPLS sensor to detect methane in parts per billion by volume could help the pipeline industry more accurately pinpoint small methane leaks.

Researchers from JPL and the Mechatronics, Embedded Systems and Automation (MESA) Lab at the University of California, Merced, conducted the flight tests in late February. They flew a small unmanned aerial system equipped with the OPLS sensor at various distances from methane-emitting gas sources. Tests were done in a controlled setting to test the accuracy and robustness of the system.

The advanced capabilities provided by sUASs, particularly enhanced vertical access, could extend the use of methane-inspection systems for detecting and locating methane gas sources.

Additional flight testing this year will feature a fixed-wing UAS, which can fly longer and farther. Those capabilities are necessary for monitoring natural-gas transmission pipeline systems, which are often hundreds of miles long and can be located in rural or remote areas.

This latest round of tests furthers the team's goal to develop sUASs to improve traditional inspection methods for natural-gas pipeline networks, which may enhance safety and improve location accuracy.

"These tests mark the latest chapter in the development of what we believe will eventually be a universal methane monitoring system for detecting fugitive natural-gas emissions and contributing to studies of climate change," said Lance Christensen, OPLS principal investigator at JPL.

NASA uses the vantage point of space to increase our understanding of our home planet, improve lives, and safeguard our future. NASA develops new ways to observe and study Earth's interconnected natural systems with long-term data records. The agency freely shares this unique knowledge and works with institutions around the world to gain new insights into how our planet is changing.

Mobile Methane Measurement Surveys

1

Beginning December 21, 2015, SCAQMD has been conducting mobile survey measurements in and around Porter Ranch to better characterize methane concentration levels and concentration gradients within the community and to support the fixed site methane monitoring efforts. For this purpose, a state-of-the-art methane analyzer (LI-COR 7700) and a Global Positioning System (GPS) were mounted on top of a hybrid vehicle and driven around Porter Ranch and other surrounding areas of the San Fernando Valley.

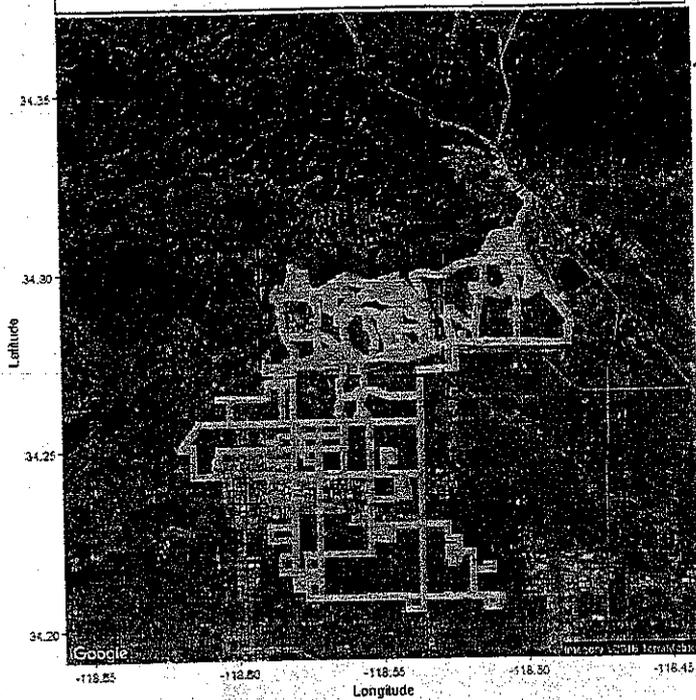

The LI-COR 7700 is an open-path instrument capable of measuring methane concentrations as low as single parts per billion (ppb) at rates as fast as 40 times per second with high accuracy and precision. This technology has previously been used and validated by the Environmental Defense Fund (EDF), Google Earth Outreach, and Colorado State University (CSU) for mapping methane plumes rising from leaking natural gas pipes below streets:

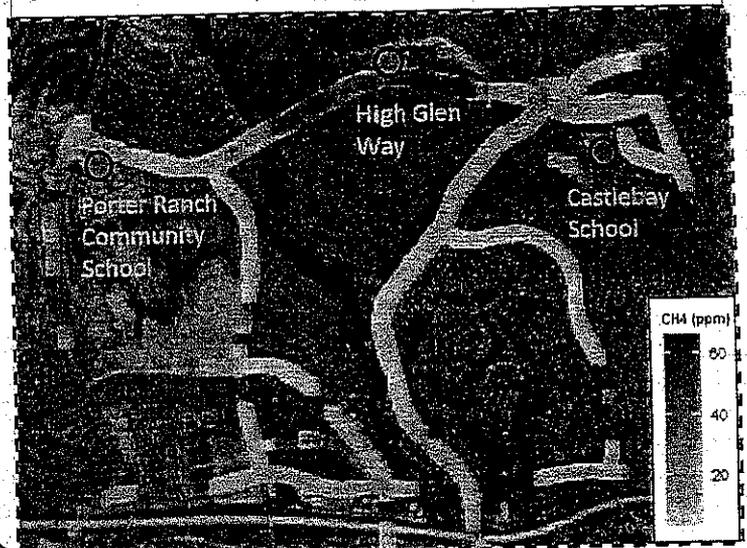

<https://www.edf.org/climate/methanemaps> (<https://www.edf.org/climate/methanemaps>)

Several routes in and around Porter Ranch and neighboring communities were selected for these surveys. Monitoring was conducted during different times of the day (e.g., morning, afternoon and evening) and under different meteorological conditions. As depicted in the map below, the highest methane concentrations measured thus far (up to 70 part per million [ppm]) were recorded at night in Sesnon Blvd, south of the Aliso Canyon Facility. These results support the placement of the SCAQMD fixed monitoring sites and the idea that the fixed SCAQMD sites will provide appropriate coverage for long term monitoring in Porter Ranch.

Area covered by mobile measurements
between 12/21/15 and 01/29/16

July 18, 2016
California Environmental Protection Agency
Air Resources Board
Byron Sher Auditorium
1001 I Street
Sacramento, California 95814

Dear Air Resources Board:

Thank you for accepting these comments submitted by Clean Air Task Force, Earthworks, Environmental Defense Fund, Natural Resources Defense Council and Sierra Club on Proposed Regulation Order 17 C.C.R. § 95665 et seq. (May 2016). We greatly appreciate the opportunity to comment on the California Air Resources Board's ("ARB") draft regulation for methane pollution from oil and gas facilities. These comments build upon recommendations that we submitted to ARB during its comprehensive stakeholder process and track closely recommendations that we made to ARB on the last draft, published February 19, 2016.¹

I. Introduction

We commend the ARB on proposing one of the strongest rules in the nation to curb the release of harmful emissions from oil and gas facilities. The draft regulation contains cost effective, technically feasible mechanisms that will achieve critically needed reductions in methane, a potent climate-altering pollutant, as well as important co-benefit reductions in volatile organic compounds (VOCs) and air toxics that pose serious threats to human health. ARB staff estimates the proposal will cut methane emissions from the over 51,500 oil and gas facilities in the state² by half³ while also removing 3,600 tons of VOCs and over 100 tons of air toxics from the atmosphere annually.⁴

Significant methane reductions are necessary for California to reach its goal of reducing greenhouse gas emissions to 1990 levels by 2020, as ARB acknowledges.⁵ As ARB's Staff Report explains, such reductions "can have an immediate beneficial impact on climate change" due to the relatively short atmospheric life of methane.⁶

Requiring oil and gas owners and operators to capture rather than vent or leak methane emissions is one of the most cost-effective and sensible ways to achieve deep and immediate reductions in GHG emissions. Natural gas is primarily methane, and as ARB's draft proposal demonstrates, in many instances operators can benefit from the natural gas recovered either by sending it to sales or utilizing it onsite. Indeed, ARB's analysis demonstrates the proposal to be

¹ Clean Air Task Force, *et al.*, "Methane comments to CARB" (February 19, 2016). (Ex. 1)

² ARB Staff Report: Initial Statement of Reasons, 6 (May 31, 2016), available at <http://www.arb.ca.gov/cc/oil-gas/Oil%20and%20Gas%20ISOR.pdf>. (Ex. 2)

³ *Id.* at ES-2.

⁴ *Id.* at ES-4.

⁵ ARB, Proposed Short-Lived Climate Pollutant Reduction Strategy, 13 (April 2016), available at <http://www.arb.ca.gov/cc/shortlived/meetings/04112016/proposedstrategy.pdf>. (Ex. 3)

⁶ *Id.* at 2.

highly cost effective at \$15 per ton of CO₂e reduced, considering savings.⁷ Even without accounting for the savings operators can achieve by capturing methane, the draft rules are still highly cost effective at \$17 per ton of CO₂e reduced.⁸ These numbers reflect only the direct benefits that accrue from the removal of 1.5 million metric tons of CO₂e from the atmosphere annually. When one considers that the implementation of the various clean air measures contained in the proposal will remove additional tons of VOCs and air toxics annually, it is clear that this proposal represents a very cost effective pathway to achieve much-needed reductions in harmful oil and gas emissions.

Moreover, the state cannot rely on federal actions to achieve the greenhouse gas reductions required by legislative and gubernatorial mandates.⁹ US EPA rules adopted to date under the New Source Performance Standards program do not apply to existing oil and gas sources,¹⁰ and therefore will have no effect on the over 50,000 existing oil and gas wells in the state. While EPA has proposed requirements directed at reducing VOC emissions from a select number of onshore oil and gas facilities (control techniques guidelines, or CTGs),¹¹ these requirements are not final, and even once they become final, will have a limited effect on existing sources both in California and nationwide: the CTGs do not directly regulate methane, nor do they apply statewide (they only apply in parts of the state that are designated as moderate or above ozone nonattainment areas), and they do not apply to offshore facilities. Moreover, the proposed control techniques guidelines do not apply to many of the onshore facilities subject to the ARB proposal, including underground natural gas storage, transmission compressor stations, intermittent bleed pneumatic controllers or any facilities located in the storage and transmission segments. Accordingly, the proposed ARB rules are necessary to achieve critical reductions in methane, VOCs and air toxics that are left unaddressed by EPA requirements.

For all of the above reasons we urge ARB to adopt the Proposed Regulation Order, 17 C.C.R. § 95665 et seq. (May 2016). However, in so doing, we respectfully request ARB to strengthen the rule in a few key ways, the basis for which we discuss in the remainder of our comments:

- Leak detection and repair (LDAR)
 - Provide operators with flexibility to seek approval for utilizing alternative leak detection methods for making inspections provided such methods are at least as effective in reducing waste and emissions as Optical Gas Imaging (OGI)-based LDAR and that the approval process is transparent and open to public participation.

⁷ *Id.* at Table 14, 127.

⁸ *Id.*

⁹ Global Warming Solutions Act of 2006 (establishing statewide GHG emissions cap for 2020, based on 1990 emissions); *see also* ARB Senate Bill 605 (requiring ARB to develop a comprehensive plan to reduce emissions of short-lived climate pollutants); *see also* Short-Lived Climate Pollutant Reduction Strategy, ARB Pollutant Reduction Strategy (2016), *supra* note 5, discussing Governor Brown's announcement of a target for reducing GHG emissions to 40 percent below 1990 levels by 2030.

¹⁰ *See* 81 Fed. Reg. 35,824 (June 3, 2016).

¹¹ *See* 80 Fed. Reg. 56,577 (Sept. 18, 2015) (announcing availability of draft control techniques guidelines for VOCs from the oil and gas sector).

- Remove the provision in Section 95669 that allows operators to reduce the inspection frequency from quarterly to annual based on the percent or number of leaking components detected.
 - Require the repair of 500 ppm leaks detected during inspections.
- Underground natural gas storage
 - Expand daily screening or continuous monitoring provisions to include all wells in the field including but not limited to observation, monitoring, disposal, production and other wells.
 - Clarify that the monitoring requirements apply not only to active wells but also to idle and plugged and abandoned wells.
 - Clarify that the inspection requirements in Section 95668 are intended to apply in lieu of the inspection requirements in Section 95669.
- Pneumatic controllers and pumps
 - Phase out existing low-bleed continuous devices, and require quarterly testing of bleed rate during phase out period.
 - Prohibit or phase out the venting of emissions from intermittent-bleed pneumatic controllers; or, at a minimum, limit emissions from such devices to low bleed levels, and require operators to verify that emissions are at low-bleed levels via direct measurement.
 - Clarify that the pneumatic pump provision apply to glycol assist pumps, and ensure that methane emissions from these pumps are indeed controlled.
- Compressors
 - Expand the requirement to perform LDAR inspections to rod packing and seals on non-production reciprocating compressors.
 - Reduce the flow rate threshold from that triggers a repair or replacement of the rod packing or seals.
- Separator and tank systems
 - Tighten deadlines related to both commencement of annual flash analysis testing and installation of vapor collection systems.
 - Require owners and operators of separator and tank systems that receive less than 50 barrels of crude oil per day and that receive less than 200 barrels of produced water per day to conduct periodic flash analysis testing.
- Liquids unloading
 - Revise definition of “liquids unloading” to remove “use of pressurized natural gas.”
 - Require operators to keep personnel onsite when conducting manual liquids unloading activities.
 - Require reporting of an enhanced list of key parameters and conditions when emissions are vented during liquids unloading.

In addition, while we commend ARB for recognizing the importance of accounting for the near term impacts of methane, we urge ARB to revise its assumptions to use the most recent IPCC AR5 20-year GWP for methane from fossil sources of 87. In supporting technical documentation and analyses for the rule, ARB assessed impacts and benefits of methane and

methane reductions using the IPCC AR4 20-year GWP of 72. Using the most updated information available will ensure that the results of analytics for the rule are as accurate and representative of methane impacts as possible.

II. Leak Detection and Repair

Frequent, comprehensive inspections of oil and gas facilities are a critical component of pollution prevention and mitigation. Direct measurement of emissions at a wide selection of oil and gas facilities across the country demonstrate that equipment malfunctions and poor maintenance can lead to significant pollution that is not represented in emission inventories. The direct measurement of scientific information demonstrates that oil and gas facilities are considerably leakier than industry reports, that operators do not and cannot predict when such failures will occur, and therefore, that frequent inspections with modern leak detection equipment are necessary to detect and promptly repair such leaks.

Fortunately, modern leak detection equipment exists to quickly and accurately find leaks. Moreover, frequent – namely, quarterly – inspections are highly cost-effective. Such inspections remove harmful pollution from the atmosphere, while also ensuring a safer and more efficient workplace.

1. Field Studies Using Direct Measurement and Recent Incidents in California Demonstrate the Need for Frequent Instrument-Based Inspections: Significant Emissions May Emanate from Individual Components and Operations

Up until recently, regulators have relied nearly exclusively on emission inventories in order to understand the magnitude of a particular pollution problem as well as the potential reductions associated with a proposed solution. Now, however, recent advances in science have added to our knowledge and understanding of emissions from oil and gas facilities. These studies demonstrate that emissions are systematically significant and, at a select number of facilities, actual emissions are magnitudes higher than emission inventories suggest. These studies strongly support at least quarterly inspections using modern leak detection technology to identify leaking equipment. In some instances, repairs can be made instantaneously with the turn of a wrench. A number of studies, as well as industry reports, note that the gas savings associated with fixing such leaks cover the costs associated with repairing them.

The first of these studies, conducted by an independent team of scientists at the University of Texas, found that emissions from equipment leaks, pneumatic controllers and chemical injection pumps were each 38 percent, 63 percent and 100 percent higher, respectively, than estimated in national inventories.¹² This study also found that 5 percent of the facilities were responsible for 27 percent of the emissions.¹³

¹² Allen, D.T., et al, (2013) “Measurements of methane emissions at natural gas production sites in the United States,” *Proc. Natl. Acad.* 2013, 110 (44), available at <http://www.pnas.org/content/110/44/17768.full>. (Ex. 4)

¹³ See Allen, D.T., et al, (2014), “Methane Emissions from Process Equipment at Natural Gas Production Sites in the United States: Pneumatic Controllers,” *Environ. Sci. Technol.*, 2015, 49 (1), pp. 633–640 (referencing 2013 Allen study), available at <http://pubs.acs.org/doi/abs/10.1021/es5040156>. (Ex. 5)

Two follow-up studies, focused specifically on emissions from pneumatic controllers and liquids unloading activities at wells, found similar results.¹⁴ Specifically, the studies found that 19 percent of the pneumatic devices accounted for 95 percent of the emissions from the devices tested, and about 20 percent of the wells with unloading emissions accounted for 65 to 83 percent of those emissions. The average methane emissions per pneumatic controller were 17 percent higher than the average emissions per pneumatic controller in EPA’s national greenhouse gas inventory.¹⁵

These findings were reiterated again in a series of direct measurement studies focusing on emissions from compressor stations in the gathering and processing segment and in the transmission and storage segment. The gathering and processing study found substantial venting from liquids storage tanks at approximately 20 percent of the sampled gathering facilities.¹⁶ Emission rates at these facilities were on average four times higher than rates observed at other facilities and, at some of these sites with substantial emissions, the authors found that company representatives made adjustments resulting in immediate reductions in emissions.

In the study on transmission and storage emissions, the two sites with very significant emissions were both due to leaks or venting at isolation valves.¹⁷ The study also found that leaks were a major source of emissions across sources, concluding that measured emissions are larger than would be estimated by the emission factors used in EPA’s reporting program.

A recent helicopter study of 8,220 well pads in seven basins confirms that leaks occur randomly and are not well correlated with characteristics of well pads, such as age, production type or well count.¹⁸ That study used statistical models to assess the relationship of detection to well pad parameters such as age, well count, gas and oil production. The study found a weak relationship between site characteristics and detected emissions. The study focused only on very high emitting sources, given the helicopter survey detection limit, which ranged from 35 to 105 metric tons per year of methane. The paper reports that emissions exceeding the high detection limits were found at 327 sites. 92 percent of the emission sources identified were associated with tanks, including some tanks with control devices that were not functioning properly and so could be expected to be addressed through a leak detection and repair program. While the study did not characterize the individually smaller but collectively significant leaks that fell below the detection limit, it nonetheless confirms that high-emitting leaks occur at a significant number of

production sites and that total emissions from such leaks are very likely underestimated in official inventories.

These studies demonstrate the importance of frequent inspections as well as the importance of comprehensive inspection requirements that apply to the full suite of components and equipment that can lead to leaks and unintentional venting. Specifically, certain components such as valves and connectors, may leak over time due to normal wear and tear. Other types of equipment, such as controlled storage tanks and pneumatic devices, may vent excess emissions when operating improperly. We commend ARB on drafting an LDAR provision that applies to both types of equipment. Under the proposal, operators must inspect controlled storage tanks, separators, vapor collection systems, circulation tanks, pneumatic devices and components such as valves and flanges on a quarterly basis using leak detection technologies. This is a critical aspect of the proposal as a comprehensive program coupled with frequent inspections is necessary to ensure operators detect all sources of unintentional leaks and venting.

The heterogeneous, unpredictable and ever-shifting nature of equipment leaks suggest that frequent leak detection and repair is essential to help identify and remediate leaks. We therefore support the finalization of a quarterly, comprehensive inspection requirement in the rule.

2. Leading States and EPA Require Quarterly Inspections

Currently, five major oil and natural gas producing states require quarterly monitoring at oil and gas facilities. In addition, EPA recently finalized a quarterly inspection requirement for compressor stations. These existing requirements demonstrate that ARB's proposed quarterly inspection requirement is both reasonable and necessary in order for California to remain one of the leaders with respect to oil and gas emissions mitigation.

EPA has finalized a quarterly inspection requirement to detect methane and VOC leaks at compressor stations.¹⁹ Per the NSPS, operators may conduct such inspections using either optical gas imaging equipment or Method 21. Components found to be leaking 500 ppm or greater with a Method 21 instrument must be repaired.²⁰

Colorado was the first state to promulgate comprehensive LDAR requirements aimed at reducing methane, as well as other pollutant emissions from a diverse suite of oil and gas facilities. Colorado's rules require operators to inspect for and repair hydrocarbon leaks, consisting of methane as well as other organic compounds, at three types of facilities: compressor stations, well sites and storage tank batteries. The rules require quarterly inspections at mid-sized facilities.²¹

¹⁹ 81 Fed. Reg. 35824, 35846 (June 3, 2016).

²⁰ *Id.*

²¹ 5 C.C.R. 1001-9, CO Reg. 7, §§ XVII.C.2.b.(ii), XVII F, (Feb. 24, 2014). Quarterly inspections are required at gathering sector compressor facilities with uncontrolled emissions between 12 and 50 tons of VOCs from equipment leaks and at well sites and tank batteries with uncontrolled emissions between 20 and 50 tons of VOCs from the largest condensate or oil storage tank onsite.

Colorado provides operators flexibility in determining what type of leak detection equipment to use and whether or not to quantify a leak. Operators may use either an IR camera, Method 21, or “other Division approved instrument based monitoring device or method.”²² To date, the Division has approved one additional device, the Rebellion photonics camera. If an operator chooses to quantify a leak, they must fix all leaks with a hydrocarbon concentration of 500 ppm from components located at new and existing well sites and new compressor stations.²³ At older, existing compressor stations, the leak threshold triggering repair is 2,000 ppm.²⁴

Pennsylvania, the second largest shale gas producing state, requires quarterly inspections of all onshore gas processing plants and compressor stations in the gathering and boosting sector.²⁵ Like Colorado, Pennsylvania requires operators to inspect for and repair methane leaks as well as VOC leaks. Pennsylvania requires that operators utilize either a forward looking infrared camera (“FLIR”) or “other leak detection monitoring devices approved by the Department”.²⁶ Pennsylvania has also announced an intent to adopt a quarterly inspection requirement at new and existing well sites.²⁷

Ohio also requires quarterly inspections for hydrocarbon, including methane, leaks at unconventional well sites.²⁸ Per the Ohio requirements, operators may use either a FLIR camera or a Method 21 compliant analyzer. When using a FLIR camera, a leak is defined as any visible emissions. When using an analyzer, a leak is defined using a 10,000 ppm threshold for all components except compressors and closed vent systems, which use a 500 ppm threshold. Ohio has also proposed to require quarterly inspections at other facilities, including compressor stations.²⁹

Wyoming requires quarterly instrument-based inspections at all new and modified well sites in its Upper Green River Basin with the potential to emit 4 tons of volatile organic compounds from fugitive components,³⁰ and has proposed to require the same for existing well

sites and compressor stations in the Basin.³¹ Operators may use either Method 21 or an optical gas imaging instrument, or other approved instrument. Wyoming's rules and permit requirements are focused on reducing VOC and HAP emissions.

Utah requires quarterly instrument-based inspections at all new and modified well sites and tank batteries.³² Utah allows operators flexibility in determining which type of leak detection to use to conduct the inspections. Operators may use an IR camera, Method 21 or a tunable diode laser absorption spectroscopy. Utah requires operators of facilities that produce at least 25,000 barrels of crude oil and/or condensate to inspect on a quarterly basis. Operators of facilities that produce less than 25,000 barrels of crude oil and/or condensate must inspect annually. Utah requires that operators inspect components in hydrocarbon service, thereby requiring operators to detect and fix methane as well as VOC leaks.

3. Quarterly Inspections Are Highly Cost Effective

Quarterly instrument-based inspections can remove significant methane, HAPs and VOCs from the atmosphere for very low costs. When considering the value of natural gas that can be sold to end users instead of being leaked into the air quarterly inspections simply make economic sense, and even more so when considering the co-benefits associated with reducing VOCs and HAPs. This is supported by ARB's analysis, which estimates that the LDAR provision can be achieved for a cost of \$15 per ton of CO₂e reduced assuming savings and \$17 per ton of CO₂e reduced not assuming savings.³³ Data from ICF, other states, LDAR service providers and companies similarly demonstrate that quarterly inspections are cost-effective:

- **ICF.** ICF developed a complex model to investigate the distribution of LDAR cost profiles at well sites. The results of the model indicate that the cost for LDAR using third-party OGI contractors ranges between \$491–793 per facility, depending on facility size.³⁴ Further, the analysis found that quarterly LDAR is cost-effective at \$258/metric ton of methane avoided for an average facility in the modeled distribution.³⁵
- **ICF** is also in the process of compiling a model that assesses the costs and cost-effectiveness of inspections using Method 21. This model also investigates the distribution of LDAR costs at facilities of varying size and emissions profiles. In addition, the model estimates costs over a period of three years, rather than simply looking at inspection costs in year one of an inspection program. The preliminary results of this model indicate that the cost for using third-party Method 21 contractors to

perform quarterly inspections at production facilities is \$8.58 per metric ton of CO₂e reduced.³⁶

- Rebellion. In comments at an EPA public hearing on the proposed NSPS in Dallas, TX, Rebellion Photonics, the maker of a leak detection technology, noted that its services are available for \$250 per site.³⁷ Rebellion noted that this cost is “turn-key,” including data management services.
- Colorado. Colorado’s economic analysis of its LDAR requirements assumed an hourly contractor rate of \$134 (reflecting a 30 percent premium).³⁸ Assuming a per-site survey time of four hours, this hourly rate yields a total per-site survey cost of \$536.³⁹
- EPA. EPA determined compressor station quarterly inspections to be cost-effective, estimating that the agency’s requirements would result in the reduction of 16,500 short tons of CH₄, 3,897 tons of VOCs, and 143 tons of HAPs at 525 compressor stations by 2020 at total annualized costs, including revenue from saved gas, of \$9,780,000.⁴⁰ For gathering and boosting compressor stations, this equates to \$685 per short ton of CH₄ reduced and \$234 per short ton of VOC reduced. For compressor stations in the transmission and storage sectors, this equates to \$251 per short ton of CH₄ reduced and \$9,072 per short ton of VOC reduced.
- EDF also contacted a number of third-party service providers and equipment rental firms, which provided costs that support the reasonableness of EPA’s determination. In particular, a FLIR presentation includes information from survey providers suggesting well-pad rates ranging from \$300 - \$800.⁴¹
- Noble and Anadarko submitted comments in response to the Colorado LDAR rule, stating that “the leak detection and repair requirements using instrument-based monitoring is [sic] a reasonable and cost effective way to reduce fugitive emissions at well production sites.”⁴² Additionally, the companies compiled a cost analysis for LDAR

³⁶ Final results of the model and an accompanying report are forthcoming and will be submitted to ARB once final.

under the Colorado rule and found that, “Based on company-specific historic data and certain estimated values, Noble anticipates that LDAR monitoring at well production facilities would cost between approximately \$260 and \$430 per inspection...”⁴³

- According to a presentation delivered by Jonah Energy at the WCCA 2015 Spring Meeting, total LDAR program costs were about \$99 per inspection in the first year, decreasing to about \$29 per inspection in the fifth year.⁴⁴

4. *Incentivizing Innovation and Continuous Improvement in LDAR Technologies and Approaches*

Although frequent OGI and Method 21-based LDAR both offer feasible and highly cost-effective approaches to reducing leak emissions, advanced LDAR technologies – and protocols for using those technologies — are being swiftly developed and refined.

The methane leak detection technology landscape is highly dynamic, with innovation happening in real time, for example through ARPA-E's MONITOR project and EDF's Methane Detectors Challenge project in partnership with Shell, six other large producers and other stakeholders. It is crucial for new ARB rules to create space for innovative technologies, which may be able to deliver improved environmental performance at reduced cost. We strongly urge the agency to adopt a robust alternative compliance pathway that is minimally prescriptive and specifically creates an entry point for appropriately qualified/demonstrated methane selective and/or multiple hydrocarbon detecting approaches. Such an approach will help catalyze a race to the top in technology, reduce costs for the regulated community, and potentially boost environmental outcomes. We urge ARB to let operators choose from a list of approved devices, and to obtain approval from ARB for an equally effective device, rather than dictating technology in the rule. We note that ARB has proposed to allow operators of underground natural gas storage facilities to use screening instruments other than OGI or Method 21 to conduct inspections of wellheads and pipelines,⁴⁵ and that U.S. EPA included a pathway for operators to obtain approval to use innovative technologies to reduce fugitive emissions at well sites and compressor stations.⁴⁶

Accordingly, we encourage ARB to provide operators with flexibility to seek approval for alternative methods of complying with LDAR requirements, provided that these alternative

compliance options are at least as effective in reducing waste and emissions as OGI-based LDAR, and that the approval process is transparent and open to public participation.

5. *ARB Should Remove the Frequency Adjustment Based on Percent or Number of Leaking Components*

Given the geographic and temporal unpredictability of leaking equipment discussed above, one of the most important aspects of an LDAR program is the frequency with which operators inspect facilities. ARB has proposed quarterly leak inspection surveys, with provisions to allow operators to reduce the frequency to annual inspections based on the percentage or number of leaking components found onsite. These provisions fall far short of what is necessary to protect public health and the environment, and lag behind what EPA, leading states and companies have already demonstrated in practice. Accordingly, we urge ARB to finalize a quarterly inspection requirement and to remove the provisions that allow operators to reduce inspection frequency to annual.

The proposal creates perverse incentives by rewarding operators for failing to identify harmful leaks. EPA investigations at petroleum refineries and other types of facilities demonstrate this to be so. A 2007 report by EPA found “significant widespread non-compliance with [LDAR] regulations” at petroleum refineries and other facilities.⁴⁷ EPA observed: “Experience has shown that poor monitoring rather than good performance has allowed facilities to take advantage of the less frequent monitoring provisions.”⁴⁸ The report recommends that “[t]o ensure that leaks are still being identified in a timely manner and that previously unidentified leaks are not worsening over time,” companies should monitor more frequently.⁴⁹

Furthermore, neither the percent nor number of leaking components is an accurate predictor of a facility’s emissions performance. At a conceptual level, if emissions from leaking components were homogeneously distributed, the percentage of components leaking at a facility would be a good indicator of facility-level emissions. However, there is overwhelming evidence that leak emissions follow a skewed, highly-heterogeneous distribution, with a relatively few number of sources accounting for a large portion of emissions.

To estimate the extent to which the percent of leaking components correlates with a facility’s emissions performance, we empirically examined the effects of EPA’s proposed 1 and 3 percent thresholds using data from the City of Fort Worth Study Air Quality Study,⁵⁰ which includes both component level emissions information and site-level data. Figures 5 and 6 below show the results of this analysis. Figure 5 compares site-level emissions to the percentage of leaking components and demonstrates that the individual sites with the highest emissions fall below EPA’s proposed 1 percent threshold. Figure 6 aggregates site-level emissions at each of these

⁴⁷ EPA, “Leak Detection and Repair: A Best Practice Guide,” October 2007, at 1, *available at* <http://www2.epa.gov/sites/production/files/2014-02/documents/ldarguide.pdf>. (Ex. 25)

⁴⁸ *Id.* at 23.

⁴⁹ *Ibid.*

⁵⁰ Eastern Research Group, Inc. and Safe Environmental Consulting, LP, “City of Fort Worth Natural Gas Air Quality Study: Final Report,” July 13, 2011, *available at*: http://fortworthtexas.gov/uploadedFiles/Gas_Wells/AirQualityStudy_final.pdf. (Ex. 26)

thresholds. Sites with less than 1 percent leaking components constituted over half of total emissions and over half of all sites. Conversely, there were no high-emitting sites with greater than 3 percent of their components leaking, and sites above a 3 percent threshold accounted for a small percentage of total emissions.

Figure 1: Site Methane Emissions (lb per year) Versus Percent Leaking Components

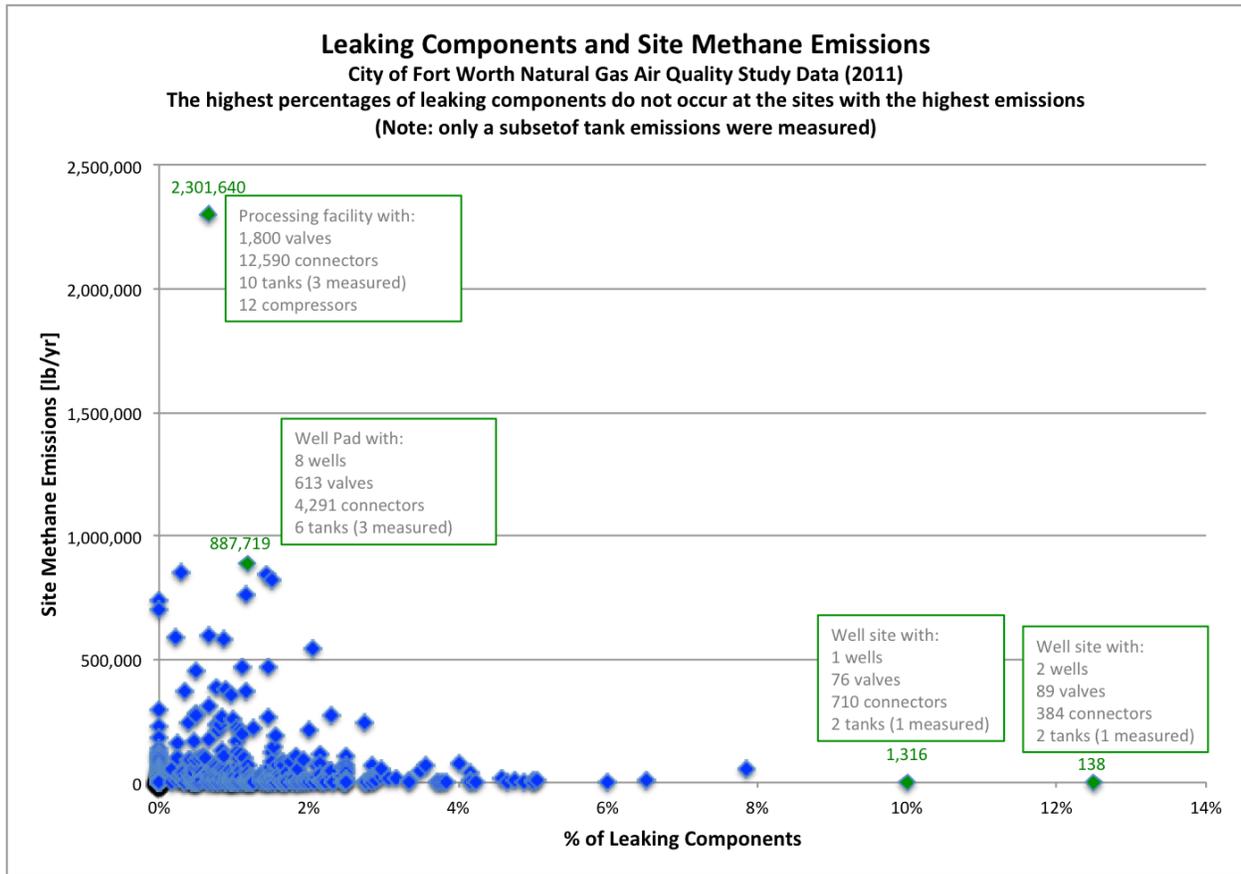

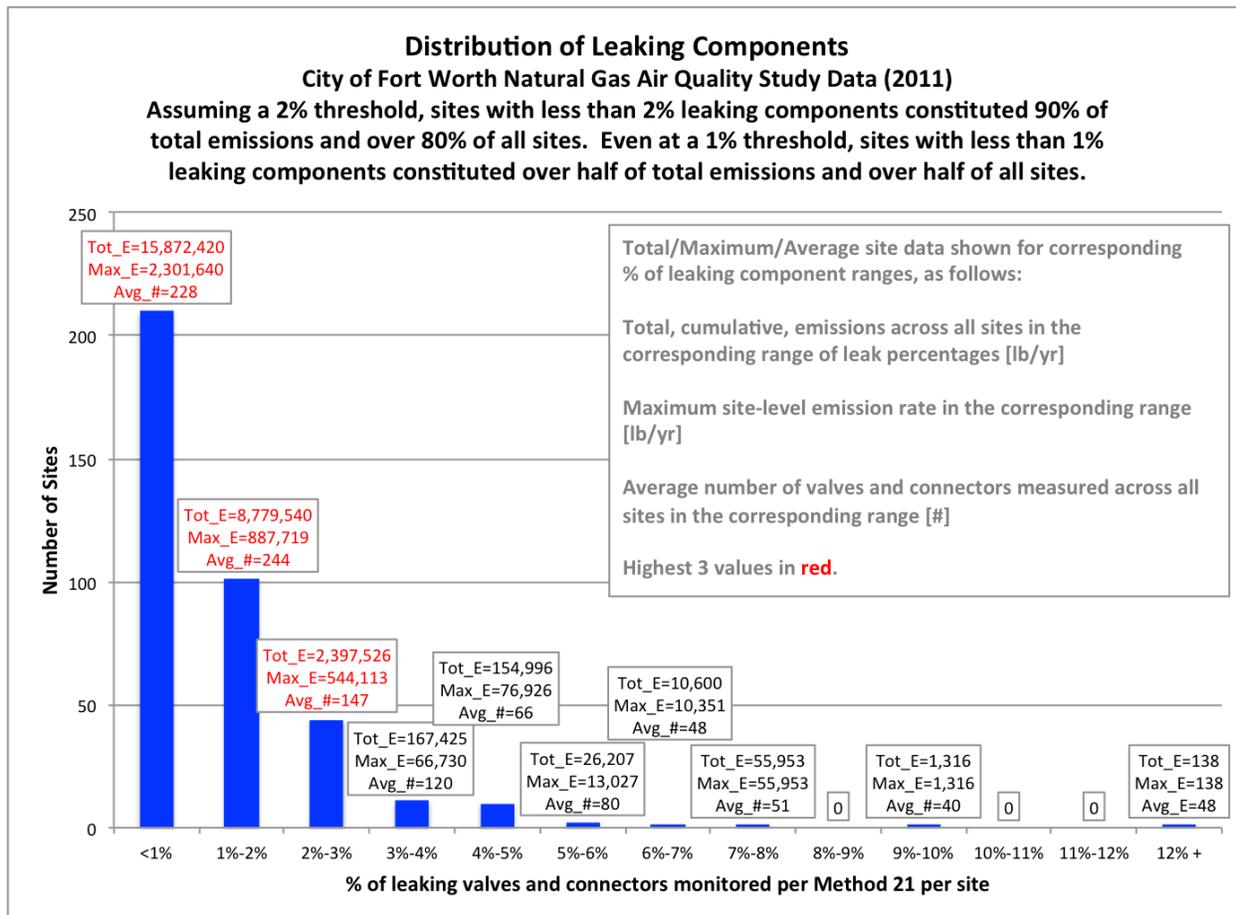

Figure 2: Number of Sites versus Percent of Leaking Valves and Connectors Monitored per Site (Method 21)

The number of leaking components is also a poor indicator of a facility’s emission performance. To test this, we empirically examined the effects of BLM’s proposed threshold using data from Allen, *et al.* (2013) and the Fort Worth Air Quality Study (2011),⁵¹ which include both component level emissions information and site-level data. Figures 3 and 4 below show the results of this analysis. Figure 3 shows the distribution of equipment leaks across the 150 production sites measured in the Allen, *et al.* (2013) study; sites with two or fewer leaks represented 70 percent of sites and constituted half of total methane emissions from leaks. Conversely, only 30 percent of sites had more than two leaks, representing only half of all emissions. In the Allen, *et al.* (2013) dataset, the site with the highest measured methane emissions from leaks had only two leaks but represented 18 percent of all emissions measured across all sites.⁵²

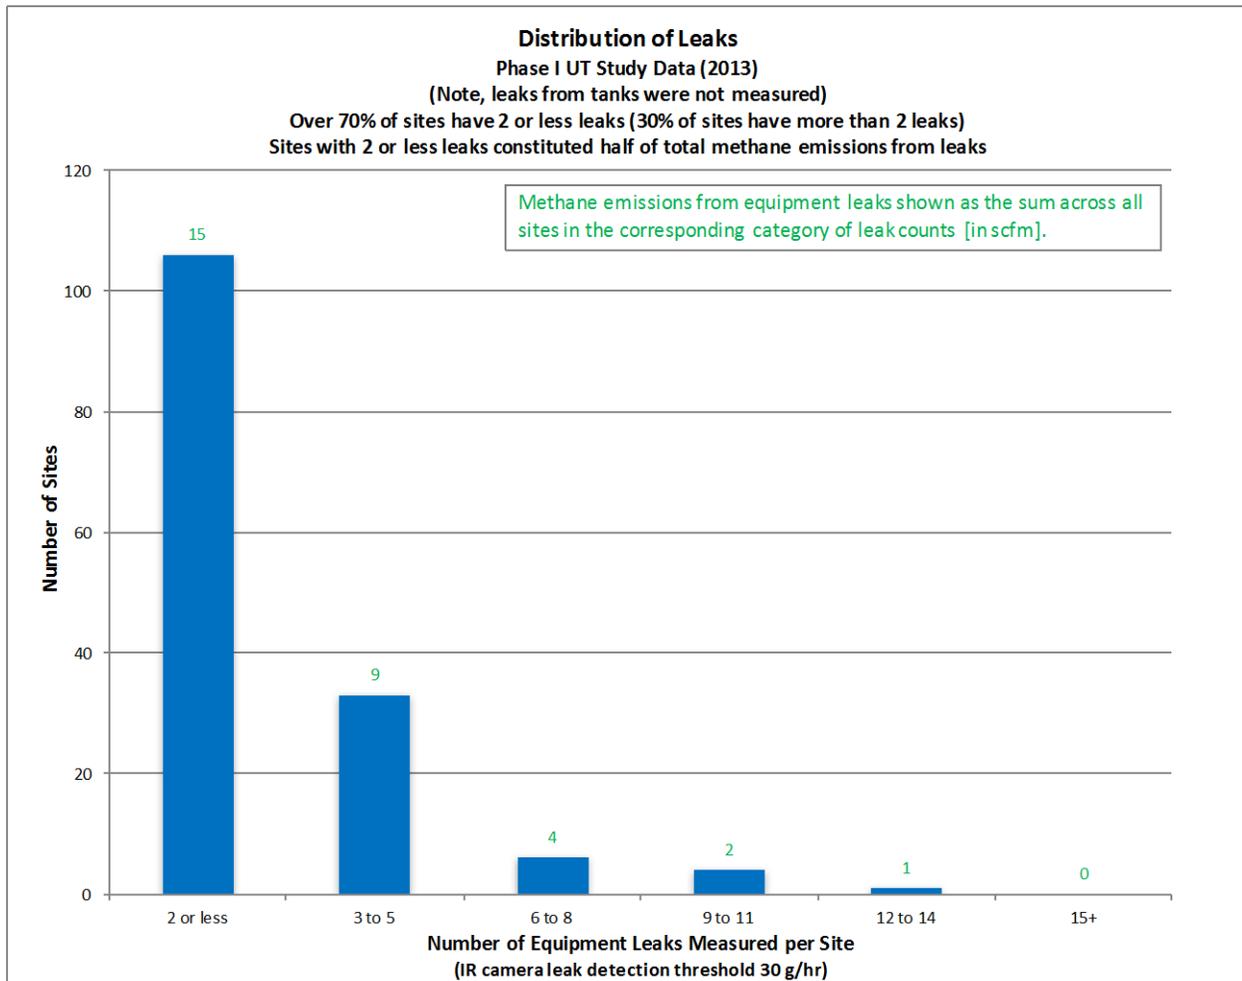

Figure 4 shows the distribution of leaks detected across the 388 sites measured in the Fort Worth Air Quality Study (2011); sites with two or fewer leaks represented 60 percent of sites and constituted 12 percent of total methane emissions from leaks. EPA reported in its Leaks White

⁵¹ *Id.*

⁵² One leaking separator vent was responsible for 5 scfm methane at this site.

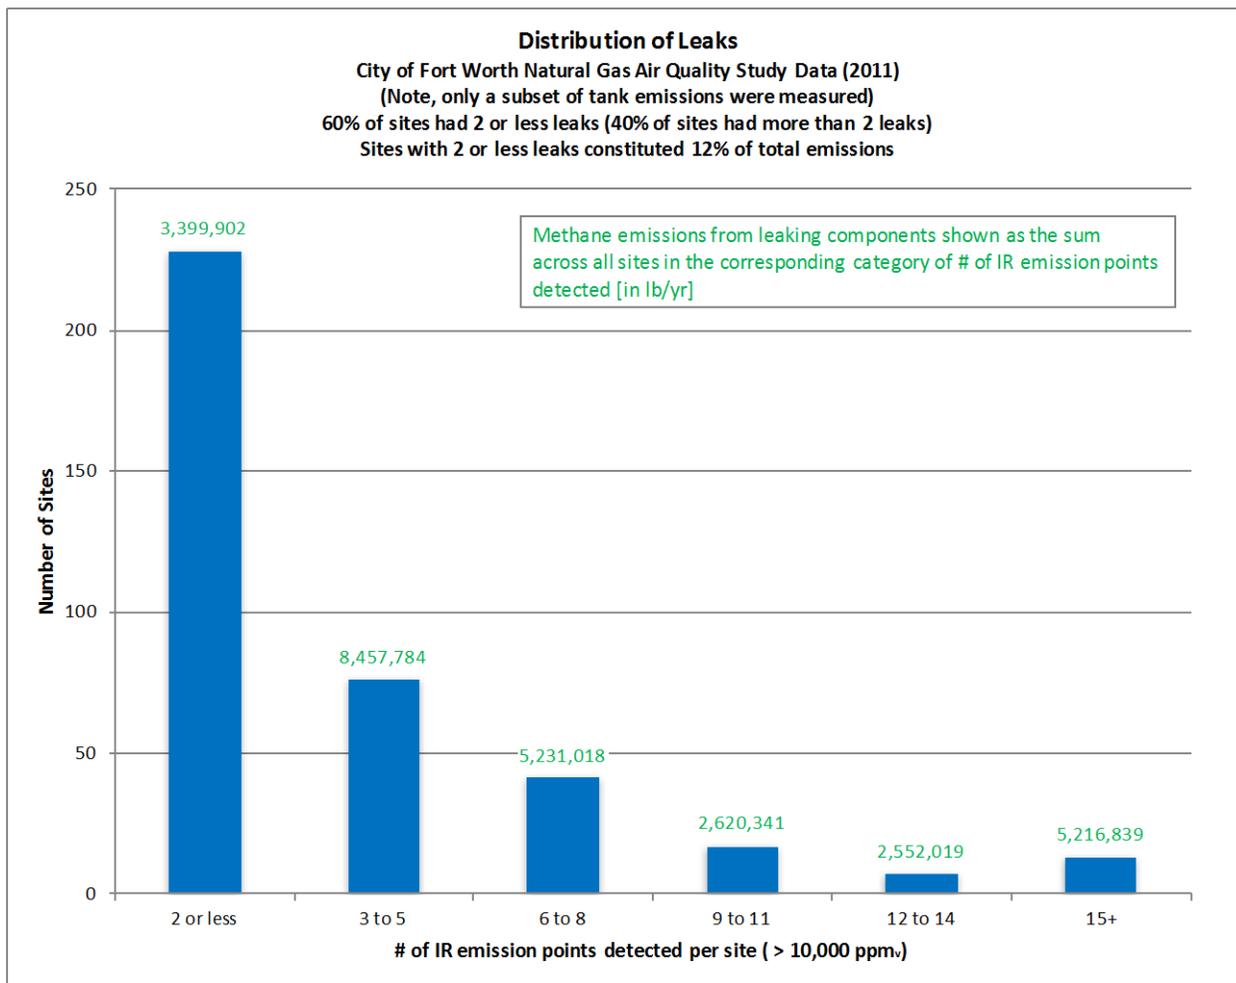

Paper that the well data provided in the Fort Worth report showed: “At least one leak was detected at 283 out of the 375 well pads monitored with an OGI technology with an average of 3.2 leaks detected per well pad; The TVA detected at least one leak greater than 500 ppm at 270 of 375 well pads that were monitored with an average of 2.0 leaks detected per well pad.”⁵³ These data indicate that significant emissions can occur at sites with few measured leaks.

Figure 3: Number of Sites versus Number of Equipment Leaks

⁵³ USEPA, “White Papers on Methane and VOC Emissions: Leaks,” available at <https://www3.epa.gov/airquality/oilandgas/2014papers/20140415leaks.pdf>. (Ex. 27)

Figure 4: Number of Sites versus Number of Large Leaks

Other LDAR rules, and information submitted by stakeholders during such rulemakings, further underscore the need for ARB to finalize a flat quarterly inspection requirement.

EPA recently finalized inspection requirements for well sites and compressor stations. EPA’s final rules require operators to inspect compressor stations quarterly and well sites semi-annually. EPA removed a provision that appeared in the proposal that would have allowed operators to reduce the inspection frequency based on the percentage of leaking components identified during an inspection. As EPA noted, “most commenters opposed performance-based monitoring frequency” on the grounds that such an approach is “costly, time-consuming, and impose[s] a complex administrative burden for the industry and states.”⁵⁴

Colorado recently proposed, and ultimately adopted, a leak detection and repair requirement that requires operators inspect for leaks at all but the smallest sites on a continuous annual, quarterly, or monthly basis.⁵⁵ This proposal had the support of three large oil and gas

⁵⁴ 81 Fed. Reg. at 35857.

⁵⁵ 5 C.C.R. 1001-9, CO Reg. 7, §§ XVII.C.2.b.(ii), XVII F, (Feb. 24, 2014).

producers, Noble Energy, Anadarko Petroleum Corporation, and Encana. Notably, Encana submitted testimony regarding its own voluntary LDAR program, which requires monthly instrument-based inspections. According to Encana, “Encana’s experience shows leaks continued to be detected well into the established LDAR program.”⁵⁶ Viewed somewhat differently, Encana’s data suggests that while the largest reductions in VOC emissions occur in the first year of an LDAR program, significant emissions reductions are still being realized in subsequent years of the LDAR program.”⁵⁷

Other information presented during the Colorado rulemaking further supports the need for frequent inspections over time. During the rulemaking, industry opponents of the Division’s proposal submitted data collected from their own LDAR monitoring experience. This data demonstrated an initial component leak rate frequency (before the first LDAR inspection) at new and modified gas processing plants of 1.7 percent.⁵⁸ The leak rate frequency falls to 0.4 percent after the first monitoring period and averages 0.3 percent over 12 consecutive calendar quarters. While it does support a decline after the first monitoring period, the data evidences a steady state of leak detection after that.

6. ARB Should Require All Leaks of 500 ppm be Repaired Upon Rule Implementation

The proposal sets the lowest leak threshold for the first year of the rule’s implementation at 10,000 ppm, and then lowers this to 1,000 in year two. A 10,000 ppm leak is a large leak, and we are not aware of any technical or other justification for allowing smaller leaks that can be detected to go unmitigated. Method 21 and OGI are both capable of detecting leaks smaller than 10,000 ppm. Moreover, other leading states with LDAR programs that contain quantitative leak thresholds such as Colorado and Pennsylvania require operators repair much smaller leaks of 500 ppm.⁵⁹ US EPA uses a leak threshold of 500 ppm for a number of LDAR requirements for new facilities under NSPS Subpart OOOO.⁶⁰ We therefore urge ARB to lower the initial leak threshold to 500 ppm to be consistent with these other states and to reflect what is technically feasible.

III. Underground Natural Gas Storage Facility Monitoring.

We applaud ARB on proposing rigorous monitoring provisions at underground natural gas storage facilities. The recent leaks at Aliso Canyon and McDonald Island demonstrate the unpredictable nature of leaks and the potential for such leaks to cause very significant harm to public health and the environment. The requirements that ARB has proposed will go a long way in ensuring that operators detect even small leaks immediately and repair them expeditiously.

⁶⁰ *See* 77 Fed. Reg. at 49490, 49498 (Aug. 16, 2016).

To address leaks from underground storage facilities, ARB has proposed a combination of ambient air monitoring and equipment monitoring. Specifically, operators must install a system capable of continuously monitoring the ambient air at the facility that can be accessed by ARB or local agencies.⁶¹ In addition, operators must perform either daily or continuous monitoring at wellheads, pipelines and the surrounding area within a 200 foot radius of the wellhead assembly.⁶² Operators must measure all leaks identified by the daily inspections or the continuous monitoring system in accordance with Method 21 (excluding the use of PID instruments) within 24 hours of detecting a leak, and repair all leaks measured above the thresholds specified in Section 95669 (the general LDAR provision) according to the timeframes specified in Section 95669.⁶³ Operators must notify ARB within 24 hours any time a leak is measured above the maximum leak threshold specified in Section 95669 or any time an air monitoring system detects levels of natural gas that exceed more than 10 percent of baseline conditions.⁶⁴ These provisions could be read as giving operators 24 hours from detection to measure a leak, and a subsequent 24 hours to report that measurement to ARB – in other words, two full days between detection and reporting. We therefore request that ARB clarify that operators must both measure any leak and report that measurement to ARB within 24 hours of detection, as we believe that this time frame is sufficient to accomplish both. The rule also requires operators to maintain records of leak measurements and submit an annual report containing leak measurement data.⁶⁵

The proposal contains a number of provisions that are critical to reducing the environmental, public health and safety threats of underground natural gas storage facilities. In particular, we strongly support the continuous ambient air monitoring combined with the daily or continuous equipment monitoring requirements. These provisions go beyond the requirements that currently apply to surface leak monitoring at natural gas storage facilities under emergency rules promulgated by the Division of Oil, Gas and Geothermal Resources (DOGGR) in response to the Aliso Canyon leak,⁶⁶ and also beyond new rules proposed by DOGGR. Indeed, per the DOGGR proposal, the ARB requirements will supersede the DOGGR surface leak monitoring requirements if ARB finalizes requirements that are at least as stringent, or more stringent, than DOGGR's rules.⁶⁷ The current draft meets this test.

We also support ARB's proposal to provide flexibility to operators in choosing what type of leak detection technologies to use in performing the daily equipment inspections.⁶⁸ As we

⁶⁷ DOGGR, Discussion Draft 14 C.C.R. Section 1726.7(e), available at <http://www.conservation.ca.gov/dog/Documents/Public%20Discussion%20Draft%20Requirements%20for%20Underground%20Gas%20Storage%20Proj.pdf>. (Ex. 32)

⁶⁸ *See id.* at Section 95668(i)(1)(B)(providing that operators may use Method 21, OGI or “other screening instruments”).

note in our comments on the general LDAR provision in Section 95669, we believe it is imperative that regulations incent or, at a minimum, allow for the use of emerging technologies, provided that there is a rigorous and transparent process whereby ARB can ensure that such technologies are at least as effective in detecting leaks as the methods explicitly allowed for in the rule. Along these lines, we urge ARB to issue clear guidelines that lay out the criteria for approval of “other screening instruments”⁶⁹ and provide an opportunity for public comment on any application to use an alternate screening instrument.

We support ARB’s proposal to require either daily screening or continuous monitoring of each natural gas injection/withdrawal wellhead assembly, attached pipelines and the surrounding area within a 200 foot radius of the wellhead assembly for leaks of natural gas; however, we request that this be expanded to include not just injection/withdrawal wells, but all wells in the field including but not limited to observation, monitoring, disposal, production and other wells, as leaks can occur from any of these well types. We also request that ARB clarify that the monitoring requirements apply not only to active wells but also to idle and plugged and abandoned wells. Given the age and long operating histories of California’s underground gas storage fields, monitoring all wells—not just active wells—is critical to detecting and stopping leaks. The Montebello and Playa Del Rey underground gas storage fields, for example, have long, documented histories of leakage from plugged and abandoned wells.⁷⁰

Lastly, it appears from the proposal that the inspection requirements in Section 95668 are intended to apply in lieu of the inspection requirements in Section 95669. However, this is not explicitly stated in the proposal. We suggest ARB clarify this in the final rule.

IV. Pneumatic Controllers and Pumps

Pneumatic equipment – natural gas driven pneumatic controllers and pneumatic pumps – are the source of enormous amounts of methane pollution. US EPA estimates that, nationwide, pneumatic equipment emitted over 3,100,000 metric tons of methane in 2014 – or 32 percent of estimated methane emissions from all oil and natural gas sources. As we describe below, cost effective technologies can essentially eliminate these emissions. We commend ARB for proposing strong standards for pneumatic equipment, but as we describe below, the proposed standards would still allow significant emissions from these types of equipment, and as such, ARB must strengthen the proposal.

ARB’s proposal:

- Prohibits venting of natural gas from any newly installed⁷¹ continuous-bleed pneumatic controller, regardless of the nominal bleed rate for the controller, and requires that all older continuous-bleed pneumatic controllers emit less than six standard cubic feet per

⁶⁹ *Id.*

⁷⁰ Chilingar, G. V., & Endres, B. (2005). Environmental hazards posed by the Los Angeles Basin urban oilfields: an historical perspective of lessons learned. *Environmental Geology*, 47(2), 302-317. (Ex. 33)

⁷¹ ARB’s proposal would not allow venting from any continuous-bleed pneumatic controller installed after January 1, 2016.

hour (scfh), including provisions requiring operators to annually verify compliance with this limit with direct measurements of the rate of venting.

- Requires operators of intermittent-bleed pneumatic controllers to verify that these devices are not emitting natural gas between actuation as part of periodic leak-detection inspections.

- Prohibits venting of natural gas from pneumatic pumps.

No other state prohibits all venting from new continuous bleed devices or new and existing pumps located at the suite of facilities subject to this proposal, nor includes all pneumatic devices, including intermittent bleed devices, in leak detection and repair requirements. These provisions will go a long way towards reducing emissions from new continuous-bleed pneumatic devices and pumps, and improperly functioning intermittent and continuous-bleed devices and pumps. Joint commenters support these provisions.

Nevertheless, ARB's proposal will continue to allow significant pollution from pneumatic controllers. In particular, the proposal will allow "grandfathered" continuous-bleed controllers to operate indefinitely, provided that their emissions remain below six scfh. And, it will allow both new and existing intermittent-bleed controllers that vent to the atmosphere to continue operating - again, indefinitely. Allowing these polluting devices to remain in operation is not necessary because, as we detail below, cost effective technologies are available to eliminate, or at least greatly reduce, venting from pneumatic controllers. ARB must strengthen the proposal so that harmful methane emissions from pneumatic controllers do not continue unnecessarily.

1. Zero-Emitting Alternatives to Natural Gas-Driven Pneumatic Controllers are Available

A number of alternative technologies and approaches that can eliminate, or at least drastically reduce, venting of natural gas from pneumatic controllers are available and in-use today at oil and gas facilities in the United States and Canada. These technologies/approaches include:

- Using compressed "instrument air," instead of natural gas, to drive pneumatic controllers.
- Using electronic control systems and electric valve actuators, instead of pneumatic controller and valve actuators, for valve automation. As described below, this approach can be used both at sites where electricity is already available and at sites without power by installing solar powered systems.
- For some applications, pneumatic controllers are available that do not release gas to the atmosphere, but rather release gas to a pressurized gas line. These are typically referred to as "bleed-to-pressure" or "integral" controllers.
- Gas released from pneumatic controllers can be routed to vapor collection systems (VCSs) or fuel lines.

Clean Air Task Force recently commissioned Carbon Limits to examine these and other alternatives to traditional, venting pneumatic controllers. Carbon Limits examined these

technologies in detail, conducting numerous interviews with oil and gas producers who have utilized them and with suppliers of these systems. The first two technologies listed above, instrument air and electric systems, are inherently non-emitting technologies; Carbon Limits' research shows that these technologies are mature and proven, with successful installation at hundreds of sites in North America. Furthermore, Carbon Limits demonstrates that for almost any configuration of oil and gas facilities, at least one of these technologies is cost effective as a means of methane abatement as compared to unmitigated natural gas-drive pneumatic controllers.

Instrument Air. Compressed air can be used instead of natural gas to drive devices. EPA's 2012 OOOO NSPS standards require all pneumatic controllers at processing plants to be zero emitting,⁷² and EPA presumes that most operators will use compressed "instrument air" systems to comply with this regulation.⁷³ Instrument air is a "well-established mature solution" to run pneumatic control systems and is in wide use globally. In fact, in some countries with significant oil production, instrument air systems are more common than natural gas-driven pneumatic controllers.⁷⁴

Instrument air systems offer several advantages over natural-gas driven pneumatic controllers, in addition to reduced emissions of methane and other pollutants in natural gas:

- Increased revenue from sales of natural gas that would otherwise be vented by gas-driven controllers.
- For many sites, instrument air systems can be simpler and cheaper to maintain. For gas-driven controllers, maintenance costs are significant if the gas at the site is wet (condensation of heavier hydrocarbons interferes with pneumatic controller operations) or sour. These costs are avoided with instrument air. Instrument air is very reliable; in contrast some sites with low gas-to-oil ratios may need to purchase natural gas or propane from offsite in order to ensure that sufficient gas is always available to drive pneumatic systems. These costs are all avoided with instrument air systems.⁷⁵

For sites with 20 or more pneumatic devices, instrument air is a cost effective and feasible approach to eliminate emissions from all types of pneumatic controllers and pneumatic chemical injection pumps or heat trace pumps when electric power is available from the grid or from on-site generators. Oil and gas production in California occurs largely in areas with access to electric power. Many centralized production sites and compressor stations have numerous pneumatic devices. Retrofit of sites with instrument air is straightforward because operators can use existing pneumatic controllers and actuators with instrument air systems.

Electric Systems. Gas-driven pneumatic controllers can now readily be replaced with electric systems at sites with and without electricity already available. These systems include electric valve actuators, electronic controllers, control panels and wiring, and—for sites without

⁷² 40 C.F.R. § 60.5390(b)(1).

⁷⁵ *Id.* at 18.

power available from the grid or from pre-installed on-site generators—solar panels and batteries.

These systems have become more mature and robust in recent years and are in use at hundreds of oil and natural gas production sites in the United States and Canada.⁷⁶ Operators report that these systems are reliable.⁷⁷ Like instrument air, these systems offer several advantages over natural-gas driven pneumatic controllers, in addition to reduced emissions of methane and other pollutants in natural gas, including:

- Increased revenue from sales of natural gas that would otherwise be vented by gas-driven controllers.
- Like instrument air, greater reliability and lower maintenance for sites with wet or sour gas, which degrades performance of gas-driven pneumatic controllers, or for sites where sufficient and steady supply of natural gas is not available.⁷⁸
- Easier and less expensive site level automation (for example, with Supervisory Control and Data Acquisition (SCADA) systems).⁷⁹ Installation of electric systems can greatly reduce costs for operators if they enable less frequent site visits. Furthermore, these systems can perform important functions such as shutting in wells in the event of large leaks, offering further environmental (and potentially health and safety) benefits. The value of these systems is recognized by ARB in the underground storage monitoring provisions of the proposed rules.

Cost Effectiveness of Instrument Air or Electric Systems as Alternatives to Gas-Driven Pneumatic Controllers. Instrument air and electric systems are mature, reliable technologies. When electric controllers are combined with solar power systems, these non-emitting technologies are widely applicable.⁸⁰ Indeed, these technologies are widely used in California. Data from the ARB Oil and Gas Industry Survey for 2007 shows that both of these approaches are very widely used in California. 37 percent of controllers in the state were electric, while 47 percent were instrument air driven (and a full 87 percent of valve actuators in the state were air driven).⁸¹

Carbon Limits also found that these technologies are cost effective as alternatives to traditional gas-driven pneumatic controllers at a wide variety of oil and gas facilities. Carbon Limits used the capital and operating costs of these systems and traditional pneumatic

⁷⁶ *Id.* at 12.

⁷⁷ *Id.* at 15.

⁷⁸ *Id.* at 15.

⁷⁹ *Id.* at 15.

⁸⁰ Carbon Limits reports that instrument air is applicable at larger sites (roughly 20 or more controllers on site) when power is available from the grid or from an on-site generator (*See* Carbon Limits at 18) and that electric controllers are applicable at sites of all sizes if power is available, and, in combination with solar power, applicable at smaller sites (20 or fewer controllers) when power is not otherwise available. *See id.* at 15. However, Carbon Limits reports that there is no technical barrier to the use of electric controllers with solar panels at larger sites; there is simply little known precedent of this type of installation. *See id.* at 16.

⁸¹ ARB (2013), *2007 Oil and Gas Industry Survey Results - Final Report (Revised)*, at Table 9-2. (Ex. 36)

controllers,⁸² together with highly conservative estimates of emissions from gas-driven pneumatic controllers⁸³ and other parameters such as the value of conserved natural gas⁸⁴ to calculate the net cost of these systems per metric ton of avoided methane pollution, using a net present value formulation. Because there are a wide variety of site configurations for oil and gas sites, and because costs for these systems do not vary in a simple linear fashion with the number of controllers at the site and other parameters, Carbon Limits calculated the costs of both instrument air systems and electric systems for many permutations of a large number of site parameters, including:

- The number of pneumatic controllers at the site (1 – 40 controllers for electric systems, 21-40 controllers for instrument air systems).
- The number of pneumatic pumps at the site (0 – 1 pump).
- The type of pneumatic controllers at the site (from all continuous-bleed to all intermittent-bleed).
- The type of gas at the site (wet gas or dry gas).
- New site or retrofit site.
- Whether electricity is available at the site (for electric controllers at sites with 20 or fewer controllers).

Carbon Limits used US EPA's latest calculation of the social cost of methane (SC-CH₄) as the threshold for cost effectiveness. Specifically, they used the mean value of the SC-CH₄ calculated for a 3 percent discount rate for emissions in 2020, in 2016 dollars, or \$1,354 per metric ton of methane, as the threshold.⁸⁵ Using the global warming potential for methane of 72, which ARB uses in this rulemaking, the abatement costs ARB calculates for the proposed standards translate to abatement costs within the range of the social cost of methane.⁸⁶ In fact, the total abatement costs for the rule are lower than the 2016-adjusted SC-CH₄ calculated by ARB.

⁸² Costs were derived from interviews with oil and gas producers, system and component suppliers, and online quotes from component suppliers.

⁸³ Carbon Limits, *supra* note 74, at 21-22.

⁸⁴ The report uses a very low price of natural gas, \$2 per thousand cubic feet (mcf). *See id.* at 21.

⁸⁵ EPA reports that the mean SC-CH₄ emitted in 2020, calculated with a 3% discount rate, will be \$1,300 per metric ton CH₄ in 2012 dollars. EPA RIA, *supra* note 40. This is converted to \$1,354 per metric ton in 2016 dollars using a cumulative rate of inflation of 4.2 percent.

⁸⁶ ARB Economic Analysis at Table B-2.

TABLE 1

| ARB Rule Provision Methane Reduction Costs per Ton | VRU For Tanks | Reciprocating Compressors | LDAR | Pneumatic Devices | Well Simulations | Centrifugal Compressors | Total |
|--|---------------|---------------------------|---------|-------------------|------------------|-------------------------|---------|
| Cost Per Ton (\$/MTCH ₄ reduced) | \$648 | \$288 | \$1,224 | \$288 | \$6,552 | \$144 | \$1,224 |
| Cost Per Ton with savings (\$/MTCH ₄ reduced) | \$576 | \$72 | \$1,008 | \$72 | \$6,552 | (\$72) | \$1,080 |

Source: Table adapted from Table B-6 of Appendix B: Economic Analysis for the proposed rule. Costs in Table B-6 were converted to \$/metric ton of methane using the IPCC AR4 20-year GWP of 72, per the ARB rulemaking analyses.

It should be noted that the SC-CH₄ costs are likely conservative. Experts widely acknowledge that social cost estimates are almost certainly underestimates of true global damages—perhaps severe underestimates. Using different discount rates; selecting different models; applying different treatments to uncertainty, climate sensitivity, and the potential for catastrophic damages; and making other reasonable assumptions could yield very different, and much larger, social cost estimates for carbon and methane.⁸⁷

In general, replacing gas-driven pneumatic controllers with either instrument air or electric controllers (or both) is cost effective at the vast majority of site configuration, even with highly conservative assumptions about emissions factors for pneumatic controllers. This finding holds for both new installations and retrofit of existing sites with pneumatic controllers. In fact, Carbon Limits found that these technologies would *not* be cost effective for just a handful of site configurations. For example, at least one of the technologies is cost effective at:

- All sites with one (or more) pneumatic pumps.
- Any new wet gas site with more than two pneumatic controllers.

For large sites with electricity, instrument air is cost effective for:

- All retrofit sites.
- All wet gas sites.

As mentioned above, these results were calculated with very conservative (low) emissions factors for gas-powered pneumatic controllers. For example, at new sites, Carbon Limits assumes that each continuous-bleed pneumatic controller will have an emissions factor of 1.39 scfh.⁸⁸ This is EPA’s emissions factor for low-bleed pneumatic controllers,⁸⁹ which operators are required to use for new continuous-bleed pneumatic controllers under NSPS Subpart

⁸⁷ Richard L. Revesz, Peter H. Howard, Kenneth Arrow, Lawrence H. Goulder, Robert E. Kopp, Michael A. Livermore, Michael Oppenheimer & Thomas Sterner, *Global Warming: Improve Economic Models for Climate Change*, 508 NATURE 173 (2014). Available at: http://www.nature.com/polopoly_fs/1.14991!/menu/main/topColumns/topLeftColumn/pdf/508173a.pdf. (Ex. 37) This study focuses on social cost of carbon, but the EPA NSPS RIA notes that “because the SC-CO₂ and SC-CH₄ methodologies are similar, the limitations also apply to the resulting SC-CH₄ estimates.” (RIA Section 4.3).

⁸⁸ Carbon Limits, *supra* note 74, at 22.

⁸⁹ See for example, 40 CFR Part 98, Subpart W, Table W-1A.

OOOO.⁹⁰ However, both NSPS Subpart OOOO⁹¹ and ARB's proposed standards for continuous-bleed pneumatic controllers (proposed § 95668(f)(2)(A)(1)) allow the use of devices that emit up to 6 scfh. Further, several recent studies based on measured emissions from pneumatic controllers have found higher average emissions from continuous-bleed pneumatic controllers classified as "low-bleed controllers."⁹² If emissions factors consistent with these studies are used instead of the very conservative emissions factors used in the calculations described above, even more sites would have abatement costs below the SC-CH₄.⁹³

In summary, Carbon Limits found that, even with very conservative assumptions, electric systems and instrument air systems are cost effective at a broad range of oil and gas facility site configurations.

Other Approaches to Eliminate Pneumatic Controller Emissions. It is important to note that other approaches can be used to eliminate emissions from pneumatic controllers, beyond instrument air and electric controllers. As listed above, two important approaches are use of "self-contained" or "integral" controllers which are designed to release the gas used in the controller into a gas pipeline, typically downstream of the controller and the valve it actuates, and routing emissions from pneumatic controllers to vapor collection systems. Data from the ARB Oil and Gas Industry Survey for 2007 shows that both of these approaches are in use in California. California operators captured gas from 6 percent of intermittent-bleed pneumatic controllers and 11 percent of piston valve actuators driven by natural gas, statewide; operators also reported 1,054 "no-bleed" controllers, which appear to self-contained/integral controllers (note that air-driven and electric controllers are separate categories in the survey).⁹⁴

Carbon Limits notes that these technologies may be applicable and cost effective for oil and gas installations, and that they represent useful alternatives to instrument air and electric controllers.⁹⁵

Summary. There are a number of non-emitting technologies and approaches that can be used in lieu of traditional gas-driven pneumatic controllers. All are in use in California. The most significant of these from both effectiveness and cost perspectives are instrument air and electric systems. Recent analysis by Carbon Limits shows that, even with very conservative assumptions, electric systems and instrument air systems are cost effective technologies to reduce methane emissions at a broad range of oil and gas facility site configurations.

2. *ARB Should Phase Out Existing Low-Bleed Continuous Devices and Require Quarterly Testing of Bleed Rate*

The proposed regulation is significantly weaker than the draft regulation that CARB posted on April 22, 2015. The proposal allows the use of continuous-bleed pneumatic devices installed before January 1, 2016, provided operators adhere to the provisions in proposed § 95668(f)(2)(A), which requires that these devices emit less than 6 scfh and that operators annually check that these devices are not emitting more than that amount and fix or replace them if they do emit over this threshold. This “grandfather” clause that allows for the *indefinite* use of continuous bleed devices is not warranted, in light of the fact that operators have a number of alternatives to continuous-bleed pneumatic controllers, and the finding that electric controllers and instrument air are proven, mature, widely applicable and cost effective technologies.

We thus recommend that ARB remove the provision allowing “low-bleed” continuous-bleed pneumatic devices that were in operation on January 1, 2016 to continue operating. If ARB concludes that such devices must be allowed to continue venting gas into the atmosphere, despite the numerous options operators have to eliminate these emissions, ARB must limit the period over which operators are allowed to continue these harmful emissions to at most a few years. Indefinite grandfathering is not warranted.

Further, the February 1, 2016 draft rule required operators to test existing devices “during each inspection period as specified in section 95669 by using a direct measurement method (high volume sampling, bagging, calibrated flow measuring instrument)”.⁹⁶ However, the current draft only requires annual testing.⁹⁷ As ARB provided no explanation for the change in testing requirements and testing devices during inspections is feasible and necessary to ensure bleed rate information is up to date, we recommend that ARB amend the current proposal to require testing during each quarterly LDAR inspection, as previously proposed.

3. *Control Emissions from Intermittent-bleed Pneumatic Devices*

ARB’s proposal for intermittent-bleed pneumatic controllers will reduce emissions from these ubiquitous devices, due to the specific annual testing requirements to ensure that these devices do not leak gas into the air when not actuating.⁹⁸ However, we reiterate our concern that, beyond this provision, the proposed regulation, like previous drafts, does not limit emissions from these devices.

These devices are a very significant source of emissions. Oil and gas producers reported over 850,000 metric tons of methane emissions nationwide in 2014 from intermittent-bleed

⁹⁶ CARB Proposed Regulation Order, February 1, 2016 Draft, § 95668(f)(2)(C). Available at http://www.arb.ca.gov/cc/oil-gas/meetings/Draft%20ARB%20OG%20Regulation_Feb%201%202016%20Clean.pdf. (Ex. 39)

⁹⁷ Appendix A: Proposed Regulation order § 95668(f)(2)(A)(3).

⁹⁸ Proposed § 95668(f)(3).

devices to US EPA’s GHGRP, far higher than the 161,000 metric tons of methane they reported from continuous-bleed devices (both high-bleed and low-bleed).⁹⁹

Intermittent-Bleed Controller Counts for California. There is very strong evidence that there are a significant number of intermittent-bleed pneumatic controllers in California. Operators in California oil and gas production basins reported over 4,100 tons of methane in 2014 from over 2,000 intermittent-bleed devices, while reporting no emissions at all from continuous-bleed devices (see Table 2).¹⁰⁰ Alarming, reported emissions from intermittent-bleed devices are increasing, both nationwide and in California (California counts leveled off between 2013 and 2014, see Table 3).¹⁰¹

Table 2. Device counts and methane emissions (in metric tons of methane) for high-bleed, intermittent-bleed, and low-bleed pneumatic controllers from oil and natural gas production basins in California as reported to US EPA’s GHGRP for 2014. All listed AAPG oil and gas production basins are entirely within California. 730: Sacramento Basin; 745: San Joaquin Basin; 750: Santa Maria Basin; 760: Los Angeles Basin.

¹⁰⁰ *Id.*

¹⁰¹ *Id.*

Table 3. EPA GHGRP Reported Onshore Production Pneumatic Device Counts by Type in California for 2011-2014. Counts are the sum of counts from the four basins shown in Table 2 above.

| Pneumatic Device Type | 201 1 | 201 2 | 201 3 | 201 4 |
|--------------------------------------|-------------------|-------------------|-------------------|-------------------|
| High-Bleed Pneumatic Devices | 23 | - | - | - |
| Intermittent Bleed Pneumatic Devices | 1,9 54 | 3,2 83 | 4,1 43 | 4,1 27 |
| Low-Bleed Pneumatic Devices | 16 | - | - | - |
| Grand Total | 1,9 92 | 3,2 83 | 4,1 43 | 4,1 27 |

Reporters to the GHGRP determine pneumatic device type “using engineering estimates based on best available information.”¹⁰² That is, operators make the determination as to pneumatic device type according to engineering assessments and available information regarding the device. Determining whether a pneumatic controller is designed to release gas intermittently or continuously is fairly straightforward. While emissions from these devices and the industry as a whole have received significant attention in recent years,¹⁰³ we are aware of no evidence or arguments that operators are over-reporting the number of intermittent-bleed controllers.

Further, according to the ARB Oil and Gas Industry Survey for 2007, there were at least 405 intermittent bleed pneumatic devices in California (accounting for about 25 percent of the total natural gas driven pneumatic controllers in the survey inventory). This information was reported a number of years ago, whereas the most recent GHGRP data is for 2014 and was reported in 2015. With the increased attention on emissions in recent years and the requirements of the GHGRP in place for several years, operators may now be more aware of the population of specific types of pneumatic controllers at their facilities than they were in 2007. In addition, operators may have installed more new intermittent-bleed controllers and/or replaced some of their continuous-bleed controllers with intermittent-bleed controllers in response to federal regulations that prohibit the installation of new high-bleed continuous controllers.¹⁰⁴

Finally, we note that the ARB MRR data for various types of pneumatic controllers may be flawed. Unfortunately we have not been able to extract data for emissions specifically from intermittent-bleed controllers, or counts of intermittent-bleed controllers, from the publically available data from this program. However, the ARB MRR apparently requires operators to sort intermittent-bleed controllers into low-bleed and high-bleed categories (based on the 6 scfh threshold) for reporting controller *counts* in Cal e-GGRT, while *emissions* from all intermittent-bleed controllers are calculated using a single emissions factor (13.5 scfh), regardless of the bleed rate:

¹⁰² 40 CFR § 98.233(a)(3).

¹⁰³ For example, Allen *et al.* (2015), *supra* note 13; also US EPA, *Inventory of U.S. Greenhouse Gas Emissions and Sinks 1990-2014: Revisions to Natural Gas and Petroleum Production Emissions*, (2016). Available at: <https://www3.epa.gov/climatechange/Downloads/ghgemissions/US-GHG-Inventory-2016-Main-Text.pdf>. (Ex. 40)

¹⁰⁴ 40 C.F.R. 0000 (2012).

3.14 How should emissions from unmetered, natural gas-powered intermittent-bleed pneumatic devices be quantified and reported, if the operator has documentation demonstrating that the actual bleed rate for the devices is less than six scf per hour?

Pursuant to MRR, “intermittent bleed devices which bleed at a cumulative rate of six standard cubic feet per hour or greater are considered high bleed devices” (section 95102(a)(252)), therefore, *emissions from devices that exceed this limit must be reported as high-bleed* in Cal e-GGRT and are subject to a compliance obligation under the Cap-and-Trade Program. A low-bleed pneumatic device is defined in MRR as a device that “vents continuously or intermittently bleeds to the atmosphere at a rate equal to or less than six standard cubic feet per hour” (section 95102(a)). *Low-bleed pneumatic devices must be reported as low-bleed* in Cal e-GGRT and emissions from such devices are not subject to a compliance obligation under the Cap-and-Trade Program.

Emissions from all unmetered, natural gas-powered intermittent-bleed pneumatic devices must be quantified using the “intermittent bleed” emission factor of 13.5 scf/hour/component listed in Table 1A of Appendix A of MRR, using Equation 2 (section 95153(b)), regardless of bleed rate. If the operator has documentation that demonstrates that the devices bleed at an actual rate of less than six scf/hour/component, such as original equipment manufacturer’s specifications, or measurement data, the operator must still quantify the emissions using the 13.5 scf/hour/component emission factor; however, the emissions may be reported as “low bleed” pneumatic emissions in Cal e-GGRT. If the device bleeds at a rate of six scf/hour/component or greater, or there is no documentation available that demonstrates that the actual bleed rate of a device is less than or equal to six scf/hour/component, the emissions for such devices must be reported as “high bleed” pneumatic device emissions in Cal e-GGRT.¹⁰⁵

This treatment of intermittent-bleed pneumatic controllers is confusing at best and suggests that ARB MRR data may not be usable to differentiate intermittent-bleed and continuous-bleed controller counts and emissions.

In summary, the available evidence shows that there are thousands of intermittent-bleed pneumatic controllers in California, with thousands of metrics tons of methane emissions. Since the proposed regulation does not allow new installation of continuous-bleed pneumatic controllers that vent to the atmosphere, but allows continued installation of intermittent-bleed pneumatic controllers, we can expect more intermittent controllers to be installed in the future, making this source of methane pollution grow.

Emissions from Properly-Operating Intermittent-Bleed Pneumatic Controllers can be Substantial. While ARB’s proposal addresses one important source of emissions from intermittent-bleed pneumatic controllers – the fact that they frequently operator improperly and emit continuously – the emissions from properly operating devices will remain high without additional standards.

¹⁰⁵ ARB (2016), *Petroleum and Natural Gas Systems Emissions Reporting Guidance for California’s Mandatory Greenhouse Gas Reporting Regulation*, at Section 3.14 (emphasis added). Available at: <http://www.arb.ca.gov/cc/reporting/ghg-rep/guidance/oil-gas.pdf>. (Ex. 41)

Not all intermittent-bleed devices actuate frequently under normal and expected operating conditions – but some actuate very frequently, and therefore emit large amounts of natural gas. For example, Allen *et al.* (2015) observed that controllers for emergency shut-off devices (ESDs) made up 12 percent of the population of controllers that they studied.¹⁰⁶ These devices will actuate very rarely, if at all. In contrast, some intermittent-bleed devices actuate very frequently. Of the 377 devices studied by Allen *et al.* (2015), 24 were intermittent-bleed devices that actuated at least 10 times during the sampling period, which was typically 15 minutes. Four actuated over 50 times while sampled.¹⁰⁷ These devices can emit at high levels – five of the 40 highest emitting devices studied by Allen *et al.* (2015) are intermittent-bleed devices that the researchers assessed to be operating properly.¹⁰⁸ These controllers emitted up to 40 scfh of whole gas.¹⁰⁹ Devices with certain specific functions, such as level controllers on separators, are likely to actuate frequently.

Since the proposed standard for intermittent-bleed pneumatic controllers does not limit emissions during actuation in any way, operators would not be required to reduce these high emissions in any way.

Suggested Approach. As noted above in Section X.1, reliable non-emitting alternatives to intermittent-bleed pneumatic controllers are available today. These technologies are mature and generally applicable and have been deployed at hundreds of sites, including in California. Critically, using these technologies as alternatives to intermittent-bleed pneumatic controllers is cost effective as a means of reducing methane emissions.

As such, ARB’s standards should prohibit or phase out venting emissions from intermittent-bleed pneumatic controllers to the atmosphere. If ARB concludes that it is warranted, specific treatment of certain intermittent-bleed devices that very rarely actuate, such as ESDs could be appropriate. However, the fact that some controllers very rarely actuate cannot be used to justify inaction for the entire class of intermittent-bleed controllers.¹¹⁰

If ARB concludes that a simple standard prohibiting venting from intermittent-bleed pneumatic controllers is not warranted, despite the numerous alternative approaches and technologies that can be used to entirely avoid these emissions, then a standard that limits emissions from these devices is needed. Even where venting natural gas-driven pneumatic devices are used, lower-bleed intermittent pneumatic devices are available. Properly designed

¹⁰⁶ Allen *et al.* (2015), *supra* note 13.

¹⁰⁷ Derived from analysis of table S4-1 in *id.*, supplemental information. Available at: <http://pubs.acs.org/doi/suppl/10.1021/es5040156>. (Ex. 5b)

¹⁰⁸ See *id.* Supporting Information, section S-8. Temporal profiles of emissions from the 40 highest-emitting controllers sampled in the study are shown. Controllers LB01-PC01, LB07-PC01, LB04-PC01, LB06-PC05, and LB04-PC03 – five of the 40 highest emitting controllers – are clearly intermittent devices which were assessed to be “operating as expected.”

¹⁰⁹ *Id.* Controller LB01-PC01 emitted 40.2 scfh whole gas; the range for the controllers listed in the previous footnote was 19.1 – 40.2 scfh.

¹¹⁰ Since some intermittent-bleed devices actuate very rarely, their emissions are low. These devices bring the average emissions factor for intermittent-bleed devices down.

intermittent bleed devices can emit below 6 scfh in many applications.¹¹¹ The US EPA emissions factor for intermittent bleed pneumatics in natural gas transmission is 2.35 scfh,¹¹² well below 6 scfh. Wyoming requires *all* pneumatic controllers to be low emitting, regardless of whether they are continuous-bleed or intermittent-bleed, at new and modified facilities.¹¹³ ARB could require operators to measure emissions from intermittent-bleed devices just as operators of continuous-bleed devices would be required to measure emissions. To verify that emissions were not above the threshold in the standard, a simple sampling protocol could be written, requiring measurement over a certain period of time, capturing emissions from any actuations that occurred during that time. Straightforward specifications for the time response and dynamic range of instrumentation could ensure that the devices used for these measurements accurately quantify the high flow rate from the controller occurring during actuation. This measurement approach would be similar to that used during a number of recent measurement studies of pneumatic controllers and other equipment, which included measurements from pneumatic controllers.¹¹⁴

Standards as described above would substantially reduce methane emissions at a reasonable cost, and serve as an important model for reducing emissions from pneumatic controllers in other jurisdictions.

4. *Pneumatic Pumps*

We commend ARB's proposal to require capture of all emissions from natural gas-driven pneumatic pumps. Pneumatic pump emissions can readily be routed to vapor collection systems; US EPA now requires emissions from new pneumatic pumps to be routed to a control device if such a device is on the site where the pneumatic pump is installed.¹¹⁵ Electric pumps are also available to perform the duties of pneumatic pumps. For example, solar-powered chemical injection pumps are quite common,¹¹⁶ and in general pumps can be electrified when electric controllers are adopted at a site, including when solar panels are used to power the systems. In fact, these systems become significantly more cost effective when they include electrification of a pneumatic pump.¹¹⁷

We believe that ARB intends the standards to apply to glycol assist pneumatic pumps, referred to as "Kimray Pumps" in EPA's GHG Inventory. These pumps are estimated to emit

¹¹¹ In their comments on EPA's 2012 oil and gas rules, the American Petroleum Institute stated, "Achieving a bleed rate of < 6 SCF/hr with an intermittent vent pneumatic controller is quite reasonable since you eliminate the continuous bleeding of a controller." In fact, API advocated intermittent-bleed devices to achieve the 6 scfh bleed rate, rather than continuous low-bleed devices. American Petroleum Institute, "Technical Review of Pneumatic Controllers," at 7 (Oct. 14, 2011), available as Attachment K to American Petroleum Institute, Comment on OOOO New Source Performance Standards (Nov. 30, 2011), <http://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2010-0505-4266>. (Ex. 42)

¹¹² 40 C.F.R. Pt. 98, subpart W, Table W-3.

¹¹³ This requirement is applied to intermittent-bleed controllers in addition to continuous-bleed controllers (email from Mark Smith, WDEQ, to David McCabe, September 22, 2014. Available at: http://www.arb.ca.gov/cc/oil-gas/meetings/CATF_et_al_attachment2_02192016.pdf). (Ex. 43)

¹¹⁷ *Id.* at 26.

76,418 metric tons of natural gas per year (nationwide), while chemical injection pumps are estimated to emit 321,777 tons.¹¹⁸ Control of emissions from glycol assist pumps is somewhat less straightforward than control of emissions from chemical injection pumps, because the natural gas used to drive the pump is typically emitted via the dehydrator vent stack. However, there are a number of options to eliminate emissions from these pumps. Electrification is an option for these pumps, just as it is for chemical injection pumps.¹¹⁹ A secondary option is the use of a low-pressure glycol separator, which can separate methane-rich gas from the glycol before it enters the regenerator.¹²⁰ If this is done, the gas can be used to fuel the boiler on the regenerator or otherwise consumed for fuel on-site.¹²¹ Finally, controls are often used to reduce emissions from dehydrator vent stacks. However, some of these controls, which are typically designed to reduce emissions of volatile organic compounds and hazardous air pollutants, will not reduce methane emissions from the dehydrator vent stack even when operating correctly.¹²² Methane from a glycol assist pump will not be abated by these types of dehydrator controls.

ARB must ensure that all methane emissions from glycol assist pumps are properly controlled and that operators are not relying on dehydrator vent stack controls that will not properly control methane, such as condensers or carbon absorption systems, to control methane emissions from these pumps. As described above, there are a number of means to eliminate methane emissions from these pumps. Of course, in the case of dehydrators with controls that do not reduce methane emissions, the most appropriate approach would be to improve the emissions control on the dehydrator to reduce methane emissions from the glycol assist pump and from the dehydrator itself.

V. Reciprocating Compressors

We support ARB's approach to control emissions from all compressors, both in the production and non-production segments, through either vapor collection systems or through requirements to measure emissions at the vent point and to repair when those emissions exceed thresholds. The scope of ARB's proposed requirements on compressors is commendable as it addresses the emissions of compressors on well pads – something that EPA's recently finalized subpart OOOOa regulations fail to do. Moreover, measurement from compressors located in the midstream segments – those at natural gas gathering and boosting stations, processing plants, transmission compressor stations and underground storage facilities – will provide more useful data on the emissions of those compressors.

Furthermore, it is encouraging that pursuant to section 95668(d)(3)(A) and 95668(d)(3)(B), CARB's proposal would require inspections for leaks originating from

¹²⁰ Kimray, Inc., "Glycol Pumps Product Bulletin," (July 2011), at 3. (Ex. 45)

¹²¹ *Id.*

¹²² For example, the National Emissions Standards for Hazardous Air Pollutants applicable to glycol dehydrators at certain facilities (NESHAP Subpart HH) allows the use of condensers or carbon absorption systems to control emissions. See 40 C.F.R. § 63.771(d)(1)(ii) and § 63.771(f)(1)(ii). These systems will not control methane emissions (the boiling point of methane is far too low for it to be captured by a condenser, and methane is not absorbed by activated charcoal to any significant degree).

compressor components and rod packing seals from production compressors at the same frequency as that required by the LDAR provisions in section 96669(g).¹²³ Likewise, ARB's proposal requires frequent inspection of non-production compressor *components*.¹²⁴ However, CARB should extend that same requirement for frequent checks to emissions from rod packing seals to non-production compressors.

While ARB's proposed rule has many helpful and protective requirements, it should be strengthened. Since even the best new, properly installed rod packing seals allow some escape of natural gas,¹²⁵ vapor collection systems should be required whenever possible. We agree that there should be an alternative option to monitor emissions by measuring and repairing rod packing when the measured flow rate exceeds an established threshold, but that alternative should be applicable only when utilization of vapor collection system is not feasible. We note that the Ohio EPA has released a draft general permit that requires operators to capture all emissions from reciprocating compressor rod packing and direct those emissions to sales, fuel lines, or 98 percent control.¹²⁶ Even if directing collected vapors to one of the uses described under proposed section 95668(c)(2) is not possible, ARB should require operators to capture and control emissions with a vapor control device as described in proposed section 95668(c)(3)-(4).

We commend ARB for requiring flow rate measurements at the rod packing or seal vent stack, as opposed to measuring hydrocarbon concentration, for compressors at gathering and boosting stations, processing plants, transmission compressor stations and underground natural gas storage facilities. This method of direct flow rate measurement (*i.e.*, high volume sampling, bagging or calibrated flow measuring instrument) provides a much more accurate representation of the actual emissions, whereas hydrocarbon concentration is more weakly correlated with emissions.¹²⁷ Routing emissions through a vent stack makes measurements more accurate and more feasible for operators. However, as was the case with the draft standards, ARB's proposed regulations still only require annual measurements for non-production compressors when a vapor collection system is not installed. ARB should finalize a quarterly measurement frequency under proposed section 95668(d)(4)(B). Infrequent annual measurements can lead to two problems. First, annual measurements would allow potentially elevated emissions to continue over a longer period than quarterly measurements would allow. Second, the lax annual frequency could encourage operators of non-production compressors without vapor collection systems to continue operating without such systems. Therefore, ARB should require quarterly measurements for non-production compressors. As we have argued previously, direct measurement of emissions rates with instruments such as flow meters and high-flow samplers is inexpensive and some vendors providing LDAR service routinely measure emissions rates in this manner; requiring measurement of the emission rate at every regular LDAR inspection would only entail very minimal additional cost.

¹²³ As discussed in more detail above, improvements to the section 95669 are needed.

¹²⁴ Proposed section 95668(d)(4)(A).

¹²⁵ ARB Staff Report, *supra* note 2 at 97, Table 9.

¹²⁷ Clearstone Engineering *et al.* (2006), *Cost-Effective Directed Inspection and Maintenance Control Opportunities at Five Gas Processing Plants and Upstream Gathering Compressor Stations and Well Sites*, 3 (available at http://www.epa.gov/gasstar/documents/clearstone_II_03_2006.pdf). (Ex. 47)

Additionally, the flow rate threshold at which ARB would require repair or replacement of rod packing or seals is far too high. As proposed, section 95668(d)(4)(D) requires repair of rod packing or seals when the measured flow rate is greater than 2 scfm per cylinder. ARB's analysis shows that using this threshold will result in costs of \$1.17/MT CO₂e, or \$84/MT methane.¹²⁸ Based on the Oil and Gas Industry Survey, ARB's analysis assumes that a compressor over 250 HP has on average 3.45 cylinders, and that the average leak rate for a cylinder during pressurized operation is 0.9 scfm.¹²⁹ Data from the survey shows that the average compressor cylinder that is emitting over the threshold of 2 scfm is emitting 3 scfm.¹³⁰ In calculating the reductions, ARB simply estimated a reduction of 1 scfm per cylinder in order to comply with the proposed standard.¹³¹ This vastly underestimates the emissions reductions that would be achieved under the proposed requirement to repair rod packing or seals if the flow rate exceeds 2 scfm.

As shown in ARB's Staff Analysis, a rod packing flow rate of 2 scfm is labeled as "poor" condition.¹³² Presumably, ARB's proposed regulation would require an operator to repair the rod packing to better than poor condition. Indeed, EPA estimates that new rod packing should emit 11-12 scfh, or roughly equivalent to 0.19 scfm. We recalculated abatement costs using the same methodology and cost inputs as ARB used in the Economic Analysis. However, for the emissions reduction achieved by the rule, we used 2.81 scfm (3 scfm to 0.19 scfm) instead of 1 scfm (3 scfm to 2 scfm) as ARB used. The resulting costs were -\$1.27 per ton CO₂e, *i.e.* the policy has net savings for operators.

Using a slightly different approach to calculating abatement cost from EPA's Natural Gas Star, but with ARB's cost assumptions¹³³ we calculated a number of different net abatement costs using the reductions that would be achieved using EPA's 0.19 scfm emission rate for a new rod packing.¹³⁴ The abatement costs calculated this way are somewhat different, but they appear to be more conservative than ARB's calculations and they show net savings at ARB's current repair threshold of 2 scfm, consistent with the calculation shown above. As Table 4 shows, ARB's cost analysis substantially overestimates the actual cost to operators and the costs of significantly tighter standards than ARB's proposed standard would be reasonable. At a flow rate threshold of 2 scfm the net cost per ton of methane removed is actually negative, meaning operators would make more money from the sale of the conserved gas than they incurred in costs. The total cost would be zero if ARB lowered the flow rate threshold to 1.82 scfm, and the net abatement cost approaches ARB's estimated average cost for the entire regulation at 0.48 scfm.

¹²⁹ *Id.* at B-29.

¹³⁰ *Id.* at B-29.

¹³¹ *Id.* at B-29.

¹³² ARB Staff Report, *supra* note 2 at 97, table 9.

¹³³ A cost of \$6,000 per rod packing, a 5 percent interest rate, an average of 6,546 pressurized operating hours and a price of \$3.44/mcf for gas.

¹³⁴ US EPA "Reducing Methane Emissions from Compressor Rod Packing Systems" (2006), available at: https://www3.epa.gov/gasstar/documents/ll_rodpack.pdf. (Ex. 48)

Table 4

| Replacement Threshold | | Net Abatement Cost | | |
|-----------------------|------|-----------------------|--------------------------------------|--------|
| scfm | scfh | \$/metric ton methane | \$/metric ton CO ₂ e (72) | \$/mcf |
| 2 | 120 | -\$22 | -\$0.31 | -\$0.3 |
| 1.82 | 109 | \$0 | \$0.00 | \$0 |
| 0.86 | 51 | \$331 | \$4.59 | \$5 |
| 0.61 | 37 | \$662 | \$9.19 | \$10 |
| 0.50 | 30 | \$992 | \$13.78 | \$15 |
| 0.48 | 29 | \$1,059 | \$14.70 | \$16 |
| 0.47 | 28 | \$1,125 | \$15.62 | \$17 |
| 0.43 | 26 | \$1,323 | \$18.38 | \$20 |
| 0.42 | 25 | \$1,389 | \$19.30 | \$21 |

Accordingly, CARB must reduce the threshold at which replacement or repair of rod packing is required. A standard set in the 0.4 – 0.5 scfm range would be cost-effective and more appropriately balance the need to reduce methane emissions, and the social costs of those emissions, while keeping costs for industry reasonable.

Finally, ARB should consider finalizing a requirement for operators of production compressors to perform direct measurement of the flow rate in a manner consistent with non-production compressors, as opposed to requiring repair based on concentration thresholds. As described above, the additional cost of direct emissions measurement during regular LDAR inspections would be quite small.

VI. Separator and Tank Systems

1. ARB Should Remove the “Low Production” Exemption

We urge ARB to remove the exemption for separator and tank systems that receive less than 50 barrels of crude oil per day and that receive less than 200 barrels of produced water per day. ARB added this exemption based on its own analysis of flash test data that indicated that emissions from such separation and tank systems will not reach the control threshold of 10 metric tons of methane per year.¹³⁵ This exemption is overly broad and may result in tanks that in fact exceed the control threshold going uncontrolled. ARB already proposes to require owners and operators of separator and tank systems covered by Section 95668(a) to either control emissions or conduct periodic flash analysis testing to determine whether or not controls are warranted. Owners and operators of separator and tank systems that receive less than 50 barrels of crude oil per day and that receive less than 200 barrels of produced water per day should still be required to conduct periodic flash analysis to ensure that any increase in production does not

¹³⁵ ARB Statement of Reasons, at 90.

result in methane emissions that trigger the control requirements. If ARB's analysis is correct, and emissions from such systems remain under 10 metric tons of methane annually, owners and operators will only be subject to the periodic modest flash analysis testing requirements which should not impose a significant burden on operators. For these reasons, we urge ARB to remove this exemption.

2. *Testing Should Occur Earlier and Controls Should be Installed Sooner*

ARB should tighten deadlines related to both commencement of annual flash analysis testing and installation of vapor collection systems. In previously submitted comments, we expressed concern that the prior version of the draft regulation allowed vessels to operate without any emission controls for an unjustifiably long period of time. Section 95668(a)(3) of the current draft provides that “[b]y January 1, 2018, owners or operators of existing separator and tank systems that are not controlled for emissions with the use of a vapor collection system shall conduct flash analysis testing of the crude oil, condensate, or produced water processed, stored, or held in the system” (with no requirement to actually control emissions unless this analysis demonstrates emissions in excess of ten metric tons of methane per year). While the prior draft of the rule required that annual flash analysis testing be conducted beginning January 1, 2017 and by no later than September 1, 2017, the latest draft clarifies the deadline for existing systems but unfortunately pushes it back to 2018. For existing systems, ARB should require that owners and operators conduct testing by a date certain that is earlier than September 1, 2017.

Furthermore, for existing separator and tank systems, the draft rule requires that by January 1, 2019, owners or operators of a system “with an annual emission rate greater than 10 metric tons per years of methane shall control the emissions from the separator and tank system and uncontrolled gauge tanks located upstream” with the use of a vapor collection system. §95668(a)(6). As with the deadline for flash analysis testing, ARB should require that owners and operators control emissions at an earlier date. As drafted, the rule would allow existing separator and tank systems that are currently emitting methane at a rate greater than 10 metric tons per year to wait almost two and a half years from now before controlling those emissions. This delay is unwarranted and the timeline for flash analysis testing and installation of a vapor collection system should be accelerated.

In previously submitted comments, we expressed concern that the prior version of the draft regulation may allow new vessels to operate without any emission controls for the first year of operation. The latest draft rule also clarifies the timing for new systems: “Beginning January 1, 2018, owners or operators of new separator and tank systems that are not controlled for emissions with the use of a vapor collection system shall conduct flash analysis testing of the crude oil, condensate, or produced water processed, stored, or held in the system *within 90 days* of initial system startup.” § 95668(a)(4) (emphasis added). The rule also clarifies that beginning January 1, 2018, owners or operators of new systems with an annual emission rate greater than 10 metric tons per year of methane must control the emissions with the use of a vapor collection system *within 180 days* of conducting flash analysis testing. 95668(a)(7) (emphasis added). Thus, under the proposed rule, a new system that exceeds the 10 metric tons per year threshold may not have to control those emissions for 270 days (approximately 9 months) after initial system startup.

Emissions are likely to be highest during the first year. Oil and gas well production generally declines during the first year of operation. Throughput of materials (oil, produced water, and other substances) in vessels tracks production, meaning that potential vessel emissions follow this curve as well. Thus, the draft regulation could allow emissions without control during a large portion of the time when those emissions will be highest.

As noted in our prior comments, other jurisdictions have successfully implemented regulations that require control of tanks much sooner after production begins at a well. Colorado requires operators to assess whether emissions will be significant from tanks – and if so, to control vessels from the date of initial production at the well. As noted in our prior comments, in crafting emission control requirements for vessels, the Colorado Air Pollution Control Division expressed concern that even allowing operators to wait *ninety days* after commencement of production to install controls on vessels would allow significant and avoidable air pollution.¹³⁶ Colorado determined that it would be cost effective to require controls to be installed on all crude oil and produced water tanks immediately, allowing operators to remove controls from a tank once testing demonstrated that the tank’s uncontrolled emissions would fall below the applicable threshold. A presumption of control has the added benefit of providing operators with an incentive to test emissions promptly. ARB should follow Colorado’s lead and assume that vessels require emission controls unless and until operators demonstrate otherwise.¹³⁷

Alternately, US EPA requires that emissions from new and modified storage vessels that have potential to emit six tons of VOC or more per year must control emissions from those vessels by 60 days after the vessel goes in service.¹³⁸ We suggest that testing should, at the very least, be carried out within 30 days of initial production, and that ARB require that controls be in place within 60 days after initial production for tanks that have potential emissions above the threshold, in line with the federal standards (note that the federal standards have a different, VOC-based threshold than the draft ARB standard). However, we reiterate that ARB should first consider requiring control from the day of initial production when emissions from the tank can be anticipated to exceed 10 metric tons per year, in accordance with the Colorado approach.

ARB must also ensure that for new wells, the Test Procedure for Determining Annual Flash Emission Rate of Methane from Crude Oil, Condensate, and Produced Water properly assesses annual emissions. It is critical that operators assess potential emissions rapidly after operation of a tank begins, so that the tank can be controlled if needed. But ARB must also ensure that operators do not use a simple extrapolation of low production in the first days after production begins to conclude that potential emissions from the vessel will be less than the 10 metric tons per year threshold. Such extrapolation would be inappropriate because for new wells, particularly wells that were hydraulically fractured, production can rise dramatically over the initial weeks after production begins. ARB thus must ensure that operators use liquid

¹³⁶ CO Economic Impact Analysis, *supra* note 38.

¹³⁷ See CATF *et al.* February 2016 comments, *supra* note 1, for a comparison of the requirements and timelines in the CARB draft rule to those in the Colorado methane rule.

¹³⁸ See 40 C.F.R. §60.5395(d)(1)(i). “For each Group 2 storage vessel affected facility [that is, vessels constructed after 12 April 2013], you must achieve the required emissions reductions by April 15, 2014, **or within 60 days after startup**, whichever is later” (emphasis added).

throughput values in Equation 1 of Section 11 of the Test Procedure that are appropriate for yearly averages for new wells.

3. Provisions Requiring Clarification or Strengthening

ARB should also clarify or strengthen the following provisions:

- 95668(a)(5)(F): “The ARB Executive Officer may request additional flash analysis testing or information in the event that the test results reported do not reflect representative results of similar systems.” Please clarify how the ARB Executive Officer would determine whether the test results “reflect representative results of similar systems.”
- 95668(a)(8): “If the results of three consecutive years of [flash analysis] test results show that the system has an annual emission rate of less than or equal to 10 metric tons per year of methane the owner or operator may reduce the frequency of testing and reporting to once every five years.” Testing once every five years is too infrequent to effectively determine if emissions have increased above 10 metric tons per year.
- 95668(a)(8)(A): “After the third consecutive year of testing, if the annual crude oil, condensate, or produced water throughput increases by more than 20 percent after one year from the date of previous flash analysis testing, then the annual methane emissions shall be recalculated using the laboratory reports from previous flash analysis testing.” The prior draft rule required recalculation of flash emissions with a *10 percent* increase in throughput, rather than 20 percent. The basis for this change is unclear since an increase in throughput of less than 20 percent could cause a meaningful increase in methane emissions. ARB should justify the 20 percent throughput threshold and if it cannot do so, require re-testing for any increase in throughput over that level tested in any of the prior testing years (or at the very least retain the 10 percent threshold). Furthermore, this provision should specify how soon after the increase of throughput must the flash emissions be recalculated. (The current draft appears to no longer include a provision specifically requiring flash analysis testing, record keeping and reporting to be conducted after adding a new well to the separator and tank system.)

VII. Liquids Unloading

We support ARB’s approach with regards to Liquids Unloading emissions, either through capturing emissions using a vapor collection system, or measuring/calculating the volume of natural gas vented, and regularly reporting that volume. Joint commenters request the following in order to strengthen the liquids unloading proposal.

First, we request that ARB revise its proposed definition of “Liquids Unloading” by striking the phrase “with the use of pressurized natural gas.”¹³⁹ Not all liquids unloading technologies use pressurized natural gas to remove liquids, so the proposed definition potentially creates a loophole in the control and reporting requirements.

¹³⁹ The current definition reads: “‘Liquids unloading’ means an activity conducted with the use of pressurized natural gas to remove liquids that accumulate at the bottom of a natural gas well and obstruct gas flow.” § 95667(a)(28).

We also urge ARB to make one improvement to the substantive control requirement and a few improvements to the reporting requirements in order to improve the protectiveness of the provision.

We urge ARB to follow the lead of Wyoming¹⁴⁰ and Colorado¹⁴¹ and to require operators to keep personnel on site when conducting manual liquids unloading activities. This ensures that any venting that occurs is kept to a minimum. We anticipate that a prudent operator would follow this practice as a matter of course, as having personnel onsite to supervise manual liquids unloading not only ensures that emissions are minimized but also results in a more effective and safe operation. ARB should include this requirement to ensure that such a prudent practice is followed across the board.

In addition, we recommend several additions to the reporting requirements to allow ARB to closely monitor liquids unloading emissions and develop targeted standards in the future, should the need arise. Given the number of mitigation techniques available to operators, we expect that liquids can be unloaded without venting in the vast majority of cases. In this light, it is important that ARB use the reporting requirements to understand *why* operators vent wells during liquids unloading. ARB thus should require operators to report a number of well variables and conditions in the cases where venting does occur.

The current standard requires operators to annually report the following information in the cases where liquids unloading emissions are not captured:

- Volume of natural gas vented to perform liquids unloading, and
- Equipment installed in the natural gas well(s) designed to automatically perform liquids unloading (*e.g.*, foaming agent, velocity tubing, plunger lift, etc.)¹⁴²

ARB should require operators to report a broader set of parameters and conditions while being more specific about the information required in the proposal. For each liquids unloading event at each well, ARB should require operators to report:

- Volume of gas vented and duration of venting event.
- Volume of liquids removed from well during venting event.
- Well Characteristics:
 - API Number
 - Spud date and completion date
 - A complete casing diagram, with all required depths reported as both measured depth and true vertical depth, including:
 - Ground elevation from sea level
 - Reference elevation (*i.e.* rig floor or Kelly bushing)
 - Well orientation: horizontal, vertical, or directional
 - Well depth

¹⁴⁰ WY Permitting Guidance, *supra* note 30.

¹⁴¹ 5 C.C.R. 1001-9, § VII.H.1.b.

¹⁴² Proposed § 95668 (g)(2).

- Sizes and weights of all casing, liners and tubing
 - Depths of shoes, stubs and liner tops
 - Depths of perforation intervals
 - Diameter and depth of hole
- Liquids accumulation rate (barrels of water accumulated per day)
- Gas production rate (before and after unloading event)
- Sales line pressure
- Shut-in pressure
- Gas temperature at wellhead
- If liquids removal technology used, details of method:
 - Plunger lift: with or without smart automation
 - Foaming agent: type
 - Velocity tubing: diameter
 - Pumps
 - Gas lift
- If no liquids removal technology used:
 - The normal operating practice for venting the well: automatic vent timer or manual vent with or without monitoring
 - Vent time

We greatly appreciate the opportunity to comment on this important proposal and thank ARB for its leadership on this key climate and public health issue.

Reducing Methane Emissions From Compressor Rod Packing Systems

Executive Summary

More than 51,000 reciprocating compressors are operating in the U.S. natural gas industry, each with an average of four cylinders, representing over 200,000 piston rod packing systems in service. These systems contribute over 72.4 Bcf per year of methane emissions to the atmosphere, one of the largest sources of emissions at natural gas compressor stations.

All packing systems leak under normal conditions, the amount of which depends on cylinder pressure, fitting and alignment of the packing parts, and amount of wear on the rings and rod shaft. A new packing system, properly aligned and fitted, may lose approximately 11 to 12 standard cubic feet per hour (scfh). As the system ages, however, leak rates will increase from wear on the packing rings and piston rod. One Natural Gas STAR Partner reported measuring emissions of 900 scfh on one compressor rod.

By using company-specific financial objectives and monitoring data, Partners can determine emission levels at which it is cost-effective to replace rings and rods. Benefits of calculating and utilizing this “economic replacement threshold” include methane emission reductions and cost savings. Using this approach, one Natural Gas STAR Partner achieves savings of over \$233,000 annually at 2006 gas prices. An economic replacement threshold approach also results in operational benefits, including a longer life for existing equipment, improvements in operating efficiencies, and long-term savings.

Technology Background

Reciprocating compressors in the natural gas industry leak natural gas during normal operation. Areas of high leak frequency include flanges, valves, and fittings located on compressors. The highest volume of gas loss, however, is associated with piston rod packing systems.

Packing systems are used to maintain a tight seal around the piston rod, preventing the gas compressed to high pressure in the compressor cylinder from leaking, while allowing the rod to move freely. Exhibit 1 shows a typical compressor rod packing system.

Compressor rod packing consists of a series of flexible rings that fit around the shaft to create a seal against leakage. The packing rings are lubricated with circulating oil to reduce wear, help seal the unit, and draw off heat. Other cooling methods include air cooling, water jacketing, and circulating coolants inside the packing box. Packing rings are held in place by a set of packing cups, normally one for each pair of rings, and kept tight against the shaft by a surrounding spring. The number of cups and rings will vary depending on the compression chamber pressures. A “nose gasket” on the end of the packing case prevents leaks around the packing cups.

Under the best conditions, new packing systems properly installed on a smooth, well-aligned shaft can be expected to leak a minimum of 11.5 scfh. Higher leak rates are a consequence of fit, alignment of the packing parts, and wear. Leakage typically occurs from four areas:

Economic and Environmental Benefits

| Method for Reducing Natural Gas Losses | Volume of Natural Gas Savings (Mcf/year) | Value of Natural Gas Savings (\$/year) | | | Implementation Cost (\$) | Payback (Months) | | |
|--|--|--|-------------|-------------|--------------------------|------------------|-------------|-------------|
| | | \$3 per Mcf | \$5 per Mcf | \$7 per Mcf | | \$3 per Mcf | \$5 per Mcf | \$7 per Mcf |
| Economic replacement of rings and rods in compressor rod packing | 865 ^a | \$2,595 | \$4,325 | \$6,055 | \$540 ^b | 3 | 2 | 1 |

General Assumptions:

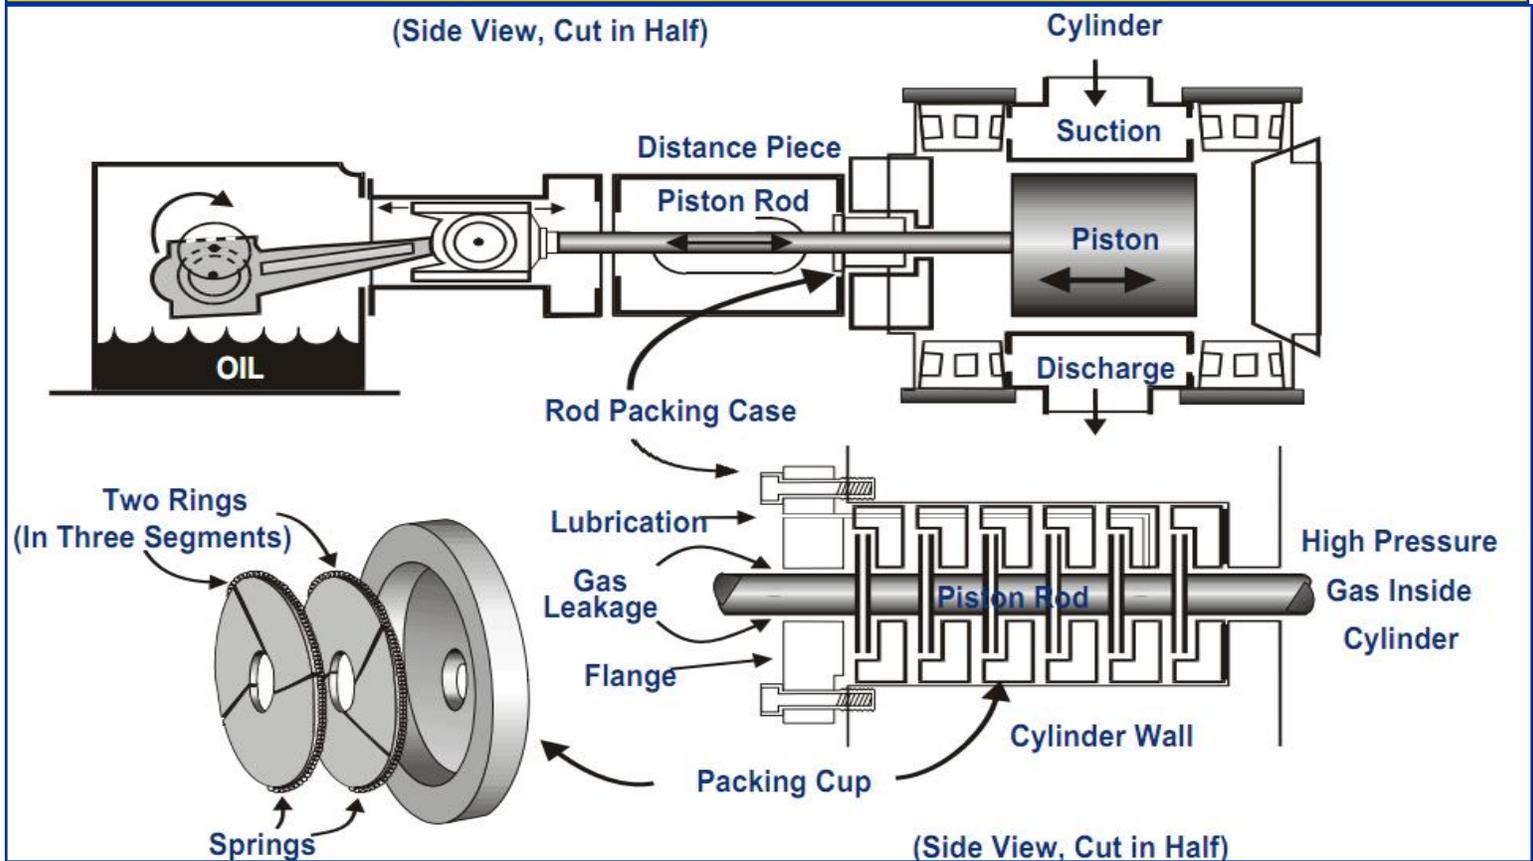

^a Pipeline Research Committee International (1999).

^b \$1,620 cost of ring replacement every three years rather than four years (industry average).

Reducing Methane Emissions From Compressor Rod Packing Systems

(Cont'd)

Exhibit 1: Typical Compressor Rod Packing System

- ★ Around the packing case through the nose gasket.
- ★ Between the packing cups, which are typically mounted metal-to-metal against each other.
- ★ Around the rings from slight movement in the cup groove as the rod moves back and forth.
- ★ Between the rings and shaft.

Leaking gases are vented to the atmosphere through packing vents on the flange. Leakage can be reduced through proper monitoring and a cost-effective schedule for replacing packing rings and piston rods. New ring materials and new designs for packing cases are emerging that should reduce emissions in the future.

Economic and Environmental Benefits

Monitoring and replacing compressor rod packing systems on a regular basis can greatly reduce methane emissions to

the atmosphere and save money. For instance, conventional bronze-metallic packing rings wear out and need to be replaced every three to five years. However, as packing deteriorates, leak rates can increase to the level at which replacing packing rings more frequently can be economically justified. In addition, more frequent ring replacement might actually extend the life of the compressor rod. Partners who institute a program of monitoring and cost-effective replacement are able to achieve several benefits:

- ★ Reduced methane emissions.
- ★ Gas savings from lower leakage rates.
- ★ Extended service life of compressor rods.

Decision Process

Companies can determine a cost-effective replacement schedule by following five simple steps.

Reducing Methane Emissions From Compressor Rod Packing Systems

(Cont'd)

Step 1: Monitor and record baseline packing leakage and piston rod wear.

Establishing baseline leakage rates and monitoring piston rod wear allows Natural Gas STAR Partners to track increases in leakage and evaluate the economics of replacing packing rings and piston rods.

The vent port on the packing case flange provides a means for gas leakage to escape to the atmosphere. However, gas can also flow along the rod and/or from the gasket at the end of the packing case, thus bypassing the packing cup vent and entering the distance piece. Consequently, where possible, measurements should encompass emissions from both the packing cup vent and distance piece. Some systems vent the packing cup into the distance piece, while others have separate vents.

Gas leakage can be measured with either a hand held or an installed measuring device. Before measurements are initiated, a check of the packing vent system should be undertaken. Failure to account for emissions escaping into the distance piece may result in an underestimation of packing-related emissions by up to 40 percent, which could impact the economics of the decision process.

It is important to take measurements immediately after installing new seals (or new rods and seals). This measurement becomes the baseline for the new packing and can serve as a suitable default baseline for other cylinders and compressors of similar type, size, pressure, and age of rods. After installation of rings, Partners should routinely monitor and record leakage rates and related operating conditions (pressure, lubrication, temperatures) over the entire life of the packing rings, usually on a monthly or quarterly basis.

Rods can be monitored periodically during ring replacements by documenting shaft dimensions and surface roughness where the rod contacts the packing rings. Piston rods wear more slowly than packing rings, having a life of about 10 years. Rods wear “out-of-round” or taper when poorly aligned, which affects the fit of

packing rings against the shaft (and therefore the tightness of the seal) and the rate of ring wear. An out-of-round shaft not only seals poorly, allowing more leakage, but also causes uneven wear on the seals, thereby shortening the life of the piston rod and the packing seal. The leakage attributable to rod wear is determined by the change in the baseline leakage rate after each successive ring replacement (assuming same operating conditions and ring type). This increase in baseline leakage can be used to establish an economic threshold for replacing the piston rod (see Step 4).

Step 2: Compare current leak rate to initial leak rate to determine leak reduction expected.

Using the monitoring data obtained in Step 1, the baseline emission measurement should be compared to the current leak rate to determine whether the current leak signals a need for packing or rod replacement. Exhibit 2 demonstrates how a comparison can be made.

Exhibit 2: Comparing Current versus Initial Leak Rates

Given:

IL = Initial leak rate at the last packing ring rod replacement
CL = Current leak rate
LRE = Leak reduction expected

Calculate:

$$\text{LRE} = \text{CL} - \text{IL}$$

For example, if the leak rate of a packing ring is currently measured at 100 standard cubic feet per hour (scfh), and the same component was measured at 11.5 scfh after the last replacement, then the leak reduction that can be expected is:

$$\begin{aligned}\text{LRE} &= 100 \text{ scfh} - 11.5 \text{ scfh} \\ \text{LRE} &= 88.5 \text{ scfh}\end{aligned}$$

For accurate analysis, Partners should calculate the “leak reduction expected” (LRE), which is the savings that will occur from installing new equipment separately for packing seals and piston rods. When determining the LRE for the installation of new rings only, assume all of the leakage increase since the last ring replacement is attributable to ring wear. When determining the LRE for replacing the piston rod and rings (note that new rings are always installed with a new rod), use the initial leakage measured immediately after the last rod replacement on this compressor. Where historical data may not be

Five Steps to Economic Packing and Piston Rod Replacement:

- Step 1: Monitor and record baseline packing leakage and piston rod wear.
- Step 2: Compare current leak rate to initial leak rate to determine leak reduction expected.
- Step 3: Assess costs of replacements.
- Step 4: Determine economic replacement threshold.
- Step 5: Replace packing and rods when cost-effective.

Reducing Methane Emissions From Compressor Rod Packing Systems

(Cont'd)

Methane Content of Natural Gas

The average methane content of natural gas varies by natural gas industry sector. The Natural Gas STAR Program assumes the following methane content of natural gas when estimating methane savings for Partner Reported Opportunities.

| | |
|-------------------------------|------|
| Production | 79 % |
| Processing | 87 % |
| Transmission and Distribution | 94 % |

available on individual compressors, data from other similar compressors with similar operating conditions can be used to establish baseline (initial leak) values.

Step 3: Assess costs of replacements.

Costs of replacing packing rings and piston rods vary between compressors. For packing ring replacements, variables include the number of compressor cylinders and the type of replacement ring. A Natural Gas STAR Partner reported that costs for a typical Teflon or moly-based, 8 to 10 cup ring set for a three-inch rod will range from \$135 to \$170 per cup, or about \$1,350 to \$1,700 total. Another source stated that a set of rings may vary between \$675 and \$1,080, or \$2,025 to \$3,375 if the cups and cases are included. Factors affecting equipment costs for rod replacements include rod dimension and type of rod. Estimates of the costs of rods can range from \$2,430 to \$4,725. Special coatings, such as ceramic, tungsten carbide, or chromium, can increase costs by \$1,350 or more—the cost of some rods may be as high as \$12,150 to \$13,500.

Installation costs vary as well, depending on site location and difficulties encountered during replacement. Both Partners and manufacturers estimate that installation costs are roughly equal to equipment costs. One Partner spent an average of \$1,420 per packing ring set for purchase and installation. Partners have found that monitoring and leak measurement costs are insignificant on a per-packing basis relative to the labor costs to install rings or rods.

Step 4: Determine economic replacement threshold.

With the information obtained from Steps 1 through 3, Partners can develop an “economic replacement threshold” that defines the specific point at which it is cost-effective to replace rings and rods. Partners have identified several methods for calculating this threshold, relying on company investment evaluation criteria and site-specific characteristics.

A simple approach is to use discounted cash flow principles to calculate an economic replacement threshold. Partners can calculate their economic replacement threshold for both packing seals and rods by using the following equation:

$$\text{Economic Replacement Threshold (scfh)} = \frac{CR * DF * 1,000}{H * GP}$$

Where:

CR = Cost of replacement (\$)

DF = Discount factor (%)

H = Hours of compressor operation per year

GP = Gas price (\$/Mcf)

The discount factor is the term used for capital recovery for equal annual revenues and is calculated from the following formula:

$$DF = \frac{i(1+i)^n}{(1+i)^n - 1}$$

Where *i* equals the discount rate or company hurdle rate expressed as a decimal and *n* equals the payback period selected. Using this formula, a 10 percent discount rate (*i* = 0.10) and a one-year payback (*n* = 1) yield a discount factor of 1.10; for a two-year payback (*n* = 2), the discount factor is 0.576, etc.

Exhibit 3 presents an example for discounted payback. This table was constructed to show the LRE necessary to pay back the investment in a new ring packing set in one year, two years, and so on. Exhibit 3 shows that the \$1,620 cost for packing ring replacement can be paid back in one year with a leak reduction of 55 scfh, in two years with a leak reduction of 29 scfh; etc. (with future leak savings discounted at 10 percent). Thus, if a Partner's

Exhibit 3: Economic Replacement Threshold for Packing Rings

| Leak Reduction Expected (scfh) | Payback Period ^a (months) |
|--------------------------------|--------------------------------------|
| 55 | 7 |
| 29 | 12 |
| 20 | 18 |
| 16 | 22 |
| 13 | 27 |

^a Assumes packing ring replacement costs of \$1,620, \$7.00/Mcf gas, and 8,000 operating hours/year.

Reducing Methane Emissions From Compressor Rod Packing Systems

(Cont'd)

Nelson Price Indexes

In order to account for inflation in equipment and operating & maintenance costs, Nelson-Farrar Quarterly Cost Indexes (available in the first issue of each quarter in the *Oil and Gas Journal*) are used to update costs in the Lessons Learned documents.

The “Refinery Operation Index” is used to revise operating costs while the “Machinery: Oilfield Itemized Refining Cost Index” is used to update equipment costs.

To use these indexes in the future, simply look up the most current Nelson-Farrar index number, divide by the February 2006 Nelson-Farrar index number, and, finally multiply by the appropriate costs in the Lessons Learned.

internal investment criterion is a two-year payback, the Partner should establish an economic replacement threshold for ring replacement at 29 scfh. In other words, when the LRE of a ring replacement reaches 29 scfh, the Partner should replace ring packing.

Similar to rings, economic replacement threshold can be determined for rod replacement by establishing the leak reduction needed in order to justify the investment in a new rod assembly. Follow the same steps above, but substitute rod capital costs for cost of replacement (CR) to determine the economic replacement threshold.

After determining the economic replacement threshold, Partners should determine the amount of methane emissions attributable to the replacement. Current leakage (CL) measurements do not distinguish between contribution from worn rings and rod wear. However, over time, the initial leakage (IL) measurements will show a gradual increase in the baseline leak rate, indicating rod wear. Partners should measure and track the change in IL to determine the amount of emissions attributable to the aging rod. Partners need to establish a baseline by which to compare piston rod-related leakage. This can be accomplished by taking measurements when the rod is first installed or by comparing measurements from similar facilities that have new rods and packing. Once this baseline is established, Partners can conduct a discounted cash flow to determine the amount of rod-related leakage that signals the need for replacement.

Exhibit 4 uses the same approach as Exhibit 3 to provide the LRE economic replacement thresholds for replacing

Exhibit 4: Economic Replacement Threshold for Rods & Rings

| Leak Reduction Expected (scfh) | Payback Period ^a (months) |
|--------------------------------|--------------------------------------|
| 376 | 7 |
| 197 | 13 |
| 137 | 18 |
| 108 | 22 |
| 90 | 27 |

^a Assumes packing ring replacement costs of \$1,620, rod replacement costs of \$9,451, \$7.00/Mcf gas, and 8,000 operating hours/year.

rings and rods. This example is based on a cost of \$11,701 to replace both the rod and packing rings. The table shows that companies desiring a payback of one year require a LRE of 376 scfh, while a company satisfied with a three-year payback should replace rods and seals when the LRE is 137 scfh (with future savings discounted at 10 percent).

One note of caution: a poorly aligned rod or poorly fitted rings can result in a high current leakage measurement, and hence a high LRE, that might not indicate the need to replace the rod, but rather a need to refit rings or realign the rod. Monitoring rod dimensions (i.e., tapering, out-of-round, scratches, and surface roughness) is necessary in determining that the increase in IL over the baseline is in fact attributable to general rod wear.

Step 5: Replace packing and rods when cost-effective.

Monitoring emissions and replacing worn rods and packing rings at the economic replacement threshold will result in an immediate reduction in emissions and compressor fuel costs. Partners should compare compressor station data to the replacement thresholds. Partners should replace

One Partner's Experience

Consumers Energy replaced worn compressor rod packing rings on 15 compressor units with total estimated savings from reduced gas leakage of \$49,000 (based on leakage reductions of 7,000 Mcf per year, and assuming a gas price of \$7 per Mcf). The costs of replacing all the packing rings, including materials and labor, was \$23,000, resulting in a payback period of six months at 2006 costs.

Reducing Methane Emissions From Compressor Rod Packing Systems

(Cont'd)

packing rings and rods when actual LREs are equal to or exceed the economic replacement thresholds. Partners are also encouraged to select economic replacement thresholds that maximize the methane reduction.

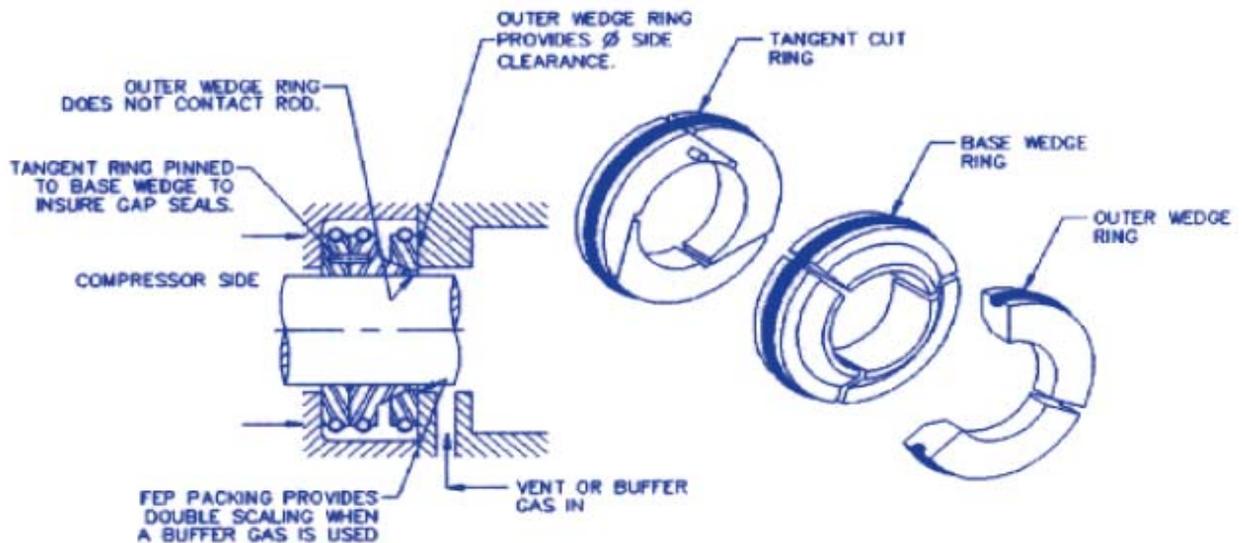

Additional Options

Partners in the Natural Gas STAR Program have not reached a consensus on standard emission reductions that can be achieved by changing compressor rod packing. Many variables are cited as affecting potential savings, including cylinder pressure, fit and alignment of packing parts, and amount of wear on the rings and rod shaft, as well as company-internal decision criteria. However, Partners agree that identifying a replacement threshold for replacing packing rings and piston rods is a practical method to reduce methane emissions from reciprocating compressors.

New materials can improve the life and performance of certain equipment and provide Partners with additional savings through reducing leakage and repair and replacement costs.

- ★ **Options for rings.** Carbon-impregnated Teflon is gradually replacing bronze metallic rings. One vendor claims that the price is about the same, with Teflon expected to last about one year longer than the conventional bronze rings. However, other factors—including proper installation, cooling, and lubrication—might play a greater role in the service life of a ring.
- ★ **Upgraded piston rods.** New or existing compressor rods coated with tungsten carbide have proven to increase service life for rods by reducing wear, as well as making them effective for “static-seal” installations (see Lessons Learned study, “*Reducing Emissions When Taking Compressors Off-Line*”). Coating each piston rod with tungsten carbide would cost an additional \$1,350 to \$2,700. Chrome coating is also used to reduce wear.
- ★ **Three-ring rod packing.** A three-ring rod packing system shown in Exhibit 5 is becoming more widespread. The rings are typically installed in one of the last two cups. The primary benefit of this

Exhibit 5: Three-Ring Fugitive Emission Rod Packing Assembly

FEP STYLE PACKING

Reducing Methane Emissions From Compressor Rod Packing Systems

(Cont'd)

arrangement is that this design can usually be installed without any replacement or modification of the packing case cup.

Lessons Learned

Partners have found that providing compressor station personnel with simple guidelines for economic replacement of reciprocating compressor piston rods and rod packing will greatly reduce methane emissions. This natural gas savings pays back the costs for more frequent replacements. The principal lessons learned are:

- ★ Develop a system for regularly measuring and monitoring leakage from piston rod packing cases. Regularly monitor lubrication and cooling to help reduce wear on packing rings. Poor heat conductivity at very high operating temperatures can be a significant factor in ring deterioration.
- ★ Establish baseline initial leakage (IL) rates for new rods and new packing rings, categorized by operating conditions and compressor types and sizes.
- ★ Share baseline initial leakage rate data with other stations to provide substitute data where specific data may not be available for all stations.
- ★ Establish a company-specific emission threshold for each compressor to serve as a useful tool for knowing when to replace packing rings and piston rods economically.
- ★ Upgrade piston rods where economically justified. The upgrades will result in fewer emissions over the life of the rod.
- ★ New packing ring materials, types, and entirely new packing systems are available and becoming more common where product values or environmental factors offset the higher costs.
- ★ For additional information, consult the Lessons Learned study entitled *Reducing Emissions When Taking Compressors Off-Line*.
- ★ When changing out packing rings and rods, record methane emissions reductions in Natural Gas STAR Program annual reports.

EXECUTIVE SUMMARY

A comprehensive measurement program has been conducted at five natural gas-processing plants in the United States to identify cost-effective opportunities for reducing natural gas losses due to fugitive equipment leaks and avoidable process inefficiencies or wastage. This program, referred to as Phase II, followed a Phase I program that surveyed four gas plants in 2000.

The second Phase study included upstream facilities such as well sites and gathering compressor stations in addition to the gas processing plants. The additional gas processing plants were selected to give a range of plant size, locations, throughput, plant age, and both sweet and sour gas facilities to ensure that the results represented the entire natural gas processing industry.

Raw natural gas is predominantly methane but may contain varying amounts of non-methane hydrocarbons (NMHC) and contaminants, such as hydrogen sulfide (H₂S), nitrogen (N₂), carbon dioxide (CO₂) and water vapor (H₂O). Natural gas losses to the atmosphere are direct emissions of these constituents. Natural gas losses into flare systems or excess fuel consumption result in atmospheric emissions of CO₂ and other combustion byproducts including unburned methane.

Here, cost effective opportunities to reduce natural gas losses are seen primarily as a sensible means of reducing methane and other greenhouse gas (GHG) emissions (predominantly CO₂), and to a lesser extent, NMHC emissions. All GHG emissions are expressed as CO₂-equivalent emissions (CO₂E) using a global warming potential of 21 for methane. A baseline assessment of the fugitive natural gas losses and target air pollutant emissions at each host facility is provided, and the potential savings and emission reductions from natural gas loss decreases are highlighted. Additionally, total hydrocarbon (THC) emission factors are presented for fugitive equipment leaks and the active natural gas-fueled process equipment surveyed.

All fieldwork was conducted during the first quarter 2004 and second quarter 2005. The work comprised a fugitive-emissions survey of equipment components in hydrocarbon gas service, measurement and characterization of flows into all key vent and flare systems, and limited performance testing of natural gas-fueled combustion equipment at three of the five surveyed sites. Emissions from selected pressure relief valves vented to the flare were measured at two sites. Residual flaring activities were also determined. Although not specifically targeted, any components in hydrocarbon-liquid or air service that were noticeably leaking were tagged and brought to the attention of site personnel. Complete component counts were prepared for the surveyed equipment.

The plants were also surveyed with an optical passive infrared camera designed specifically for leak detection. A comparison between leak detection methods is included in this second Phase report.

A total of 74,438 individual equipment components from five gas processing facilities, 12 well sites, and seven upstream gathering compressor stations were surveyed. Sufficient process information was collected to determine total annual emissions from the compiled measurement results. Additionally, specific emission-control opportunities were identified, and a preliminary cost-benefit analysis was performed to evaluate these opportunities. The analysis considered the estimated cost of repair and corresponding lifetime and the conserved gas value. Site personnel were solicited to provide input and assistance in identifying site-specific constraints and to help ensure that cost data were satisfactorily considered.

EMISSIONS INVENTORY OVERVIEW

Total atmospheric methane emissions from all sources at the combined sites are estimated at 8,071 tonnes per year. Corresponding GHG and NMHC emissions are estimated at 598,184 tonnes per year CO₂E and 3,625 tonnes per year, respectively. The majority of total methane emissions resulted from fugitive equipment leaks (55%). Incomplete combustion by natural gas-fuelled equipment and process venting are also noteworthy methane emissions sources (17% and 16%, respectively). The major GHG emissions sources are fuel consumption by compressor engines and process heaters (74%), fugitive equipment leaks (17%), process venting (5%), and flare/vent systems (3%). Fugitive equipment leaks are the primary NMHC emissions source (73%). In general, gathering compressor stations offered cost-effective opportunities with the majority of the methane emissions from fugitive leaks associated with leaking compressors. From the twelve wells surveyed, opportunities exist at well heads that have separators, tanks, and heater treaters.

NATURAL GAS LOSSES OVERVIEW

The value of all five sites natural gas losses - including direct atmospheric emissions, gas leakage into flare systems, and excess fuel consumption by process equipment - is estimated to be \$8.4 million per year (an average of \$1.7 million per year per plant). The *fugitive* emission opportunities totalled \$2.9 million dollar or \$580,000 per facility per year. The cost to survey and repair these leaks is approximately \$ 74,200 per facility (i.e. survey cost for one site at \$25,000 plus cost of repairs for leakers with positive net present value, averaged \$49,200 per site).

These estimates do not include the cost of identifying and evaluating natural gas loss reduction opportunities; however, such costs are typically small compared to the net benefit obtained. For example, the current five site survey costs, when expressed in terms of the total number of components in gas service, were approximately \$1.5 per component, which is more than the cost of conventional VOC LDAR programs. This per component cost may be reduced if a routine survey were to be implemented and maybe artificially high as a result of the R&D activities. Actual per-component costs vary between facilities and tend to increase with the operation complexity, facility remoteness, work condition severity, and the relative number of vents, combustion sources and control opportunities identified. The current study identified more than \$3,200 in annual

gross savings, or \$3,000 in net savings (including after repair or control costs), per component for control opportunities having a less than a 1-year payback based on a gas value of \$7.15/Mscf (\$6.78/GJ). Considering opportunity identification costs reduces the net savings by only about 4%. If a value is assigned to the resulting GHG credits, work is done as a routine commercial service rather than as a study, and efforts are focused on the plant areas most likely to offer meaningful control opportunities, improved economics would be realized.

Overall, it is estimated that up to 96.6% of total fugitive natural gas losses are cost-effective to reduce with no net financial burden to surveyed sites. If the cost of natural gas increases, the number of components that are cost effective to repair will not increase significantly however, the saving realized will scale commensurate with the price increase. These reductions would result in emission reductions of 61% for methane, 17% for GHG CO₂E, and 67% for NMHC considering emissions from all sources. The relatively low impact on GHG CO₂E emissions is due to the significant contribution of CO₂ emissions from fuel consumption to total GHG emissions.

The main cost-effective control opportunities identified at the sites are:

- **Fugitive Equipment Leaks:**

Approximately 2.2% of the equipment components (approximately 1,629 out of 74,438) in hydrocarbon service were determined to be leaking (i.e., had a screening value of 10,000 ppm or more) at the combined sites. Commensurate with the findings from the initial gas plant surveys, components in vibrational, high-use, and thermal-cycle gas services were the most leak prone. The majority of the identified natural gas losses from fugitive equipment leaks were attributed to a relatively small number of leaking components. Open-ended lines emissions were the greatest contributor to this source category, accounting for 32% of the total, followed by connectors (30%), compressor seals (20%), and block valves (15%). The remaining 3% were from pressure relief valves, regulators, orifice meters, control valves, and crank case vents.

It is estimated that implementing all cost-effective equipment-repair or replacement opportunities identified would reduce natural gas losses from *fugitive* equipment leaks by 96.6% and result in gross annual cost savings of approximately \$2.9 million (based on a gas value \$7.15/Mscf or \$6.78/GJ). This equates to an average gross annual savings of approximately \$580,000 per site. Site-specific values ranged from \$75,646 to \$1.2 million. Lower losses and fewer loss-reduction opportunities would be expected at newer plants. Conversely, higher losses and more loss-reduction opportunities would likely be found at older and/or poorly maintained plants.

Repairs to the 10 largest emitting cost-effective-to-repair components at each site (refer to Appendix I for a components list ranked by emission rate) would reduce natural gas losses by approximately 521 Mscfd, or 58%.

- **Flaring:**
The five sites flare or main vent systems residual gas flows (i.e., flows excluding blowdown and emergency relief events) totalled 496 Mscfd. In several cases, the system flows were sufficient to potentially justify installing a vent- or flare-gas recovery unit. Alternatively, the residual gas flow source or sources (e.g., excess purge gas consumption and leaking pressure-relief devices, drains, and blowdown valves connected to the flare header) could be repaired. However, these sources are often difficult to isolate, usually require a major plant shutdown to fix, and are likely to reoccur. Installing economically feasible flare-gas recovery units would reduce surveyed plants GHG emission by approximately 16,609 tonnes CO₂E per year, and take less than a year to pay out.
- **Natural Gas-Fueled Process Equipment:**
While several of the compressor engines tested would have benefited from tuning, most units proved to be operating efficiently (i.e., air-to-fuel ratios and flue gas combustibles concentrations were at or near manufacturers recommended values). This likely reflects the high attention level typically given to combustion equipment at continuously manned facilities such as those surveyed. Greater combustion efficiency improvement opportunities are believed to exist for tuning heaters and engines at unmanned field facilities. Total avoidable fuel consumption from servicing all economic-to-tune engines and heaters at the five sites is estimated to be 446 Mscfd, which equals GHG emission reductions of 13,100 tonnes CO₂E per year.

The natural gas-fueled engines surveyed were all properly matched with the current process load requirements (i.e., the units were operating within the optimum portion of their performance curve). Notwithstanding this, situations may arise where engines are operated outside their performance curve optimum area (e.g., due to changes in original load requirements caused by production changes or initial equipment mismatching with process applications) causing significant excessive operating costs.

KEY FINDINGS

- The value of natural gas losses from all five facilities in the Phase II DI&M survey - including direct atmospheric emissions, gas leakage into flare systems, and excess fuel consumption by process equipment - is estimated to be \$8.4 million per year (an average of \$1.7 million per year per plant). The findings from these additional 5 plant surveys solidify the economic benefits of voluntarily adopting and initiating DI&M.

The table below summarizes the finding from the Phase II DI&M site surveys.

| Table I - Summary of Phase II Plants Surveyed | | | | | | | |
|---|-------|------|-----------------|-----------------------------|-------------------------------|-------------------------|-----------------|
| Site # | Type | Age | Component Count | Fugitive Gas Losses (Mscfd) | Annual Value of Lost Gas (\$) | Gas Throughput (mMscfd) | % of Throughput |
| 1 | Sweet | 6 | 22,290 | 271 | \$757,259 | 500 | 0.05 |
| 2 | Sweet | 28 | 12,330 | 23 | \$75,646 | 206 | 0.01 |
| 3 | Sweet | 39 | 18,353 | 117 | \$612,593 | 130 | 0.09 |
| 4 | Sour | 27 | 16,687 | 69 | \$193,978 | 45 | 0.15 |
| 5 | Sour | 57 | 4,778 | 423 | \$1,296,510 | 87 | 0.48 |
| Average | | 31.4 | 14,887 | 903 | \$587,197 ^A | 193.6 | 0.16 |

^A This value excludes sources from combustion, flare activities, well sites and storage tanks.

- The results show that facilities surveyed with more than 30 years of service have significantly higher methane emissions per volume gas throughput, and higher overall leak frequencies than facilities with less than 30 years of service. The facilities survey during this Phase of the program ranged from 6 to 57 years with an average of 30.4 years. Facilities processing sour gas have higher methane emissions per volume gas throughout and leak frequencies than facilities processing sweet gas streams. Statistical comparisons for surveyed sites on the effects of gas plant service years and process stream type were not attempted due to the limited number of sites surveyed. It is recommended that additional analyses, including results from the Phase I and other surveys, be conducted to develop statistically significant correlations of fugitive equipment leak rates with service years and process gas type.
- A targeted DI&M program aimed at proven opportunities can significantly reduce the time and resources required to identify and repair those leaks that represent the “low hanging fruit” within the facility. Components associated with vibration (i.e. compressors) and heat-cycle (i.e. mole sieve) services contributed 97% of the total fugitive equipment leaks. These results again emphasize that employing a targeted DI&M program would significantly reduce the cost of initiating a DI&M program. However, significant additional opportunities were discovered at each site that would have been overlooked if the scope was narrowed to only include these targeted sources.
- A Phase I test site was selected for retest in Phase II to determine changes in fugitive leaks characteristics. Process changes at this site resulted in thirty percent of the Phase I components being decommissioned. These process units were replaced prior to the Phase II survey. While fugitive emissions from the new process units components tested in Phase II were only 20% of the fugitive emissions from the decommissioned components tested in Phase I, the overall Phase II site level fugitive emissions were still 50% higher than in Phase I. This

indicates higher Phase II fugitive emission leaks from 70% of components that were not replaced between Phases, and suggests that the facility DI&M program has not been effective at controlling fugitive equipment leaks at this site. In addition, a comparison of the average Phase I and Phase II emission factors by component type shows a very different distribution between Phase I and II sites.

GLOSSARY

- Blow-By** Gas from a piston cylinder that leaks past the piston rings into the crankcase.
- Carbon Dioxide Equivalent (CO₂E) -** Carbon dioxide equivalent is an expression of the total emissions from all the greenhouse gases, based on the gases relative ability to trap heat in the atmosphere.
- Greenhouse gases (GHGs) are atmospheric compounds that trap heat in the atmosphere by absorbing long-wave radiation from the earth's surface while allowing the sun's energy to pass through. The most relevant GHGs for natural gas systems are carbon dioxide (CO₂), methane (CH₄) and nitrous oxide (N₂O). Global warming potentials (GWPs) were developed as a simple measure of the global warming effects of various greenhouse gases emissions relative to carbon dioxide emissions. The current practice (IPCC, 1996) is to use a 100-year time horizon for global warming potentials. Therefore, the GWPs used in this document are: CO₂ = 1.0, CH₄ = 21.0 and N₂O = 310.
- Greenhouse gases emissions are converted to carbon dioxide equivalent (CO₂E) emissions by multiplying the mass emissions of each gas by the appropriate global warming potential and summing the CO₂E emissions. CO₂E emissions are expressed in metric tonnes.
- Centrifugal Compressor Seal Systems -** Centrifugal compressors generally require shaft-end seals between the compressor and bearing housings. Either face-contact oil-lubricated mechanical seals or oil-ring shaft seals, or dry-gas shaft seals are used. Seal leakage will tend to increase with wear between the seal and compressor shaft, operating pressure, and shaft rotational speed.
- Combustion Efficiency -** The extent to which all input combustible material has been completely oxidized (i.e., to produce H₂O, CO₂ and SO₂). Complete combustion is often approached but is never actually achieved. The main factors that contribute to incomplete combustion are thermodynamic, kinetic, mass transfer and heat transfer limitations. In fuel rich systems, oxygen deficiency is also a factor.

- Connectors - A connector is any flanged or threaded connection, or mechanical coupling, but excludes all welded or back-welded connections. If properly installed and maintained, a connector can provide essentially leak-free service for extended time periods. However, there are many factors that can cause leakage problems. Common leak causes include vibration, thermal stress and cycles, dirty or damaged contact surfaces, incorrect sealing material, improper tightening, misalignment, and external abuse.
- Crank Case - The crank case on reciprocating engines and compressors houses the crank shaft and associated parts, and typically an oil supply to lubricate the crank shaft. Integral compressors have a single crank case because the engine and compressor share a common crank shaft. Non-integral compressors typically have two crank cases, one on the engine side and another on the compression side.
- Destruction Efficiency - The extent to which a target substance present in the input combustibles has been destroyed (i.e., converted to intermediate, partially-oxidized, and fully-oxidized products of combustion). DE is typically expressed as a percentage: $100 * (in - out)/in$.
- Flare and vent systems - Venting and flaring are common disposal methods for gas processing plants waste gas. The stacks are designed to provide safe effluent dispersion. Flares are normally used where the waste gas contains odorous or toxic components (e.g., hydrogen sulfide). Otherwise, the gas is usually vented. Typically, separate flare/vent systems are used for high- and low-pressure waste gas streams.
- Fugitive Emissions - Unintentional leaks from equipment components including, but not limited to, valves, flanges and other connections, pumps and compressors, pressure relief devices, process drains, open-ended valves, pump and compressor seals, system degassing vents, accumulator vessel vents, agitator seals, and access door seals. Fugitive sources tend to be continuous emitters and have low to moderate emission rates.
- Gas Plant - A gas processing plant is a facility for extracting condensable hydrocarbons from natural gas and for upgrading the gas quality to market specifications (i.e., removing contaminants such as H₂O, H₂S and CO₂ and possibly adjusting the heating value).

| | |
|--|--|
| Heat Rate - | The heat energy (based on the fuel net or lower heating value) which must be input to a combustion device to produce the rated power output. Heat rate is usually expressed in terms of net J/kW·h. |
| Integral Compressor | A reciprocating compressor that shares a common crankshaft and crankcase with the engine. |
| Methane Leak | Greater than 10,000 parts per million as measured by a dual-element hydrocarbon detector (i.e., catalytic-oxidation/thermal-conductivity). |
| Molecular Sieve | Absorbers composed of zeolites (aluminosilicate crystalline polymers) used to remove water vapor from natural gas. Zeolites are regenerated periodically by heating. |
| Long-Term Natural Gas Contract Price - | Historically, long-term contracts have been used by buyers to secure a natural gas supply and by sellers to reduce large reserve development risk. During the 1960s and 70s, these contracts were established for terms of up to 20 to 25 years and the gas price was determined by periodic negotiations. The recent trend is towards shorter contract durations, and most new long-term contracts index the gas price to spot market rates. Today, a typical long-term contract with a cogeneration plant is about 15 years. Given the sellers and buyers interest in risk management, there is also a trend towards greater standardization of long-term contracts to facilitate hedging activity in the financial or the over-the-counter markets. |
| Open-ended Valves and Lines - | <p>An open-ended valve is any valve that releases process fluids directly to the atmosphere from valve seat leakage. The leakage may be caused by improper seating due to an obstruction or sludge accumulation, or a damaged or worn seat. An open-ended line is a pipe or tube segment attached to a leaking valve and that opens to the atmosphere.</p> <p>Few open-ended valves and lines are designed into process systems. However, actual numbers can be quite significant at some sites due to poor operating practices and various process modifications that may occur over time.</p> <p>Some common examples of open ended valves and lines are:</p> |

- scrubber, compressor-unit, station, and mainline blowdown valves;
- supply-gas valve for a gas-operated engine starter (i.e., where natural gas is the supply medium);
- instrument block valves where the instrument has been removed for repair or other reasons; and
- purge or sampling points.

Power Output -

The net shaft power available from an engine after all losses and power take-offs (e.g., ignition-system power generators, cooling fans, turbo chargers and pumps for fuel, lubricating oil, and liquid coolant) have been subtracted. For heaters and boilers, it is the net heat transferred to a target process fluid or system.

Pressure-Relief or Safety Valves -

Pressure relief or safety valves are used to protect process piping and vessels from being accidentally over-pressured. They are spring loaded so that they are fully closed when the upstream pressure is below the set point, and only open when the set point is exceeded. Relief valves open in proportion to the overpressure to provide modulated venting. Safety valves pop to a full-open position on activation.

When relief or safety valves reseal after activation, they often leak because the original tight seat is not regained either due to seating surface damage or foreign material build-up on the seat plug. As a result, they are often responsible for fugitive emissions. Another problem develops if the operating pressure is too close to the set pressure, causing the valve to "simmer" or "pop" at the set pressure.

Gas that leaks from a pressure-relief valve may be detected at the vent pipe (or horn) end. Additionally, there normally is a monitoring port located on the bottom of the horn near the valve.

Products of Incomplete Combustion (PICs) -

These are any compounds, excluding CO₂, H₂O, SO₂, HCl and HF, which contain C, H, S, Cl or F and occur in combusted gases. These compounds may result from thermodynamic, kinetic or transport limitations in the various combustion zones. All input combustibles are potential PICs. Intermediate substances formed by dissociation and recombination effects may also occur as PICs (CO is often the most abundant combustible PIC

GLOSSARY

- Blow-By** Gas from a piston cylinder that leaks past the piston rings into the crankcase.
- Carbon Dioxide Equivalent (CO₂E) -** Carbon dioxide equivalent is an expression of the total emissions from all the greenhouse gases, based on the gases relative ability to trap heat in the atmosphere.
- Greenhouse gases (GHGs) are atmospheric compounds that trap heat in the atmosphere by absorbing long-wave radiation from the earth's surface while allowing the sun's energy to pass through. The most relevant GHGs for natural gas systems are carbon dioxide (CO₂), methane (CH₄) and nitrous oxide (N₂O). Global warming potentials (GWPs) were developed as a simple measure of the global warming effects of various greenhouse gases emissions relative to carbon dioxide emissions. - supply-gas valve for a gas-operated engine starter (i.e., where natural gas is the supply medium);
- instrument block valves where the instrument has been removed for repair or other reasons; and
- purge or sampling points.

Power Output -

The net shaft power available from an engine after all losses and power take-offs (e.g., ignition-system power generators, cooling fans, turbo chargers and pumps for fuel, lubricating oil, and liquid coolant) have been subtracted. For heaters and boilers, it is the net heat transferred to a target process fluid or system.

Pressure-Relief or Safety Valves -

Pressure relief or safety valves are used to protect process piping and vessels from being accidentally over-pressured. They are spring loaded so that they are fully closed when the upstream pressure is below the set point, and only open when the set point is exceeded. Relief valves open in proportion to the overpressure to provide modulated venting. Safety valves pop to a full-open position on activation.

When relief or safety valves reseal after activation, they often leak because the original tight seat is not regained either due to seating surface damage or foreign material build-up on the seat plug. As a result, they are often responsible for fugitive emissions. Another problem develops if the operating pressure is too close to the set pressure, causing the valve to "simmer" or "pop" at the set pressure.

Gas that leaks from a pressure-relief valve may be detected at the vent pipe (or horn) end. Additionally, there normally is a monitoring port located on the bottom of the horn near the valve.

Products of Incomplete Combustion (PICs) -

These are any compounds, excluding CO₂, H₂O, SO₂, HCl and HF, which contain C, H, S, Cl or F and occur in combusted gases. These compounds may result from thermodynamic, kinetic or transport limitations in the various combustion zones. All input combustibles are potential PICs. Intermediate substances formed by dissociation and recombination effects may also occur as PICs (CO is often the most abundant combustible PIC

formed).

Pump Seals -

Positive displacement pumps are normally used for pumping hydrocarbon liquids at oil and gas facilities. Positive displacement pumps have a reciprocating piston, diaphragm or plunger, or else a rotary screw or gear.

Packing, with or without a sealant, is the simplest means of controlling leakage around the pump shaft. It may be used on both rotating and reciprocating pumps. Specially designed packing materials are available for different service types. The selected material is placed in a stuffing box and the packing gland is tightened to compress the packing around the shaft. All packings leak and generally require frequent gland tightening and periodic packing replacement.

Particulate contamination, overheating, seal wear, sliding seal leakage, and vibration will contribute to increased leakage rates over time.

Reciprocating Compressor Packing Systems -

Packings are used on reciprocating compressors to control leakage around the piston rod on each cylinder. Conventional packing systems have always been prone to leaking a certain amount, even under the best of conditions. According to one manufacturer, leakage from within the cylinder or through any of the various vents will be on the order of 1.7 to 3.4 m³/h under normal conditions and for most gases. However, these rates may increase rapidly with normal system wear and degradation.

Standard Reference Conditions -

Most equipment manufacturers reference flow, concentration, and equipment performance data to ISO standard conditions of 15°C, 101.325 kPa, sea level and 0.0 % relative humidity.

Thermal Efficiency -

The percentage or portion of input energy converted to useful work or heat output. For combustion equipment, typical convention is to express the input energy in terms of the net (lower) heating value of the fuel. This results in the following relation for thermal efficiency:

$$\eta = \text{Thermal Efficiency} = \frac{\text{Useful Work/Heat Output}}{\text{Net Heat/Energy Input}} \times 100\%$$

Alternatively, thermal efficiency may be expressed in terms

of energy losses as follows:

$$\eta = \left(1 - \frac{\Sigma \text{Energy Losses}}{\text{Net Heat/Energy Input}} \right) \times 100\%$$

Thermal efficiency losses can occur due to the following factors:

- combustion exhaust heat losses (i.e., residual heat value in the exhaust gases);
- heat rejected to cooling jacket water and lubrication oil;
- radiation from equipment hot surfaces;
- air infiltration;
- incomplete combustion; and
- mechanical losses (e.g., friction losses and energy needed to run cooling fans and lubricating-oil pumps).

Total Hydrocarbons -

All compounds containing at least one hydrogen atom and one carbon atom, with the exception of carbonates and bicarbonates.

Total Organic Compounds (TOC) -

TOC comprises all VOCs plus all non-reactive organic compounds (i.e., methane, ethane, methylene chloride, methyl chloroform, many fluorocarbons, and certain classes of per fluorocarbons).

Valves -

There are three main locations on a typical valve where leakage may occur: (1) from the valve body and around the valve stem, (2) around the end connections, or (3) past the valve seat. Leaks of the first type are referred to as valve leaks. Emissions from the end connections are classified as connector leaks. Leakage past the valve seat is only a potential emissions source if the valve, or any downstream piping, is open to the atmosphere. This is referred to as an open-ended valve or line.

The potential leak points on the different valve types are, as applicable: around the valve stem, body seals (e.g., where the bonnet bolts to the valve body, retainer connections), body fittings (e.g., grease nipples, bleed ports), packing guide, and any stem packing system monitoring ports. Typically, the most likely part to leak is the valve-stem packing.

The different valve types include gate, globe, butterfly, ball, and plug. The first two types are a rising-stem design

and the rest are quarter-turn valves. Valves may either be equipped with a hand-wheel or lever for manual operations, or an actuator or motor for automated operation.

Vented Emissions -

Vented emissions are releases to the atmosphere by design or operational practice, and may occur on either a continuous or intermittent basis. The most common vented emissions causes or sources are gas-operated devices that use natural gas as the supply medium (e.g., compressor start motors, chemical injection and odorization pumps, instrument control loops, valve actuators, and some types of glycol circulation pumps), equipment blowdowns and purging activities, and glycol dehydrators still-column off-gas venting.

Volatile Organic
Compounds (VOC) -

Any compound of carbon, excluding carbon monoxide, and carbon dioxide, which participates in atmospheric chemical reactions. This excludes methane, ethane, methylene chloride, methyl chloroform, many fluorocarbons, and certain classes of per fluorocarbons.

ACKNOWLEDGEMENTS

The funding provided by US Environmental Protection Agency (Grant Number XA-83046001-1) in support of this project is gratefully acknowledged. Special thanks are given to the personnel at each of the host facilities for their help, interest in the work being done, and useful feedback, and to all the sponsors for their constructive review comments.

1 INTRODUCTION

An intensive fugitive emissions screening and measurement program was conducted during the first quarter 2004 and second quarter 2005 at five gas processing facilities in the USA. The selected facilities were of various ages, types, and throughputs and were evaluated with a strong emphasis on identifying and quantifying natural gas losses from leaking equipment components in heat-cycle and vibration services. The facilities included sweet and sour gas processing, and a variety of processes including compression, separation, storage, and flare systems.

The study's primary objective was to demonstrate the cost-effectiveness of conducting a comprehensive leak detection and repair (LDAR) program at domestic gas production and processing facilities using HiFlow™ Sampler technology. Field measurements also included an assessment of emissions from continuous vents, combustion equipment, and flare systems and natural gas-fuelled equipment diagnostic checks. Such efforts are employed to achieve sensible and verifiable reductions in methane, GHG, and NMHC emissions, while providing industry with potentially noteworthy emissions reduction opportunities with commensurate financial incentives. These opportunities were presented to surveyed plants in the plant level reports. Based on the compiled test results, the greatest opportunities for cost-effective reduction of natural gas losses are from the control of leaking equipment components and leakage of process gas into vent and flare systems. Therefore, the report emphasizes fugitive leak opportunities.

Background information, on key differences between the conventional EPA Method 21 approach to leak detection and repair and the approach used here, is provided in Section 2. A more detailed description of the current approach and other measurement techniques employed plus an overview of the basic assessment methodology are presented in Section 3. Section 3 also delineates the economic criteria used to evaluate the identified emission control opportunities.

The measurement program results are presented in Section 4. These results include an overview of the identified control opportunities, measured emissions and natural gas loss inventories, average emission factors, and leak statistics. The study conclusions and recommendations are presented in Section 5, and cited references are listed in Section 6. Detailed listings of all the identified equipment leaks are provided in Appendices I and II, ranked by emission rate and payout period, respectively. The following information is provided for each component: Site No., Tag No., Process Unit, Component Description, Emission Rate ($10^3 \text{ m}^3/\text{yr}$), Estimated Repair Costs (\$), Net Present Value of Repair (\$), CO₂E Emissions (tonne/yr), and Repair Payback Period (yr).

Appendix III presents detailed accounts of the combustion analysis and efficiency testing results for each tested unit. Average equipment component schedules by process unit type are provided in Appendix IV. The financial considerations and assumptions applied are summarized in Appendix V while the assumed component repair costs and mean repair lives are provided in Appendix VI. Physical Acoustics V-Pac measurements are detailed in Appendix VII.

2 BACKGROUND

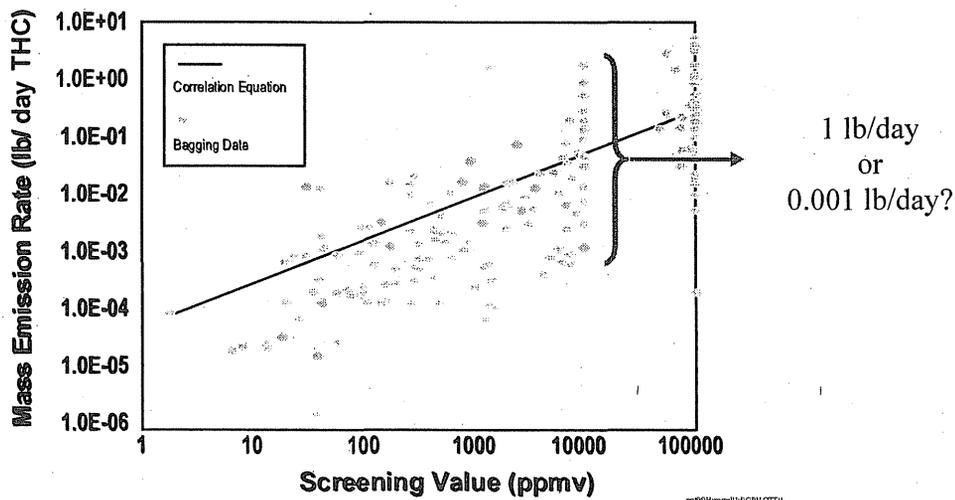

Under the settlement terms of a recent Consent Decree, deadlines are established for EPA to review and, if appropriate, revise the NSPS standards for Subparts J, VV and GGG, 40 CFR 60.100–109, 60.480–498, 60.590–593. The New Source Performance Standards in 40 CFR Part 60 KKK (back reference VV) provides the regulatory requirements for conducting a leak detection and repair (LDAR) program for the onshore natural gas processing industry. This standard is directed at controlling/reducing volatile organic compound (VOC) emissions and specifically excludes methane and ethane. Therefore, gas-processing facilities have typically only included the light liquid and refrigeration areas in leak detection programs. Subsequently, very little information pertaining to potential leakage from the remainder of the facility (i.e. non-regulated) was available. The primary project objectives were to evaluate leak potentials and the cost-effectiveness of implementing LDAR programs at natural gas processing facilities.

Most natural gas industry LDAR programs rely on U.S. EPA Method 21. Depending upon the leak screening instrument detector, the concentration of either total hydrocarbons (THC) or VOCs in the air from a leaking component is measured, and then the leak rate is estimated using a correlation equation or measured using the bag and sample procedure. In a conventional LDAR program for fugitive emissions control, U.S. EPA's Method 21 is utilized to screen the facility for leaks at a prescribed frequency (e.g. quarterly, bi-annually or annually). All components that screen above a given threshold (typically 10,000 parts per million) are to be repaired.

There are a numerous shortcomings with the Method 21 approach. The uncertainties in emissions estimates calculated using the correlation equation are very high. Additionally, the correlation equations only go to screening concentrations of 10,000 or 100,000 parts per million – any leak above these screening concentrations has the same estimated leak rate (known as a “pegged source” emission factor). Figure 1 shows the correlation equation and screening concentration values measured using Method 21 plotted against the leak rate measured with the bag and sample procedure. The data scatter is about \pm two orders of magnitude. The bag and sample procedure directly measures leak rates; however, is very time intensive and expensive and the correlation equation approach is therefore used for most large scale LDAR programs. Data collected in Phase 1 showed that 65% of the natural gas facilities fugitive components that screened above 10,000 parts per million are cost-effective to repair. Consequently, by repairing all components that screen above 10,000 parts per million per Method 21, resources are wasted by repairing components – 35% of the total based on the Phase I results – whose repair costs exceed the value of gas saved. Another shortcoming of the conventional Method 21 approach is that it does not accurately measure either the facility baseline emissions or the emissions reduction (error is \pm 300%). Because the emissions reduction cannot be accurately determined, the benefits of implementing an LDAR program cannot be evaluated.

The HiFlow™ Sampler, described in Section 3.1.2, quickly and accurately quantifies fugitive emissions leak rates and has significantly reduced natural gas plants LDAR programs costs. Cost-effective repairs, those with repair costs less than the saved gas value, can be identified and completed while non cost-effective repairs are not performed and maintenance resources are optimized. The Phase 1 data showed that 80 to 90 % of facility emissions are often emitted from a small fraction of the leaks; thus, significant emissions reductions can be achieved by repairing a few big leakers. In addition, a HiFlow™ Sampler LDAR program accurately measures the facility baseline emissions¹ and the emissions reduction can be accurately determined. Therefore, the LDAR program implementation benefits can be evaluated.

Figure 1 Leak Rate versus Concentration

The primary objective of the overall study is to assess baseline methane (CH₄) emissions at natural gas processing and production facilities, and delineate and quantify the extent of cost-effective opportunities for reducing these emissions. A secondary objective is to evaluate the potential for cost-effective reduction of other GHG emissions (primarily CO₂) through process efficiency gains, and to establish a Best Management Practice for conducting DI&M programs.

Primary sources of methane emissions include, leakage, venting, storage losses, incomplete combustion (fuel use and flaring). Other methane losses includes, increased fuel use due to avoidable inefficiencies, thermal efficiency of fired equipment, compression efficiency, tail gas incinerators, electric power generation, and horsepower mismatch to required work.

Phase II addressed data gaps identified during the Phase I study and improved the overall statistical significance of the Phase I study for system wide extrapolation of results and

serves as the basis for developing an industry specific best management practices guidance document.

Phase II provided the following:

- An increased number and type of gas processing facilities and components within the current database giving an improved statistical basis for extrapolation of the results system-wide.
- An indication of the effectiveness of repairs to the major leakers at a Phase I facility and the increases in leakage over time at gas plants.
- An initial indication of CH₄ and GHG emission reduction opportunities at gas production facilities upstream of the gas processing plant (e.g., gas-gathering systems including compression and well-site facilities).

Although the primary goal of Phase II was to expand the results of the prior Phase I DI&M study through broader industry participation and an increased emissions database, a secondary goal was to assess and integrate a suite of tools for improving survey efficiency. The scope of work and project approach for the second Phase was consistent with the Phase I study and allows for direct comparison with the previous results.

3 METHODOLOGY

This section describes the methodology used by the study team to identify and evaluate cost-effective emission-reduction opportunities at the gas processing facilities. The different measurement techniques considered for each primary source type are delineated.

The five selected test facilities were chosen to provide a representative cross section of gas plant ages with significant on-site compression since these types of facilities were expected to offer the greatest opportunities for cost-effective reduction of natural gas losses. As shown in Table 1, three sweet and two sour gas processing plants were selected. These plants ranged from 6 to 57 years in age, for an average age of 31, and all of them have compression facilities and mole sieve dehydration units. In comparison, the average age of gas processing facilities in the United States is estimated at 26 years.

| Site # | Type | Age | Component Count | Gas Throughput (MMscfd) |
|---------|-------|------|-----------------|-------------------------|
| 1 | Sweet | 6 | 22,290 | 500 |
| 2 | Sweet | 28 | 12,330 | 206 |
| 3 | Sweet | 39 | 18,353 | 130 |
| 4 | Sour | 27 | 16,687 | 45 |
| 5 | Sour | 57 | 4,778 | 87 |
| Average | | 31.4 | 14,887 | 193.6 |

The component counts presented in Table 1 above include components less than 0.5" nominal pipe size. Overall, 14.5% of these component counts are components less than 0.5" nominal pipe size.

3.1 Emissions Survey

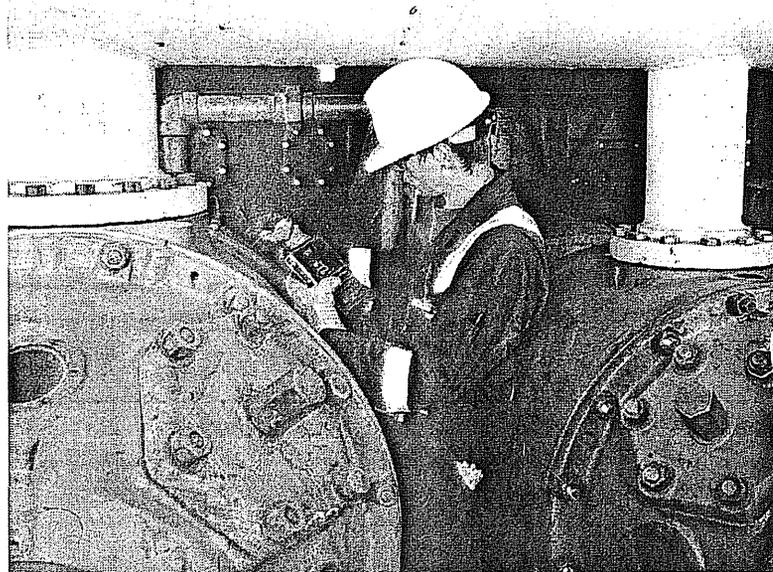

The site surveys included all or some of the following elements, as applicable:

- screening equipment components to detect leaks;
- measuring leaking equipment components (i.e., leakers) emission rates;
- measuring continuous vents emissions and emergency vents residual flows during passive periods;
- counting the surveyed equipment components;
- measuring residual flare-gas rates;
- performance testing natural gas-fueled combustion equipment;
- performance testing of compressors (newly added for Phase II);
- sampling process and waste streams;
- determining site-specific average emission factors for fugitive equipment leaks; and
- conducting an identified control opportunities cost-benefit analysis.

3.1.1 Component Screening

Equipment components on most process-, fuel- and waste-gas systems were screened for leaks. Components types surveyed included flanged and threaded connections (i.e., connectors), valves, pressure-relief devices, open-ended lines, blowdown vents (i.e., during passive periods), instrument fittings, regulator and actuator diaphragms, compressor seals, engine and compressor crankcase vents (see Figure 2), sewer drains, sump, drain tank vents and tank hatch seals.

Figure 2 Survey Team Using Gas Detector to Quantify Concentration and Screen Compressor Leaks

Components in light-liquid service generally were not screened since the program focus was natural gas losses. Furthermore, light-liquid service components do not contribute significantly to total hydrocarbon losses at gas processing plants due to their low average leak rates (U.S. EPA, 1995) and relative numbers. Leak detection (or screening) was conducted using bubble tests with soap solution, portable hydrocarbon gas detectors (Bascom-Turner Gas Sentry CGI-201 and CGI-211 and a GMI Gas Surveyor3) and an acoustic leak detector (SDT International, SDT-120).

Bubble tests, shown in Figure 3, were performed on the majority of components (including pipe threads, tubing connections, and valves) because it is usually the fastest screening technique. Components that could not be screened using bubble tests included any in high-temperature service, certain flanged connections and open-ended lines. These were screened using the gas detectors. Component determined to be leaking by the bubble tests were then screened using a hydrocarbon vapor analyzer. Hydrocarbon analyzer screening values of 10,000 parts per million or greater defined components as leaking or "leakers."

Under normal operation, waste gas volumes from blowdown or depressurization events are sent to the flare system. If the valves do not properly reseat after one of these events, gas will continuously leak through the valves. The Physical Acoustics Corporation VPAC™ model 5131 ultrasonic detectors were used to detect through- valve leakage into closed loop vent systems routed to flares.

Figure 3. Physical Acoustics VPAC

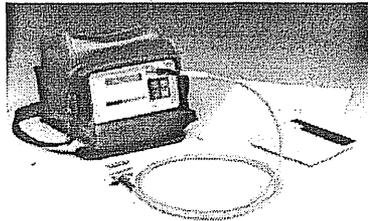

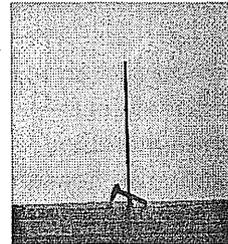

Figure 4. Residual Flaring

Ultrasonic measurements coupled with data on valve size, type, and differential pressure is used to derive mass rate loss estimates. The hand held instrument uses an acoustically coupled sensor that is held against the pipe upstream and downstream of the pressure relief valve and the relief valve body. At each location the sound level in decibels is detected. Leaking valves will have a larger signal than completely sealed valves. Appendix VII provides measurement details.

All identified leaking components were tagged (shown in Figure 4) and the specific leak source and date were noted on the tag. The emission rates for all leakers were determined using the procedures described in Sections 3.1.2 and 3.1.3. All leaker tags were left in place after the leak rate measurement to allow follow-up action by facility personnel. A total of 74,438 individual equipment components and numerous process vents, natural gas-fueled compressor and generator engines, process heaters, and flare/vent systems were surveyed. Sufficient process information was collected to determine total annual emissions from the compiled measurement results.

Additionally, specific emission-control opportunities were identified, and a preliminary cost-benefit analysis was performed to evaluate these opportunities. The analysis considers the estimated cost of repair and corresponding lifetime and the conserved gas value. Site personnel were solicited to provide input and assistance in identifying site-specific constraints and to help ensure that cost data were satisfactorily considered.

3.1.2 Leak Detection Methods

Conventional leak detection techniques, including bubble tests, handheld organic vapor analyzers and acoustic ultrasonic leak detection equipment, have traditionally been used to screen equipment components for leaks in accordance with Method 21 (U.S. EPA, 1997). These traditional leak detection techniques are

thorough; however, they tend to be quite time consuming. More recently, optical passive infrared camera technologies have been developed in an effort to improve the leak detection process efficiency. Although the optical IR cameras have performed well during numerous field trials, there are not yet sufficient data to demonstrate that the technology should be adopted in lieu of traditional screening techniques.

Although separated and excluded from the EPA portion of the scope of work, all five facilities integrated a passive midwave infrared camera in the leak surveys. A secondary program objective was to compare the performance of the passive IR camera optical leak detection method with conventional leak detection methods. Although individual DI&M surveys did not yield sufficient data to provide a quantitative comparison of the conventional methods and the camera, sufficient information for a qualitative comparison of the methodologies and performance exists.

As optical infrared technology advancements rapidly progress the state of the science, it is likely that EPA will consider addressing remote leak detection methods within future revisions to the New Source Performance Standard (Under the settlement terms of a recent Consent Decree, deadlines are established for EPA to review and, if appropriate, revise the NSPS standards for Subparts J, VV and GGG, 40 CFR 60.100–109, 60.480–498, 60.590–593.) The findings discussed below highlight considerations for future method development.

Noteworthy findings from integrating optical remote sensing in DI&M include:

- The IR camera is capable of screening leaks approximately 3 times faster than conventional methods (for two people: typically 2,400 components/day for conventional versus 6,400 components/day for the optical);
- The IR camera is not currently capable of quantifying a leak and can only be used to identify leak sources. The camera is capable of identifying leaks (using a variety of lenses) that are inaccessible to conventional techniques that principally rely on direct access.
- The camera offers visual confirmation of leaking emissions sources and allows rapid source identification; however, ambient hydrocarbon concentrations may interfere with the camera ability to isolate a leak source. Engine magnetos caused interference and precluded leak screening on fuel gas headers, individual cylinder connections, and fuel injectors, significant leakage sources on older engines;
- Water vapor overlays the hydrocarbon absorption spectra and therefore steam plumes are visually comparable to hydrocarbon leaks and very difficult to differentiate;
- Rain and fog limit the IR camera utilization; and
- The IR camera cost is approximately \$75,000 to \$100,000 compared to \$5,000 to \$10,000 for conventional leak screening tools. Typical daily costs for a conventional leak screening team is \$1,500 plus expenses while a typical daily charge for an experienced IR camera team is \$3,000 plus expenses.

Leaks can occur through valves and pressure relief valves that have not seated properly after activation. This leak is not out of the process equipment and so cannot be seen with optical methods or by organic vapor analyzers. Instead an acoustic method has been developed that measures the noise generated by gas flowing through a small gap. The acoustic detector compares the sound before the valve, at the valve and downstream from the valve and compares the sound to a database of previously measured leaks. This instrument was used to measure leaks at pressure relief valves.

Due to the high volume of flared hydrocarbons at several sites and the large number of possible sources tied into the flare system (e.g., leaking pressure-relief devices, drains, and blowdown valves connected to the header), connecting the flare to a vapor recovery unit should be considered as a cost effective option for capturing the residual gas flow. Another option is to target the individual residual gas flow sources; however, these sources are often difficult to isolate, usually require a major plant shutdown to fix (i.e., resulting in significant indirect costs), and are likely to reoccur.

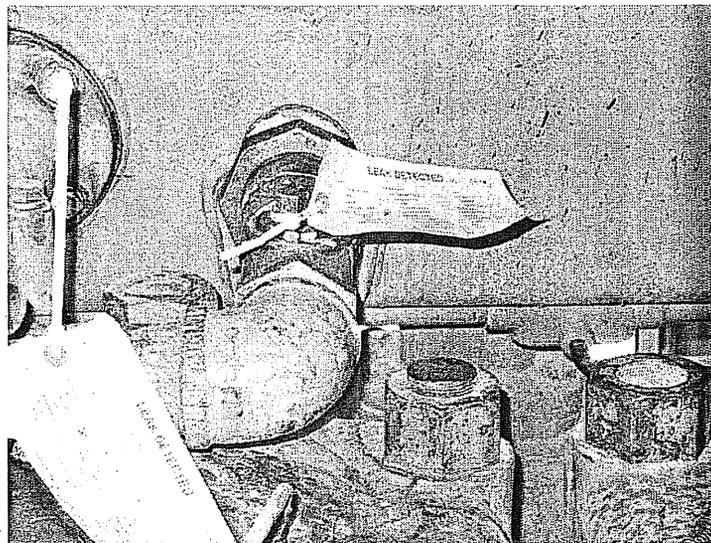

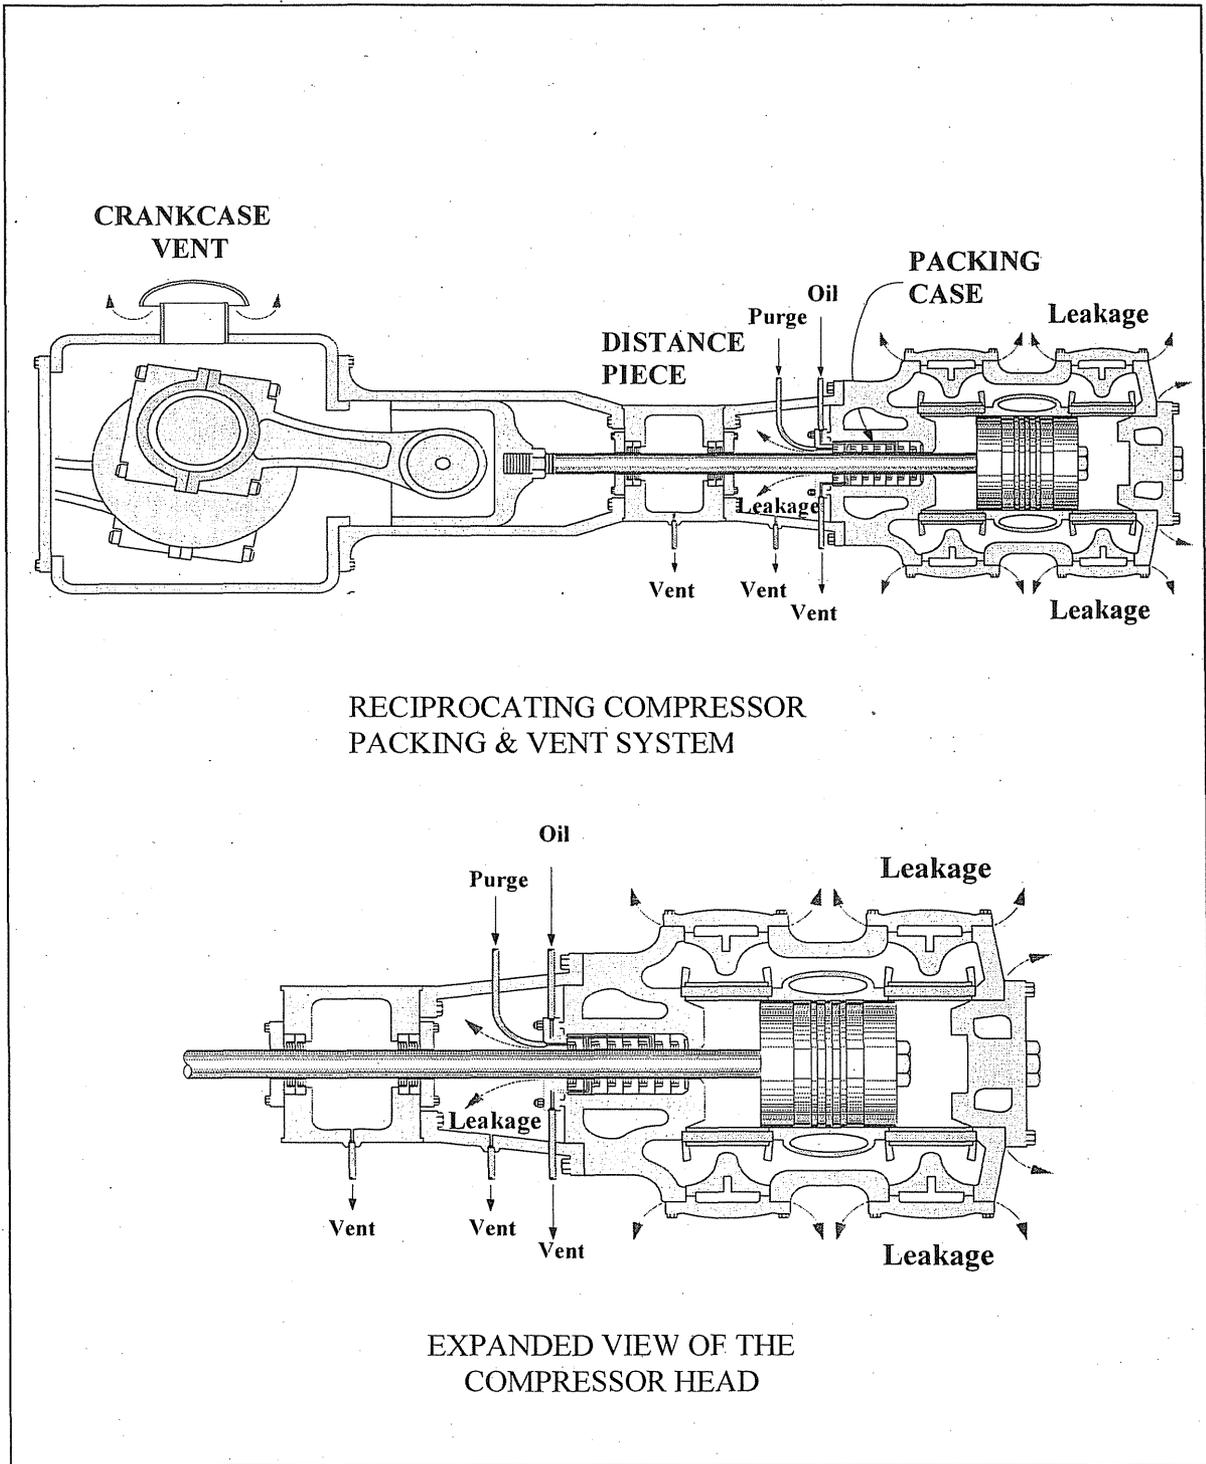

Figure 7. Cut-Away View Of A Natural Gas Compressor Showing The Potential Leak-Points Including The-Compressor-Seals And Crankcase Vent.

The following basic information was recorded for each leaking component:

- Type
- Model or Style
- Service
- Size
- Process Unit
- Process Stream
- Pressure and Temperature

3.1.3 Leak-Rate Measurements

The HiFlow™ Sampler was the primary emission rates measurement method for leaking equipment components. The HiFlow™ Sampler was not used for components leaking at rates above the equipment upper limit (i.e., about 14 m³/h for the current HiFlow™ design) and for most open-ended lines and vents. Either bagging or direct measurement techniques, as appropriate, were used in these cases (see Section 3.1.3). The same HiFlow™ prototype was used between Phase I and Phase II for consistency. The following provides a brief description of the HiFlow™ Sampler.

The HiFlow™ Sampler is an economic means of measuring individual leaking equipment components emission rates with sufficient accuracy for objective repair opportunities cost-benefit analyses. Bagging all leakers to differentiate between economic-to-repair and uneconomic-to-repair components is expensive and, therefore, is not normally done (typically, 10 to 30 leak-rate measurements per hour can be performed using the HiFlow™ Sampler compared to only 2 per hour using bagging techniques). Furthermore, compiling Method 21 (U.S. EPA, 1997) components screening data and then applying leak-rate correlations or stratified emission factors to determine leak rates does not provide sufficient accuracy for economic analysis. The correlation leak rate uncertainty for individual components is ± two orders of magnitude and the stratified emission factors are even less reliable. In comparison, the HiFlow™ Sampler and bagging measurements uncertainties are only about ±10 to 15%. Accordingly, the HiFlow™ Sampler (shown in Figure 6) provides a practicable means of making objective repair decisions. The reliability and use of the HiFlow™ Sampler has been demonstrated in a number of studies (Howard *et al.*, 1994; Lott *et al.*, 1995).

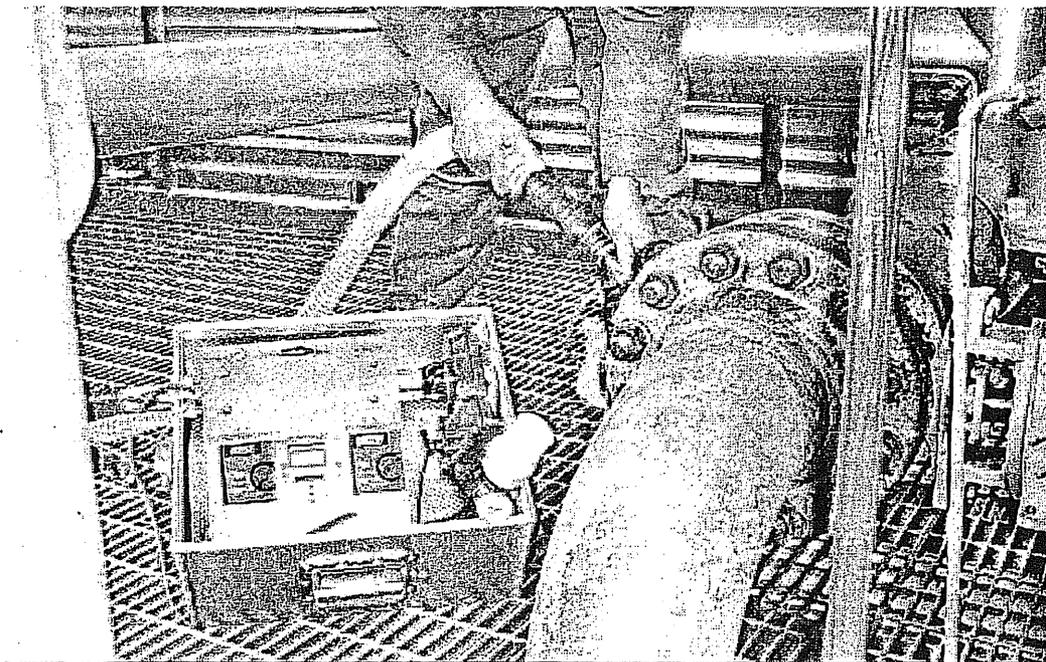

The HiFlow™ Sampler operating principle is simple – a variable-rate induced-flow sampling system provides total or near total leaking component emissions capture. Specially-designed attachments are used to encapsulate the leaking component and allow ambient air to flow over the component; the air-leaking gas mixture is drawn into the Sampler with a vacuum pump. A dual-element hydrocarbon detector (i.e., catalytic-oxidation/thermal-conductivity), inserted directly in the HiFlow™ sample line, measures hydrocarbon concentrations in the captured air-gas stream ranging from 0.01 to 100%. A background sample-

collection line and hydrocarbon detector allow the sample readings to be corrected for ambient gas concentrations, which is particularly important in buildings and confined areas. A thermal anemometer, also inserted directly into the sample line, monitors the sampled air-hydrocarbon gas mixture flow rate. The HiFlow™ Sampler is intrinsically safe and is equipped with a grounding wire to dissipate static charge formed as air passes through the sample collection line and instrument.

The HiFlow™ Sampler battery-operated fan can generate a maximum sampling velocity of approximately 366 m/min (1200 ft/min), which corresponds to a maximum leak rate measurement capacity of 14 m³/h (8.5 scfm). Increasing the sampling rate generally improves the leak capture efficiency up to the point of total capture. Increasing sampling rates beyond this point causes increased emissions dilution with ambient air. Excessive dilution may cause the pollutant concentration to either fall below the sample detector range or to decrease to background levels resulting in a zero reading. The sampling rate is adjusted manually using a backpressure valve mounted on the fan outlet. For large leaks, the backpressure valve is left open; while for small leaks, the airflow rate is reduced so that the hydrocarbon concentration is within the detector sensing range.

The HiFlow™ Sampler sample and background hydrocarbon detectors were calibrated with 100% methane and 2.5% methane-in-air to cover both ranges of the dual-element detector system. The detectors were zeroed using ambient air upwind of the facilities. The calibrations were done prior to HiFlow™ Sampler use at each site, and then periodically thereafter to ensure that no significant drift occurred. The HiFlow™ Sampler was also periodically calibrated by releasing known methane flows, determined using a bubblometer or diaphragm meter, into the sampler and comparing the leak rate measured by the HiFlow™ to the metered gas release rate. Three correction factors are applied to the raw data.

Figure 8. Prototype GRI HiFlow™ Sampler

3.1.4 Vents and Open-ended Lines Emissions Measurements

The emission rates from open-ended lines and vents were measured using an appropriate flow-through measurement device (i.e., a precision rotary meter, diaphragm flow meter, or rotameter, depending on the flow rate) if total flow capture was safe and practicable to achieve and the resulting backpressure on the vent system did not impact the gas flow. Otherwise, flows were determined by measuring the flow area and velocity profile across the vent line.

Where total flow capture was possible, the vent or open ended line pipe or tube was connected to the flow-through measurement device with PVC tubing. The tubing-pipe and tubing-flow meter connections were sealed with custom-fabricated slip-on sheaths made of neoprene or plastic sheeting. Each flow measurement was averaged over a 2 to 20 minute interval, depending on the flow volume and variability.

When measuring flows from vents, a distinction was made between continuous and intermittent vent systems. Emissions from intermittent vents during inactive periods (i.e. non-venting operation) were defined as leakage. Emissions from continuous vent systems and intermittent vent systems during active periods were defined as venting emissions. Vent and open-ended line leaks were detected by hydrocarbon sensor screening.

3.1.5 Residual Flaring Rates Determination

Flare line flows were determined using two methods:

- **Flare Line Velocity Profile and Flow Area Measurement** - Flow velocities were measured using a pitot tube, hot-wire anemometer or thermal dispersion anemometer. The traverse points were selected in accordance with U.S. EPA Methods 1 and 1A. Safe-to-access ports on the stack, the common line to the flare, or on each branch line connected to the flare system are required.
- **Flow Rate Calculated from Pressure Drops Measurements** - the pressure drop between the flare tip and a suitable upstream point on the flare line is measured and the gas flow required to produce that pressure drop is calculated. Several inches of water column pressure drop is needed for reasonable flow rate estimation. Low flow velocities in large diameter pipes may not produce measurable pressure drops despite significant volumetric flows.

The direct measurement method is more accurate and was used when sample ports were accessible. The gas stream hydrocarbon concentrations were either determined using a portable combustible-gas detector or from flare gas laboratory analyses (where available).

Continuous flare systems flows include purge gas flows and equipment fugitive leaks into the flare system. To distinguish between purge gas flows and leakage, the minimum required purge gas rate was calculated using the procedure presented by Stone *et al.* (1992). The difference between the total flare system gas flow rate and the calculated purge gas flow rate was assumed to be the leakage or potentially avoidable natural gas loss. The economics of conserving the gas losses can then be determined.

Primary sources of flaring and vented emissions include disposal of waste associated gas at oil production facilities, casing gas vents at heavy oil wells, gas operated devices, still column off-gas vents on glycol dehydrators, leakage into vent/flare header (5-10% of valves leak and 1-2% of these contribute 75%), excessive purge gas rates and inspection and maintenance activities including well testing, servicing, and pipeline tie-ins.

3.1.6 Natural Gas-Fueled Equipment Performance Testing

Natural gas-fueled engines, process heaters, and boilers were tested to identify avoidable inefficiencies causing excessive fuel consumption and emissions. The focus was on identifying situations where equipment required tuning, optimization, or repairs, or was mismatched with the current process demands causing operation outside the performance curve. The identification of

opportunities to recoup waste heat from the units or to reduce energy requirements through process modifications was beyond the project scope.

The testing on each unit involved analyzing the flue gas, measuring the flue gas temperature, obtaining a fuel gas composition analysis, and where possible, measuring the flow rate of one or more of the following: fuel gas, combustion air, and flue gas. The flue gas analyses were conducted using an Enerac 2000E Portable Combustion Analyzer equipped with detectors for O₂, CO, CO₂, NO_x, and combustibles and thermocouples for measuring ambient and stack-gas temperatures. The flue gas was sampled through either an exhaust stack sampling port or at the stack top. Additionally, the unit, make, and model and site ambient conditions (i.e., temperature and barometric pressure) were recorded.

Typically, insufficient process data were available to reliably estimate the total useful process work done by each unit, or to determine overall unit performance. Consequently, a simplified approach was used where the following parameters were evaluated and their deviations from proper operating conditions were indicators of improvement opportunities:

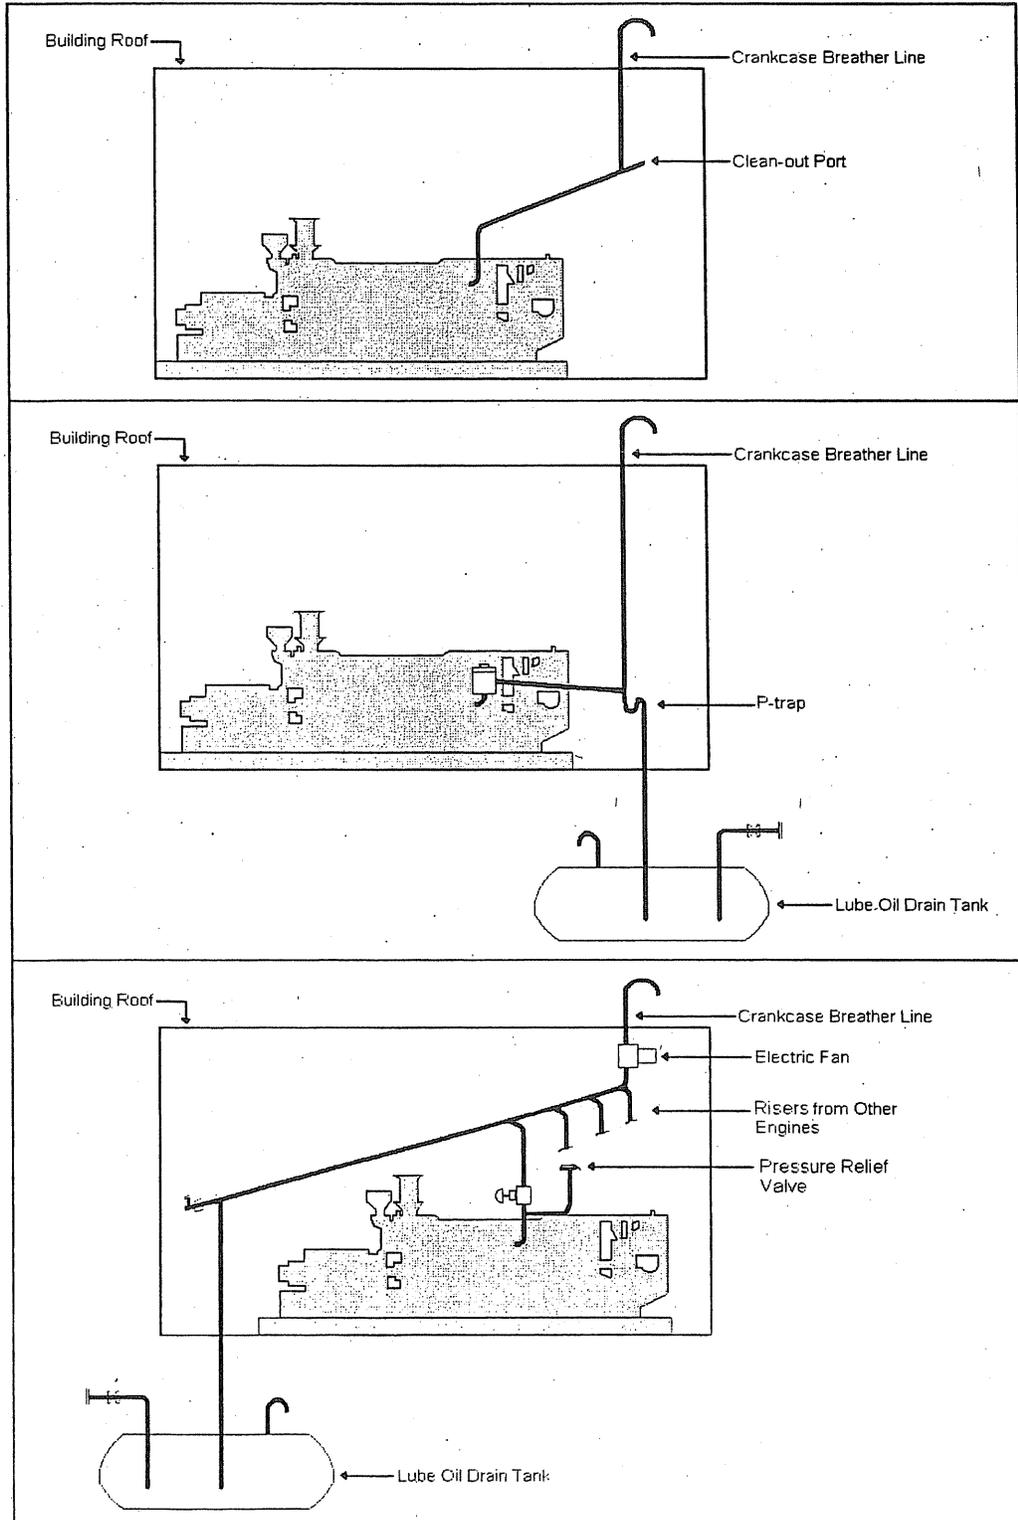

- flue gas residual heat content (i.e., stack losses);
- excess air setting; and
- flue gas concentrations of carbon monoxide and unburned hydrocarbons.

Additionally, reciprocating engines crankcase vents were checked for significant blow-by (i.e., leakage past the piston rings into the crankcase) because blow-by reduces cylinder compression that causes inefficient operation and contributes to unburned and partially burned fuel emissions. As a first approximation of the resulting performance loss, measurements were performed to quantify the combustible gases emitted as crankcase vent blow-by. These results are presented as fugitive equipment leaks. On integral compressor units (i.e., compressor units where the engine and compressor share a common crankshaft and crankcase), crankcase vent emissions potentially include engine cylinders blow-by and compressor seals leakage which enters the crankcase through the distance piece. This is shown in Figure 5.

In many cases, the engine crankcase was vented inside a building or work area. This poses a potential health and safety risk. Figure 7 depicts various venting configurations recommended by the engine manufacturers.

Key sources of combustion emissions include, oversized engines, heaters and boilers, poor tuning (e.g., air/fuel ratio), leakage past pistons in engines, lack of waste heat utilization, and fouled burner tubes.

Figure 9. Typical Stationary Compressor Engines Crankcase Vent Configurations Recommended by Manufacturers.

Where possible, equipment-specific emissions factors on either a kilogram-per-cubic-meter fuel basis (if the unit fuel consumption rate was known) or on a kilogram-per-day basis (if the flue gas flow rate was known) were generated for estimating CO, NO_x, CO₂ and combustibles emissions. A detailed calculations summary and a discussion of normal operating efficiencies and losses are provided in Appendix III.

3.1.7 Compression Equipment Analysis

This section outlines calculation methodology used in analyzing the compressor efficiencies and presents detailed results of the calculations. A reciprocating gas compression equipment analysis was conducted to identify avoidable compression inefficiencies caused by pulsation losses and internal gas leakage past the valves and piston rings. An acceptable energy loss from compression inefficiencies is 5% of the ideal energy requirement and excessive losses are generally avoidable (Hanlon, 2001). Another avoidable inefficiency associated with gas compression is excessive pressure drop through interstage coolers. Typically, interstage coolers have a design pressure drop of about 101 kPa, and excessive pressure drops may indicate cooler fouling.

The compression process is nearly adiabatic when no attempt is made to cool the gas internally as it is being compressed. If the process is assumed to be adiabatic and changes to the kinetic and potential energies of the gas are neglected, the work of compression varies with the change in enthalpy according to the following equation:

$$W = \dot{m}(h_d - h_s) \quad (\text{D.1})$$

Where:

- W is the compressor work
- \dot{m} is the mass flow rate of gas
- h_s is the suction enthalpy
- h_d is the discharge enthalpy

The following property data was collected for each stage of compression:

- $P_{s,m}$ – measured suction pressure
- $T_{s,m}$ – measured suction temperature
- $P_{d,m}$ – measured discharge pressure
- $T_{d,m}$ – measured discharge temperature

For a simple compressible system the state is specified by two independent intensive properties. Therefore, other properties of interest such as enthalpy and entropy follow from the temperature and pressure measurements and the actual work of compression can be calculated using Equation D.1.

For adiabatic compression the ideal process is isentropic. The suction state for the ideal process is still defined by the measured suction properties. Where as the ideal discharge state is defined is defined by the discharge entropy and measured discharge pressure. For an isentropic process entropy is conserved and the discharge entropy is determined from the suction state. The suction enthalpy follows from the state definition and the ideal compression work can be calculated using Equation D.1. This ideal compressor work is corrected to account for valve pressure drop based on the method presented in Figure 13-14 of Gas Processors Suppliers Association Engineering Data Book Volume 1. The corrected ideal state is then defined by the enthalpy calculated using equation D.1 and the measured discharge pressure. The corrected ideal discharge temperature follows from the state definition.

In practice the extent to which the corrected ideal compressor efficiency can be achieved is limited by physical constraints such as pulsation losses and valve slippage. For the purpose of this analysis an acceptable energy loss is taken as 5% of the corrected ideal energy requirements (Hanlon, 2001). The acceptable discharge state is then defined by the enthalpy calculated using Equation D.1 and the measure discharge pressure. The acceptable discharge temperature follows from the acceptable discharge state.

For situations where the actual compressor work is greater then the acceptable compressor work a potential savings is estimated. This estimate takes into account the efficiency of the compressor driver and the price of natural gas.

Key sources of compressor inefficiencies include, internal valve and cylinder leakage in reciprocating compressors, pulsation losses, excessive gas recirculation, non-optimal loading.

3.1.8 Storage Tanks Excess Emissions Evaluations

Storage tanks are a potentially significant emission sources due to evaporation losses, particularly where intentional product boiling or flashing occurs. Primary sources of storage tank emissions include:

- Flashing losses at production facilities;
- Unintentional gas carry-through to storage tanks;
- Leaking drain and dump valves;
- Malfunctioning level controllers;
- Inefficient upstream gas/liquid separation;
- Piping changes resulting in unstabilized product going to tanks;
- Malfunctioning vapor recovery systems;
- Faulty blanket gas regulators or pressure controllers; and
- Fouled vapor collection lines.

However, other less recognized, and often unnoticed; contributions to atmospheric emissions or vapor losses from storage tanks include the following:

- Process gas or volatile product leakage past drain or blowdown valves seats into the product header leading to the tanks;
- Inefficient upstream gas/liquid separation allowing some gas carry-through (by entrainment) to the tanks. This usually occurs where facility inlet liquid production (e.g., produced water) has increased significantly over time causing inlet separators to be undersized for current conditions;
- Piping modifications causing unintentional routing of high vapor pressure product to tanks not equipped with appropriate vapor controls;
- Storage tanks overheating or hot product rundown to tanks containing volatile material;
- Malfunctioning or improperly set blanket gas regulators and vapor control valves can cause excessive blanket gas use and, consequently, increased flows to a vent or control device (e.g., flare or vapor recovery compressor). The blanket gas is both a product vapors carrier and a potential pollutant itself (i.e., natural gas is usually used as the blanket medium for blanketed tanks at gas processing plants); and
- Leaking hatches and pressure-vacuum valves on tanks equipped with gas blanketing systems result in direct atmospheric emissions of product vapors and blanket gas.

The last two leaks are reported under flare systems and fugitive equipment leaks, respectively. The other leaks were determined by measuring venting rates (see Section 3.1.3) and comparing the observed emissions to calculated working losses for conditions at the time of testing.

3.1.9 Component Counts

Equipment component counts were prepared based on an initial review of the process and instrumentation drawings, followed by a site walk-through inspection of each process unit. The following component information was collected:

- type (e.g., connector, valve, control valve, pressure relief valve, pressure regulator, orifice meter, other flow meter, blowdown, open-ended line, etc.);
- style (e.g., threaded and flanged connection, coupling, ball valve, plug valve, globe valve, gate valve, butterfly valve, pump seal, compressor seal, regulator, sampling connection, etc.);
- nominal size;
- process temperature and pressure;
- service (i.e., natural gas, light hydrocarbon liquid); and
- application (i.e. process stream and unit).

3.1.10 Average Emission Factors Development

The average emission factor for each component type was determined by dividing the aggregate component emissions by the number of components. Total emissions are the sum of emissions from both leaking and non-leaking components. Leaking components (i.e., those with screening values of $\geq 10,000$ ppm) emission rates were quantified using the methods described in Section 3.1.2. Non-leaking components were assigned the average non-leaking emission rates presented in the Protocol for Equipment Leak Emission Estimates (U.S. EPA, 1995).

3.1.11 Emission Control Guidelines

There are currently no regulations or codes of practice that apply specifically to fugitive equipment leaks emissions control for natural gas processing facilities. Guidelines typically used are maximum leak frequencies of 10% for compressor seals, 0.5% for connectors, and 2% for other component types

3.2 Equipment Repair Cost-Benefit Analyses

Practicable opportunities for reducing fugitive equipment leak and process venting emissions were assessed on a source-by-source basis. The net cost/benefits of identified control options were determined in dollars per tonne of CO₂-equivalent annual emissions reduction. The information and assumptions regarding the cost estimates, the lost gas value, and repair lives used in these analyses are summarized below. The financial discount rate and other financial considerations applied in these analyses are summarized in Appendix V.

3.2.1 Equipment Repair Cost Estimating

Detection and control costs are assessed on an individual-source or per-component basis according to estimated average site-specific costs. Actual costs will vary with the facility location and layout, the required work, the service type (i.e., sweet or sour), and the actual repairs or control measures required.

The basic cost to repair or replace a leaking equipment component is estimated based on the component type and size, typical billing rates quoted by the service providers (e.g., compressor maintenance and repair companies, and valve repair and servicing companies) and the estimated labour and materials requirements. Where possible, both direct and indirect costs are considered. Direct costs are the actual costs for parts, onsite labour, equipment, tools and disbursements, and are summarized in Appendix VI. Indirect costs are revenue losses due to any process shutdowns or interruptions beyond normally scheduled facility turnarounds, and the value of gas vented or flared during the specified repair or replacement activity. Where indirect costs render the repair or replacement cost ineffective, it is assumed that the work will be delayed until the next scheduled plant

turnaround. Otherwise, it is assumed that the repairs are made soon after the leak detection and evaluation.

3.2.2 Natural Gas Value

The value of natural gas was assumed to be \$7.15/Mscf (\$6.78/GJ). The propane, butane and condensate values were assumed to be: propane \$8.13/GJ; butanes \$9.63/GJ and condensate \$9.63/GJ. The actual value of avoided natural gas losses is very site-specific and can depend on many factors including:

- Local market pricing;
- Impact of emission reductions on specific energy consumption, equipment life, workplace safety, and system operability, reliability and deliverability;
- Contract terms;
- Facility remoteness;
- Gas concentrations of contaminants and NMHCs;
- Applicable taxes and tax shields.

3.2.3 Repair Life

It was assumed that a leak, once repaired, will remain fixed for some finite time period, and then will reoccur. The mean time between failures depends on the component type, style, quality, application, and activity levels (e.g., number of valve operations) and site maintenance practices. Estimates of the mean time between failures for each component type are provided in Appendix VI. These values are very crude estimates based on the author's experiences and limited host facilities feedback. The relatively low mean time between failures for connectors reflects wear and tear from inspection and maintenance of associated equipment units. In a formal leak detection and repair program, information on maintenance practices and mean times between failures is tracked and is used to identify problem service applications and to evaluate the need to change to component specifications and maintenance practices.

3.2.4 Cost Curves

A cost curve shows the estimated net cost required for different levels of site emission reductions. Each point on the curve represents the impact of implementing a different emission-reduction measure. The costs are based on a mix of facility and vendor data and consensus estimates developed in consultation with the facilities. The presented costs do not include those to find and evaluate emissions reduction opportunities and are therefore biased slightly low (typically, these costs are small compared to the control costs). Different control actions have different lifetimes; therefore, for comparison purposes, the credited emission reduction for each control option on the cost curve only includes the first year emission reduction (for these analyses, the shortest repair lifetime is assumed to

be one year). Control measures with lifetimes greater than one year will have reduced costs per unit emission reduction.

4 RESULTS

This section provides an overview of the atmospheric emissions and natural gas losses determined for each of the five sites, and delineate the main cost-effective loss-reduction opportunities. Additionally, average total hydrocarbon (THC) emission factors and leak statistics are presented for fugitive equipment leaks at these facilities.

Tagged-component information and individual leak rates for all leaking components are presented in Appendices I and II. Detailed results of the performance tests done on all active combustion sources are provided in Appendix III.

4.1 Emission Inventory

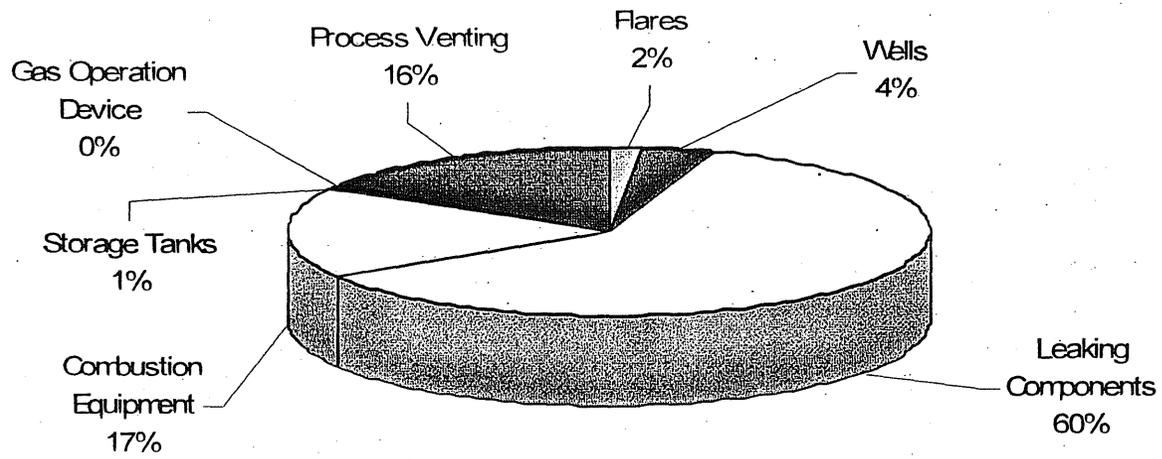

Total atmospheric emissions of methane, NMHC and GHG emissions from the five host gas processing plants amounted to 8,072 and 3,625 tonnes per year and 598,184 tonnes CO₂E per year, respectively. The relative distributions of these emissions by source category are presented in Figures 8 to 10. The carbon dioxide equivalent GHG emissions were calculated using the most recent 100-year global warming potentials (IPCC, 1996) (i.e., 1 for CO₂ and 21 for CH₄). GHG emissions consider methane and CO₂ only and do not include Nitrous Oxide (N₂O) emissions from combustion sources. The methane content of the measured THC emissions was determined based on typical gas analyses for the site and the analysis results for samples collected during the measurement program. Emissions of nitrous oxide were not evaluated but would be expected to contribute only a few % to total GHG emissions at each site.

As shown in Figure 8, fugitive equipment leaks (leaking components) are the dominant source of methane emissions, accounting for 60% from all sources. This is followed by incomplete fuel combustion (17%), process venting (16%), wells (4%), incomplete flare gas combustion (2%), and a small amount (1%) from storage tanks and gas operated devices.

Figure 9 shows fugitive leaks (leaking components) are the major source of NMHC emissions (73%). The rest (27%) was contributed primarily by combustion equipment and wells.

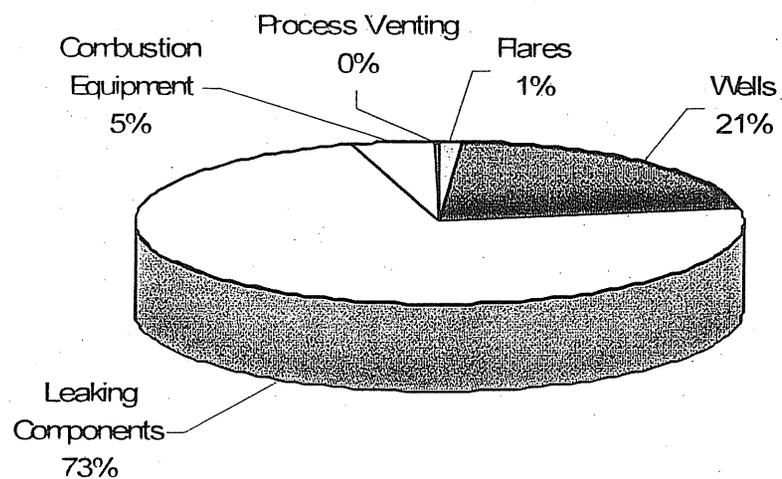

The CO₂E GHG emissions are predominantly from fuel consumption by combustion equipment (74%) as shown in Figure 10. However, fugitive equipment leaks (17%), as well as process vents (5%) may generally offer more cost-effective control opportunities.

GHG Emissions = 598,184 CO₂E tonne/yr

4.2 Natural Gas Losses

The value of natural gas is taken to be \$7.15 Mscf (\$6.78/GJ). The values for propane, butane and condensate are taken to be as follows: propane \$8.13/GJ; butanes \$9.63/GJ and condensate \$9.63/GJ. The determined gas losses include direct leakage and venting of natural gas to the atmosphere as well as losses into the process (e.g., excess fuel consumption by out-of-tune or inefficiently-operated engines and heaters, and gas leakage into flare systems). These latter losses lead to increased combustion emissions without any net process benefit.

The relative distribution of natural gas losses by source category is shown in Figure 11. Leaking equipment components are the greatest source of natural gas losses at the gas plants, accounting for 55% of the total. Other major sources include leakage into flare systems (24%), process venting (9%) and wells (8%). As shown in figure 12, natural gas losses from equipment leaks are contributed by open-ended lines, connectors, compressor seals and block valves, accounting for 32, 30, 20 and 15%, respectively. The top ten leakers at each site (other than site 1) contributed over half of the total natural gas losses from fugitive equipment leaks (refer to Table 2).

4.3 Fugitive Equipment Leaks

The following subsections characterize the fugitive equipment leaks for components in natural gas service at the surveyed gas plants. An overview of the fugitive leaks from gas processing plants, gathering compressor stations, and well sites is shown in Table 3. The lost values from these sources are \$536,270 from gas plants, \$49,018 from gathering compressor stations, and \$3,183 from well sites per year.

4.3.1 Average Emission Factors

Average emission factors were determined for each type of equipment component in natural gas service at the surveyed sites. The results are presented in Table 4 and are compared to corresponding factors published by U.S. EPA (1995) for oil and gas production operations and by U.S. EPA and GRI (1996) for natural gas facilities. Overall, the developed average emission factors are greater than those for oil and gas production facilities, and more comparable to the previous values for natural gas facilities.

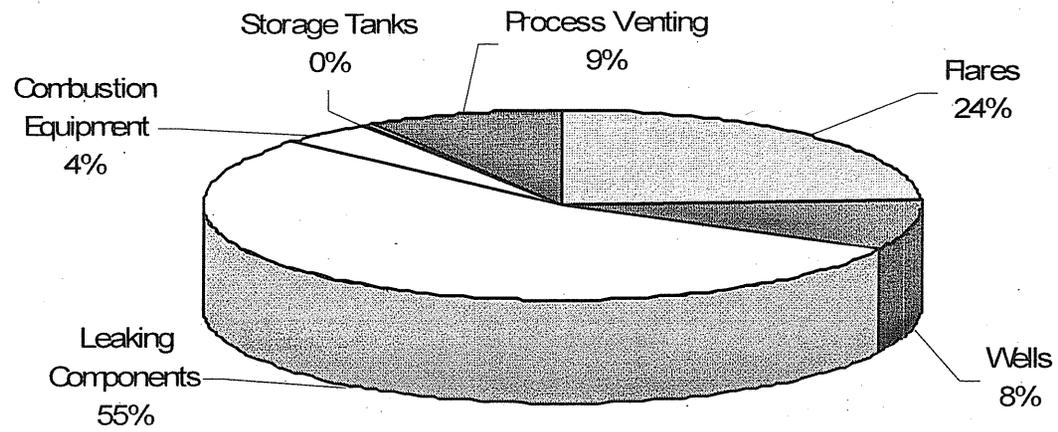

The average emission factors are simply the total emissions from all tested components divided by the total number of components of that type surveyed. Quantification of emissions from non-leaking components (i.e., components with screening values between zero and 10,000 parts per million) was not attempted. Instead, emissions from these components were assumed to be represented by the average no-leak emission rates presented in the Protocol for Equipment Leak Emission Estimates (U.S. EPA, 1995).

| Plant No. | Gas Losses from Top 10 Leakers (Mscfd) | Gas Losses from Measurable Fugitive Leaks (Mscfd) | % Contribution by Top 10 Leakers | % of Total Leakers |
|-----------|--|---|----------------------------------|--------------------|
| 1 | 78 | 271 | 29 | 0.04 |
| 2 | 13 | 23 | 56 | 0.08 |
| 3 | 53 | 117 | 45 | 0.05 |
| 4 | 60 | 69 | 87 | 0.06 |
| 5 | 317 | 423 | 75 | 0.21 |
| Combined | 521 | 903 | | |

^A Source: U.S. EPA. 1995. Protocol for Equipment Leak Emission Estimates. Research Triangle Park, NC 27711.

^B Source: U.S. EPA and GRI. 1996. Methane Emissions from the Natural Gas Industry. Volume 8: Equipment Leaks. Research Triangle Park, NC 27711.

^C The factors presented in the column are for methane emissions only but should be comparable to, although slightly less than, the corresponding THC values for the applicable component categories. The factors presented in the other two columns are for THC emissions.

^D Compressor seals component category accounts for emissions from individual compressor seals. As compressor seal leakage was typically measured from common vent and drain lines, emissions have been divided evenly among the seals on units with detected leakage.

4.3.2 Average Leak-Rate Trends

A statistical analysis of the compiled leak data was performed to identify any trends or correlations that could be used to help focus leak detection and control efforts. The effects of component type and style, process temperature and pressure, component size, application (i.e., type of process unit on which the component is used), and type of process stream (e.g., fuel gas, residue gas, acid gas, etc) were evaluated. In the following section, the average emission factors are given as total hydrocarbons on a kg/h/source basis to be consistent with published average emission factors (U.S. EPA, 1995). The main findings are as follows:

- Average hydrocarbon fugitive emission rates for connectors, open-ended lines and block valves are shown by stream types as shown in Figure 13, 14, and 15, respectively. These three components account for 77% of the total natural

gas fugitive emissions. Components in fuel gas and process gas services, even though not registered to have the highest average emission rates, have consistently to be on the highest four averaged emission rates among these three component types. In Figure 14, open-ended lines in propane and C₄ streams have significantly higher average emissions rates. This resulted from a combination of low component counts and was dominated by a large leak identified in the categories. Each point on figures 13-15 denotes the average emission factor for the corresponding streams the component is serving on the horizontal axis. The integer shown adjacent to each emission factor value is the number of data used to develop the factor. The vertical line through each average emission factor denotes the 95% confidence limits based on the variance in the compiled data and number of data points assuming a normal distribution. Under each of the component categories shown, one can not conclude an average emission rate is a function of stream type due to the large 95% confidence interval. However, general trends were implicated.

- Average hydrocarbon fugitive emission rates for connectors, open-ended lines and block valves are shown *by process unit* as shown in Figures 16, 17, and 18, respectively. For all three component types shown, their average emission rates in compressors and mole sieve units are among the top three process unit types. While connectors, and block valves in sales units have relatively low average emission rates, open-ended line in sales unit registered the highest average emission rate among all process units. This resulted from the combination of low overall component counts of open-ended lines in sale unit and one single big leaker identified in this category.
- Components tend to have greater average emissions where subjected to frequent thermal cycling, vibrations, or cryogenic service (see figures 16-18).
- All other parameters had little or no impact on average emissions.

In the Figures below, C₂ = ethane, R = residue gas, FG = fuel gas, PG = process gas, P= propane refrigerant, C₄= butane, NGL = natural gas liquids, C₃= propane , LPG = liquefied petroleum gas.

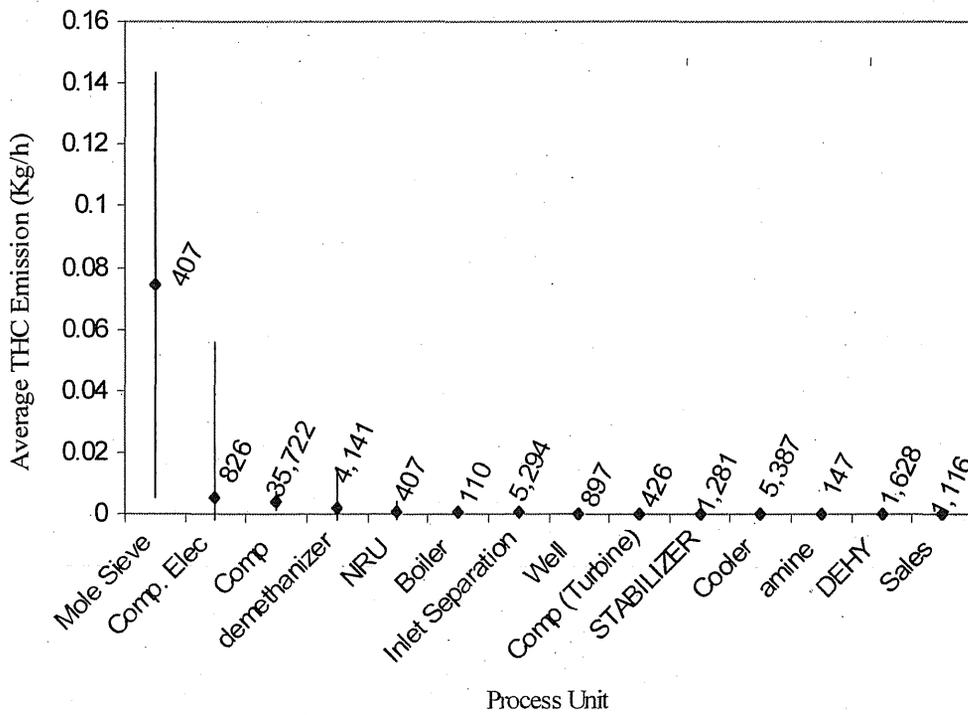

Figure 19 Average THC Emissions for Open-Ended Line By Process Unit

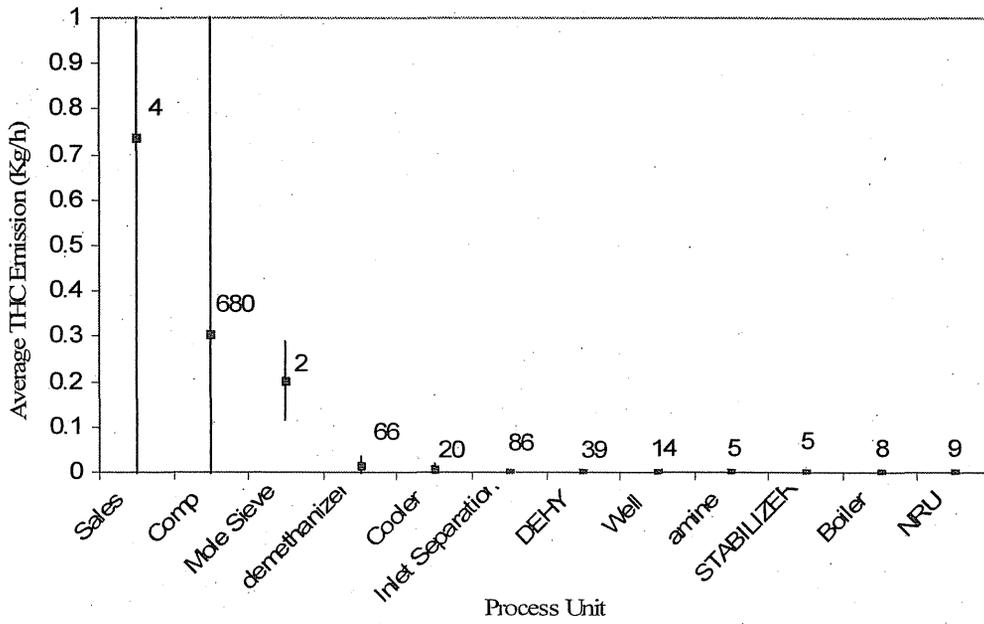

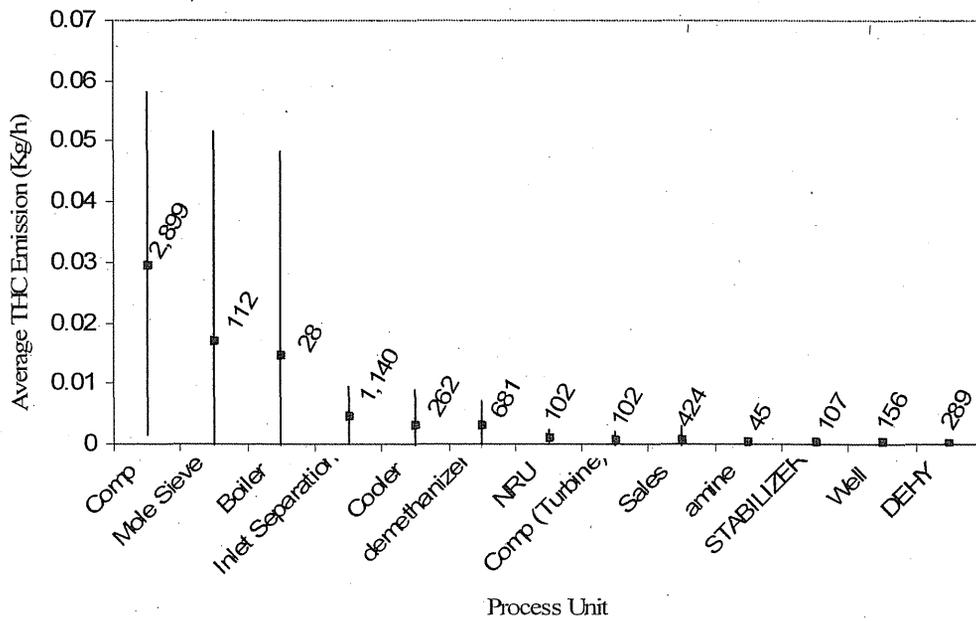

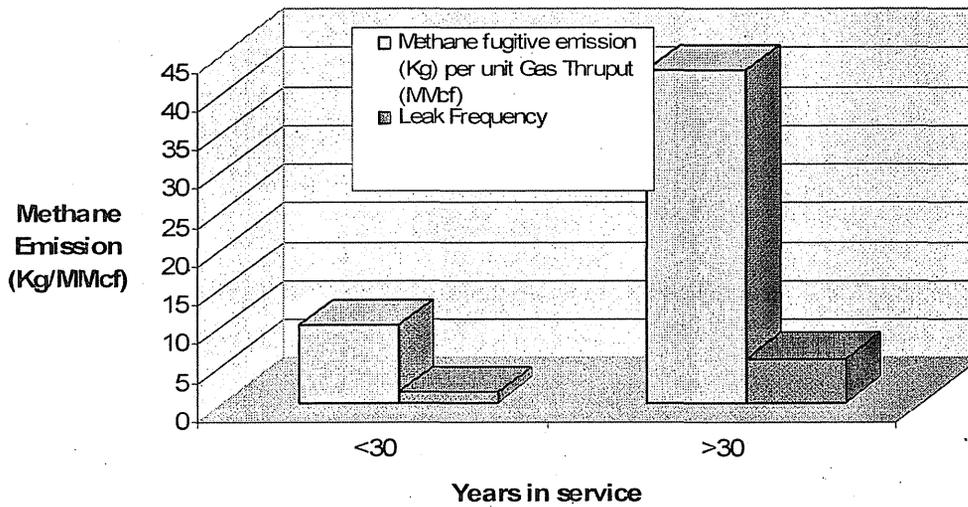

Figure 20 Average THC Emissions for Block Valves By Process Unit

Additional trends on the age of a facility, sweet/sour raw gas stream, and the potential of implementing a process-unit-targeted DI&M program are illustrated in the figures that follow.

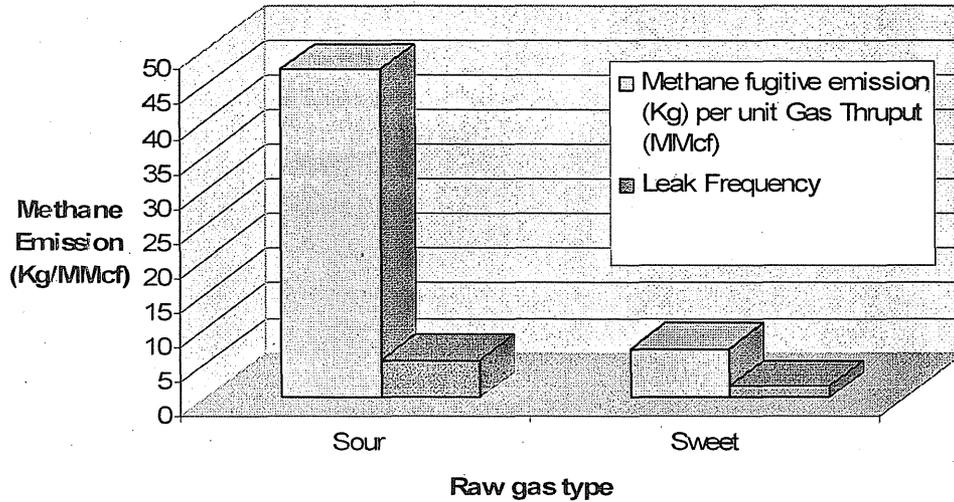

In Figure 19, the methane fugitive emission per unit gas throughput (kg / MMcf) and the leak frequency (%) are shown against years of service for the surveyed facilities. Facilities with longer than 30 years of service have higher methane fugitive emission per unit throughput and higher leak frequencies than those with less than 30 years of service. However, due to the limited number of surveyed facilities (3 with less than 30 years of service and 2 with longer than 30 years of service), it can not be concluded with statistical significance.

Figure 21 Methane Emissions Per Unit Gas Throughput For Plants With Different Service Duration

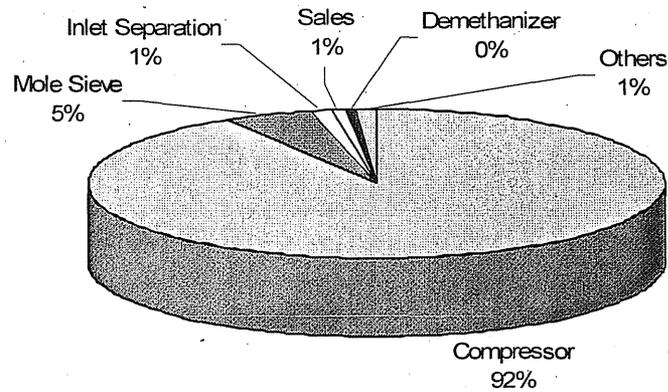

In Figure 20, the methane fugitive emission per unit gas throughput (kg / MMcf) and leak frequency are shown against raw gas type. Facilities with sour raw gas have significantly higher methane emission per unit gas throughput and higher leak frequency as well when compared with facilities with sweet raw gas input. As mentioned earlier, due to the limited number of surveyed facilities (3 with sweet and 2 with sour raw gas), the significance of sour versus sweet process plants can not be concluded with statistical significance.

Figure 22 Figure F Methane Emissions Per Unit Gas Throughput For Plants With Different Raw Gas Type

In Figure 21, fugitive methane emissions are shown against the process units. Compressor related components contributed the majority of methane fugitive emissions at 92% with the mole sieve being a distant second in methane emission contribution at 5%. These results validated the components under vibration (compressor units) and heat-cycle (mole sieve units) services are a lot more prone to leaks. The overwhelming percentage of methane emissions contributed by these two processes and related components warrants instituting a targeted DI&M program.

Figure 23 Methane Emissions Percentage by Process Units

4.3.3 Leak Frequencies

Fugitive equipment leaks are generally considered to be well controlled when the leak frequency for each component type (except connectors, compressor and pump seals) is 2% or less. For connectors, the allowable percentage of leaking components is 0.5%, and for compressor and pump seals the allowable percentage is 10%. Based on these guidelines, none of the categories for the combined plants would be considered adequately controlled (see Table 5). However, some categories at individual plants would have passed (i.e., connectors and block valves at Site 2). Table 5 below summarizes the most leak prone components. Compressor seals, orifice meters, control valves, and open ended lines constitute greater than 70% of the leak frequency. Figure 23 further illustrates the contribution of each component type to total THC emissions.

Table 5 Number of Components And Leak Frequency At Each Of The Five Gas Plants.

| | | Connectors | Block Valves | Control Valves | Pressure Relief Valves | Regulators | Orifice Meters | Crank Case Vents | Open-Ended Lines | Compressor Seals | Total |
|--------|------------------|------------|--------------|----------------|------------------------|------------|----------------|------------------|------------------|------------------|--------|

4.4 Tank Emissions

Of the five sites surveyed, three contains leaky tanks that were measured during the site surveys. Thief hatches were found to be leaking and subsequently the volume flow was measured. The average value of gas loss is \$906,296 per year per site (see Table 6).

| Facility | THC Emissions (MMcf/year) | Methane Emissions (MMcf/year) | GHG Emissions (tonnes CO2E/year) | Value of Lost Product (\$/Year) |
|--------------------|--------------------------------------|--|---|--|
| Gas Plant 1 | 158.8 | 93.6 | 37,801 | 2,670,645 |
| Gas Plant 2 | 0.46 | 0.42 | 183 | 3,429 |
| Gas Plant 3 | 3.50 | 2.86 | 1,320 | 44,813 |
| Gas Plant 4 | NA | NA | NA | NA |
| Gas Plant 5 | NA | NA | NA | NA |
| Total | 162.7 | 96.9 | 39,304 | 2,718,887 |
| Average | 54.2 | 32.3 | 13,101 | 906,296 |

4.5 Results for Retested Site

One of the four surveyed sites from Phase I was retested in Phase II to investigate changes in its fugitive leak characteristics. Some of the process units from Phase I were decommissioned and replaced with new process units. Component count from the decommissioned process units (5,590 components) is about 30% of the total plant count from Phase I (18,390 components). The following sections discuss the process units that were replaced and the changes in fugitive emissions between the Phase I and Phase II plant surveys.

4.5.1 Overall Plant

Figure 22 shows the overall THC emissions between Phase I and II for the retest site. Component level emissions for each Phase were also demonstrated. The THC emissions increased about 50% from Phase I to Phase II. While the major THC contributors are the same between Phase I and II programs, the percentage contributions from each source following changes at the site were very different. The changes in the average THC emission rate for each component type are contrasted in Figure 23.

Figure 24 Total THC Emissions Between Phases

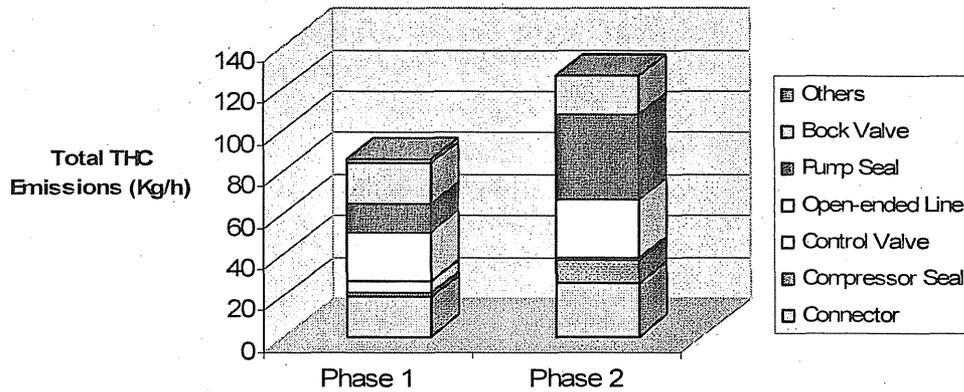

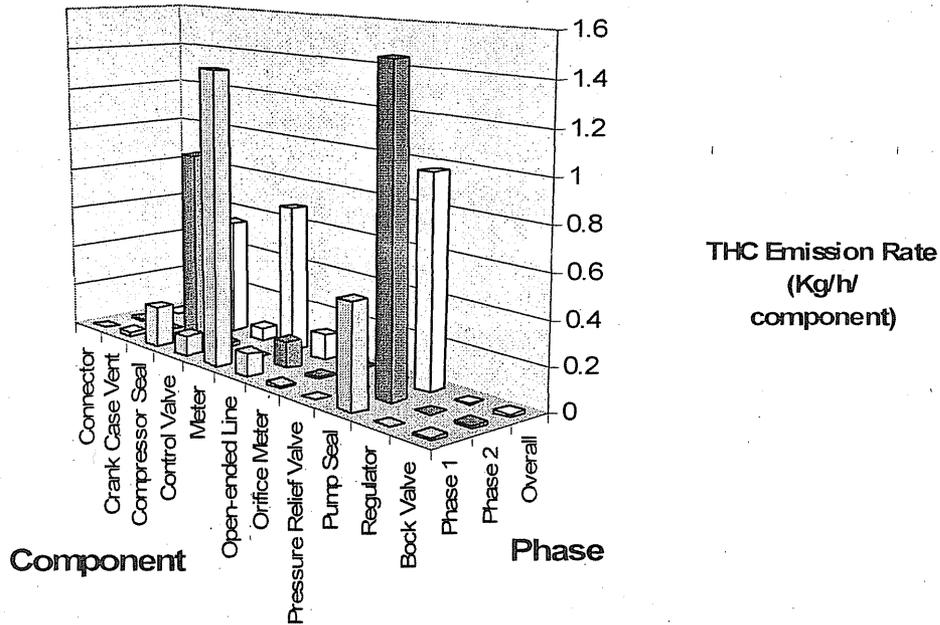

Figure 25 Component Emission Rate Between Phases

4.5.2 Replaced Process Units

About 30% of the original component count from Phase I was not active during the Phase II survey due to decommissioning and replacing equipment. These decommissioned process units were replaced with new process units and their

associated fugitive equipment emissions were compared with those from the decommissioned process units in Phase I. In Figure 24, the total THC emissions for these two sets of process units were compared. The THC emissions reduced by an estimate of 80% from Phase I (decommissioned units) to Phase II (new units). The average emission rates per component between Phase I and II are compared and are shown in Figure 25. With open-ended lines being the exception, all other components have significantly lower average emission rates in the newly added process units.

Figure 26 Total THC Emissions Between Phases

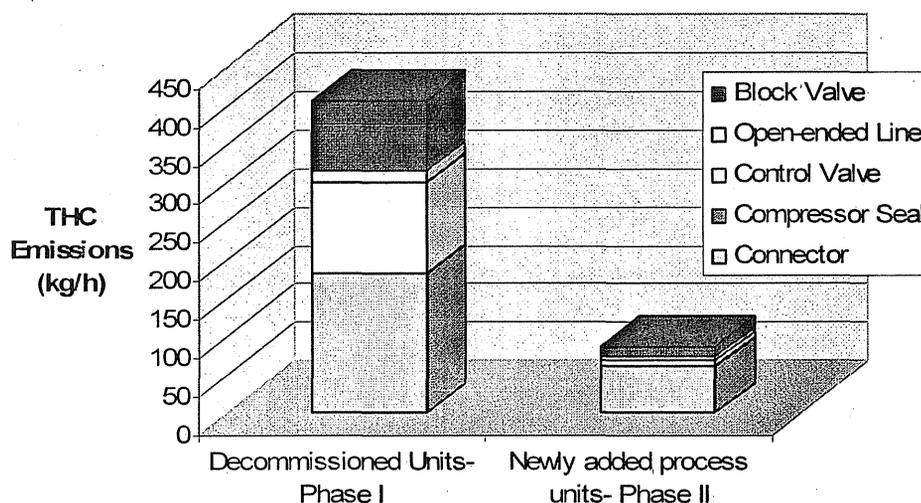

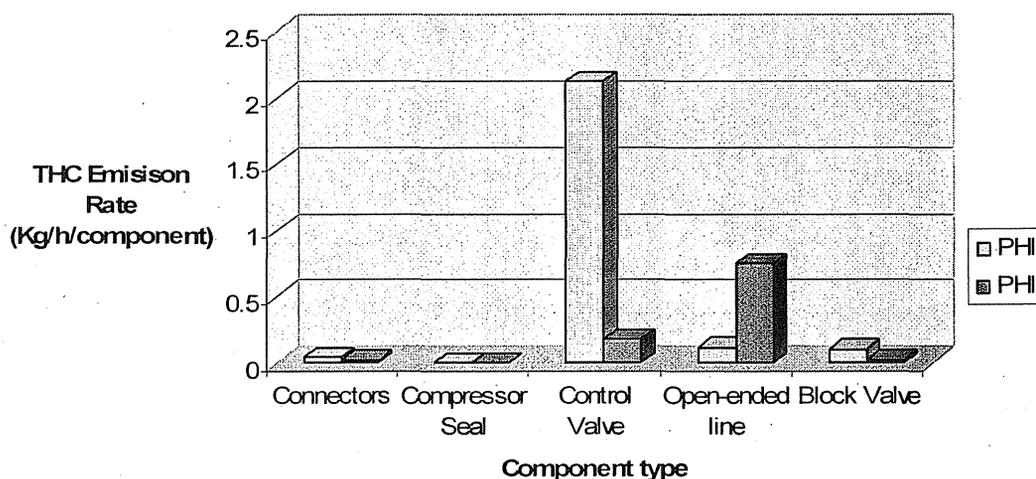

Figure 27 Component Emission Rate Between Phases

The results of this comparison tend to suggest that the DI&M program conducted at this facility has been ineffective at controlling emissions from fugitive equipment leaks. This apparent inability to control fugitive emissions using a

DI&M program may be attributed to a number of factors including: excessive duration between surveys; inadequate follow up to maintenance recommendations and insufficient documentation of maintenance activities. The 5 year time frame between these two surveys exceeds the estimated mean repair life for most components. This makes it difficult to assess the effectiveness of any repairs made in response to the Phase I survey because the leaks are likely to have reoccurred. Increasing the frequency of leak surveys to annually or bi-annually would allow for a better assessment of the effectiveness of maintenance activities and enable new leaks to be identified and repaired sooner. It is unclear what maintenance activities were undertaken in response to the Phase I survey. For example, a substantial leak from a weld failure identified during the Phase I survey was also found to be leaking during the Phase II survey. In order for the program to be effective, all cost-effective control opportunities should be acted on by either repairing the leak or reevaluating the economics to justify no action. Any maintenance performed in response to the survey should be adequately documented so the success of the repair can be addressed during subsequent site surveys. Accurate maintenance records will facilitate in tracking the true economics of the repair, and ultimately assist in establishing future control opportunities.

4.6 Control Opportunities

Practicable opportunities for reducing the identified natural gas losses were identified and assessed on a source-by-source basis. Overall, it is estimated that up to 96.6% of total fugitive natural gas losses could be avoided if all control opportunities with positive net cost or a positive payback are implemented (see Figure 26). This would result in corresponding reductions of 97% in fugitive methane emissions, 97% in fugitive GHG emissions, and 98% in fugitive NMHC emissions in the first year alone. Moreover, many of the control options have multi-year life expectancies resulting in significant emission reductions in subsequent years as well.

4.6.1 Cost Curve for Reduction of GHG Emissions

To further evaluate the control of natural gas losses as a means of reducing GHG emissions, it is useful to express the results in terms of a cost curve. Figure 27 presents the net annualized cost curve for implementation of the various opportunities identified at the five gas plants. The net cost of each target control opportunity is calculated as the equalized annual implementation cost over the life of the project (i.e., the net present cost of the opportunity expressed as an equivalent series of equal annual payments over the life of the project) divided by the resulting average annual CO₂-equivalent emission reduction.

Figure 27 shows that the incremental cost per tonne of CO₂E GHG emission reduction resulting from implementation of the available control opportunities in ranked order from most to least cost effective (i.e., see Table II-1 in Appendix II). The point at which the curve crosses over the abscissa axis (i.e., the axis of

cumulative CO₂E GHG emission reduction) is the amount of CO₂E emission reduction that could be achieved if only opportunities with a zero cost or a positive payback are implemented (i.e., 103,363 tonnes CO₂E reduction per year). This reduction amounts to 17% of total estimated GHG emissions from the five gas plants.

If a value is assigned to GHG emission reduction credits, then companies may choose to pursue opportunities even further out on the cost curve. The shape of the cost curve shows that there are a few very attractive control opportunities, a large number of moderate control opportunities, and eventually a point of diminishing returns.

Figure 1 Emissions From Economically Repairable Sources

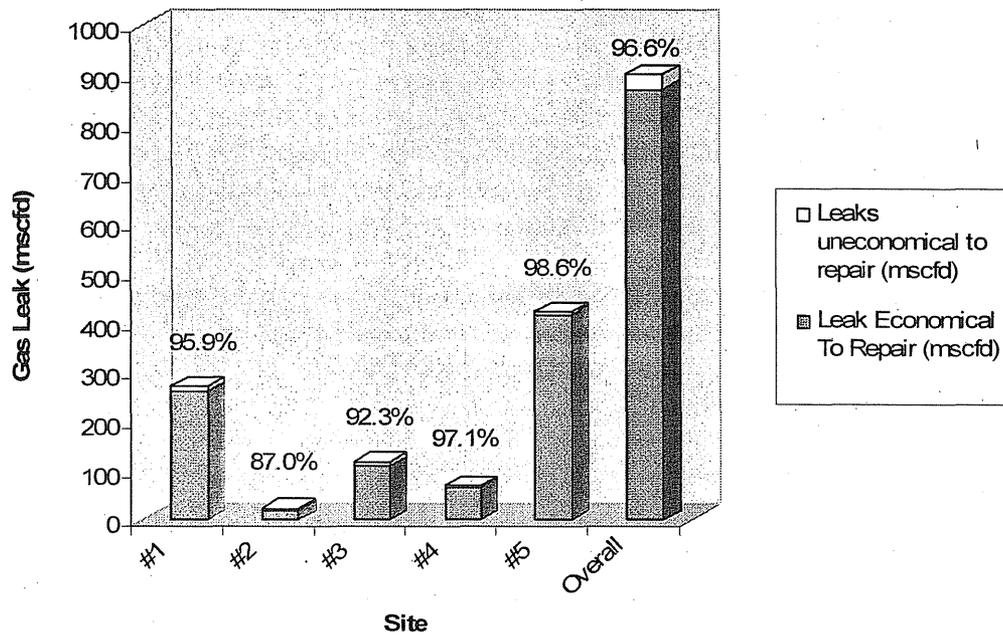

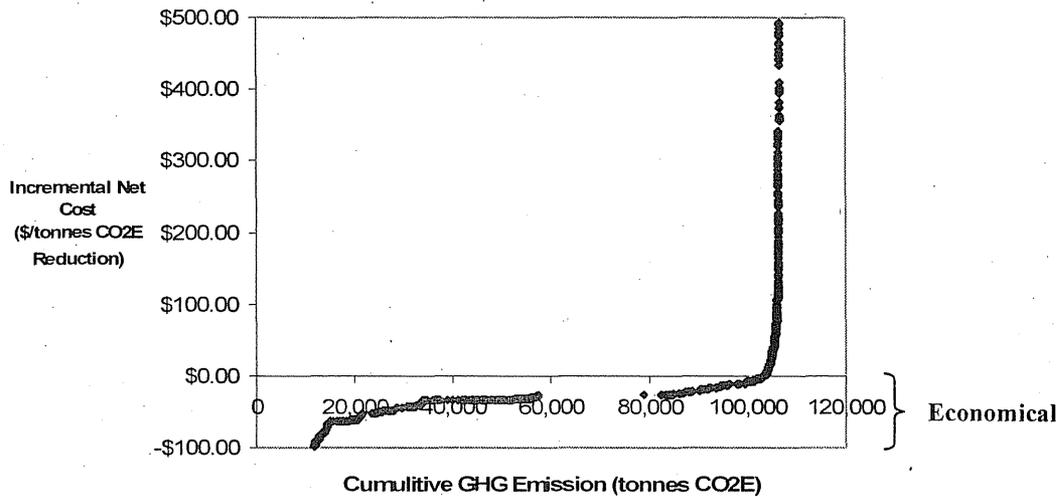

Figure 2 Incremental Net Cost Curve For Cumulative CO₂E Emission Reductions At Surveyed Gas Plants

4.6.2 Control Opportunities With a Payback of 1 Year or Less

On a purely financial basis, opportunities to reduce natural gas losses must compete against other investment opportunities to receive funding. A common parameter used to evaluate opportunities is either the effective rate of return on the investment or the payback period. To justify equipment upgrades or process enhancements, companies often look for a payback period of 1 year or less. Accordingly, it is useful to consider only opportunities to reduce natural gas losses that have a payback period of 1 year or less.

If only these control opportunities are implemented, it is estimated that total natural gas losses, including unnecessary fuel consumption, would be reduced by 97%. Corresponding reductions in NMHC and GHG emissions would both amount to 97% as well.

The 10 greatest individual control opportunities in the 1-year payback category are listed in Table 7. Collectively, they account for 42% of total natural gas losses in this category.

| Table 7. Summary of Top Ten Sources of Natural Gas Losses Identified | | | | | |
|---|----------|--|------------------------|-----------------------|-----------------------------|
| Tag ID | Site No. | Process Unit / Location | Component Type | Gas Leak Rate (Mscfd) | Value of Lost Gas (\$/year) |
| 5935 | 5 | Compressor - 2" waterjacket connection | Open-Ended Line - 2" | 194.25 | \$621,168 |
| 5488 | 4 | LP FG Scrubber - corrosion hole in bottle below HLL alarm | Corrosion Hole | 46.90 | \$102,893 |
| 6074 | 5 | Flare fuel gas line - | Corrosion Hole | 42.92 | \$111,631 |
| 6075 | 5 | Compressor | Variable Volume Pocket | 30.45 | \$97,380 |
| 5956 | 5 | Compressor | Compressor Seal | 16.27 | \$52,044 |
| 7355 | 1 | Compressor- distance piece vent (leak overwhelmed hiflow) | Compressor Seal | 11.27 | \$33,573 |
| 7010 | 1 | Residue compressor (north caterpillar) - common packing case drain | Compressor Seal | 9.75 | \$25,863 |
| 7168 | 1 | Residue compressor (#2 ingersoll-rand) - | Valve Cap | 9.34 | \$24,787 |
| 6708 | 3 | Amine Tank | PRV | 9.34 | \$24,559 |
| 7322 | 1 | Compressor -reptured diaphragm on 4 NPS control valve | Control Valve - 4" | 8.25 | \$21,899 |
| Total | | | | 378.75 | \$1,115,799 |

5 CONCLUSIONS AND RECOMMENDATIONS

5.1 Conclusions

The second Phase added five additional gas processing plants to the four plants surveyed in the first Phase. The plants chosen for this study varied in plant age, throughput, size, location and sweet and sour gas. The second Phase also included well sites and gathering compressor stations located upstream from the gas processing plants. The variation ensures that the data collected represents an average for the natural gas processing industry. A comparison was conducted between the traditional leak detection methods and an optical passive infrared camera was conducted at all sites.

The sources with the greatest natural gas losses were not necessarily the most economical to control. Actual cost-effective emissions reduction opportunities may vary greatly between sites and not all gas plants will necessarily offer sufficient opportunities to justify the associated identification and control costs. In addition, actual economic opportunities depend on the natural gas value, and will therefore vary with fluctuations in the natural gas market price. Nonetheless, it is clear from the available data that significant cost-effective emissions reduction opportunities do exist at all surveyed facilities and a rational approach to finding these opportunities at all gas plants may be economically attractive to industry.

While any economical-to-repair leaking components detected by such efforts should be repaired, average leak rates based on combined data from the five test sites suggest that the most cost-effective approach would be to generally focus on the following types of components:

- block and control valves,
- orifice meters,
- open ended lines,
- pressure relief valves,
- regulators,
- flange connections,
- crankcase vents,
- compressor seals, and
- compressor valve stems and valve caps.

Additionally, components operating in thermal cycling (mole sieve) and vibration (compressor) applications have higher leak rates than other components. The results show that components in these two applications contributed 97% of the fugitive leaks and suggest that process-unit-targeted DI&M programs would have tremendous cost-effective emissions reduction potential. A DI&M program focusing on equipment in vibration and/or thermal cycling operation would likely identify and repair nearly all the large leaks at a fraction of a full facility DI&M program cost.

5.2 Recommendations for Further Work

Specific recommendations are:

- The amount and composition of emissions from engine and compressor crankcase vents, and field practices for the vent systems design should be examined more closely. In particular, the potential for air-toxic emissions from crankcase vents, especially those on engines, should be determined. Moreover, the practice of some companies to exhaust crankcase vents into buildings and work areas, a practice manufacturers discourage, should be evaluated.
- There are a wide variety of available technologies, as well as design and operating practices that would help companies cost-effectively reduce natural gas losses; however, these technologies and practices are under-utilized. One such example is the application of flow sensors, which can be installed on compressor seal vents at a relatively low cost. Flow sensors provide real-time excessive leakage detection. They may also be applied to crankcase and other vents. Only one of the five sites had installed seal vent flow sensors, and the operators did not monitor the sensors readings. Additionally, emergency flare systems are not normally equipped with flow meters, so in-leakage and excessive purge gas consumption often go unnoticed until natural gas losses produce a noticeably larger flame. Historically, meters were not installed because conventional obstruction meters do not provide reliable readings over the wide flow ranges and cause excessive system backpressure; however, non-intrusive ultrasonic flow meters, which overcome these problems, are now available. Moreover, ultrasonic techniques are available for identifying and quantifying leakage past valve seats into flare and vent systems.
- It is recommended that a best practices document be developed to disseminate and encourage the compilation and use of cost-effective emissions reduction practices. The document should also provide information required by companies to develop site-specific programs for reducing their methane and non-methane hydrocarbon losses, and greenhouse gas emissions (e.g., delineate source categories and/or facility areas to focus efforts on for maximum benefit, generic cost data for evaluating control options, recommended monitoring frequencies, and typical repairs life expectancy by source type and service category).
- Analysis of the Phase I and Phase II results to determine the relative cost-effectiveness of a facility wide DI&M program and a process-unit-targeted DI&M program focused on components in vibration (i.e. compressor) or heat-cycle (i.e. mole sieve) services

Further analysis combining the data from Phase I and Phase II to improve the results statistical significance. Analyses should include, at a minimum, the plant level trends identified in the Phase 2 report (i.e. impacts of facility age and sweet or sour gas on methane emissions). Potential benefits include an age-based and/or gas-type-based DI&M program that would also reduce the cost of DI&M program.

- Use of the combustion equipment and compressor performance tests (new tests implemented in Phase 2) in future surveys. These tests, when implemented in the surveyed facilities, contributed significantly to the methane and overall GHG emissions inventories.
- A follow up program to evaluate the impact of monitoring frequency on gas processing facilities DI&M programs cost effectiveness.

General Permit 17.1 Template

Reciprocating or centrifugal compressor for natural gas service

B. Facility-Wide Terms and Conditions

The following are the terms and conditions for a General PTIO to be issued to a non-Title V facility

1. This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).
 - a) For the purpose of a permit-to-install document, the facility-wide terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.
 - (1) None
 - b) For the purpose of a permit-to-operate document, the facility-wide terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.
 - (1) None
2. The emissions unit contained in this permit must comply with various federal New Source Performance Standards (NSPS). The complete NSPS requirements may be accessed via the internet from the Electronic Code of Federal Regulations (e-CFR) website <http://www.ecfr.gov> or by contacting the appropriate Ohio EPA District Office or local air agency. The permittee must comply with the applicable requirements of 40 CFR Part 60 Subpart OOOO/OOOOa as they apply to the emissions source.
3. Records related to this PTIO may be maintained at an off-site location (e.g. regional office), provided they are made accessible when the need arises, otherwise by the next business day upon Ohio EPA request (or made viewable electronically on-site and submitted to Ohio EPA within 24 hours).

C. Emissions Unit Terms and Conditions

Note: The following are the terms and conditions for a General PTIO to be issued to a non-Title V facility

1. [Reciprocating or centrifugal Natural Gas Compressor], [P001]

Operations, Property and/or Equipment Description:

Reciprocating or centrifugal compressor constructed, modified, or reconstructed after 8/23/11 and located between the wellhead and the point of custody transfer to the natural gas transmission and storage segment, and designed to be driven by an engine or motor of less than or equal to 3600 horsepower. Includes emissions from normal compressor operation, and blowdown and other releases from periodic maintenance activities, as well as leakage through seals, packing and vents during periods of either intermittent or prolonged shutdown of the compressor.

a) This permit document constitutes a permit-to-install issued in accordance with ORC 3704.03(F) and a permit-to-operate issued in accordance with ORC 3704.03(G).

(1) For the purpose of a permit-to-install document, the emissions unit terms and conditions identified below are federally enforceable with the exception of those listed below which are enforceable under state law only.

(a) None.

(2) For the purpose of a permit-to-operate document, the emissions unit terms and conditions identified below are enforceable under state law only with the exception of those listed below which are federally enforceable.

(a) None

b) Applicable Emissions Limitations and/or Control Requirements

(1) The specific operations(s), property, and/or equipment that constitute each emissions unit along with the applicable rules and/or requirements and with the applicable emissions limitations and/or control measures. Emissions from each unit shall not exceed the listed limitations, and the listed control measures shall be specified in narrative form following the table.

| | Applicable Rules/Requirements | Applicable Emissions Limitations/Control Measures |
|----|--|--|
| a. | OAC rule 3745-31-05(A)(3) as effective June 30, 2008 | <p>Volatile organic compound (VOC) emissions shall not exceed 0.35 tons per month averaged over a 12-month rolling period.</p> <p>See c)(2) and c)(3).</p> |

| | | |
|----|--|--|
| | | See b(2)a. below. |
| b. | OAC rule 3745-31-05(A)(3)(a)(ii) as effective June 30, 2008 | The Best Available Technology (BAT) requirements under OAC rule 3745-31-05(A)(3) do not apply to the VOC emissions from this air contaminant source since the potential to emit is less than 10 tons/year. See b(2)b. below. |
| c. | 40 CFR Part 60 Subpart OOOO In accordance with 40 CFR 60.5365(c), this emissions unit is a centrifugal compressor or a reciprocating compressor subject to the Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution. 40 CFR 60.5380; 40 CFR 60.5385 | Meet all applicable requirements of 40 CFR Part 60, Subpart OOOO upon initial startup. |
| d. | OAC rule 3745-31-05(E) | The compressor shall be designed so that no gas from the rod packing seals (for a reciprocating unit) or wet shaft seals (for a centrifugal unit), compressor isolation valves, or compressor blowdown vents is emitted into the atmosphere. This requirement can be met by a design that captures 100% of the gasses from these sources, and routes them to (1) a flare designed for 98% destruction, (2) the fuel gas system for burning as a fuel, or (3) back into the product pipeline. The above design requirements shall be met at all times that pressure is present at the inlet or discharge isolation valve, including periods of either intermittent or prolonged shutdown of the compressor. |

(2) Additional Terms and Conditions

- a. The BAT emission limit applies until U.S. EPA approves OAC paragraph 3745-31-05(A)(3)(a)(ii) (the less than 10 tons per year BAT exemption) into the Ohio SIP.
- b. These requirements apply once U.S. EPA approves OAC paragraph 3745-31-05(A)(3)(a)(ii) (the less than 10 tons per year BAT exemption) as part of the Ohio SIP

c) Operational Restrictions

- (1) The permittee of a reciprocating unit shall operate the rod packing emissions collection system under negative pressure and route emissions to a process through a closed vent system that meets the requirements of 40 CFR Part 60 Section 5411(a) at all times when pressure is present at the inlet or discharge isolation valve.

[40 CFR 60.5385(a)], [40 CFR 60.5410(c)], [40 CFR 60.5415(c)(3)], and [40 CFR 60.5370(a)]

- (2) The permittee of a centrifugal unit of wet seal seal design shall equip the unit with a cover that captures the seal emissions that meets the requirements of 40 CFR Part 60 Section 5411(b) and that connects to a closed vent system that meets the requirements of 40 CFR Part 60 Section 5411(a) and routes the emissions to a process or to a control device that meets the conditions specified in 40 CFR Section 5412 paragraphs (a), (b), and (c), except that where "95.0 percent by weight" appears under Section 5412, the permittee shall be subject to a 98.0 percent by weight requirement. Capture and control or diversion to a process shall be maintained at all times when pressure is present at the inlet or discharge isolation valve.
- (3) All emissions from maintenance blowdown events shall be captured and reduced by at least 98.0 percent by weight.
- (4) At all times when the reciprocating or centrifugal compressor is maintained in a depressurized state, the leakage passing through the isolation valves and released from the compressor through blowdown vents or other routes shall be captured and reduced by at least 98.0 percent by weight.
- (5) The permittee shall minimize the frequency and size of blowdown events by conducting routine operation and maintenance activities in a manner consistent with safety and good air pollution control practices.
- (6) The permittee of a reciprocating or a centrifugal unit shall demonstrate continuous compliance with the requirements of this permit by conforming to the applicable requirements of 40 CFR Part 60 Section 5415, except that where "95 percent by weight" appears, "98 percent by weight" shall apply.

d) Monitoring and/or Recordkeeping Requirements

- (1) The permittee shall perform initial and subsequent annual inspections of the closed vent system, covers, and bypass devices installed on the reciprocating or centrifugal compressor as prescribed by 40 CFR Part 60 Section 5416.

[40 CFR 60.5420(c)(3)], [40 CFR 60.5385(b) and (d)], [40 CFR 60.5410(c)(1) and (4)], [40 CFR 60.5415(c)(1)], and with [ORC 3704.03(T)]

- (2) The permittee shall maintain monthly records of the following information:
 - a. number of compressor blowdown events;
 - b. mole fraction of each VOC component in the gas stream using a representative analysis;
 - c. the volume of gas emitted from all compressor blowdown events for each month, in scf; and
 - d. the rolling, 12-month summation of the volume of gas emitted from all compressor blowdown events, in scf.

At the end of each year or PER reporting period, the permittee shall calculate the emissions from compressor maintenance blowdowns, using the calculation in the Testing Section, and shall maintain the record of the emission estimates for a period of five years.

e) Reporting Requirements

- (1) The permittee shall submit an annual Permit Evaluation Report (PER) to the Ohio EPA District Office or Local Air Agency by the due date identified in the Authorization section of this permit. The permit evaluation report shall cover a reporting period of no more than twelve months for each air contaminant source identified in this permit. It is recommended that the PER be submitted electronically through the Ohio EPA's "e-Business Center: Air Services" although PERs can be submitted via U.S. postal service or can be hand delivered.

[OAC rule 3745-15-03(B)(2) and (D)]

- (2) The permittee shall submit an initial annual report within 90 days after the end of the initial compliance period as determined according to 40 CFR 60.5410. Subsequent annual reports are due on the same date each year following the initial report. The annual reports shall include the following information:
 - a. company name and address of the affected facility;
 - b. identification of each affected facility included in the annual report*;
 - c. beginning and ending dates of the reporting period;
 - d. the identification of each reciprocating or centrifugal compressor;
 - e. the cumulative number hours of operation or the number of months of operation since initial startup of the reciprocating or

centrifugal compressor, or since the effective date of the NSPS, whichever is later;

- f. records of any deviations; and
- g. certification of the responsible official of truth, accuracy, and completeness.

* One report for multiple affected facilities may be submitted provided the report contains all of the information required and clearly identified for each.

[40 CFR 60.5420(b)(1) and (4)], [40 CFR 60.5410(c)(2) and (3)], [40 CFR 60.5385(d)], and [40 CFR 60.5415(c)(2)]

- (3) The permittee shall submit to the appropriate district or local office of the EPA Division of Air Pollution Control notification of:
 - a. the date construction or reconstruction of the emissions unit is commenced, no later than 30 days after such date; and
 - b. notification of any physical or operational change to the existing facility which may increase the emission rate of any air pollutant to which the standard applies (unless that change is specifically exempted under the NSPS or in 40 CFR 60.14(e)) shall be postmarked 60 days before the change is commenced (or as soon as practicable) and shall include information describing the precise nature of the change, productive capacity of the facility before and after the change, and the expected completion date of the change.

The Director may request additional relevant information subsequent to this notice.

[40 CFR 60.5410(c)(2)] and [40 CFR 60.7(a)(1) and (4)]

- (4) Any calculated exceedance of the VOC emission limit shall be included in the annual PER.

f) Testing Requirements

- (1) Compliance with the Emissions Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

Emissions Limitation:

VOC emissions shall not exceed 4.194 tons per rolling, 12-month period.

Applicable Compliance Method:

Compliance with the VOC emissions limitation shall be based upon the following calculation and the recordkeeping requirements in d)(1):

VOC (tons/month) = sum of the following for each VOC component:

$$= \left[\text{molecular weight} \times \left(\frac{\text{volume of gas emitted/month} \times \text{mole fraction of each VOC component/month}}{\text{molar volume conversion}} \right) \times (1 - 0.98 \text{ control factor}) \right]$$

Where:

molecular weight = constant, in lb/lb-mole;

volume of gas emitted/month = from records specified in d)(1)c, in scf;

mole % of each VOC component/month = from analysis required in d)(1)b, in %; and

molar volume conversion = 379.5 scf/lb-mole, at 60 deg F and 1 atm.

Compliance with the monthly average VOC emissions, for each rolling 12-month period, shall be determined by adding the result to the emissions calculated for the previous 11 months.

- (2) Compliance with Emissions Limitations and/or Control Requirements specified in section b) of these terms and conditions shall be determined in accordance with the following methods:

a. Design Efficiency:

Install a system (high pressure flare, routing to fuel line, etc.) suitable for control of maintenance blowdown events with 100 percent capture and greater than or equal to 98 percent control efficiency for VOC.

Applicable Compliance Method:

Compliance is demonstrated by the system manufacturer's design efficiency with 100 percent capture and greater than or equal to 98 percent control efficiency.

b. Design Efficiency:

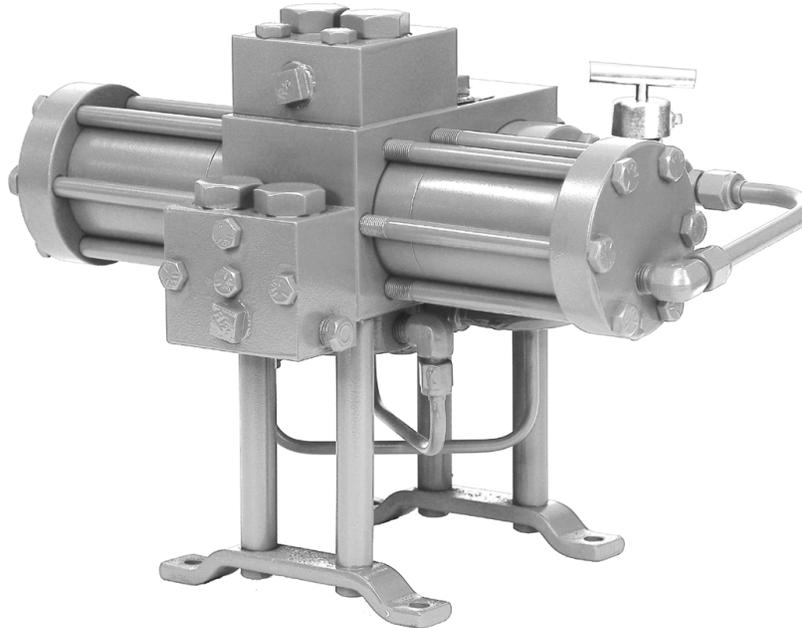

Install a flare or other device to perform 100 percent capture of leakage through seals and closed valves and reduce the quantity of VOC by at least 98 percent prior to release to the atmosphere, by combustion or by diversion into the product or the fuel system.

Applicable Compliance Method

Compliance is demonstrated by the equipment manufacturer's design efficiency with 100 percent capture and greater than or equal to 98 percent control efficiency.

g) Miscellaneous Requirements

Any amendment to Part 60, Subpart OOOOa shall supersede the Subpart OOOO compliance limitations and/or options contained in this permit.

Introduction

The Glycol Pump utilizes the energy of wet glycol at absorber pressure as a source of power to circulate the glycol in a gas dehydrator. The pump transfers the energy available from the wet glycol, at absorber pressure, to an "equivalent" volume of dry glycol at reboiler pressure. In order to circulate the glycol, additional energy is needed to overcome friction losses within the pump and connecting piping. This additional energy is supplied by gas at absorber pressure.

| Summary: | |
|------------------|---|
| Pump Description | Energy Exchange |
| Normal Service | Glycol |
| Connection Size: | See table 4, page 6 |
| Connection Type: | NPT |
| Operating Range: | 300 - 2000 psi for PV 100 - 500 psi for SC |
| Temperature: | Standard -30° to 200° |

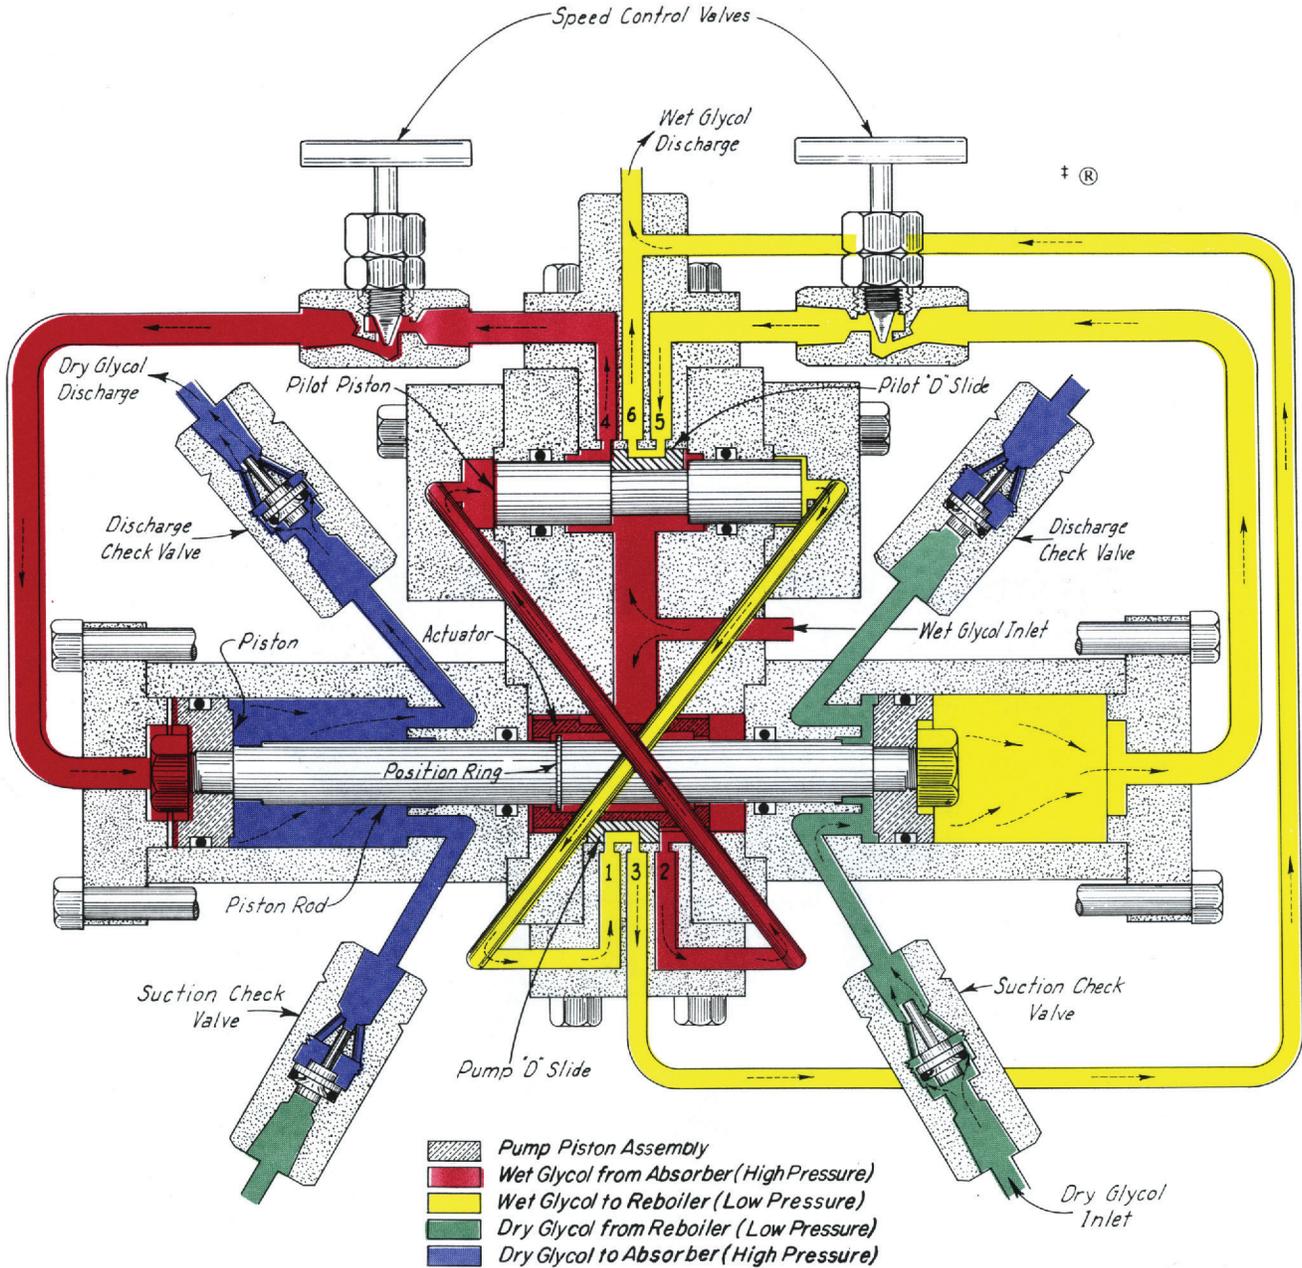

Figure 1

Principles of Operation

The Kimray glycol pump is double acting, powered by wet glycol and a small quantity of gas at absorber pressure (Red). Yellow denotes wet glycol (Blue) is being pumped to the absorber. Green is dry glycol suction from the reboiler.

Wet glycol (Red) from the absorber flows through port #4 and of the pump piston assembly, moving this assembly from left to right. Dry glycol (Blue) is being pumped from the left cylinder to the absorber while the right cylinder is being filled with dry glycol (Green) from the reboiler.

At the same time wet glycol (Yellow) is discharging from the right end of the pump piston assembly to a low pressure or atmospheric system. As the pump piston assembly nears the end of its stroke, the position ring on the piston rod contacts the right end of the actuator. Further movement to the right moves the actuator and pump "D" slide to uncover port number one and communicate ports two and three. This exhausts wet glycol (Red) to the right end of the pilot position. this causes the pilot piston and pilot "D" slide to be driven from right to left.

In it's new position, the pilot "D" slide uncovers port number five and communicate ports number four and six. This exhausts wet glycol (Red) from the left end of the pump piston assembly through ports four and six to the low pressure wet glycol (Yellow) system. Ports number 5 (which was communicated with port number 6) now admits wet glycol (Red) through the right hand speed control valve to the right end of the pump piston assembly. The pump piston assmby now starst the stroke from right to left. Follow above procedure reversing directions of flow.

Actions of each of the two basic pumps are completely dependent upon the other. The pilor "D" slide actuated by the pilot piston alternately feeds, and exhausts absorber pressure to the power cylinders at opposite ends of the piston rod assembly. Likewise, the pump "D" slide actuated by the piston rod assembly alternately feeds and exhausts absorber pressure to opposite ends of the pilot piston.

The force to circulate glycol within the dehydration system is supplied by absorber pressure acting on the area of the piston rod at its o-ring seals. The area of the piston rod is approximately 20 percent of that of the pressure acting on the area of the piston. Neglecting pump frection and line losses, the resultant force is sufficient to produce a theoretical discharge pressure 25 percent greater than absorber pressure. The theoretical discharge pressure, for example, at 1500 psig absorber pressure would be 1875 psig. This theoretical "over-pressure" would develop against a block discharge line but is not sufficient to cause damage or create a hazzard.

Approximately 25 to 30 psig pressure is required to overcome pump friction leaving the additional "over pressure" for the losses and circulation. It is recommended that these losses be held to approximately 10 percent of the absorber pressure or as noted in catalog.

Two speed control values are provided to regulate the flow of wet glycol and gas to and from the power cylinders. Reversing the direction of flow through the speed control valves provides a flushing action which cleans the valve orifices.

If the wet glycol, returning to the pump from the absorber were to be completely fill the cylinder, no additional gas would be needed. However, the wet glycol will only occupy approximately 65 percent of the total volume of the cylinder and connecting tubing leaving 35 percent to be filled by gas from the absorber. This gas volume amounts to 1.7S.C.F. per gallon of dry glycol at 300 psig absorber pressure and 8.3S.C.F. at 1500 psig and may be considered as continuing power cost for pump operation. This gas can be utilized in the regeneration process of the dehydrator for "rolling" and "stripping" purposes. It may also be recovered in a low pressure glycol gas separator and used to fire the reboiler. By supplying some absorber gas to the cylinders, the wet glycol level is maintained at the wet glycol outlet connection on the absorber and eliminates the need of a liquid level controller and its attendant problems. Excess liquids such as hydrocarbons are removed from the absorber at approximately 55 percent of the pump rate, reducing the hazard of dumping a large volume of hydrocarbons into the reboiler as would be the case with a liquid level controller.

| Pressure Volume PV & SC Pump | | |
| Type | Max. Gallons Per Hour | Operating Pressure |
| 1720 PV | 40 | 300 to 2000 psig Max |
| 4020 PV | 40 | 300 to 2000 psig Max. |
| 9020 PV | 90 | 300 to 2000 psig Max. |
| 21020 PV | 210 | 400 to 2000 psig Max. |
| 45020 PV | 450 | 400 to 2000 psig Max. |
| 2015 SC | 20 | 100 to 500 psig Max |
| 5015 SC | 50 | 100 to 500 psig Max |
| 10015 SC | 100 | 100 to 500 psig Max |
| 20015 SC | 200 | 100 to 500 psig Max |

Circulating pump for gas glycol dehydrators.
 Circulating pump for gas amine desulphurizers.

Pump **PV** Working pressure of **300 - 2000 psig**.
 Pump **SC** Working pressure of **100 - 500 psig**

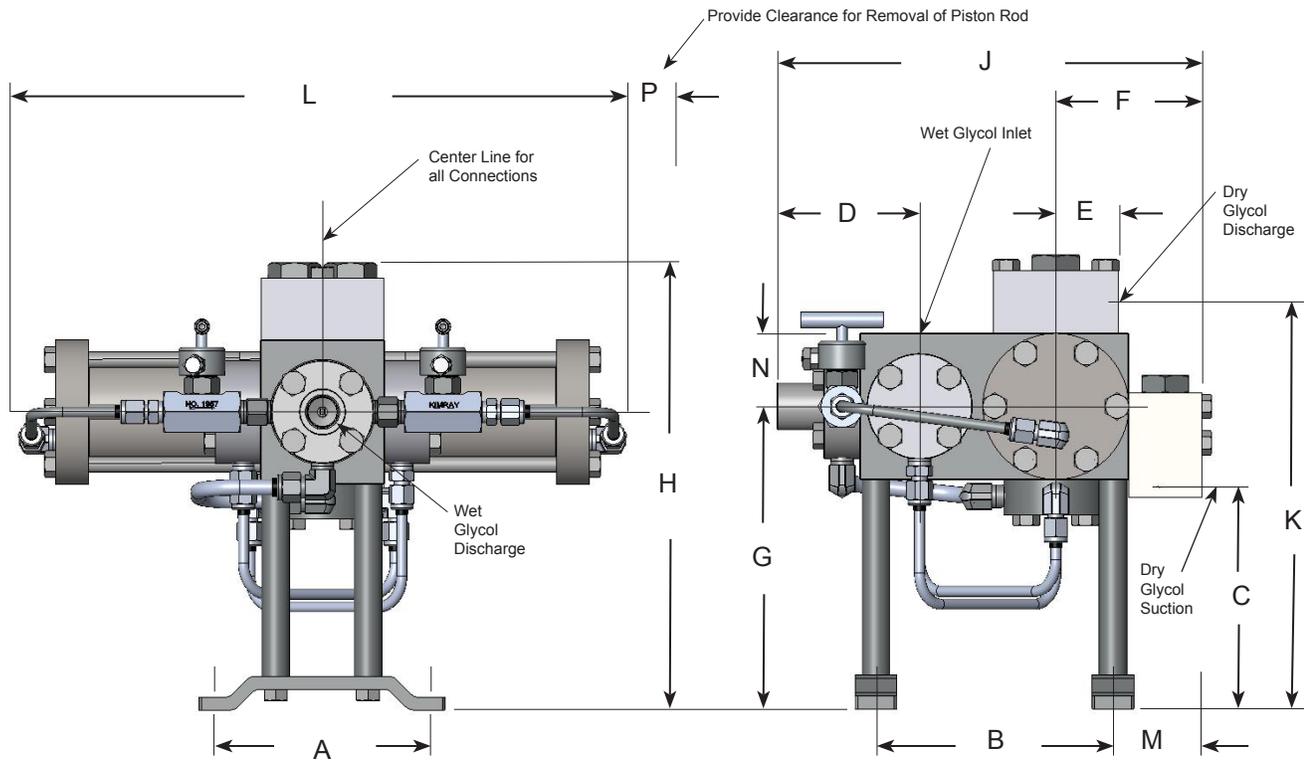

Figure 7

Table 3 - Glycol Pump Dimensions

| Model PV, SC | A | B | C | D | E | F | G | H | J | K | L | M | N | P |
|---------------------|------------------------|--------------------------|-----------------------|-----------------------|----------------------|-----------------------|------------------------|------------------------|-------------------------|------------------------|--------------------|-----------------------|----------------------|-------------------|

| 2015 SC | .33 | 20 | 1/2 in NPT (12 mm) | 3/8 in. dia (9.52 mm) | 66 lbs (29.93 kg) | 55 | 147 | 0.0068 |
| 5015 SC | .83 | 50 | 3/4 in NPT (19 mm) | 1/2 in. dia (12 mm) | 119 lbs (53.97 kg) | 50 | 52 | 0.019 |
| 10015 SC | 1.67 | 100 | 1 in NPT (25 mm) | 1/2 in. dia (12 mm) | 215 lbs (97.52 kg) | 48 | 25 | 0.040 |
| 20015 SC | 3.33 | 200 | 1 1/2 in NPT (38 mm) | 1/2 in. dia (12 mm) | 500 lbs (22.68 kg) | 40 | 8.8 | 0.114 |

| Table 5 - Materials of Construction | | |
|-------------------------------------|-------------------------|---------------------|
| Valve Components | Standard | Optional |
| Body | Ductile, ASTM A395 | |
| Suction Block | Ductile, ASTM A395 | |
| Discharge Block | Ductile, ASTM A395 | |
| Main Valve Housing | Steel | |
| Pilot Valve Housing | Steel | |
| Port Plates | Stellite 3 | |
| Cylinder Heads | Ductile, ASTM A395 | |
| Pilot Piston Caps | Ductile, ASTM A395 | |
| Cylinders | Stainless Steel | |
| Pistons | Steel | |
| Pilot Pistons | 17-4 PH Stainless Steel | |
| Piston Rod | 17.4 PH Stainless Steel | |
| Piston Rod Glands | Ductile, ASTM A395 | |
| Fittings | Steel | SS6 |
| Tubing | 304 Stainless Steel | SS6 |
| O-Rings | Nitrile | Viton®, Afias®, HSN |
| Backups | Glass Filled Teflon | |

| Table 6 - Parts Required to Convert From PV to SC Series | | | | | |
|--|-------------------|--------------------|---------------------|----------------------|----------------------|
| Part Name | Quantity Required | 4020 PV to 2015 SC | 9020 PV to 10015 SC | 21020 PV to 10015 SC | 45020 PV to 20015 SC |
| Cylinder Liner | 2 | 2108 | 2373 | 2412 | ‡1505 |
| Piston | 2 | 1506 | 776 | 1507 | 1508 |
| Piston Seal Retainer | 2 | 1509 | 1510 | 1511 | 1512 |
| Piston "O" Ring | 2 | 156 | 773 | 774 | 329 |
| Back-up Ring | 4 | 1513 | 1457 | 1458 | 772 |
| "O" Ring | 2 | 154 | 154 | 155 | 1107 |
| Lock Nut (Piston) | 2 | * _ | 906 | 175 | 1140 |
| Cylinder "O" Ring | 2 | 773 | 774 | 329 | |

* The piston is the nut for this model and is furnished with a socket head set screw.

‡Full cylinder only.

‡Model 20015 SC only, requires 8, No. 772 Back-up rings.

Kimray is an ISO 9001- certified manufacturer.
Kimray quality assurance process maintains strict controls
of materials and the certification of parts used in Kimray glycol pumps.

ANNEX 3 Methodological Descriptions for Additional Source or Sink Categories

3.1. Methodology for Estimating Emissions of CH₄, N₂O, and Indirect Greenhouse Gases from Stationary Combustion

Estimates of CH₄ and N₂O Emissions

Methane (CH₄) and nitrous oxide (N₂O) emissions from stationary combustion were estimated using emission factors and methods from the Intergovernmental Panel on Climate Change (IPCC). Estimates were obtained by multiplying emission factors—by sector and fuel type—by fossil fuel and wood consumption data. This “top-down” methodology is characterized by two basic steps, described below. Data are presented in Table A-86 through Table A-91.

Step 1: Determine Energy Consumption by Sector and Fuel Type

Energy consumption from stationary combustion activities was grouped by sector: industrial, commercial, residential, electric power, and U.S. Territories. For CH₄ and N₂O from industrial, commercial, residential, and U.S. Territories, estimates were based upon consumption of coal, gas, oil, and wood. Energy consumption and wood consumption data for the United States were obtained from the Energy Information Administration’s (EIA) *Monthly Energy Review, February 2016* and Published Supplemental Tables on Petroleum Product detail (EIA 2016). Because the United States does not include U.S. Territories in its national energy statistics, fuel consumption data for U.S. Territories were collected separately from the EIA’s *International Energy Statistics* (Jacobs 2010).⁴⁰ Fuel consumption for the industrial sector was adjusted to subtract out construction and agricultural use, which is reported under mobile sources.⁴¹ Construction and agricultural fuel use was obtained from EPA (2013). The energy consumption data by sector were then adjusted from higher to lower heating values by multiplying by 0.90 for natural gas and wood and by 0.95 for coal and petroleum fuel. This is a simplified convention used by the International Energy Agency (IEA). Table A-86 provides annual energy consumption data for the years 1990 through 2014.

In this Inventory, the emission estimation methodology for the electric power sector was revised from Tier 1 to Tier 2 as fuel consumption by technology-type for the electricity generation sector was obtained from the Acid Rain Program Dataset (EPA 2015a). This combustion technology-and fuel-use data was available by facility from 1996 to 2014. Since there was a difference between the EPA (2015a) and EIA (2016) total energy consumption estimates, the remainder between total energy consumption using EPA (2015a) and EIA (2016) was apportioned to each combustion technology type and fuel combination using a ratio of energy consumption by technology type from 1996 to 2014.

Energy consumption estimates were not available from 1990 to 1995 in the EPA (2015a) dataset, and as a result, consumption was calculated using total electric power consumption from EIA (2016) and the ratio of combustion technology and fuel types from EPA 2015a. The consumption estimates from 1990 to 1995 were estimated by applying the 1996 consumption ratio by combustion technology type to the total EIA consumption for each year from 1990 to 1995.

Lastly, there were significant differences between wood biomass consumption in the electric power sector between the EPA (2015a) and EIA (2016) datasets. The difference in wood biomass consumption in the electric power sector was distributed to the residential, commercial, and industrial sectors according to their percent share of wood biomass energy consumption calculated from EIA (2016).

Step 2: Determine the Amount of CH₄ and N₂O Emitted

Activity data for industrial, commercial, residential, and U.S. Territories and fuel type for each of these sectors were then multiplied by default Tier 1 emission factors to obtain emission estimates. Emission factors for the residential, commercial, and industrial sectors were taken from the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*

⁴⁰ U.S. Territories data also include combustion from mobile activities because data to allocate U.S. Territories’ energy use were unavailable. For this reason, CH₄ and N₂O emissions from combustion by U.S. Territories are only included in the stationary combustion totals.

⁴¹ Though emissions from construction and farm use occur due to both stationary and mobile sources, detailed data was not available to determine the magnitude from each. Currently, these emissions are assumed to be predominantly from mobile sources.

(IPCC 2006). These N₂O emission factors by fuel type (consistent across sectors) were also assumed for U.S. Territories. The CH₄ emission factors by fuel type for U.S. Territories were estimated based on the emission factor for the primary sector in which each fuel was combusted. Table A-87 provides emission factors used for each sector and fuel type. For the electric power sector, emissions were estimated by multiplying fossil fuel and wood consumption by technology- and fuel-specific Tier 2 IPCC emission factors shown in Table A-88. Emission factors were used from the *2006 IPCC Guidelines* as the factors presented in these IPCC guidelines were taken directly from U.S. Environmental Protection Agency (EPA) publications on emissions rates for combustion sources.

Estimates of NO_x, CO, and NMVOC Emissions

Emissions estimates for NO_x, CO, and NMVOCs were obtained from data published on the National Emission Inventory (NEI) Air Pollutant Emission Trends web site (EPA 2015b), and disaggregated based on EPA (2003).

For indirect greenhouse gases, the major source categories included coal, fuel oil, natural gas, wood, other fuels (i.e., bagasse, liquefied petroleum gases, coke, coke oven gas, and others), and stationary internal combustion, which includes emissions from internal combustion engines not used in transportation. EPA periodically estimates emissions of NO_x, CO, and NMVOCs by sector and fuel type using a "bottom-up" estimating procedure. In other words, the emissions were calculated either for individual sources (e.g., industrial boilers) or for many sources combined, using basic activity data (e.g., fuel consumption or deliveries, etc.) as indicators of emissions. The national activity data used to calculate the individual categories were obtained from various sources. Depending upon the category, these activity data may include fuel consumption or deliveries of fuel, tons of refuse burned, raw material processed, etc. Activity data were used in conjunction with emission factors that relate the quantity of emissions to the activity.

The basic calculation procedure for most source categories presented in EPA (2003) and EPA (2009) is represented by the following equation:

$$E_{p,s} = A_s \times EF_{p,s} \times (1 - C_{p,s}/100)$$

where,

- E = Emissions
- p = Pollutant
- s = Source category
- A = Activity level
- EF = Emission factor
- C = Percent control efficiency

The EPA currently derives the overall emission control efficiency of a category from a variety of sources, including published reports, the 1985 National Acid Precipitation and Assessment Program (NAPAP) emissions inventory, and other EPA databases. The U. S. approach for estimating emissions of NO_x, CO, and NMVOCs from stationary combustion as described above is similar to the methodology recommended by the IPCC (IPCC 2006).

3.2. Methodology for Estimating Emissions of CH₄, N₂O, and Indirect Greenhouse Gases from Mobile Combustion and Methodology for and Supplemental Information on Transportation-Related GHG Emissions

Estimating CO₂ Emissions by Transportation Mode

Transportation-related CO₂ emissions, as presented in the CO₂ Emissions from Fossil Fuel Combustion section of the Energy chapter, were calculated using the methodology described in Annex 2.1. This section provides additional information on the data sources and approach used for each transportation fuel type. As noted in Annex 2.1, CO₂ emissions estimates for the transportation sector were calculated directly for on-road diesel fuel and motor gasoline based on data sources for individual modes of transportation (considered a bottom up approach). For most other fuel and energy types (aviation gasoline, residual fuel oil, natural gas, LPG, and electricity), CO₂ emissions were calculated based on transportation sector-wide fuel consumption estimates from the Energy Information Administration (EIA 2016 and EIA 2015) and apportioned to individual modes (considered a “top down” approach). Carbon dioxide emissions from commercial jet fuel use are obtained directly from the Federal Aviation Administration (FAA 2016), while CO₂ emissions from other aircraft jet fuel consumption is determined using a top down approach.

Based on interagency discussions between EPA, EIA, and FHWA beginning in 2005, it was agreed that use of “bottom up” data would be more accurate for diesel fuel and motor gasoline consumption in the transportation sector, based on the availability of reliable data sources. A “bottom up” diesel calculation was first implemented in the 1990 through 2005 Inventory, and a bottom-up gasoline calculation was introduced in the 1990 through 2006 Inventory for the calculation of emissions from on-road vehicles. Estimated motor gasoline and diesel consumption data for on-road vehicles by vehicle type come from FHWA’s *Highway Statistics*, Table VM-1 (FHWA 1996 through 2015),⁴² and are based on federal and state fuel tax records. These fuel consumption estimates were then combined with estimates of fuel shares by vehicle type from DOE’s Transportation Energy Data Book Annex Tables A.1 through A.6 (DOE 1993 through 2015) to develop an estimate of fuel consumption for each vehicle type (i.e., passenger cars, light-duty trucks, buses, medium- and heavy-duty trucks, motorcycles). The on-road gas and diesel fuel consumption estimates by vehicle type were then adjusted for each year so that the sum of gasoline and diesel fuel consumption across all on-road vehicle categories matched the fuel consumption estimates in *Highway Statistics*’ Table MF-27 (FHWA 1996 through 2015). This resulted in a final “bottom up” estimate of motor gasoline and diesel fuel use by vehicle type, consistent with the FHWA total for on-road motor gasoline and diesel fuel use.

A primary challenge to switching from a top-down approach to a bottom-up approach for the transportation sector relates to potential incompatibilities with national energy statistics. From a multi-sector national standpoint, EIA develops the most accurate estimate of total motor gasoline and diesel fuel supplied and consumed in the United States. EIA then allocates this total fuel consumption to each major end-use sector (residential, commercial, industrial and transportation) using data from the *Fuel Oil and Kerosene Sales* (FOKS) report for distillate fuel oil and FHWA for motor gasoline. However, the “bottom-up” approach used for the on-road and non-road fuel consumption estimate, as described above, is considered to be the most representative of the transportation sector’s share of the EIA total consumption. Therefore, for years in which there was a disparity between EIA’s fuel allocation estimate for the transportation sector and the “bottom-up” estimate, adjustments were made to other end-use sector fuel allocations (residential, commercial and industrial) in order for the consumption of all sectors combined to equal the “top-down” EIA value.

In the case of motor gasoline, estimates of fuel use by recreational boats come from the NONROAD component of EPA’s MOVES2014a model (EPA 2015d), and these estimates, along with those from other sectors (e.g., commercial sector, industrial sector), were adjusted for years in which the bottom-up on-road motor gasoline consumption estimate exceeded the EIA estimate for total gasoline consumption of all sectors. Similarly, to ensure consistency with EIA’s total diesel estimate for all sectors, the diesel consumption totals for the residential, commercial, and industrial sectors were adjusted proportionately.

⁴² In 2011 FHWA changed its methods for estimating vehicle miles traveled (VMT) and related data. These methodological changes included how vehicles are classified, moving from a system based on body-type to one that is based on wheelbase. These changes were first incorporated for the 2010 Inventory and apply to the 2007-14 time period. This resulted in large changes in VMT and fuel consumption data by vehicle class, thus leading to a shift in emissions among on-road vehicle classes. For example, the category “Passenger Cars” has been replaced by “Light-duty Vehicles-Short Wheelbase” and “Other 2 axle-4 Tire Vehicles” has been replaced by “Light-duty Vehicles, Long Wheelbase.” This change in vehicle classification has moved some smaller trucks and sport utility vehicles from the light truck category to the passenger vehicle category in this emission inventory. These changes are reflected in a large drop in light-truck emissions between 2006 and 2007.

Estimates of diesel fuel consumption from rail were taken from the Association of American Railroads (AAR 2008 through 2015) for Class I railroads, the American Public Transportation Association (APTA 2007 through 2015 and APTA 2006) and Gaffney (2007) for commuter rail, the Upper Great Plains Transportation Institute (Benson 2002 through 2004) and Whorton (2006 through 2013) for Class II and III railroads, and DOE's *Transportation Energy Data Book* (DOE 1993 through 2015) for passenger rail. Estimates of diesel from ships and boats were taken from EIA's *Fuel Oil and Kerosene Sales* (1991 through 2015).

As noted above, for fuels other than motor gasoline and diesel, EIA's transportation sector total was apportioned to specific transportation sources. For jet fuel, estimates come from: FAA (2016) for domestic and international commercial aircraft, and DESC (2015) for domestic and international military aircraft. General aviation jet fuel consumption is calculated as the difference between total jet fuel consumption as reported by EIA and the total consumption from commercial and military jet fuel consumption. Commercial jet fuel CO₂ estimates are obtained directly from the Federal Aviation Administration (FAA 2016), while CO₂ emissions from domestic military and general aviation jet fuel consumption is determined using a top down approach. Domestic commercial jet fuels CO₂ from FAA is subtracted from total domestic jet fuel CO₂ emissions, and this remaining value is apportioned among domestic military and domestic general aviation based on their relative proportion of energy consumption. Estimates for biofuels, including ethanol and biodiesel were discussed separately in Chapter 3.2 Carbon Emitted from Non-Energy Uses of Fossil Fuels under the methodology for Estimating CO₂ from Fossil Combustion, and in Chapter 3.10 Wood Biomass and Ethanol Consumption and were not apportioned to specific transportation sources. Consumption estimates for biofuels were calculated based on data from the Energy Information Administration (EIA 2016).

Table A-92 displays estimated fuel consumption by fuel and vehicle type. Table A-93 displays estimated energy consumption by fuel and vehicle type. The values in both of these tables correspond to the figures used to calculate CO₂ emissions from transportation. Except as noted above, they are estimated based on EIA transportation sector energy estimates by fuel type, with activity data used to apportion consumption to the various modes of transport. The motor gasoline and diesel fuel consumption volumes published by EIA and FHWA include ethanol blended with gasoline and biodiesel blended with diesel. Biofuels blended with conventional fuels were subtracted from these consumption totals in order to be consistent with IPCC methodological guidance and UNFCCC reporting obligations, for which net carbon fluxes in biogenic carbon reservoirs in croplands are accounted for in the estimates for Land Use, Land-Use Change and Forestry chapter, not in Energy chapter totals. Ethanol fuel volumes were removed from motor gasoline consumption estimates for years 1990 through 2014 and biodiesel fuel volumes were removed from diesel fuel consumption volumes for years 2001 through 2014, as there was negligible use of biodiesel as a diesel blending component prior to 2001. The subtraction or removal of biofuels blended into motor gasoline and diesel were conducted following the methodology outlined in Step 2 ("Remove Biofuels from Petroleum") of the EIA's *Monthly Energy Review* (MER) Section 12 notes.

In order to remove the volume of biodiesel blended into diesel fuel, the refinery and blender net volume inputs of renewable diesel fuel sourced from EIA Petroleum Supply Annual (EIA 2015) *Table 18 - Refinery Net Input of Crude Oil and Petroleum Products* and *Table 20 - Blender Net Inputs of Petroleum Products* were subtracted from the transportation sector's total diesel fuel consumption volume (for both the "top-down" EIA and "bottom-up" FHWA estimates). To remove the fuel ethanol blended into motor gasoline, ethanol energy consumption data sourced from MER *Table 10.2b - Renewable Energy Consumption: Industrial and Transportation Sectors* (EIA 2016) were subtracted from the total EIA and FHWA transportation motor gasoline energy consumption estimates.

Total ethanol and biodiesel consumption estimates are shown separately in Table A-94.⁴³

⁴³ Note that the refinery and blender net volume inputs of renewable diesel fuel sourced from EIA's Petroleum Supply Annual (PSA) differs from the biodiesel volume presented in Table A-94. The PSA data is representative of the amount of biodiesel that refineries and blenders added to diesel fuel to make low level biodiesel blends. This is the appropriate value to subtract from total diesel fuel volume, as it represents the amount of biofuel blended into diesel to create low-level biodiesel blends. The biodiesel consumption value presented in Table A-93 is representative of the total biodiesel consumed and includes biodiesel components in all types of fuel formulations, from low level (<5%) to high level (6-20%, 100%) blends of biodiesel. This value is sourced from MER Table 10.4 and is calculated as biodiesel production plus biodiesel net imports minus biodiesel stock exchange.

- Unreported or zero

^a In 2011, FHWA changed its methodology for Table VM-1, which impacts estimates for the 2007-2014 time period. These methodological changes include how on-road vehicles are classified, moving from a system based on body-type to one that is based on wheelbase. This resulted in large changes in fuel consumption data by vehicle class between 2006 and 2007.

^b Figures do not include ethanol blended in motor gasoline or biodiesel blended into distillate fuel oil. Net carbon fluxes associated with ethanol are accounted for in the Land Use, Land-Use Change and Forestry chapter. This table is calculated with the heat content for gasoline without ethanol (from Table A.2 in the EIA Annual Energy Review) rather than the annually variable quantity-weighted heat content for gasoline with ethanol, which varies by year. In addition, updates to the distillate fuel oil heat content data from EIA for years 1993 through present resulted in changes to the time series for energy consumption and emissions compared to the previous Inventory.

^c Gasoline and diesel highway vehicle fuel consumption estimates are based on data from FHWA Highway Statistics Table VM-1 and MF-27 (FHWA 1996 through 2015). These fuel consumption estimates are combined with estimates of fuel shares by vehicle type from DOE's TEDB Annex Tables A.1 through A.6 (DOE 1993 through 2015). TEDB data for 2014 has not been published yet, therefore 2013 data is used as a proxy.

^d Fluctuations in recreational boat gasoline estimates reflect the use of this category to reconcile bottom-up values with EIA total gasoline estimates.

^e Class II and Class II diesel consumption data for 2014 is not available yet, therefore 2013 data is used as a proxy.

^f Estimated based on EIA transportation sector energy estimates by fuel type, with bottom-up activity data used for apportionment to modes.

^g Fluctuations in reported fuel consumption may reflect data collection problems.

^h Million Kilowatt-hours

-Unreported or zero

^a Note that updates to the distillate fuel oil heat content data from EIA for years 1993 through present resulted in changes to the time series for energy consumption and emissions compared to the previous Inventory.

^b In 2011, FHWA changed its methodology for Table VM-1, which impacts estimates for the 2007-2014 time period. These methodological changes include how on-road vehicles are classified, moving from a system based on body-type to one that is based on wheelbase. This resulted in large changes in fuel consumption data by vehicle class between 2006 and 2007.

^c Figures do not include ethanol blended in motor gasoline or biodiesel blended into distillate fuel oil. Net carbon fluxes associated with ethanol are accounted for in the Land Use, Land-Use Change and Forestry chapter.

^d Gasoline and diesel highway vehicle fuel consumption estimates are based on data from FHWA Highway Statistics Table VM-1 and MF-27 (FHWA 1996 through 2015). These fuel consumption estimates are combined with estimates of fuel shares by vehicle type from DOE's TEDB Annex Tables A.1 through A.6 (DOE 1993 through 2015). TEDB data for 2014 has not been published yet, therefore 2013 data is used as a proxy.

^e Fluctuations in recreational boat gasoline estimates reflect the use of this category to reconcile bottom-up values with EIA total gasoline estimates.

^f Class II and Class III diesel consumption data for 2014 is not available yet, therefore 2013 data is used as a proxy.

^g Estimated based on EIA transportation sector energy estimates, with bottom-up data used for apportionment to modes.

^h Fluctuations in reported fuel consumption may reflect data collection problems. Residual fuel oil for ships and other boats data is based on EIA's December 2015 Monthly Energy Review data.

Table A-94: Transportation Sector Biofuel Consumption by Fuel Type (million gallons)

| Fuel Type | 1990 | 1995 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 |
|-----------|------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|--------|--------|--------|--------|--------|--------|
| Ethanol | 712 | 1,326 | 1,590 | 1,660 | 1,975 | 2,689 | 3,375 | 3,860 | 5,207 | 6,563 | 9,263 | 10,537 | 12,282 | 12,329 | 12,324 | 12,646 | 12,900 |
| Biodiesel | NA | NA | NA | 10 | 16 | 14 | 27 | 91 | 261 | 354 | 304 | 322 | 260 | 886 | 899 | 1,429 | 1,417 |

NA – Not Available

Note: According to the MER, there was no biodiesel consumption prior to 2001.

Estimates of CH₄ and N₂O Emissions

Mobile source emissions of greenhouse gases other than CO₂ are reported by transport mode (e.g., road, rail, aviation, and waterborne), vehicle type, and fuel type. Emissions estimates of CH₄ and N₂O were derived using a methodology similar to that outlined in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2006).

Activity data were obtained from a number of U.S. government agencies and other publications. Depending on the category, these basic activity data included fuel consumption and vehicle miles traveled (VMT). These estimates were then multiplied by emission factors, expressed as grams per unit of fuel consumed or per vehicle mile.

Methodology for On-Road Gasoline and Diesel Vehicles

Step 1: Determine Vehicle Miles Traveled by Vehicle Type, Fuel Type, and Model Year

VMT by vehicle type (e.g., passenger cars, light-duty trucks, medium- and heavy-duty trucks,⁴⁴ buses, and motorcycles) were obtained from the Federal Highway Administration's (FHWA) *Highway Statistics* (FHWA 1996 through 2015).⁴⁵ As these vehicle categories are not fuel-specific, VMT for each vehicle type was disaggregated by fuel type (gasoline, diesel) so that the appropriate emission factors could be applied. VMT from *Highway Statistics* Table VM-1 (FHWA 1996 through 2015) was allocated to fuel types (gasoline, diesel, other) using historical estimates of fuel shares reported in the Appendix to the *Transportation Energy Data Book, Tables A.5 and A.6* (DOE 1993 through 2015). These fuel shares are drawn from various sources, including the Vehicle Inventory and Use Survey, the National Vehicle Population Profile, and the American Public Transportation Association. Fuel shares were first adjusted proportionately such that gasoline and diesel shares for each vehicle/fuel type category equaled 100 percent of national VMT. VMT for alternative fuel vehicles (AFVs) was calculated separately, and the methodology is explained in the following section on AFVs. Estimates of VMT from AFVs were then subtracted from the appropriate total VMT estimates to develop the final VMT estimates by vehicle/fuel type category.⁴⁶ The resulting national VMT estimates for gasoline and diesel on-road vehicles are presented in Table A-95 and Table A-96, respectively.

Total VMT for each on-road category (i.e., gasoline passenger cars, light-duty gasoline trucks, heavy-duty gasoline vehicles, diesel passenger cars, light-duty diesel trucks, medium- and heavy-duty diesel vehicles, and motorcycles) were distributed across 30 model years shown for 2014 in Table A-97. This distribution was derived by weighting the appropriate age distribution of the U.S. vehicle fleet according to vehicle registrations by the average annual age-specific vehicle mileage accumulation of U.S. vehicles. Age distribution values were obtained from EPA's MOBILE6 model for all years before 1999 (EPA 2000) and EPA's MOVES2014a model for years 2009 forward (EPA 2015d).⁴⁷ Age-specific vehicle mileage accumulations were also obtained from EPA's MOVES2014a model (EPA 2015d).⁴⁸

Step 2: Allocate VMT Data to Control Technology Type

VMT by vehicle type for each model year was distributed across various control technologies as shown in Table A-103 through Table A-106. The categories "EPA Tier 0" and "EPA Tier 1" were used instead of the early three-way catalyst and advanced three-way catalyst categories, respectively, as defined in the *Revised 1996 IPCC Guidelines*. EPA Tier 0, EPA Tier 1, EPA Tier 2, and LEV refer to U.S. emission regulations, rather than control technologies; however, each does correspond to particular combinations of control technologies and engine design. EPA Tier 2 and its predecessors EPA

⁴⁴ Medium- and heavy-duty trucks correspond to FHWA's reporting categories of single-unit trucks and combination trucks. Single-unit trucks are defined as single frame trucks that have 2-axes and at least 6 tires or a gross vehicle weight rating (GVWR) exceeding 10,000 lbs.

⁴⁵ In 2011 FHWA changed its methods for estimated vehicle miles traveled (VMT) and related data. These methodological changes included how vehicles are classified, moving from a system based on body-type to one that is based on wheelbase. These changes were first incorporated for the 2010 Inventory and apply to the 2007-14 time period. This resulted in large changes in VMT data by vehicle class, thus leading to a shift in emissions among on-road vehicle classes. For example, the category "Passenger Cars" has been replaced by "Light-duty Vehicles-Short Wheelbase" and "Other 2 axle-4 Tire Vehicles" has been replaced by "Light-duty Vehicles, Long Wheelbase." This change in vehicle classification has moved some smaller trucks and sport utility vehicles from the light truck category to the passenger vehicle category in this emission inventory. These changes are reflected in a large drop in light-truck emissions between 2006 and 2007.

⁴⁶ In Inventories through 2002, gasoline-electric hybrid vehicles were considered part of an "alternative fuel and advanced technology" category. However, vehicles are now only separated into gasoline, diesel, or alternative fuel categories, and gas-electric hybrids are now considered within the gasoline vehicle category.

⁴⁷ Age distributions were held constant for the period 1990-1998, and reflect a 25-year vehicle age span. EPA (2015b) provides a variable age distribution and 31-year vehicle age span beginning in year 1999.

⁴⁸ The updated vehicle distribution and mileage accumulation rates by vintage obtained from the MOVES 2014a model resulted in a decrease in emissions due to more miles driven by newer light-duty gasoline vehicles.

Tier 1 and Tier 0 apply to vehicles equipped with three-way catalysts. The introduction of “early three-way catalysts,” and “advanced three-way catalysts,” as described in the *Revised 1996 IPCC Guidelines*, roughly correspond to the introduction of EPA Tier 0 and EPA Tier 1 regulations (EPA 1998b).⁴⁹ EPA Tier 2 regulations affect vehicles produced starting in 2004 and are responsible for a noticeable decrease in N₂O emissions compared EPA Tier 1 emissions technology (EPA 1999b).

Control technology assignments for light and heavy-duty conventional fuel vehicles for model years 1972 (when regulations began to take effect) through 1995 were estimated in EPA (1998). Assignments for 1998 through 2014 were determined using confidential engine family sales data submitted to EPA (EPA 2015f). Vehicle classes and emission standard tiers to which each engine family was certified were taken from annual certification test results and data (EPA 2015e). This information was used to determine the fraction of sales of each class of vehicle that met EPA Tier 0, EPA Tier 1, Tier 2, and LEV standards. Assignments for 1996 and 1997 were estimated based on the fact that EPA Tier 1 standards for light-duty vehicles were fully phased in by 1996. Tier 2 began initial phase-in by 2004.

Step 3: Determine CH₄ and N₂O Emission Factors by Vehicle, Fuel, and Control Technology Type

Emission factors for gasoline and diesel on-road vehicles utilizing Tier 2 and Low Emission Vehicle (LEV) technologies were developed by ICF (2006b); all other gasoline and diesel on-road vehicle emissions factors were developed by ICF (2004). These factors were based on EPA, CARB and Environment Canada laboratory test results of different vehicle and control technology types. The EPA, CARB and Environment Canada tests were designed following the Federal Test Procedure (FTP), which covers three separate driving segments, since vehicles emit varying amounts of GHGs depending on the driving segment. These driving segments are: (1) a transient driving cycle that includes cold start and running emissions, (2) a cycle that represents running emissions only, and (3) a transient driving cycle that includes hot start and running emissions. For each test run, a bag was affixed to the tailpipe of the vehicle and the exhaust was collected; the content of this bag was later analyzed to determine quantities of gases present. The emission characteristics of Segment 2 was used to define running emissions, and subtracted from the total FTP emissions to determine start emissions. These were then recombined based upon MOBILE6.2’s ratio of start to running emissions for each vehicle class to approximate average driving characteristics.

Step 4: Determine the Amount of CH₄ and N₂O Emitted by Vehicle, Fuel, and Control Technology Type

Emissions of CH₄ and N₂O were then calculated by multiplying total VMT by vehicle, fuel, and control technology type by the emission factors developed in Step 3.

Methodology for Alternative Fuel Vehicles (AFVs)

Step 1: Determine Vehicle Miles Traveled by Vehicle and Fuel Type

VMT for alternative fuel and advanced technology vehicles were calculated from “Methodology for Highway Vehicle Alternative Fuel GHG Projections Estimates” (Browning, 2015). Alternative Fuels include Compressed Natural Gas (CNG), Liquid Natural Gas (LNG), Liquefied Petroleum Gas (LPG), Ethanol, Methanol, Biodiesel, Hydrogen and Electricity. Most of the vehicles that use these fuels run on an Internal Combustion Engine (ICE) powered by the alternative fuel, although many of the vehicles can run on either the alternative fuel or gasoline (or diesel), or some combination.⁵⁰ Except for electric vehicles and plug-in hybrid vehicles, the alternative fuel vehicle VMT were calculated using the Energy Information Administration (EIA) Alternative Fuel Vehicle Data. The EIA data provides vehicle counts and fuel use for fleet vehicles used by electricity providers, federal agencies, natural gas providers, propane providers, state agencies and transit agencies for calendar years 2003 through 2013. For 1992 to 2002, EIA Data Tables were used to estimate fuel consumption and vehicle counts by vehicle type. These tables give total vehicle fuel use and vehicle counts by fuel and calendar year for the United States over the period 1992 through 2010. Breakdowns by vehicle type for 1992 through 2002 (both fuel consumed and vehicle counts) were assumed to be at the same ratio as for 2003 where data existed. For 1990, 1991 and 2014, fuel consumed by alternative fuel and vehicle type were extrapolated based on a regression analysis using the best curve fit based upon R² using the nearest 5 years of data.

For the current Inventory, counts of electric vehicles (EVs) and plug-in hybrid-electric vehicles (PHEVs) were taken from data compiled by the Electric Drive Transportation Association from 2011 to 2014 (EDTA 2015). EVs were

⁴⁹ For further description, see “Definitions of Emission Control Technologies and Standards” section of this annex below.

⁵⁰ Fuel types used in combination depend on the vehicle class. For light-duty vehicles, gasoline is generally blended with ethanol and diesel is blended with biodiesel; dual-fuel vehicles can run on gasoline or an alternative fuel – either natural gas or LPG – but not at the same time, while flex-fuel vehicles are designed to run on E85 (85 percent ethanol) or gasoline, or any mixture of the two in between. Heavy-duty vehicles are more likely to run on diesel fuel, natural gas, or LPG.

divided into cars and trucks using confidential engine family sales data submitted to EPA (EPA 2015f). Fuel use per vehicle for personal EVs and PHEVs were assumed to be the same as those for the public fleet vehicles surveyed by EIA and provided in their data tables.

Because AFVs run on different fuel types, their fuel use characteristics are not directly comparable. Accordingly, fuel economy for each vehicle type is expressed in gasoline equivalent terms, i.e., how much gasoline contains the equivalent amount of energy as the alternative fuel. Energy economy ratios (the ratio of the gasoline equivalent fuel economy of a given technology to that of conventional gasoline or diesel vehicles) were taken from the Argonne National Laboratory's GREET2015 model (ANL 2015). These ratios were used to estimate fuel economy in miles per gasoline gallon equivalent for each alternative fuel and vehicle type. Energy use per fuel type was then divided among the various weight categories and vehicle technologies that use that fuel. Total VMT per vehicle type for each calendar year was then determined by dividing the energy usage by the fuel economy. Note that for AFVs capable of running on both/either traditional and alternative fuels, the VMT given reflects only those miles driven that were powered by the alternative fuel, as explained in Browning (2015). VMT estimates for AFVs by vehicle category (passenger car, light-duty truck, medium-duty and heavy-duty vehicles) are shown in Table A-97, while more detailed estimates of VMT by control technology are shown in Table A-98.

Step 2: Determine CH₄ and N₂O Emission Factors by Vehicle and Alternative Fuel Type

Methane and N₂O emission factors for alternative fuel vehicles (AFVs) are calculated according to studies by Argonne National Laboratory (2006) and Lipman & Delucchi (2002), and are reported in ICF (2006a). In these studies, N₂O and CH₄ emissions for AFVs were expressed as a multiplier corresponding to conventional vehicle counterpart emissions. Emission estimates in these studies represent the current AFV fleet and were compared against Tier 1 emissions from light-duty gasoline vehicles to develop new multipliers. Alternative fuel heavy-duty vehicles were compared against gasoline heavy-duty vehicles as most alternative fuel heavy-duty vehicles use catalytic after treatment and perform more like gasoline vehicles than diesel vehicles. These emission factors are shown in Table A-108.

Step 3: Determine the Amount of CH₄ and N₂O Emitted by Vehicle and Fuel Type

Emissions of CH₄ and N₂O were calculated by multiplying total VMT for each vehicle and fuel type (Step 1) by the appropriate emission factors (Step 2).

Methodology for Non-Road Mobile Sources

Methane and N₂O emissions from non-road mobile sources were estimated by applying emission factors to the amount of fuel consumed by mode and vehicle type.

Activity data for non-road vehicles include annual fuel consumption statistics by transportation mode and fuel type, as shown in Table A-102. Consumption data for ships and other boats (i.e., vessel bunkering) were obtained from DHS (2008) and EIA (1991 through 2015) for distillate fuel, and DHS (2008) and EIA (2015) for residual fuel; marine transport fuel consumption data for U.S. Territories (EIA 2015) were added to domestic consumption, and this total was reduced by the amount of fuel used for international bunkers.⁵¹ Gasoline consumption by recreational boats was obtained from the NONROAD component of EPA's MOVES2014a model (EPA 2015d). Annual diesel consumption for Class I rail was obtained from the Association of American Railroads (AAR 2008 through 2015), diesel consumption from commuter rail was obtained from APTA (2007 through 2015) and Gaffney (2007), and consumption by Class II and III rail was provided by Benson (2002 through 2004) and Whorton (2006 through 2013).⁵² Diesel consumption by commuter and intercity rail was obtained from DOE (1993 through 2015). Data on the consumption of jet fuel and aviation gasoline in aircraft were obtained from EIA (2016) and FAA (2016), as described in Annex 2.1: Methodology for Estimating Emissions of CO₂ from Fossil Fuel Combustion, and were reduced by the amount allocated to international bunker fuels (DESC 2015 and FAA 2016). Pipeline fuel consumption was obtained from EIA (2007 through 2015) (note: pipelines are a transportation source but are stationary, not mobile, sources). Data on fuel consumption by all non-transportation mobile sources were obtained from the NONROAD component of EPA's MOVES2014a model (EPA 2015d) and from FHWA (1996 through 2015) for gasoline consumption for trucks used off-road.⁵³

⁵¹ See International Bunker Fuels section of the Energy Chapter.

⁵² Diesel consumption from Class II and Class III railroad were unavailable for 2014. Values are proxied from 2013, which is the last year the data was available.

⁵³ "Non-transportation mobile sources" are defined as any vehicle or equipment not used on the traditional road system, but excluding aircraft, rail and watercraft. This category includes snowmobiles, golf carts, riding lawn mowers, agricultural equipment, and trucks used for off-road purposes, among others.

Emissions of CH₄ and N₂O from non-road mobile sources were calculated by multiplying U.S. default emission factors in the 2006 IPCC Guidelines by activity data for each source type (see Table A-109).

Estimates of NO_x, CO, and NMVOC Emissions

The emission estimates of NO_x, CO, and NMVOCs from mobile combustion (transportation) were obtained from preliminary data (EPA 2015g), which, in final iteration, will be published on the EPA's National Emission Inventory (NEI) Air Pollutant Emission Trends web site. This EPA report provides emission estimates for these gases by fuel type using a procedure whereby emissions were calculated using basic activity data, such as amount of fuel delivered or miles traveled, as indicators of emissions. Table A-110 through Table A-112 provides complete emission estimates for 1990 through 2014.

Table A-95: Vehicle Miles Traveled for Gasoline On-Road Vehicles (million miles)

| Year | Passenger Cars | Light-Duty Trucks | Heavy-Duty Vehicles ^b | Motorcycles |
|-------------------|----------------|-------------------|----------------------------------|-------------|
| 1990 | 1,391.4 | 554.8 | 25.8 | 9.6 |

Source: Derived from FHWA (1996 through 2014), Browning (2015).

^a In 2011, FHWA changed its methodology for Table VM-1, which impacts estimates for the 2007 to 2014 time period. These methodological changes include how on-road vehicles are classified, moving from a system based on body-type to one that is based on wheelbase. This resulted in large changes in VMT data by vehicle class between 2006 and 2007.

^b Heavy-Duty Vehicles includes Medium-Duty Trucks, Heavy-Duty Trucks, and Buses.

Note: In 2015, EIA changed its methods for estimating AFV fuel consumption. These methodological changes included how vehicle counts are estimated, moving from estimates based on modeling to one that is based on survey data. EIA now publishes data about fuel use and number of vehicles for only four types of AFV fleets: federal government, state government, transit agencies, and fuel providers. These changes were first incorporated in this year's inventory and apply to the 1990-2014 time period. This resulted in large reductions in AFV VMT, thus leading to a shift in VMT to conventional on-road vehicle classes.

Note: Gasoline and diesel highway vehicle mileage are based on data from FHWA Highway Statistics Table VM-1 (FHWA 1996 through 2015). These mileage consumption estimates are combined with estimates of fuel shares by vehicle type from DOE's TEDB Annex Tables A.1 through A.6 (DOE 1993 through 2015). TEDB data for 2014 has not been published yet, therefore 2013 data is used as a proxy.

+ Does not exceed 0.05 million vehicle miles traveled

Note: Throughout the rest of this Inventory, medium-duty trucks are grouped with heavy-duty trucks; they are reported separately here because these two categories may run on a slightly different range of fuel types.

In 2015, EIA changed its methods for estimating AFV fuel consumption. These methodological changes included how vehicle counts are estimated, moving from estimates based on modeling to one that is based on survey data.

EIA now publishes data about fuel use and number of vehicles for only four types of AFV fleets: federal government, state government, transit agencies, and fuel providers. These changes were first incorporated for the 2014

Inventory and apply to the 1990-2014 time period. This resulted in large reductions in AFV VMT, thus leading to a shift in VMT to conventional on-road vehicle classes.

Source: Derived from Browning (2015).

^a For aircraft, this is aviation gasoline. For all other categories, this is motor gasoline.

^b Commercial aviation, as modeled in FAA's AEDT, consists of passenger aircraft, cargo, and other chartered flights.

^c Includes equipment, such as cranes, dumpers, and excavators, as well as fuel consumption from trucks that are used off-road in construction.

^d Includes equipment, such as tractors and combines, as well as fuel consumption from trucks that are used off-road in agriculture.

^e "Other" includes snowmobiles and other recreational equipment, logging equipment, lawn and garden equipment, railroad equipment, airport equipment, commercial equipment, and industrial equipment, as well as fuel consumption from trucks that are used off-road for commercial/industrial purposes.

Note: In 2015, EPA incorporated the NONROAD2008 model into MOVES2014a. This year's inventory uses the NONROAD component of MOVES2014a for years 1999 through 2014. This update resulted in small changes (<2%) to the 1999-2013 time series for NONROAD fuel consumption due to differences in the gasoline and diesel default fuel densities used within the model iterations.

^a Detailed descriptions of emissions control technologies are provided in the following section of this Annex.

^b The proportion of LEVs as a whole has decreased since 2001, as carmakers have been able to achieve greater emission reductions with certain types of LEVs, such as ULEVs. Because ULEVs emit about half the emissions of LEVs, a carmaker can reduce the total number of LEVs they need to build to meet a specified emission average for all of their vehicles in a given model year.

Source: IPCC (2006) and ICF (2009).

^a Includes equipment, such as tractors and combines, as well as fuel consumption from trucks that are used off-road in agriculture.

^b Includes equipment, such as cranes, dumpers, and excavators, as well as fuel consumption from trucks that are used off-road in construction.

^c "Other" includes snowmobiles and other recreational equipment, logging equipment, lawn and garden equipment, railroad equipment, airport equipment, commercial equipment, and industrial equipment, as well as fuel consumption from trucks that are used off-road for commercial/industrial purposes.

^d Emissions of CH₄ from jet fuels have been zeroed out across the time series. Recent research indicates that modern aircraft jet engines are typically net consumers of methane (Santoni et al. 2011). Methane is emitted at low power and idle operation, but at higher power modes aircraft engines consumer methane. Over the range of engine operating modes, aircraft engines are net consumers of methane on average. Based on this data, methane emissions factors for jet aircraft were changed to zero in this year's Inventory to reflect the latest emissions testing data.

Definitions of Emission Control Technologies and Standards

The N₂O and CH₄ emission factors used depend on the emission standards in place and the corresponding level of control technology for each vehicle type. Table A-103 through Table A-106 show the years in which these technologies or standards were in place and the penetration level for each vehicle type. These categories are defined below and were compiled from EPA (1993, 1994a, 1994b, 1998, 1999a) and IPCC/UNEP/OECD/IEA (1997).

Uncontrolled

Vehicles manufactured prior to the implementation of pollution control technologies are designated as uncontrolled. Gasoline passenger cars and light-duty trucks (pre-1973), gasoline heavy-duty vehicles (pre-1984), diesel vehicles (pre-1983), and motorcycles (pre-1996) are assumed to have no control technologies in place.

Gasoline Emission Controls

Below are the control technologies and emissions standards applicable to gasoline vehicles.

Non-catalyst

These emission controls were common in gasoline passenger cars and light-duty gasoline trucks during model years (1973-1974) but phased out thereafter, in heavy-duty gasoline vehicles beginning in the mid-1980s, and in motorcycles beginning in 1996. This technology reduces hydrocarbon (HC) and carbon monoxide (CO) emissions through adjustments to ignition timing and air-fuel ratio, air injection into the exhaust manifold, and exhaust gas recirculation (EGR) valves, which also helps meet vehicle NO_x standards.

Oxidation Catalyst

This control technology designation represents the introduction of the catalytic converter, and was the most common technology in gasoline passenger cars and light-duty gasoline trucks made from 1975 to 1980 (cars) and 1975 to 1985 (trucks). This technology was also used in some heavy-duty gasoline vehicles between 1982 and 1997. The two-way catalytic converter oxidizes HC and CO, significantly reducing emissions over 80 percent beyond non-catalyst-system capacity. One reason unleaded gasoline was introduced in 1975 was due to the fact that oxidation catalysts cannot function properly with leaded gasoline.

EPA Tier 0

This emission standard from the Clean Air Act was met through the implementation of early "three-way" catalysts, therefore this technology was used in gasoline passenger cars and light-duty gasoline trucks sold beginning in the early 1980s, and remained common until 1994. This more sophisticated emission control system improves the efficiency of the catalyst by converting CO and HC to CO₂ and H₂O, reducing NO_x to nitrogen and oxygen, and using an on-board diagnostic computer and oxygen sensor. In addition, this type of catalyst includes a fuel metering system (carburetor or fuel injection) with electronic "trim" (also known as a "closed-loop system"). New cars with three-way catalysts met the Clean Air Act's amended standards (enacted in 1977) of reducing HC to 0.41 g/mile by 1980, CO to 3.4 g/mile by 1981 and NO_x to 1.0 g/mile by 1981.

EPA Tier 1

This emission standard created through the 1990 amendments to the Clean Air Act limited passenger car NO_x emissions to 0.4 g/mi, and HC emissions to 0.25 g/mi. These bounds respectively amounted to a 60 and 40 percent reduction from the EPA Tier 0 standard set in 1981. For light-duty trucks, this standard set emissions at 0.4 to 1.1 g/mi for NO_x, and 0.25 to 0.39 g/mi for HCs, depending on the weight of the truck. Emission reductions were met through the use of more advanced emission control systems, and applied to light-duty gasoline vehicles beginning in 1994. These advanced emission control systems included advanced three-way catalysts, electronically controlled fuel injection and ignition timing, EGR, and air injection.

EPA Tier 2

This emission standard was specified in the 1990 amendments to the Clean Air Act, limiting passenger car NO_x emissions to 0.07 g/mi on average and aligning emissions standards for passenger cars and light-duty trucks. Manufacturers can meet this average emission level by producing vehicles in 11 emission "Bins," the three highest of which expire in 2006.

These new emission levels represent a 77 to 95 percent reduction in emissions from the EPA Tier 1 standard set in 1994. Emission reductions were met through the use of more advanced emission control systems and lower sulfur fuels and are applied to vehicles beginning in 2004. These advanced emission control systems include improved combustion, advanced three-way catalysts, electronically controlled fuel injection and ignition timing, EGR, and air injection.

Low Emission Vehicles (LEV)

This emission standard requires a much higher emission control level than the Tier 1 standard. Applied to light-duty gasoline passenger cars and trucks beginning in small numbers in the mid-1990s, LEV includes multi-port fuel injection with adaptive learning, an advanced computer diagnostics systems and advanced and close coupled catalysts with secondary air injection. LEVs as defined here include transitional low-emission vehicles (TLEVs), low emission vehicles, ultra-low emission vehicles (ULEVs) and super ultra-low emission vehicles (SULEVs). In this analysis, all categories of LEVs are treated the same due to the fact that there are very limited CH₄ or N₂O emission factor data for LEVs to distinguish among the different types of vehicles. Zero emission vehicles (ZEVs) are incorporated into the alternative fuel and advanced technology vehicle assessments.

Diesel Emission Controls

Below are the three levels of emissions control for diesel vehicles.

Moderate control

Improved injection timing technology and combustion system design for light- and heavy-duty diesel vehicles (generally in place in model years 1983 to 1995) are considered moderate control technologies. These controls were implemented to meet emission standards for diesel trucks and buses adopted by the EPA in 1985 to be met in 1991 and 1994.

Advanced control

EGR and modern electronic control of the fuel injection system are designated as advanced control technologies. These technologies provide diesel vehicles with the level of emission control necessary to comply with standards in place from 1996 through 2006.

Aftertreatment

Use of diesel particulate filters (DPFs), oxidation catalysts and NO_x absorbers or selective catalytic reduction (SCR) systems are designated as aftertreatment control. These technologies provide diesel vehicles with a level of emission control necessary to comply with standards in place from 2007 on.

Supplemental Information on GHG Emissions from Transportation and Other Mobile Sources

This section of this Annex includes supplemental information on the contribution of transportation and other mobile sources to U.S. greenhouse gas emissions. In the main body of the Inventory report, emission estimates are generally presented by greenhouse gas, with separate discussions of the methodologies used to estimate CO₂, N₂O, CH₄, and HFC emissions. Although the inventory is not required to provide detail beyond what is contained in the body of this report, the IPCC allows presentation of additional data and detail on emission sources. The purpose of this sub-annex, within the Annex that details the calculation methods and data used for non-CO₂ calculations, is to provide all transportation estimates presented throughout the report in one place.

This section of this Annex reports total greenhouse gas emissions from transportation and other (non-transportation) mobile sources in CO₂ equivalents, with information on the contribution by greenhouse gas and by mode, vehicle type, and fuel type. In order to calculate these figures, additional analyses were conducted to develop estimates of CO₂ from non-transportation mobile sources (e.g., agricultural equipment, construction/mining equipment, recreational vehicles), and to provide more detailed breakdowns of emissions by source.

Estimation of CO₂ from Non-Transportation Mobile Sources

The estimates of N₂O and CH₄ from fuel combustion presented in the Energy chapter of the Inventory include both transportation sources and other mobile sources. Other mobile sources include construction/mining equipment, agricultural equipment, vehicles used off-road, and other sources that have utility associated with their movement but do not have a primary purpose of transporting people or goods (e.g., snowmobiles, riding lawnmowers, etc.). Estimates of CO₂ from non-transportation mobile sources, based on EIA fuel consumption estimates, are included in the agricultural, industrial, and commercial sectors. In order to provide comparable information on transportation and mobile sources, Table A-113 provides estimates of CO₂ from these other mobile sources, developed from EPA's NONROAD model and FHWA's *Highway*

Statistics. These other mobile source estimates were developed using the same fuel consumption data utilized in developing the N₂O and CH₄ estimates.

Table A-113: CO₂ Emissions from Non-Transportation Mobile Sources (MMT CO₂ Eq.)

| Fuel Type/Vehicle Type | 1990 | 1995 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 |
|--|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|
| Agricultural Equipment ^a | 31.0 | 36.6 | 39.3 | 41.5 | 42.7 | 43.7 | 46.7 | 47.4 | 49.6 | 49.0 | 46.0 | 47.2 | 48.2 | 49.9 | 51.4 | 50.4 | 51.2 |
| Construction/Mining Equipment ^b | 42.0 | 48.9 | 56.2 | 60.4 | 62.2 | 64.0 | 65.8 | 66.9 | 68.3 | 68.8 | 70.3 | 71.6 | 73.9 | 75.1 | 76.8 | 82.2 | 80.4 |
| Other Sources ^c | 54.5 | 59.9 | 62.6 | 70.1 | 71.8 | 73.7 | 75.7 | 75.9 | 77.1 | 75.9 | 76.6 | 77.3 | 80.2 | 79.9 | 79.4 | 80.3 | 81.7 |
| Total | 127.6 | 145.4 | 158.1 | 172.0 | 176.7 | 181.3 | 188.2 | 190.2 | 195.1 | 193.7 | 192.9 | 196.1 | 202.3 | 204.9 | 207.6 | 212.9 | 213.3 |

^a Includes equipment, such as tractors and combines, as well as fuel consumption from trucks that are used off-road in agriculture.

^b Includes equipment, such as cranes, dumpers, and excavators, as well as fuel consumption from trucks that are used off-road in construction.

^c "Other" includes snowmobiles and other recreational equipment, logging equipment, lawn and garden equipment, railroad equipment, airport equipment, commercial equipment, and industrial equipment, as well as fuel consumption from trucks that are used off-road for commercial/industrial purposes.

Note: In 2015, EPA incorporated the NONROAD2008 model into MOVES2014a. This year's inventory uses the NONROAD component of MOVES2014a for years 1999 through 2014. This update resulted in small changes (<2%) to the 1999-2013 time series for NONROAD fuel consumption due to differences in the gasoline and diesel default fuel densities used within the model iterations.

Estimation of HFC Emissions from Transportation Sources

In addition to CO₂, N₂O and CH₄ emissions, transportation sources also result in emissions of HFCs. HFCs are emitted to the atmosphere during equipment manufacture and operation (as a result of component failure, leaks, and purges), as well as at servicing and disposal events. There are three categories of transportation-related HFC emissions; Mobile air-conditioning represents the emissions from air conditioning units in passenger cars and light-duty trucks; Comfort Cooling represents the emissions from air conditioning units in passenger trains and buses; and Refrigerated Transport represents the emissions from units used to cool freight during transportation.

Table A-114 below presents these HFC emissions. Table A-115 presents all transportation and mobile source greenhouse gas emissions, including HFC emissions.

Table A-114: HFC Emissions from Transportation Sources (MMT CO₂Eq.)

| Vehicle Type | 1990 | 1995 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 |

Note: Totals may not sum due to independent rounding.

Contribution of Transportation and Mobile Sources to Greenhouse Gas Emissions, by Mode/Vehicle Type/Fuel Type

Table A-115 presents estimates of greenhouse gas emissions from an expanded analysis including all transportation and additional mobile sources, as well as emissions from electricity generation by the consuming category, in CO₂ equivalents. In total, transportation and non-transportation mobile sources emitted 2,029.7 MMT CO₂ Eq. in 2014, an increase of 21 percent from 1990. Transportation sources account for 1,814.5 MMT CO₂ Eq. while non-transportation mobile sources account for 215.3 MMT CO₂ Eq. These estimates include HFC emissions for mobile AC, comfort cooling for trains and buses, and refrigerated transport. These estimates were generated using the estimates of CO₂ emissions from transportation sources reported in the Carbon Dioxide Emissions from Fossil Fuel Combustion section, and CH₄ emissions and N₂O emissions reported in the Mobile Combustion section of the Energy chapter; information on HFCs from mobile air conditioners, comfort cooling for trains and buses, and refrigerated transportation from the Substitutes for Ozone Depleting Substances section of the IPPU chapter; and estimates of CO₂ emitted from non-transportation mobile sources reported in Table A-111 above.

Although all emissions reported here are based on estimates reported throughout this Inventory, some additional calculations were performed in order to provide a detailed breakdown of emissions by mode and vehicle category. In the case of N₂O and CH₄, additional calculations were performed to develop emission estimates by type of aircraft and type of heavy-duty vehicle (i.e., medium- and heavy-duty trucks or buses) to match the level of detail for CO₂ emissions. N₂O estimates for both jet fuel and aviation gasoline, and CH₄ estimates for aviation gasoline were developed for individual aircraft types by multiplying the emissions estimates for each fuel type (jet fuel and aviation gasoline) by the portion of fuel used by each aircraft type (from FAA 2016 and DESC 2015). Emissions of CH₄ from jet fuels are no longer considered to be emitted from aircraft gas turbine engines burning jet fuel A at higher power settings. This update applies to the entire time series.⁵⁴ Recent research indicates that modern aircraft jet engines are typically net consumers of methane (Santoni et al 2011). Methane is emitted at low power and idle operation, but at higher power modes aircraft engines consume methane. Over the range of engine operating modes, aircraft engines are net consumers of methane on average. Based on this data, CH₄ emission factors for jet aircraft were reported as zero to reflect the latest emissions testing data.

Similarly, N₂O and CH₄ estimates were developed for medium- and heavy-duty trucks and buses by multiplying the emission estimates for heavy-duty vehicles for each fuel type (gasoline, diesel) from the Mobile Combustion section in the Energy chapter, by the portion of fuel used by each vehicle type (from DOE 1993 through 2015). Carbon dioxide emissions from non-transportation mobile sources are calculated using data from EPA's NONROAD component of MOVES2014a (EPA 2015d). Otherwise, the table and figure are drawn directly from emission estimates presented elsewhere in the Inventory, and are dependent on the methodologies presented in Annex 2.1 (for CO₂), Chapter 4, and Annex 3.8 (for HFCs), and earlier in this Annex (for CH₄ and N₂O).

Transportation sources include on-road vehicles, aircraft, boats and ships, rail, and pipelines (note: pipelines are a transportation source but are stationary, not mobile sources). In addition, transportation-related greenhouse gas emissions also include HFC released from mobile air-conditioners and refrigerated transport, and the release of CO₂ from lubricants (such as motor oil) used in transportation. Together, transportation sources were responsible for 1,814.5 MMT CO₂ Eq. in 2014.

On-road vehicles were responsible for about 75 percent of all transportation and non-transportation mobile greenhouse gas emissions in 2014. Although passenger cars make up the largest component of on-road vehicle greenhouse gas emissions, medium- and heavy-duty trucks have been the primary sources of growth in on-road vehicle emissions. Between 1990 and 2014, greenhouse gas emissions from passenger cars increased by 16 percent, while emissions from light-duty trucks increased by one percent.⁵⁵ Meanwhile, greenhouse gas emissions from medium- and heavy-duty trucks increased 76 percent between 1990 and 2014, reflecting the increased volume of total freight movement and an increasing share transported by trucks.

⁵⁴ Recommended Best Practice for Quantifying Speciated Organic Gas Emissions from Aircraft Equipped with Turbofan, Turbojet and Turboprop Engines," EPA-420-R-09-901, May 27, 2009 (see <<http://www.epa.gov/otaq/regs/nonroad/aviation/420r09901.pdf>>).

⁵⁵ In 2011 FHWA changed how they defined vehicle types for the purposes of reporting VMT for the years 2007-2010. The old approach to vehicle classification was based on body type and split passenger vehicles into "Passenger Cars" and "Other 2 Axle 4-Tire Vehicles". The new approach is a vehicle classification system based on wheelbase. Vehicles with a wheelbase less than or equal to 121 inches are counted as "Light-duty Vehicles—Short Wheelbase". Passenger vehicles with a wheelbase greater than 121 inches are counted as "Light-duty Vehicles - Long Wheelbase". This change in vehicle classification has moved some smaller trucks and sport utility vehicles from the light truck category to the passenger vehicle category in this Inventory. These changes are reflected in a large drop in light-truck emissions between 2006 and 2007.

Greenhouse gas emissions from aircraft decreased 20 percent between 1990 and 2014. Emissions from military aircraft decreased 56 percent between 1990 and 2014. Commercial aircraft emissions rose 27 percent between 1990 and 2007 then dropped 18 percent from 2007 to 2014, a change of approximately 5 percent between 1990 and 2014.

Non-transportation mobile sources, such as construction/mining equipment, agricultural equipment, and industrial/commercial equipment, emitted approximately 215.3 MMT CO₂ Eq. in 2014. Together, these sources emitted more greenhouse gases than ships and boats, and rail combined. Emissions from non-transportation mobile sources increased rapidly, growing approximately 67 percent between 1990 and 2014. Methane and N₂O emissions from these sources are included in the “Mobile Combustion” section and CO₂ emissions are included in the relevant economic sectors.

Contribution of Transportation and Mobile Sources to Greenhouse Gas Emissions, by Gas

Table A-116 presents estimates of greenhouse gas emissions from transportation and other mobile sources broken down by greenhouse gas. As this table shows, CO₂ accounts for the vast majority of transportation greenhouse gas emissions (approximately 97 percent in 2014). Emissions of CO₂ from transportation and mobile sources increased by 327.8 MMT CO₂ Eq. between 1990 and 2014. In contrast, the combined emissions of CH₄ and N₂O decreased by 28.5 MMT CO₂ Eq. over the same period, due largely to the introduction of control technologies designed to reduce criteria pollutant emissions.⁵⁶ Meanwhile, HFC emissions from mobile air-conditioners and refrigerated transport increased from virtually no emissions in 1990 to 47.2 MMT CO₂ Eq. in 2014 as these chemicals were phased in as substitutes for ozone depleting substances. It should be noted, however, that the ozone depleting substances that HFCs replaced are also powerful greenhouse gases, but are not included in national greenhouse gas inventories per UNFCCC reporting requirements.

Greenhouse Gas Emissions from Freight and Passenger Transportation

Table A-117 and

Table A-118 present greenhouse gas estimates from transportation, broken down into the passenger and freight categories. Passenger modes include light-duty vehicles, buses, passenger rail, aircraft (general aviation and commercial aircraft), recreational boats, and mobile airconditioners, and are illustrated in Table A-117. Freight modes include medium- and heavy-duty trucks, freight rail, refrigerated transport, waterborne freight vessels, pipelines, and commercial aircraft and are illustrated in

Table A-118. Commercial aircraft do carry some freight, in addition to passengers, and emissions have been split between passenger and freight transportation. The amount of commercial aircraft emissions to allocate to the passenger and freight categories was calculated using BTS data on freight shipped by commercial aircraft, and the total number of passengers enplaned. Each passenger was considered to weigh an average of 150 pounds, with a luggage weight of 50 pounds. The total freight weight and total passenger weight carried were used to determine percent shares which were used to split the total commercial aircraft emission estimates. The remaining transportation and mobile emissions were from sources not considered to be either freight or passenger modes (e.g., construction/mining and agricultural equipment, lubricants).

The estimates in these tables are derived from the estimates presented in Table A-115. In addition, estimates of fuel consumption from DOE (1993 through 2015) were used to allocate rail emissions between passenger and freight categories.

In 2014, passenger transportation modes emitted 1,261.5 MMT CO₂ Eq., while freight transportation modes emitted 518.3 MMT CO₂ Eq. Between 1990 and 2014, the percentage growth of greenhouse gas emissions from freight sources was 47 percent, while emissions from passenger sources grew by 9 percent. This difference in growth is due largely to the rapid increase in emissions associated with medium- and heavy-duty trucks.

⁵⁶ The decline in CFC emissions is not captured in the official transportation estimates.

Table A-115: Total U.S. Greenhouse Gas Emissions from Transportation and Mobile Sources (MMT CO₂ Eq.)

| Mode / Vehicle Type / Fuel Type | 1990 | 1995 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | Percent Change 1990-2014 |

+ Does not exceed 0.05 MMT CO₂ Eq.

NA - Not Applicable, as there were no HFC emissions allocated to the transport sector in 1990, and thus a growth rate cannot be calculated.

^a Not including emissions from international bunker fuels.

^b Gasoline and diesel highway vehicle fuel consumption estimates are based on data from FHWA Highway Statistics Table VM-1 and MF-27 (FHWA 1996 through 2015). These fuel consumption estimates are combined with estimates of fuel shares by vehicle type from DOE's TEDB Annex Tables A.1 through A.6 (DOE 1993 through 2015). TEDB data for 2014 has not been published yet, therefore 2013 data is as a proxy.

^c Updates to the distillate fuel oil heat content data from EIA for years 1993 through present resulted in changes to the time series for energy consumption and emissions compared to the previous Inventory.

^d In 2015, EIA changed its methods for estimating AFV fuel consumption. These methodological changes included how vehicle counts are estimated, moving from estimates based on modeling to one that is based on survey data. EIA now publishes data about fuel use and number of vehicles for only four types of AFV fleets: federal government, state government, transit agencies, and fuel providers. These changes were first incorporated in this year's inventory and apply to the 1990-2014 time period. This resulted in large reductions in AFV VMT, thus leading to a shift in VMT to conventional on-road vehicle classes.

^e Updated Commodity Flow Survey data was used to allocate refrigerated transport emissions to the trucking, rail and marine sectors in 2014.

^f Updates to the jet fuel heat content used in the mobile N₂O emissions estimates for years 1990 through present resulted in small changes to the time series emissions compared to the previous Inventory.

^g Fluctuations in emission estimates reflect data collection problems. Note that CH₄ and N₂O from U.S. Territories are included in this value, but not CO₂ emissions from U.S. Territories, which are estimated separately in the section on U.S. Territories.

^h Domestic residual fuel for ships and boats is estimated by taking the total amount of residual fuel and subtracting out an estimate of international bunker fuel use.

ⁱ Class II and Class III diesel consumption data for 2014 is not available yet, therefore 2013 data is used as a proxy.

^j Other emissions from electricity generation are a result of waste incineration (as the majority of municipal solid waste is combusted in "trash-to-steam" electricity generation plants), electrical transmission and distribution, and a portion of Other Process Uses of Carbonates (from pollution control equipment installed in electricity generation plants).

^k Includes only CO₂ from natural gas used to power natural gas pipelines; does not include emissions from electricity use or non-CO₂ gases.

^l Includes equipment, such as tractors and combines, as well as fuel consumption from trucks that are used off-road in agriculture.

^m Includes equipment, such as cranes, dumpers, and excavators, as well as fuel consumption from trucks that are used off-road in construction.

ⁿ "Other" includes snowmobiles and other recreational equipment, logging equipment, lawn and garden equipment, railroad equipment, airport equipment, commercial equipment, and industrial equipment, as well as fuel consumption from trucks that are used off-road for commercial/industrial purposes.

Notes: Increases to CH₄ and N₂O emissions from mobile combustion relative to previous Inventories are largely due to updates made to the Motor Vehicle Emissions Simulator (MOVES2014a) model that is used to estimate on-road gasoline vehicle distribution and mileage across the time series. See Section 3.1 "CH₄ and N₂O from Mobile Combustion" for more detail. In 2015, EPA incorporated the NONROAD2008 model into MOVES2014a. This year's inventory uses the NONROAD component of MOVES2014a for years 1999 through 2014. This update resulted in small changes (<2%) to the 1999-2013 time series for NONROAD fuel consumption due to differences in the gasoline and diesel default fuel densities used within the model iterations.

Table A-116: Transportation and Mobile Source Emissions by Gas (MMT CO₂ Eq.)

| | 1990 | 1995 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | Percent Change 1990-2014 |

- Unreported or zero

NA - Not applicable, as there were no HFC emissions allocated to the transport sector in 1990, and thus a growth rate cannot be calculated.

^aTotal excludes other emissions from electricity generation and CH₄ and N₂O emissions from electric rail.

Note: The current Inventory includes updated vehicle population data based on the MOVES 2014a Model.

Gasoline and diesel highway vehicle mileage are based on data from FHWA Highway Statistics Table VM-1 (FHWA 1996 through 2015). These mileage consumption estimates are combined with estimates of fuel shares by vehicle type from DOE's TEDB Annex Tables A.1 through A.6 (DOE 1993 through 2015). TEDB data for 2014 has not been published yet, therefore 2013 data is used as a proxy.

^aThe current Inventory includes updated vehicle population data based on the MOVES 2014a Model.

Notes: Data from DOE (1993 through 2015) were used to disaggregate emissions from rail and buses. Emissions from HFCs have been included in these estimates. Updates to the distillate fuel oil heat content data from EIA for years 1993 through present resulted in changes to the time series for energy consumption and emissions compared to the previous Inventory. In 2015, EPA incorporated the NONROAD2008 model into MOVES2014a. This year's inventory uses the NONROAD component of MOVES2014a for years 1999 through 2014. This update resulted in small changes (<2%) to the 1999-2013 time series for NONROAD fuel consumption due to differences in the gasoline and diesel default fuel densities used within the model iterations. In 2015, EIA changed its methods for estimating AFV fuel consumption. These methodological changes included how vehicle counts are estimated, moving from estimates based on modeling to one that is based on survey data. EIA now publishes data about fuel use and number of vehicles for only four types of AFV fleets: federal government, state government, transit agencies, and fuel providers. These changes were first incorporated in this year's inventory and apply to the 1990-2014 time period. This resulted in large reductions in AFV VMT, thus leading to a shift in VMT to conventional on-road vehicle classes

3.3. Methodology for Estimating Emissions from Commercial Aircraft Jet Fuel Consumption

IPCC Tier 3B Method: Commercial aircraft jet fuel burn and carbon dioxide (CO₂) emissions estimates were developed by the U.S. Federal Aviation Administration (FAA) using radar-informed data from the FAA Enhanced Traffic Management System (ETMS) for 2000 through 2014 as modeled with the Aviation Environmental Design Tool (AEDT). This bottom-up approach is built from modeling dynamic aircraft performance for each flight occurring within an individual calendar year. The analysis incorporates data on the aircraft type, date, flight identifier, departure time, arrival time, departure airport, arrival airport, ground delay at each airport, and real-world flight trajectories. To generate results for a given flight within AEDT, the radar-informed aircraft data is correlated with engine and aircraft performance data to calculate fuel burn and exhaust emissions. Information on exhaust emissions for in-production aircraft engines comes from the International Civil Aviation Organization (ICAO) Aircraft Engine Emissions Databank (EDB). This bottom-up approach is in accordance with the Tier 3B method from the *2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2006).

International Bunkers: The IPCC guidelines define international aviation (International Bunkers) as emissions from flights that depart from one country and arrive in a different country. Bunker fuel emissions estimates for commercial aircraft were developed for this report for 2000 through 2014 using the same radar-informed data modeled with AEDT. Since this process builds estimates from flight-specific information, the emissions estimates for commercial aircraft can include emissions associated with the U.S. Territories (i.e., American Samoa, Guam, Puerto Rico, U.S. Virgin Islands, Wake Island, and other U.S. Pacific Islands). However, to allow for the alignment of emissions estimates for commercial aircraft with other data that is provided without the U.S. Territories, this annex includes emissions estimates for commercial aircraft both with and without the U.S. Territories included.

Time Series and Analysis Update: The FAA incrementally improves the consistency, robustness, and fidelity of the CO₂ emissions modeling for commercial aircraft, which is the basis of the Tier 3B inventories presented in this report. While the FAA does not anticipate significant changes to the AEDT model in the future, recommended improvements are limited by budget and time constraints, as well as data availability. For instance, previous reports included reported annual CO₂ emission estimates for 2000 through 2005 that were modeled using the FAA's System for assessing Aviation's Global Emissions (SAGE). That tool and its capabilities were significantly improved after it was incorporated and evolved into AEDT. For this report, the AEDT model was used to generate annual CO₂ emission estimates for 2000, 2005, 2010, 2011, 2012, 2013 and 2014 only. The reported annual CO₂ emissions values for 2001 through 2004 were estimated from the previously reported SAGE data. Likewise, CO₂ emissions values for 2006 through 2009 were estimated by interpolation to preserve trends from past reports.

Commercial aircraft radar data sets are not available for years prior to 2000. Instead, the FAA applied a Tier3B methodology by developing Official Airline Guide (OAG) schedule-informed estimates modeled with AEDT and great circle trajectories for 1990, 2000 and 2010. The ratios between the OAG schedule-informed and the radar-informed inventories for the years 2000 and 2010 were applied to the 1990 OAG scheduled-informed inventory to generate the best possible CO₂ inventory estimate for commercial aircraft in 1990. The resultant 1990 CO₂ inventory served as the reference for generating the additional 1991-1999 emissions estimates, which were established using previously available trends.

Notes on the 1990 CO₂ Emissions Inventory for Commercial Aircraft: There are uncertainties associated with the modeled 1990 data that do not exist for the modeled 2000 to 2014 data. Radar-based data is not available for 1990. The OAG schedule information generally includes fewer carriers than radar information, and this will result in a different fleet mix, and in turn, different CO₂ emissions than would be quantified using a radar-based data set. For this reason, the FAA adjusted the OAG-informed schedule for 1990 with a ratio based on radar-informed information. In addition, radar trajectories are also generally longer than great circle trajectories. While the 1990 fuel burn data was adjusted to address these differences, it inherently adds greater uncertainty to the revised 1990 commercial aircraft CO₂ emissions as compared to data from 2000 forward. Also, the revised 1990 CO₂ emissions inventory now reflects only commercial aircraft jet fuel consumption, while previous reports may have aggregated jet fuel sales data from non-commercial aircraft into this category. Thus, it would be inappropriate to compare 1990 to future years for other than qualitative purposes.

The 1990 commercial aircraft CO₂ emissions estimate is approximately 5 percent lower than the 2014 CO₂ emissions estimate. It is important to note that the distance flown increased by more than 40 percent over this 25-year period

and that fuel burn and aviation activity trends over the past two decades indicate significant improvements in commercial aviation's ability to provide increased service levels while using less fuel.⁵⁷

Methane Emissions: Contributions of methane (CH₄) emissions from commercial aircraft are reported as zero. Years of scientific measurement campaigns conducted at the exhaust exit plane of commercial aircraft gas turbine engines have repeatedly indicated that CH₄ emissions are consumed over the full mission flight envelope (Santoni et al. 2011). As a result, the U.S. EPA published that "...methane is no longer considered to be an emission from aircraft gas turbine engines burning Jet A at higher power settings and is, in fact, consumed in net at these higher powers."⁵⁸ In accordance with the following statements in the 2006 IPCC Guidelines (IPCC 2006), the FAA does not calculate CH₄ emissions for either the domestic or international bunker commercial aircraft jet fuel emissions inventories. "*Methane (CH₄) may be emitted by gas turbines during idle and by older technology engines, but recent data suggest that little or no CH₄ is emitted by modern engines.*" "*Current scientific understanding does not allow other gases (e.g., N₂O and CH₄) to be included in calculation of cruise emissions.*" (IPCC 1999).

Results: For each inventory calendar year the graph and table below include four jet fuel burn values. These values are comprised of domestic and international fuel burn totals for the U.S. 50 States and the U.S. 50 States + Territories. Data are presented for domestic defined as jet fuel burn from any commercial aircraft flight departing and landing in the U.S. 50 States and for the U.S. 50 States + Territories. The data presented as international is respective of the two different domestic definitions, and represents flights departing from the specified domestic area and landing anywhere in the world outside of that area.

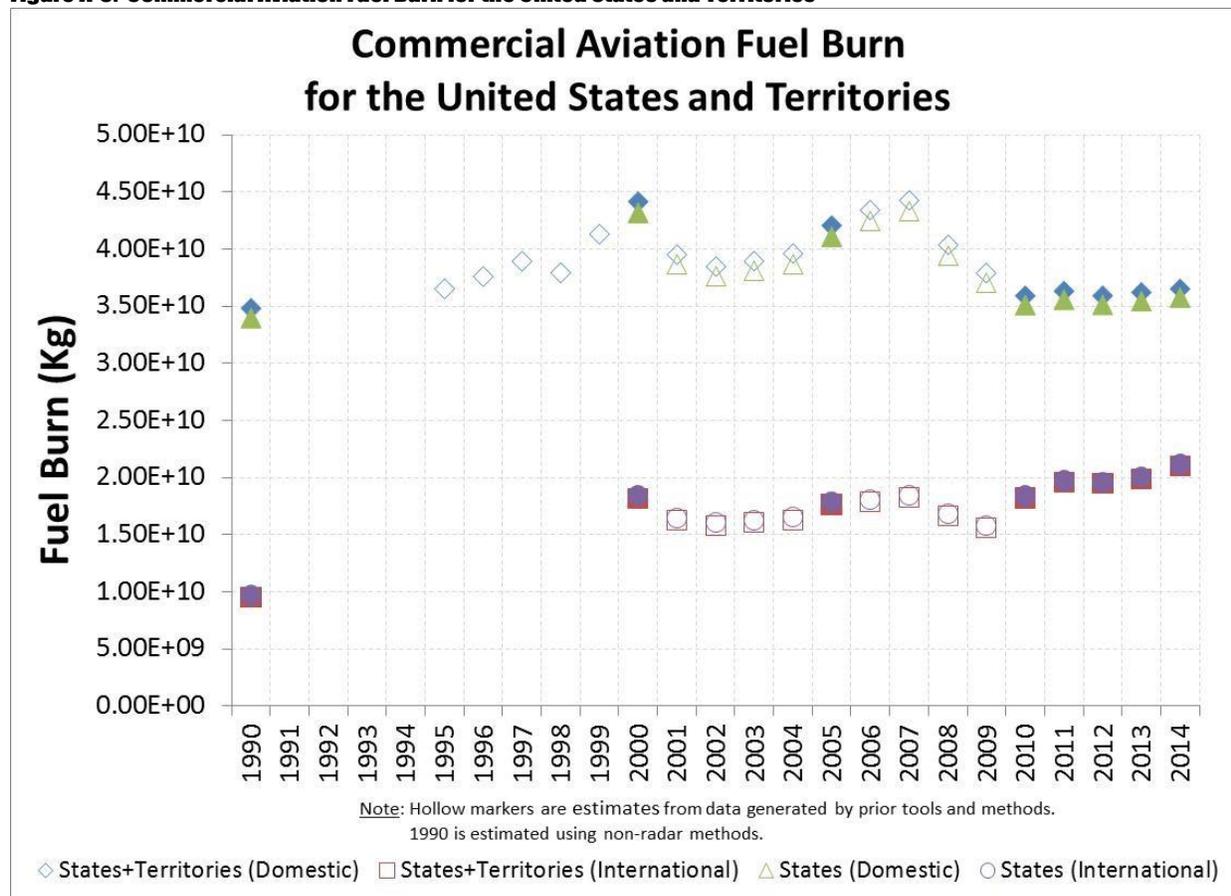

Note that the graph and table present less fuel burn for the international U.S. 50 States + Territories than for the international U.S. 50 States. This is because the flights between the 50 states and U.S. Territories are "international" when only the 50 states are defined as domestic, but they are "domestic" for the U.S. 50 States + Territories definition.

3.4. Methodology for Estimating CH₄ Emissions from Coal Mining

The methodology for estimating CH₄ emissions from coal mining consists of two steps:

- **Estimate emissions from underground mines.** These emissions have two sources: ventilation systems and degasification systems. They are estimated on a mine-by-mine basis, then summed to determine total CH₄ liberated. The CH₄ recovered and used is then subtracted from this total, resulting in an estimate of net emissions to the atmosphere.
- **Estimate CH₄ emissions from surface mines and post-mining activities.** This step does not use mine-specific data; rather, it consists of multiplying coal-basin-specific coal production by coal-basin-specific gas content and an emission factor.

Step 1: Estimate CH₄ Liberated and CH₄ Emitted from Underground Mines

Underground mines generate CH₄ from ventilation systems and from degasification systems. Some mines recover and use the generated CH₄, thereby reducing emissions to the atmosphere. Total CH₄ emitted from underground mines equals the CH₄ liberated from ventilation systems, plus the CH₄ liberated from degasification systems, minus CH₄ recovered and used.

Step 1.1: Estimate CH₄ Liberated from Ventilation Systems

All coal mines with detectable CH₄ emissions use ventilation systems to ensure that CH₄ levels remain within safe concentrations. Many coal mines do not have detectable levels of CH₄; others emit several million cubic feet per day (MMCFD) from their ventilation systems. On a quarterly basis, the U.S. Mine Safety and Health Administration (MSHA) measures CH₄ emissions levels at underground mines. MSHA maintains a database of measurement data from all underground mines with detectable levels of CH₄ in their ventilation air (MSHA 2015).⁵⁹ Based on the four quarterly measurements, MSHA estimates average daily CH₄ liberated at each of these underground mines.

For 1990 through 1999, average daily CH₄ emissions from MSHA were multiplied by the number of days in the year (i.e., coal mine assumed in operation for all four quarters) to determine the annual emissions for each mine. For 2000 through 2014, the average daily CH₄ emissions were multiplied by the number of days corresponding to the number of quarters the mine vent was operating. For example, if the mine vent was operational in one out of the four quarters, the average daily CH₄ emissions were multiplied by 92 days. Total ventilation emissions for a particular year were estimated by summing emissions from individual mines.

Since 2011, the nation's "gassiest" underground coal mines—those that liberate more than 36,500,000 actual cubic feet of CH₄ per year (about 14,700 MT CO₂ eq.)—have been required to report to the EPA's GHGRP (EPA 2015).⁶⁰ Mines that report to the GHGRP must report quarterly measurements of CH₄ emissions from ventilation systems to EPA; they have the option of recording their own measurements, or using the measurements taken by MSHA as part of that agency's quarterly safety inspections of all mines in the U.S. with detectable CH₄ concentrations.⁶¹

Since 2013, ventilation emission estimates have been calculated based on both GHGRP data submitted by underground mines that recorded their own measurements, and on quarterly measurement data obtained directly from MSHA for the remaining mines (not MSHA data reported by the mines to the GHGRP).⁶² The quarterly measurements are used to determine the average daily emissions rate for the reporting year quarter. The CH₄ liberated from ventilation systems was estimated by summing the emissions from the GHGRP self-reported mines and emissions based on MSHA quarterly measurements for the remaining mines.

⁵⁹ MSHA records coal mine methane readings with concentrations of greater than 50 ppm (parts per million) methane. Readings below this threshold are considered non-detectable.

⁶⁰ Underground coal mines report to EPA under Subpart FF of the GHGRP. In 2014, 128 underground coal mines reported to the program.

⁶¹ MSHA records coal mine CH₄ readings with concentrations of greater than 50 ppm (parts per million) CH₄. Readings below this threshold are considered non-detectable.

⁶² EPA has determined that certain mines are having difficulty interpreting the MSHA data so that they report them correctly to the GHGRP. EPA is working with these mines to correct their GHGRP reports, and in the meantime is relying on data obtained directly from MSHA for purposes of the national inventory.

Table A-120: Mine-Specific Data Used to Estimate Ventilation Emissions

| Year | Individual Mine Data Used |
|------|--|
| 1990 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 1991 | 1990 Emissions Factors Used Instead of Mine-Specific Data |
| 1992 | 1990 Emissions Factors Used Instead of Mine-Specific Data |
| 1993 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 1994 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 1995 | All Mines Emitting at Least 0.5 MMCFD (Assumed to Account for 94.1% of Total)* |
| 1996 | All Mines Emitting at Least 0.5 MMCFD (Assumed to Account for 94.1% of Total)* |
| 1997 | All Mines with Detectable Emissions (Assumed to Account for 100% of Total) |
| 1998 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 1999 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 2000 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 2001 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 2002 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 2003 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 2004 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 2005 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 2006 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 97.8% of Total)* |
| 2007 | All Mines with Detectable Emissions (Assumed to Account for 100% of Total) |
| 2008 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 98.96% of Total)** |
| 2009 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 98.96% of Total)** |
| 2010 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 98.96% of Total)** |
| 2011 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 98.96% of Total)** |
| 2012 | All Mines Emitting at Least 0.1 MMCFD (Assumed to Account for 98.96% of Total)** |
| 2013 | All Mines with Detectable Emissions and GHGRP reported data (Assumed to account for 100% of Total) |
| 2014 | All Mines with Detectable Emissions and GHGRP reported data (Assumed to account for 100% of Total) |

* Factor derived from a complete set of individual mine data collected for 1997.

** Factor derived from a complete set of individual mine data collected for 2007.

Step 1.2: Estimate CH₄ Liberated from Degasification Systems

Coal mines use several types of degasification systems to remove CH₄, including pre-mining vertical and horizontal wells (to recover CH₄ before mining) and post-mining vertical wells and horizontal boreholes (to recover CH₄ during mining of the coal seam). Post-mining gob wells and cross-measure boreholes recover CH₄ from the overburden (i.e., gob area) after mining of the seam (primarily in longwall mines).

Twenty-five mines employed degasification systems in 2014, and the CH₄ liberated through these systems was reported to the EPA's GHGRP (EPA 2015). Sixteen of these mines reported CH₄ recovery and use projects, and the other nine reported emitting CH₄ from degasification systems to the atmosphere. Several of the mines venting CH₄ from degasification systems use a small portion of the gas to fuel gob well blowers or compressors in remote locations where electricity is not available. However, this CH₄ use is not considered to be a formal recovery and use project.

Degasification information reported to the GHGRP by underground coal mines is the primary source of data used to develop estimates of CH₄ liberated from degasification systems. Data reported to the GHGRP were used to estimate CH₄ liberated from degasification systems at 20 of the 25 mines that used degasification systems in 2014.

Degasification volumes for the life of any pre-mining wells are attributed to the mine as emissions in the year in which the well is mined through.⁶³ The GHGRP does not require gas production from virgin coal seams (coalbed methane) to be reported by coal mines under subpart FF. Most pre-mining wells drilled from the surface are considered coalbed methane wells and are reported under another subpart of the program (subpart W, "Petroleum and Natural Gas Systems"). As a result, for the 10 mines with degasification systems that include pre-mining wells, GHGRP information was supplemented with historical data from state gas well production databases (GSA 2016; WVGES 2015), as well as with mine-specific information regarding the dates on which pre-mining wells are mined through (JWR 2010; El Paso 2009). For pre-mining wells, the cumulative CH₄ production from the well is totaled using gas sales data, and considered liberated from the mine's degasification system the year in which the well is mined through.

⁶³ A well is "mined through" when coal mining development or the working face intersects the borehole or well.

EPA's GHGRP reports with CH₄ liberated from degasification systems are reviewed for errors in reporting. For some mines, GHGRP data are corrected for the inventory based on expert judgment. Common errors include reporting CH₄ liberated as CH₄ destroyed and vice versa. Other errors include reporting CH₄ destroyed without reporting any CH₄ liberated by degasification systems. In the rare cases where GHGRP data are inaccurate and gas sales data unavailable, estimates of CH₄ liberated are based on historical CH₄ liberation rates.

Step 1.3: Estimate CH₄ Recovered from Ventilation and Degasification Systems, and Utilized or Destroyed (Emissions Avoided)

Of the 16 active coal mines with operational CH₄ recovery and use projects in 2014, 14 sold the recovered CH₄ to a pipeline, including one that also used CH₄ to fuel a thermal coal dryer. Uses at other mines include electrical power generation (one mine) and heating mine ventilation air (one mine).

Ten of the 16 mines deployed degasification systems in 2014; for those mines, estimates of CH₄ recovered from the systems were exclusively based on GHGRP data. Based on weekly measurements of gas flow and CH₄ concentrations, the GHGRP summary data for degasification destruction at each mine were added together to estimate the CH₄ recovered and used from degasification systems.

Of the 10 mines with degasification systems in 2014, four intersected pre-mining wells in 2014. GHGRP and supplemental data were used to estimate CH₄ recovered and used at two of these mines, while supplemental data alone were used at the other two mines, that reported as a single entity to the GHGRP. Supplemental information was used for these four mines because estimating CH₄ recovery and use from pre-mining wells requires additional data (not reported under subpart FF of the GHGRP; see discussion in step 1.2 above) to account for the emissions avoided. The supplemental data came from state gas production databases (GSA 2016; WVGES 2015), as well as mine-specific information on the timing of mined-through pre-mining wells (JWR 2010; El Paso 2009). For pre-mining wells, the cumulative CH₄ production from the wells was totaled using gas sales data, and considered to be CH₄ recovered and used from the mine's degasification system the year in which the well is mined through.

EPA's GHGRP reports with CH₄ recovered and used from degasification systems are reviewed for errors in reporting. For some mines, GHGRP data are corrected for the inventory based on expert judgment (see further discussion in Step 1.2). In 2014, GHGRP information was not used to estimate CH₄ recovered and used at two mines because of a lack of mine-provided information used in prior years and GHGRP reporting discrepancies.

In 2014, one mine destroyed a portion of its CH₄ emissions from ventilation systems using thermal oxidation technology. The amount of CH₄ recovered and destroyed by the project was determined through publicly available emission reduction project information (CAR 2015).

Step 2: Estimate CH₄ Emitted from Surface Mines and Post-Mining Activities

Mine-specific data were not available for estimating CH₄ emissions from surface coal mines or for post-mining activities. For surface mines, basin-specific coal production obtained from the Energy Information Administration's *Annual Coal Report* was multiplied by basin-specific gas contents and a 150 percent emission factor (to account for CH₄ from over- and under-burden) to estimate CH₄ emissions (see King 1994; Saghafi 2013). For post-mining activities, basin-specific coal production was multiplied by basin-specific gas contents and a mid-range 32.5 percent emission factor accounting for CH₄ desorption during coal transportation and storage (Creedy 1993). Basin-specific *in situ* gas content data were compiled from AAPG (1984) and USBM (1986). Beginning in 2006, revised data on *in situ* CH₄ content and emissions factors have been used (EPA 1996, 2005).

Step 2.1: Define the Geographic Resolution of the Analysis and Collect Coal Production Data

The first step in estimating CH₄ emissions from surface mining and post-mining activities was to define the geographic resolution of the analysis and to collect coal production data at that level of resolution. The analysis was conducted by coal basin as defined in Table A-121, which presents coal basin definitions by basin and by state.

The Energy Information Administration's *Annual Coal Report* (EIA 2015) includes state- and county-specific underground and surface coal production by year. To calculate production by basin, the state level data were grouped into coal basins using the basin definitions listed in Table A-121. For two states—West Virginia and Kentucky—county-level production data were used for the basin assignments because coal production occurred in geologically distinct coal basins within these states. Table A-122 presents the coal production data aggregated by basin.

Step 2.2: Estimate Emissions Factors for Each Emissions Type

Emission factors for surface-mined coal were developed from the *in situ* CH₄ content of the surface coal in each basin. Based on analyses conducted in Canada and Australia on coals similar to those present in the U.S. (King 1994; Saghafi 2013), the surface mining emission factor used was conservatively estimated to be 150 percent of the *in situ* CH₄ content of the basin. Furthermore, the post-mining emission factors used were estimated to be 25 to 40 percent of the average *in situ* CH₄ content in the basin. For this analysis, the post-mining emission factor was determined to be 32.5 percent of the *in situ* CH₄ content in the basin. Table A-123 presents the average *in situ* content for each basin, along with the resulting emission factor estimates.

Step 2.3: Estimate CH₄ Emitted

The total amount of CH₄ emitted from surface mines and post-mining activities was calculated by multiplying the coal production in each basin by the appropriate emission factors.

Table A-121 lists each of the major coal mine basins in the United States and the states in which they are located. As shown in Figure A-6, several coal basins span several states. Table A-122 shows annual underground, surface, and total coal production (in short tons) for each coal basin. Table A-123 shows the surface, post-surface, and post-underground emission factors used for estimating CH₄ emissions for each of the categories. Table A-124 presents annual estimates of CH₄ emissions for ventilation and degasification systems, and CH₄ used and emitted by underground coal mines. Table A-125 presents annual estimates of total CH₄ emissions from underground, post-underground, surface, and post-surface activities. Table A-126 provides the total net CH₄ emissions by state.

Table A-121: Coal Basin Definitions by Basin and by State

| Basin | States |
|------------------------------|--|
| Northern Appalachian Basin | Maryland, Ohio, Pennsylvania, West Virginia North |
| Central Appalachian Basin | Kentucky East, Tennessee, Virginia, West Virginia South |
| Warrior Basin | Alabama, Mississippi |
| Illinois Basin | Illinois, Indiana, Kentucky West |

3.5. Methodology for Estimating CH₄ and CO₂ Emissions from Petroleum Systems

The methodology for estimating CH₄ and non-combustion CO₂ emissions from the production, refineries and transportation segments of petroleum systems is generally based on EPA's Greenhouse Gas Reporting Program (GHGRP) data for 2014; the 1999 EPA report, Estimates of Methane Emissions from the U.S. Oil Industry (EPA 1999); and the study, Methane Emissions from the U.S. Petroleum Industry (EPA/GRI 1996). Fifty-seven activities that emit CH₄ and thirty-two activities that emit non-combustion CO₂ from petroleum systems were examined from these reports and the GHGRP data. Most of the activities are part of crude oil production field operations, which accounted for approximately 99 percent of total oil industry CH₄ emissions. Crude transportation and refining accounted for the remaining CH₄ emissions of approximately 0.3 and 0.9 percent, respectively. Non-combustion CO₂ emissions were analyzed for production operations and asphalt blowing, flaring, and process vents in refining operations. Non-combustion CO₂ emissions from transportation operations are not included because they are negligible. The following steps were taken to estimate CH₄ and CO₂ emissions from petroleum systems.

Step 1: Calculate Potential Methane (or Net Emissions)

Activity Data

Activity data were taken from the following source: DrillingInfo (2015), the Energy Information Administration annual and monthly reports (EIA 1990 through 2015), (EIA 1995 through 2015a, 2015b), "Methane Emissions from the Natural Gas Industry by the Gas Research Institute and EPA" (EPA/GRI 1996a-d), "Estimates of Methane Emissions from the U.S. Oil Industry" (EPA 1999), consensus of industry peer review panels, BOEMRE and BOEM reports (BOEMRE 2004, BOEM 2011), analysis of BOEMRE data (EPA 2005, BOEMRE 2004), the Oil & Gas Journal (OGJ 2015), the Interstate Oil and Gas Compact Commission (IOGCC 2012), the United States Army Corps of Engineers, (1995-2015), and the GHGRP (2010-2014).

For many sources, complete activity data were not available for all years of the time series. In such cases, one of three approaches was employed. Where appropriate, the activity data were calculated from related statistics using ratios developed based on EPA 1996, and/or GHGRP data. For major equipment, pneumatic controllers, and chemical injection pumps, GHGRP subpart W data were used to develop activity factors (i.e., count per well) that are applied to calculated activity in recent years; to populate earlier years of the time series, linear interpolation is used to connect GHGRP-based estimates with existing estimates in years 1990 to 1995. For hydraulically fractured oil well completions, EPA developed activity data specific to each year of the time series using the date of completion or first reported production available from a data set licensed by DrillingInfo, Inc. For more information on the DrillingInfo data processing, please see Annex 3.6 Methodology for Estimating CH₄ and CO₂ from Natural Gas Systems. In other cases, the activity data were held constant from 1990 through 2014 based on EPA (1999). Lastly, the previous year's data were used when data for the current year were unavailable. For offshore production, the number of platforms in shallow water and the number of platforms in deep water are used as activity data and are taken from Bureau of Ocean Energy Management (BOEM) (formerly Bureau of Ocean Energy Management, Regulation, and Enforcement [BOEMRE]) datasets (BOEM 2011a,b,c).

For petroleum refining activities, 2010 to 2014 emissions were directly obtained from EPA's GHGRP. All refineries have been required to report CH₄ and CO₂ emissions for all major activities since 2010. The national totals of these emissions for each activity were used for the 2010 to 2014 emissions. The national emission totals for each activity were divided by refinery feed rates for those four Inventory years to develop average activity-specific emission factors, which were used to estimate national emissions for each refinery activity from 1990 to 2009 based on national refinery feed rates for each year (EPA 2015d).

The activity data for the total crude transported in the transportation sector is not available. In this case, all the crude oil that was transported was assumed to go to refineries. Therefore, the activity data for the refining sector (i.e., refinery feed in 1000 bbl/year) was used also for the transportation sector. In the few cases where no data were located, oil industry data based on expert judgment was used. In the case of non-combustion CO₂ emission sources, the activity factors are the same as for CH₄ emission sources. In some instances, where 2014 data are not yet available 2013 or prior data has been used as proxy.

Potential methane factors and emission factors

The CH₄ emission factors for the majority of the activities are taken from the 1999 EPA draft report, which contained the most recent and comprehensive determination of CH₄ emission factors for the 57 CH₄-emitting activities in the oil industry at that time. Since the time of this study, practices and technologies have changed. While this study still represents best available data in many cases, using these emission factors alone to represent actual emissions without adjusting for emissions controls would in many cases overestimate emissions. For this reason, "potential methane" is

calculated using the data, and then recent data on voluntary and regulatory emission reduction activities (Step 3) is deducted to calculate actual emissions.

For certain CH₄ emissions sources, new data and information allows for net emissions to be calculated directly: Oil well completions with hydraulic fracturing, pneumatic controllers, chemical injection pumps, and refineries. For these sources, EPA used emissions factors that directly reflect recent practice and the use of control technologies. The controlled and uncontrolled emission factors for hydraulically fractured (HF) well completions were developed using data analyzed for the 2015 NSPS OOOOa proposal. The gas engine emission factor is taken from the EPA/GRI 1996b study. For pneumatic controllers, separate estimates are developed for low bleed, high bleed, and intermittent controllers. Chemical injection pumps estimate are calculated with an emission factor developed with GHGRP data, which is based on the previous GRI/EPA factor but takes into account operating hours. The refineries emission factors were also developed from GHGRP data.

Other emission factors that are not based on the 1999 report include oil tank venting and offshore platforms. The oil tank venting emission factor is taken from the API E&P Tank Calc weighted average for API gravity less than 45 API degrees with the distribution of gravities taken from a sample of production data from the HPDI database. Offshore emissions from shallow water and deep water oil platforms are taken from analysis of the Gulf-wide Offshore Activity Data System (GOADS) report (EPA 2015; BOEM 2014). The emission factors were assumed to be representative of emissions from each source type over the period 1990 through 2014, and are used for each year throughout this period.

In general, the CO₂ emission factors were derived from the corresponding source CH₄ emission factors. The amount of CO₂ in the crude oil stream changes as it passes through various equipment in petroleum production operations. As a result, four distinct stages/streams with varying CO₂ contents exist. The four streams that are used to estimate the emissions factors are the associated gas stream separated from crude oil, hydrocarbons flashed out from crude oil (such as in storage tanks), whole crude oil itself when it leaks downstream, and gas emissions from offshore oil platforms. The standard approach used to estimate CO₂ emission factors was to use the existing CH₄ emissions factors and multiply them by a conversion factor, which is the ratio of CO₂ content to methane content for the particular stream. Ratios of CO₂ to CH₄ volume in emissions are presented in Table A-131. The exceptions are the emissions factor for storage tanks, which are estimated using API E&P Tank Calc simulation runs of tank emissions for crude oil of different gravities less than 45 API degrees; emission factors for shallow water and deep water platforms, which are estimated from analysis of the *2011 Gulf-Wide Emission Inventory Study* (BOEM 2014) and the emissions estimates for refineries, which are estimated using the data from U.S. EPA's GHGRP.

Step 2: Compile Reductions Data

The methane emissions calculated in Step 1 above generally represent expected emissions from an activity in the absence of emissions controls (with the exceptions of pneumatic controllers, completions with hydraulic fracturing, etc. as noted above), and do not take into account any use of technologies or practices that reduce emissions. To take into account use of such technologies, data were collected on voluntary reductions. Voluntary reductions included in the Petroleum Sector calculations were those reported to Natural Gas STAR for the following activities: Artificial lift: gas lift, Artificial lift: use compression, Artificial lift: use pumping unit, Consolidate crude oil prod and water storage tanks, Lower heater-treater temperature, Re-inject gas for enhanced oil recovery, Re-inject gas into crude, and Route casing head gas to VRU or compressor.

Industry partners report CH₄ emission reductions by project to the Natural Gas STAR Program. The reductions from the implementation of specific technologies and practices are calculated by the reporting partners using actual measurement data or equipment-specific emission factors. The reductions undergo quality assurance and quality control checks to identify errors, inconsistencies, or irregular data before being incorporated into the Inventory. The technology-specific approach for pneumatic controllers allows net emissions to be calculated directly. Pneumatic controller-related reductions were removed from the Gas STAR reduction data set before it was used to adjust the petroleum segment estimates.

Step 3: Calculate Net Methane and Carbon Dioxide Emissions for Each Activity for Each Year

Annual CH₄ emissions from each of the 57 petroleum system activities and CO₂ emissions from the 32 petroleum system activities were estimated by multiplying the activity data for each year by the corresponding emission factor, except for petroleum refineries segment. Emissions from refineries were obtained directly from the GHGRP data for 2010 through 2014; these four years of data were used to develop emission factors and activity data that are applied for the remainder of the time-series (i.e., 1990 through 2009). These annual emissions for each activity were then summed to estimate the total annual CH₄ and CO₂ emissions, respectively. As a final step, the relevant Natural Gas STAR reductions data is summed for each year and deducted from the total emissions to estimate net CH₄ emissions for the Inventory.

Table A-127, Table A-128, Table A-129, and Table A-132 provide 2014 activity data, emission factors, and emission estimates and Table A-130 and Table A-133 provide a summary of emission estimates for the years 1990, 1995, 2000, and 2005 through 2014. Table A-131 provides the CO₂ content in natural gas for equipment in different crude streams to estimate CO₂ emission factors using CH₄ emission factors.

The tables provide references for emission factors and activity data in footnotes (the lettered footnotes). The tables also provide information on which method was used for supplying activity data for 2014 (the numbered footnotes).

Key to table notations on methods for supplying activity data for 2014 for all tables:

1. Ratios relating other factors for which activity data are available.
2. Activity data for 2014 available from source.
3. Activity data were held constant from 1990 through 2014 based on EPA (1999).
4. 2009, 2010, 2011, 2012, or 2013 activity data are used to determine some or all of the 2014 activity data.

Table A-127: 2014 CH₄ Emissions from Petroleum Production Field Operations

| Activity/Equipment | 2014 EPA Inventory Values | | Emissions (Bcf/yr) | Emissions (kt/yr) |
|---|---|---|-----------------------|----------------------|
| | Emission Factor | Activity Data | | |
| Vented Emissions | | | 128.872 | 2,478.3 |
| Oil Tanks | 7.4 scf of CH ₄ /bbl crude ^a | 2,782 MMbbl/yr (non-stripper wells) ^{b,c,d,1} | 20.575 | 395.7 |
| Pneumatic controllers, High Bleed | 622 scfd CH ₄ /controller ^r | 43,211 No. of high-bleed controllers ^{r,2} | 9.806 | 188.6** |

3.6. Methodology for Estimating CH₄ and CO₂ Emissions from Natural Gas Systems

As described in the main body text on Natural Gas Systems, the Inventory methodology involves the calculation of CH₄ and CO₂ emissions for over 100 emissions sources, and then the summation of emissions for each natural gas sector stage.

Step 1: Calculate Potential Methane (or Net Emissions)

Potential methane factors and emission factors

The primary basis for potential CH₄ factors and emission factors for non-combustion-related CO₂ emissions from the U.S. natural gas industry is a detailed study by the Gas Research Institute and EPA (EPA/GRI 1996). The EPA/GRI study developed over 80 CH₄ emission factors to characterize emissions from the various components within the operating stages of the U.S. natural gas system. Since the time of this study, practices and technologies have changed. While this study still represents best available data in many cases, using these emission factors alone to represent actual emissions without adjusting for emissions controls would in many cases overestimate emissions. For this reason, “potential methane” is calculated using the data, and then recent data on voluntary and regulatory emission reduction activities (Step 3) is deducted to calculate actual emissions. See Section 3.7 of the main document on Natural Gas Systems for more information.

For certain CH₄ emissions sources, new data and information allows for net emissions to be calculated directly: gas well completions and workovers with hydraulic fracturing, liquids unloading, condensate storage tanks, centrifugal compressors, pneumatic controllers, chemical injection pumps, transmission and storage station fugitives and compressors, M&R stations, and distribution pipeline leaks. For these sources, EPA used emissions factors that directly reflect the use of control technologies. For gas well completions and workovers with hydraulic fracturing, separate emissions estimates were developed for hydraulically fractured completions and workovers that vent, flared hydraulic fracturing completions and workovers, hydraulic fracturing completions and workovers with reduced emissions completions (RECs), and hydraulic fracturing completions and workovers with RECs that flare. For liquids unloading, separate emissions estimates were developed for wells with plunger lifts and wells without plunger lifts. Likewise, for condensate tanks, emissions estimates were developed for tanks with and without control devices. For pneumatic controllers, separate estimates are developed for low bleed, high bleed, and intermittent controllers. Chemical injection pumps estimates are calculated with an emission factor developed with GHGRP data, which is based on the previous GRI/EPA factor but takes into account operating hours.

For potential CH₄ factors and emission factors used in the Inventory, see Table A-134 to Table A-138. Methane compositions from GTI 2001 are adjusted year to year using gross production for National Energy Modeling System (NEMS) oil and gas supply module regions from the EIA. These adjusted region-specific annual CH₄ compositions are presented in Table A-139 (for general sources), Table A-140 (for gas wells without hydraulic fracturing), and Table A-141 (for gas wells with hydraulic fracturing). Therefore, emission factors may vary from year to year due to slight changes in the CH₄ composition between each NEMS oil and gas supply module region.

1990-2014 Inventory updates to emission factors

Summary information for emission factors for sources with updates in this year’s inventory is below. The details are presented in four memoranda addressing production, gathering and boosting, transportation and storage, and distribution (See “Revisions to Natural Gas and Petroleum Production Emissions”, “Revisions to Natural Gas Gathering and Boosting Emissions”, “Revisions to Natural Gas Transmission and Storage Emissions”, and “Revisions to Natural Gas Distribution Emissions” [EPA 2016a through 2016d]).⁶⁴

For the production segment, bleed type-specific (i.e., continuous high bleed, continuous low bleed, and intermittent bleed) emission factors for pneumatic controllers are based on GHGRP data (used for the full time series). Emission factors for gathering and boosting stations based on Marchese et al. are used for the full time series.

For the transmission and storage segment, station-level emission factors for transmission and storage stations and factors for compressors are based on the Zimmerle et al. study and used for 2011 to 2014. Emission factors for transmission and storage pneumatic controllers are from GHGRP and are used for the full time series.

For the distribution segment, emission factors for M&R stations and for emissions per leak for pipeline leaks are from the Lamb et al. study (used for 2011 to 2014). Emission factors for residential customer meters and

⁶⁴ See <<https://www3.epa.gov/climatechange/ghgemissions/usinventoryreport/natural-gas-systems.html>>.

commercial/industrial customer meters are from the 2009 GTI study and 2011 Clearstone study and are used for the full time series.

In order to create time series consistency for emission factors between earlier years' estimates (1990 to 1992) that generally rely on data from GRI/EPA 1996 and the most recent years' estimates (2011 to 2014) that were calculated using data from studies or GHGRP, linear interpolation between the data endpoints of 1992 (GRI/EPA) and 2011 (GHGRP) was typically used for calculations. Exceptions to the use of linear interpolation include gathering and boosting stations and residential and commercial/industry customer meters.

Activity Data

Activity data were taken from the following sources: DrillingInfo, Inc. (DrillingInfo 2015); American Gas Association (AGA 1991–1998); Bureau of Ocean Energy Management, Regulation and Enforcement (previous Minerals and Management Service) (BOEMRE 2011a, 2011b, 2011c, 2011d); Monthly Energy Review (EIA 2012f, 2012g, 2012h, 2011a, 2011b, 2011c, 2011d); Natural Gas Liquids Reserves Report (EIA 2005); Natural Gas Monthly (EIA 2012c, 2012d, 2012e, 2013a, 2013b, 2013c); the Natural Gas STAR Program annual emissions savings (EPA 2012a, 2013c); Oil and Gas Journal (OGJ 1997–2015); Pipeline and Hazardous Materials Safety Administration (PHMSA 2015); Federal Energy Regulatory Commission (FERC 2014); GHGRP data for natural gas systems (40 CFR 98, subpart W); and other Energy Information Administration publications (EIA 2001, 2004, 2010, 2011, 2012i, 2015); (EPA 1999); Wyoming Oil and Gas Conservation Commission (Wyoming 2015); and the Alabama State Oil and Gas Board (Alabama 2015). Activity data are presented in Table A-134 through Table A-138.

For a few sources, recent direct activity data were not available. For these sources, either 2013 data were used as proxy for 2014 data or a set of industry activity data drivers was developed and was used to update activity data. Drivers include statistics on gas production, number of wells, system throughput, miles of various kinds of pipe, and other statistics that characterize the changes in the U.S. natural gas system infrastructure and operations. The key activity drivers are presented in Table A-142.

EPA used DI Desktop, a production database maintained by DrillingInfo, Inc. (DrillingInfo 2015), covering U.S. oil and natural gas wells to populate activity data for non-associated gas wells, oil wells (in petroleum systems), gas wells with hydraulic fracturing, and completions with hydraulic fracturing. EPA queried DI Desktop for relevant data on an individual well basis—including location, natural gas and liquids (i.e., oil and condensate) production by year, drill type (e.g., horizontal or vertical), and date of completion or first production. Non-associated gas wells were classified as any well within DI Desktop that had non-zero gas production in a given year, and with a gas-to-oil ratio (GOR) of greater than 100 mcf/bbl in that year. Oil wells were classified as any well that had non-zero liquids production in a given year, and with a GOR of less than or equal to 100 mcf/bbl in that year. Gas wells with hydraulic fracturing were assumed to be the subset of the non-associated gas wells that were horizontally drilled and/or located in an unconventional formation (i.e., shale, tight sands, or coalbed). Unconventional formations were identified based on well basin, reservoir, and field data reported in DI Desktop referenced against a formation type crosswalk developed by EIA (EIA 2012a).

For 1990 through 2010, gas well completions with hydraulic fracturing were identified as a subset of the gas wells with hydraulic fracturing that had a date of completion or first production in the specified year. To calculate workovers for 1990 through 2010, EPA applied a refracture rate of 1 percent (i.e., 1 percent of all wells with hydraulic fracturing are assumed to be refractured in a given year) to the total counts of wells with hydraulic fracturing from the DrillingInfo data. For 2011 through 2014, EPA used GHGRP data for the total number of well completions and workovers. The GHGRP data represents a subset of the national completions and workovers, due to the reporting threshold, and therefore using this data without scaling it up to national level results in an underestimate. However, because EPA's GHGRP counts of completions and workovers were higher than national counts of completions and workovers, obtained using DI Desktop data, EPA directly used the GHGRP data for completions and workovers for 2011 through 2014.

EPA calculated the percentage of gas well completions and workovers with hydraulic fracturing in the each of the four control categories using 2011 through 2014 Subpart W data. EPA assumed 0 percent RECs use from 1990 through 2000, used GHGRP RECs percentage for 2011 through 2014, and then used linear interpolation between the 2000 and 2011 percentages. For flaring, EPA used an assumption of 10 percent (the average of the percent of completions and workovers that were flared in 2011 through 2013 GHGRP data) flaring from 1990 through 2010 to recognize that some flaring has occurred over that time period. For 2011 through 2014, EPA used the GHGRP data on flaring.

Summary information for activity data for sources with updates in this year's inventory is below. The details are presented in four memoranda addressing production, gathering and boosting, transportation and storage, and distribution (see "Revisions to Natural Gas and Petroleum Production Emissions", "Revisions to Natural Gas Gathering and Boosting

Emissions”, “Revisions to Natural Gas Transmission and Storage Emissions”, and “Revisions to Natural Gas Distribution Emissions” [EPA 2016a through 2016d)].⁶⁵

For the production segment, GHGRP-based activity factors (i.e., counts per gas well) were used for the years 2011 to 2014 for in-line heaters, separators, dehydrators, compressors, meters/piping, pneumatic pumps, and pneumatic controllers. In addition, for years 2011 to 2014, bleed type-specific (i.e., continuous high bleed, continuous low bleed, and intermittent bleed) activity data for pneumatic controllers were developed from GHGRP.

For the transmission and storage segment, activity factors (transmission stations; storage stations per storage field) are based on Zimmerle et al. study and applied for 2011 to 2014, reciprocating and centrifugal compressor activity data and compressor seal types (i.e., wet versus dry seals) are based on GHGRP and Zimmerle et al. study data for 2011-2014, and activity factors (i.e., controllers per station) for transmission and storage pneumatic controllers based on GHGRP and Zimmerle et al. study for 2011 to 2014.

For the distribution segment, activity factors for M&R stations for 2011 to 2014 are based on GHGRP and Lamb et al. study. Activity data for meters are from EIA for the full time series. Activity data for pipeline blowdowns and mishaps/dig-ins are from PHMSA for the full time series.

For sources where new activity data was determined to be applicable for only recent years of the time series, in order to create time series consistency for activity data between earlier years’ estimates (1990 to 1992) that generally rely on data from GRI/EPA 1996 and the most recent years’ estimates (2011 to 2014) that were calculated using data from studies or GHGRP, linear interpolation between the data endpoints of 1992 (GRI/EPA) and 2011 (GHGRP) was typically used for calculations. Exceptions to the use of linear interpolation include gathering and boosting stations and residential and commercial/industry customer meters.

Step 2: Compile Reductions Data

The emissions calculated in Step 1 above represent expected emissions from an activity in the absence of emissions controls (with the exceptions of emission sources that use a “net” approach such as pneumatic controllers, gas well completions and workovers with hydraulic fracturing, liquids unloading, centrifugal compressors, condensate tanks, distribution M&R stations, distribution pipelines, etc. as noted above), and do not take into account any use of technologies or practices that reduce emissions. To take into account use of such technologies, data were collected on voluntary and regulatory reductions. Voluntary reductions included in the Inventory were those reported to Gas STAR for activities such as replacing a high bleed pneumatic controllers with a low bleed controller and replacing wet seals with dry seals at reciprocating compressors. Regulatory actions reducing emissions include National Emission Standards for Hazardous Air Pollutants (NESHAP) regulations for dehydrator vents and condensate tanks.

Voluntary reductions

Industry partners report CH₄ emission reductions by project to the Natural Gas STAR Program. The reductions from the implementation of specific technologies and practices (e.g., vapor recovery units,) are calculated by the reporting partners using actual measurement data or equipment-specific emission factors. Natural Gas STAR Partners do not report reductions when they are required due to regulation. The reductions undergo quality assurance and quality control checks to identify errors, inconsistencies, or irregular data before being incorporated into the Inventory. In general, the Inventory uses aggregated Gas STAR reductions by natural gas system stage (i.e., production, processing, transmission and storage, and distribution). However, aggregate emissions reductions data by Gas STAR technology are provided for several sources, as shown in Table A-143. For those sources, EPA has also used data on potential emissions, and the Gas STAR data on reductions, to calculate net emissions, as shown in Table A-149 (along with other sources calculated with net emission factors). Many of the activities reported to Gas STAR are cross-cutting and apply to more than one emissions source and therefore cannot be assigned to one emissions source, but instead are included in the “other” category. For Inventory sources with emission factors that already take into account the use of control technologies (i.e., “net” emission sources) Natural Gas STAR reported reductions for those activities are not incorporated into the Inventory, as this would double count reductions. CH₄ emission reductions from the Natural Gas STAR Program are summarized in Table A-143.

For sources where net factor approaches are used, the use of data from the GHGRP and recent studies to revise certain emission factors as discussed above obviated the need to apply Gas STAR reductions data for these sources (i.e., the calculated emissions were already net emissions, instead of potential emissions).

⁶⁵ See <<https://www3.epa.gov/climatechange/ghgemissions/usinventoryreport/natural-gas-systems.html>>.

There are significant Gas STAR reductions in the production segment that are not classified as applicable to specific emission sources (“other voluntary reductions” are 18 MMT CO₂ eq. of CH₄ in year 2014). As many sources in production are now calculated with net factor approaches, to address potential double-counting of reductions, a scaling factor was applied to the “other voluntary reductions” to reduce this reported amount based an estimate of the fraction of those reductions that occur in the sources that are now calculated using net emissions approaches. This fraction was developed by dividing the net emissions from sources with net approaches, by the total production segment emissions (without deducting the Gas STAR reductions). The result for 2014, is that around 50 percent of the reductions were estimated to occur in sources for which net emissions are now calculated, which yields an adjusted other reduction number of 9 MMT CO₂ Eq.

Federal regulations.

The 1990 Clean Air Act (CAA) sets limits on the amount of hazardous air pollutants (HAPs) that can be emitted in the United States. The NESHAP regulations set the standards to limit emissions of HAPs. The emission sources are required to use the Maximum Achievable Control Technology (MACT), giving the operators flexibility to choose the type of control measure(s) to implement. In regards to the oil and natural gas industry, the NESHAP regulation addresses HAPs from the oil and natural gas production sectors and the natural gas transmission and storage sectors of the industry. Though the regulation deals specifically with HAPs reductions, methane emissions are also incidentally reduced.

The NESHAP regulation requires that glycol dehydration unit vents and storage tanks that have HAP emissions and exceed a gas throughput and liquids throughput threshold, respectively, be connected to a closed loop emission control system that reduces emissions by 95 percent. Also, gas processing plants exceeding the threshold natural gas throughput limit are required to routinely implement Leak Detection and Repair (LDAR) programs. The emissions reductions achieved as a result of NESHAP regulations were calculated using data provided in the Federal Register Background Information Document (BID) for this regulation. The BID provides the levels of control measures in place before the enactment of regulation. The emissions reductions were estimated by analyzing the portion of the industry without control measures already in place that would be impacted by the regulation. CH₄ emission reductions from federal regulations, such as NESHAP, are summarized in Table A-144. In addition to the NESHAP applicable to natural gas, the Inventory reflects the 2012 New Source Performance Standards (NSPS) subpart OOOO for oil and gas, through the use of a net factor approach that captures shifts to lower emitting technologies. By separating gas well completions and workovers with hydraulic fracturing into four categories and developing control technology-specific methane emission factors for each category, EPA is implicitly accounting for subpart OOOO reductions from hydraulically fractured gas wells. This is also the case for high bleed pneumatic controllers in the production segment.

Step 3: Calculate Net Methane and Carbon Dioxide Emissions for Each Activity for Each Year

Annual CH₄ emissions and CO₂ emissions for each source were estimated by multiplying the activity data for each year by the corresponding emission factor. These annual emissions for each activity were then summed to estimate the total annual CH₄ and CO₂ emissions, respectively. As a final step, the relevant Natural Gas STAR reductions data from each segment is summed for each year and deducted from the total emissions to estimate net CH₄ emissions for the Inventory.

The same procedure for estimating CH₄ emissions holds true for estimating non-energy related CO₂ emissions, except the emission estimates are not adjusted for reductions due to the Natural Gas STAR program or regulations.

Produced natural gas is composed of primarily CH₄, but as shown in Table A-150, the natural gas contains, in some cases, as much as 8 percent CO₂. The same vented and fugitive natural gas that led to CH₄ emissions also contains a certain volume of CO₂. Accordingly, the CO₂ emissions for each sector can be estimated using the same activity data for these vented and fugitive sources. The emission factors used to estimate CH₄ were also used to calculate non-combustion CO₂ emissions. The Gas Technology Institute’s (GTI, formerly GRI) Unconventional Natural Gas and Gas Composition Databases (GTI 2001) were used to adapt the CH₄ emission factors into non-combustion related CO₂ emission factors. Additional information about CO₂ content in transmission quality natural gas was obtained from numerous U.S. transmission companies to help further develop the non-combustion CO₂ emission factors. For the CO₂ content used to develop CO₂ emission factors from CH₄ potential factors, see Table A-150. The detailed source emission estimates for CH₄ and CO₂ from the production sector are presented in Table A-145 and Table A-154, respectively.

In the processing sector, the CO₂ content of the natural gas remains the same as the CO₂ content in the production sector for the equipment upstream of the acid gas removal unit because produced natural gas is usually only minimally treated after being produced and then transported to natural gas processing plants via gathering pipelines. The CO₂ content in gas for the remaining equipment that is downstream of the acid gas removal is the same as in pipeline quality gas. The EPA/GRI study estimates the average CH₄ content of natural gas in the processing sector to be 87 percent CH₄. Consequently, the processing sector CO₂ emission factors were developed using CH₄ emission factors, proportioned to

reflect the CO₂ content of either produced natural gas or pipeline quality gas using the same methodology as the production sector. The detailed source emission estimates for CH₄ and CO₂ from the processing sector are presented in Table A-146 and Table A-152, respectively.

For the transmission sector, CO₂ content in natural gas transmission pipelines was estimated for the top 20 transmission pipeline companies in the United States (separate analyses identified the top 20 companies based on gas throughput and total pipeline miles). The weighted average CO₂ content in the transmission pipeline quality gas in both cases—total gas throughput and total miles of pipeline—was estimated to be about 1 percent. To estimate the CO₂ emissions for the transmission sector, the CH₄ emission factors were proportioned from the 93.4 percent CH₄ reported in EPA/GRI (1996) to reflect the 1 percent CO₂ content found in transmission quality natural gas. The detailed source emissions estimates for CH₄ and CO₂ for the transmission sector are presented in Table A-147 and Table A-153, respectively.

The natural gas in the distribution sector of the system has the same characteristics as the natural gas in the transmission sector. The CH₄ content (93.4 percent) and CO₂ content (1 percent) are identical to transmission segment contents due to the absence of any further treatment between sector boundaries. Thus, the CH₄ emissions factors were converted to CO₂ emission factors using the same methodology as discussed for the transmission sector. The detailed source emission estimates for CH₄ and CO₂ for the distribution sector are presented in Table A-148 and Table A-154, respectively.

Three exceptions to this methodology are CO₂ emissions from flares, CO₂ from acid gas removal units, and CO₂ from condensate tanks. In the case of flare emissions, a direct CO₂ emission factor from EIA (1996) was used. This emission factor was applied to the portion of offshore gas that is not vented and all of the gas reported as vented and flared onshore by EIA, including associated gas. The amount of CO₂ emissions from an acid gas unit in a processing plant is equal to the difference in CO₂ concentrations between produced natural gas and pipeline quality gas applied to the throughput of the plant. This methodology was applied to the national gas throughput using national average CO₂ concentrations in produced gas (3.45 percent) and transmission quality gas (1 percent). Data were unavailable to use annual values for CO₂ concentration. For condensate tanks, a series of E&P Tank (EPA 1999) simulations provide the total CO₂ vented per barrel of condensate throughput from fixed roof tank flash gas for condensate gravities of API 45 degree and higher. The ratios of emissions to throughput were used to estimate the CO₂ emission factor for condensate passing through fixed roof tanks.

Table A-134 through Table A-138 display the 2012 activity data, CH₄ emission factors, and calculated potential CH₄ emissions for each stage.

The tables provide references for emission factors and activity data in footnotes (the lettered footnotes). The tables also provide information on which method was used for supplying activity data for 2014 (the numbered footnotes).

Key to table notations on methods for supplying activity data for 2014 for all tables:

1. Ratios relating other factors for which activity data are available.
2. Activity data for 2014 available from source.
3. Activity data were held constant from 1990 through 2014 based on EPA (1999).

Table A-134: 2014 Data and Calculated CH₄ Potential Emissions (Mg) for the Natural Gas Production Stage

| Activity | 2014 EPA Inventory Values | | |
|--|---|--|---|
| | National Activity Data | National Emission Factor or Range of Regional Values (Potential) ^{aa} | Calculated Potential (Mg) ^{bb} |

Note: This table presents net emissions for each natural gas system stage, and also presents net emissions for select emissions sources for which disaggregated Gas STAR data and/or regulation reduction data can be matched to an Inventory source category, and sources for which emissions are calculated using net emission factors. In general, the Inventory uses aggregated Gas STAR reductions by natural gas system stage (i.e., production, processing, transmission and storage, and distribution). In some cases, emissions reductions reported to Gas STAR have been matched to potential emissions calculated in the Inventory, to provide a net emissions number for specific emissions sources. Net emission values presented here were calculated by deducting the voluntary reductions (Table A-143) and the regulatory reductions (Table A-144) from the potential emissions values in Table A-145 through Table A-148. Some reported Gas STAR reduction activities are cross-cutting and cover multiple Inventory sources. It is not possible to attribute those reductions to specific Inventory source categories, and they are included in the "Other" category.

Table A-150: U.S. Production Sector CO₂ Content in Natural Gas by NEMS Region and Formation Type for all years

| Formation Types | U.S. Region | | | | | | |
|-------------------|-------------|--------------|------------|------------|----------------|------------|-----------------|
| | North East | Midcontinent | Gulf Coast | South West | Rocky Mountain | West Coast | Lower-48 States |
| Conventional | 0.92% | 0.79% | 2.17% | 3.81% | 7.95% | 0.16% | 3.41% |
| Non-conventional* | 7.42% | 0.31% | 0.23% | NA | 0.64% | NA | 4.83% |
| All types | 3.04% | 0.79% | 2.17% | 3.81% | 7.58% | 0.16% | 3.45% |

3.7. Methodology for Estimating CO₂, N₂O, and CH₄ Emissions from the Incineration of Waste

Emissions of CO₂ from the incineration of waste include CO₂ generated by the incineration of plastics, synthetic rubber and synthetic fibers in municipal solid waste (MSW), and incineration of tires (which are composed in part of synthetic rubber and C black) in a variety of other combustion facilities (e.g., cement kilns). Incineration of waste also results in emissions of N₂O and CH₄. The methodology for calculating emissions from each of these waste incineration sources is described in this Annex.

CO₂ from Plastics Incineration

In the *Municipal Solid Waste Generation, Recycling, and Disposal in the United States: Facts and Figures* reports (EPA 1999 through 2003, 2005 through 2014) and *Advancing Sustainable Materials Management: Facts and Figures 2013 – Assessing Trends in Material Generation, Recycling and Disposal in the United States* (EPA 2015), the flows of plastics in the U.S. waste stream are reported for seven resin categories. For 2014, the quantity generated, recovered, and discarded for each resin is shown in Table A-155. The data set for 1990 through 2014 is incomplete, and several assumptions were employed to bridge the data gaps. The EPA reports do not provide estimates for individual materials landfilled and incinerated, although they do provide such an estimate for the waste stream as a whole. To estimate the quantity of plastics landfilled and incinerated, total discards were apportioned based on the proportions of landfilling and incineration for the entire U.S. waste stream for each year in the time series according to *Biocycle’s State of Garbage in America* (van Haaren et al. 2010), Themelis and Shin (in press) and Shin (2014). For those years when distribution by resin category was not reported (1990 through 1994), total values were apportioned according to 1995 (the closest year) distribution ratios. Generation and recovery figures for 2002 and 2004 were linearly interpolated between surrounding years’ data.

Table A-155: 2014 Plastics in the Municipal Solid Waste Stream by Resin (kt)

| Waste Pathway | PET | HDPE | PVC | LDPE/ | | PP | PS | Other | Total |
|-------------------------|-------|-------|------|-------|-------|-------|-------|---------------|-------|
| | | | | LLDPE | | | | | |
| Generation | 4,246 | 5,062 | 816 | 6,768 | 6,713 | 2,059 | 3,837 | 29,502 | |
| Recovery | 844 | 517 | 0 | 426 | 36 | 27 | 871 | 2,722 | |
| Discard | 3,402 | 455 | 816 | 6,341 | 6,677 | 2,032 | 2,921 | 26,781 | |
| Landfill | 3,143 | 420 | 754 | 5,859 | 6,170 | 1,878 | 2,699 | 20,924 | |
| Combustion | 259 | 35 | 62 | 482 | 507 | 154 | 222 | 1,721 | |
| Recovery ^a | 20% | 10% | 0% | 6% | 1% | 1% | 23% | 9% | |
| Discard ^a | 80% | 9% | 100% | 94% | 99% | 99% | 76% | 91% | |
| Landfill ^a | 74% | 8% | 92% | 87% | 92% | 91% | 70% | 71% | |
| Combustion ^a | 6% | 1% | 8% | 7% | 8% | 7% | 6% | 6% | |

^a As a percent of waste generation.

Note: Totals may not sum due to independent rounding. Abbreviations: PET (polyethylene terephthalate), HDPE (high density polyethylene), PVC (polyvinyl chloride), LDPE/LLDPE (linear low density polyethylene), PP (polypropylene), PS (polystyrene).

Fossil fuel-based CO₂ emissions were calculated as the product of plastic combusted, C content, and fraction oxidized (see Table A-156). The C content of each of the six types of plastics is listed, with the value for “other plastics” assumed equal to the weighted average of the six categories. The fraction oxidized was assumed to be 98 percent.

Table A-156: 2014 Plastics Incinerated (kt), Carbon Content (%), Fraction Oxidized (%) and Carbon Incinerated (kt)

| Factor | PET | HDPE | PVC | LDPE/ | | PP | PS | Other | Total |
|---|------------|------------|------------|------------|------------|------------|------------|--------------|-------|
| | | | | LLDPE | | | | | |
| Quantity Combusted | 259 | 35 | 62 | 482 | 507 | 154 | 222 | 1,721 | |
| Carbon Content of Resin | 63% | 86% | 38% | 86% | 86% | 92% | 66% | - | |
| Fraction Oxidized | 98% | 98% | 98% | 98% | 98% | 98% | 98% | - | |
| Carbon in Resin Combusted | 158 | 29 | 23 | 405 | 426 | 140 | 143 | 1,325 | |
| Emissions (MMT CO₂ Eq.) | 0.6 | 1.1 | 0.1 | 1.5 | 1.6 | 0.5 | 0.5 | 4.9 | |

^a Weighted average of other plastics produced.

Note: Totals may not sum due to independent rounding.

CO₂ from Incineration of Synthetic Rubber and Carbon Black in Tires

Emissions from tire incineration require two pieces of information: the amount of tires incinerated and the C content of the tires. “2013 U.S. Scrap Tire Management Summary” (RMA 2014a) reports that 2,120 thousand of the 3,667 thousand tons of scrap tires generated in 2013 (approximately 58 percent of generation) were used for fuel purposes. Using

RMA's estimates of average tire composition and weight, the mass of synthetic rubber and C black in scrap tires was determined:

- Synthetic rubber in tires was estimated to be 90 percent C by weight, based on the weighted average C contents of the major elastomers used in new tire consumption.⁶⁶ Table A-157 shows consumption and C content of elastomers used for tires and other products in 2002, the most recent year for which data are available.
- C black is 100 percent C (Aslett Rubber Inc. n.d.).

Multiplying the mass of scrap tires incinerated by the total C content of the synthetic rubber, C black portions of scrap tires, and then by a 98 percent oxidation factor, yielded CO₂ emissions, as shown in Table A-158. The disposal rate of rubber in tires (0.3 MMT C/yr) is smaller than the consumption rate for tires based on summing the elastomers listed in Table A-155 (1.3 MMT/yr); this is due to the fact that much of the rubber is lost through tire wear during the product's lifetime and may also reflect the lag time between consumption and disposal of tires. Tire production and fuel use for 1990 through 2014 were taken from RMA 2006, RMA 2009, RMA 2011; RMA 2014a; where data were not reported, they were linearly interpolated between bracketing years' data or, for the ends of time series, set equal to the closest year with reported data.

In 2009, RMA changed the reporting of scrap tire data from millions of tires to thousands of short tons of scrap tire. As a result, the average weight and percent of the market of light duty and commercial scrap tires was used to convert the previous years from millions of tires to thousands of short tons (STMC 1990 through 1997; RMA 2002 through 2006, 2014b).

Table A-157: Elastomers Consumed in 2002 (kt)

| Elastomer | Consumed | Carbon Content | Carbon Equivalent |
|---------------------------------------|--------------|----------------|-------------------|
| Styrene butadiene rubber solid | 768 | 91% | 700 |
| For Tires | 660 | 91% | 602 |
| For Other Products* | 108 | 91% | 98 |
| Polybutadiene | 583 | 89% | 518 |
| For Tires | 408 | 89% | 363 |
| For Other Products | 175 | 89% | 155 |
| Ethylene Propylene | 301 | 86% | 258 |
| For Tires | 6 | 86% | 5 |
| For Other Products | 295 | 86% | 253 |
| Polychloroprene | 54 | 59% | 32 |
| For Tires | 0 | 59% | 0 |
| For Other Products | 54 | 59% | 32 |
| Nitrile butadiene rubber solid | 84 | 77% | 65 |
| For Tires | 1 | 77% | 1 |
| For Other Products | 83 | 77% | 64 |
| Polyisoprene | 58 | 88% | 51 |
| For Tires | 48 | 88% | 42 |
| For Other Products | 10 | 88% | 9 |
| Others | 367 | 88% | 323 |
| For Tires | 184 | 88% | 161 |
| For Other Products | 184 | 88% | 161 |
| Total | 2,215 | - | 1,950 |
| For Tires | 1,307 | - | 1,174 |

* Used to calculate C content of non-tire rubber products in municipal solid waste.

- Not applicable

Note: Totals may not sum due to independent rounding.

⁶⁶The carbon content of tires (1,174 kt C) divided by the mass of rubber in tires (1,307 kt) equals 90 percent.

Table A-158: Scrap Tire Constituents and CO₂ Emissions from Scrap Tire Incineration in 2014

| Material | Weight of Material (MMT) | Fraction Oxidized | Carbon Content | Emissions (MMT CO ₂ Eq.) |
|------------------|--------------------------|-------------------|----------------|-------------------------------------|
| Synthetic Rubber | 0.3 | 98% | 90% | 1.2 |
| Carbon Black | 0.4 | 98% | 100% | 1.4 |
| Total | 0.7 | - | - | 2.6 |

- Not applicable

CO₂ from Incineration of Synthetic Rubber in Municipal Solid Waste

Similar to the methodology for scrap tires, CO₂ emissions from synthetic rubber in MSW were estimated by multiplying the amount of rubber incinerated by an average rubber C content. The amount of rubber discarded in the MSW stream was estimated from generation and recycling data⁶⁷ provided in the *Municipal Solid Waste Generation, Recycling, and Disposal in the United States: Facts and Figures* reports (EPA 1999 through 2003, 2005 through 2014), *Advancing Sustainable Materials Management: Facts and Figures 2013: Assessing Trends in Material Generation, Recycling and Disposal in the United States* (EPA 2015) and unpublished backup data (Schneider 2007). The reports divide rubber found in MSW into three product categories: other durables (not including tires), non-durables (which includes clothing and footwear and other non-durables), and containers and packaging. EPA (2015) did not report rubber found in the product category “containers and packaging;” however, containers and packaging from miscellaneous material types were reported for 2009 through 2014. As a result, EPA assumes that rubber containers and packaging are reported under the “miscellaneous” category; and therefore, the quantity reported for 2009 through 2014 were set equal to the quantity reported for 2008. Since there was negligible recovery for these product types, all the waste generated is considered to be discarded. Similar to the plastics method, discards were apportioned into landfilling and incineration based on their relative proportions, for each year, for the entire U.S. waste stream. The report aggregates rubber and leather in the MSW stream; an assumed synthetic rubber content of 70 percent was assigned to each product type, as shown in Table A-159.⁶⁸ A C content of 85 percent was assigned to synthetic rubber for all product types (based on the weighted average C content of rubber consumed for non-tire uses), and a 98 percent fraction oxidized was assumed.

Table A-159: Rubber and Leather in Municipal Solid Waste in 2014

| Product Type | Incinerated (kt) | Synthetic Rubber (%) | Carbon Content (%) | Fraction Oxidized (%) | Emissions (MMT CO ₂ Eq.) |
|---------------------------------|------------------|----------------------|--------------------|-----------------------|-------------------------------------|
| Durables (not Tires) | 261 | 70% | 85% | 98% | 0.8 |
| Non-Durables | 77 | - | - | - | 0.2 |
| Clothing and Footwear | 59 | 70% | 85% | 98% | 0.2 |
| Other Non-Durables | 18 | 70% | 85% | 98% | 0.1 |
| Containers and Packaging | 2 | 70% | 85% | 98% | 0.0 |
| Total | 341 | - | - | - | 1.1 |

- Not Applicable.

CO₂ from Incineration of Synthetic Fibers

Carbon dioxide emissions from synthetic fibers were estimated as the product of the amount of synthetic fiber discarded annually and the average C content of synthetic fiber. Fiber in the MSW stream was estimated from data provided in the *Municipal Solid Waste Generation, Recycling, and Disposal in the United States: Facts and Figures* reports (EPA 1999 through 2003, 2005 through 2015) for textiles. Production data for the synthetic fibers was based on data from the American Chemical Society (FEB 2009). The amount of synthetic fiber in MSW was estimated by subtracting (a) the amount recovered from (b) the waste generated (see Table A-160). As with the other materials in the MSW stream, discards were apportioned based on the annually variable proportions of landfilling and incineration for the entire U.S. waste stream, as found in van Haaren et al. (2010), Themelis and Shin (in press), and Shin (2014). It was assumed that approximately 55 percent of the fiber was synthetic in origin, based on information received from the Fiber Economics Bureau (DeZan 2000). An average C content of 70 percent was assigned to synthetic fiber using the production-weighted average of the C contents of the four major fiber types (polyester, nylon, olefin, and acrylic) produced in 1999 (see Table A-161). The equation relating CO₂ emissions to the amount of textiles combusted is shown below.

$$\text{CO}_2 \text{ Emissions from the Incineration of Synthetic Fibers} = \text{Annual Textile Incineration (kt)} \times (\text{Percent of Total Fiber that is Synthetic}) \times (\text{Average C Content of Synthetic Fiber}) \times (44 \text{ g CO}_2 / 12 \text{ g C})$$

⁶⁷ Discards = Generation minus recycling.

⁶⁸ As a sustainably harvested biogenic material, the incineration of leather is assumed to have no net CO₂ emissions.

Table A-160: Synthetic Textiles in MSW (kt)

| Year | Generation | Recovery | Discards | Incineration |
|------|------------|----------|----------|--------------|
| 1990 | 2,884 | 328 | 2,557 | 332 |
| 1995 | 3,674 | 447 | 3,227 | 442 |
| 1996 | 3,832 | 472 | 3,361 | 467 |
| 1997 | 4,090 | 526 | 3,564 | 458 |
| 1998 | 4,269 | 556 | 3,713 | 407 |
| 1999 | 4,498 | 611 | 3,887 | 406 |
| 2000 | 4,706 | 655 | 4,051 | 417 |
| 2001 | 4,870 | 715 | 4,155 | 432 |
| 2002 | 5,123 | 750 | 4,373 | 459 |
| 2003 | 5,297 | 774 | 4,522 | 472 |
| 2004 | 5,451 | 884 | 4,567 | 473 |
| 2005 | 5,714 | 913 | 4,800 | 480 |
| 2006 | 5,893 | 933 | 4,959 | 479 |
| 2007 | 6,041 | 953 | 5,088 | 470 |
| 2008 | 6,305 | 968 | 5,337 | 470 |
| 2009 | 6,424 | 978 | 5,446 | 458 |
| 2010 | 6,508 | 998 | 5,510 | 441 |
| 2011 | 6,513 | 1,003 | 5,510 | 419 |
| 2012 | 7,114 | 1,117 | 5,997 | 456 |
| 2013 | 7,496 | 894 | 6,602 | 502 |
| 2014 | 7,496 | 894 | 6,602 | 502 |

Table A-161: Synthetic Fiber Production in 1999

| Fiber | Production (MMT) | Carbon Content |
|--------------|------------------|----------------|
| Polyester | 1.8 | 63% |
| Nylon | 1.2 | 64% |
| Olefin | 1.4 | 86% |
| Acrylic | 0.1 | 68% |
| Total | 4.5 | 70% |

N₂O and CH₄ from Incineration of Waste

Estimates of N₂O emissions from the incineration of waste in the United States are based on the methodology outlined in the EPA's Compilation of Air Pollutant Emission Factors (EPA 1995) and presented in the *Municipal Solid Waste Generation, Recycling, and Disposal in the United States: Facts and Figures* reports (EPA 1999 through 2003, 2005 through 2014), *Advancing Sustainable Materials Management: Facts and Figures 2013: Assessing Trends in Material Generation, Recycling and Disposal in the United States* (EPA 2015), and unpublished backup data (Schneider 2007). According to this methodology, emissions of N₂O from waste incineration are the product of the mass of waste incinerated, an emission factor of N₂O emitted per unit mass of waste incinerated, and an N₂O emissions control removal efficiency. The mass of waste incinerated was derived from the results of the biannual national survey of Municipal Solid Waste (MSW) Generation and Disposition in the U.S., published in *BioCycle* (van Haaren et al. 2010), Themelis and Shin (in press), and Shin (2014). For waste incineration in the United States, an emission factor of 50 g N₂O/metric ton MSW based on the 2006 IPCC Guidelines and an estimated emissions control removal efficiency of zero percent were used (IPCC 2006). It was assumed that all MSW incinerators in the United States use continuously-fed stoker technology (Bahor 2009, ERC 2009).

Estimates of CH₄ emissions from the incineration of waste in the United States are based on the methodology outlined in IPCC's 2006 IPCC Guidelines for National Greenhouse Gas Inventories (IPCC 2006). According to this methodology, emissions of CH₄ from waste incineration are the product of the mass of waste incinerated and an emission factor of CH₄ emitted per unit mass of waste incinerated. Similar to the N₂O emissions methodology, the mass of waste incinerated was derived from the information published in *BioCycle* (van Haaren et al. 2010) for 1990 through 2008. Data for 2011 were derived from information forthcoming in Themelis and Shin (in press) and Shin (2014). For waste incineration in the United States, an emission factor of 0.20 kg CH₄/kt MSW was used based on the 2006 IPCC Guidelines and assuming that all MSW incinerators in the United States use continuously-fed stoker technology (Bahor 2009; ERC 2009). No information was available on the mass of waste incinerated for 2012, 2013, or 2014, so these values were assumed to be equal to the 2011 value.

Despite the differences in methodology and data sources, the two series of references (EPA 2014; van Haaren, Rob, Themelis, N., and Goldstein, N. 2010) provide estimates of total solid waste incinerated that are relatively consistent (see Table A-162).

Table A-162: U.S. Municipal Solid Waste Incinerated, as Reported by EPA and BioCycle (Metric Tons)

| Year | EPA | BioCycle |
|------|-------------------------|-------------------------|
| 1990 | 28,939,680 | 30,632,057 |
| 1995 | 32,241,888 | 29,639,040 |
| 2000 | 30,599,856 | 25,974,978 |
| 2001 | 30,481,920 | 25,942,036 ^a |
| 2002 | 30,255,120 | 25,802,917 |
| 2003 | 30,028,320 | 25,930,542 ^b |
| 2004 | 28,585,872 | 26,037,823 |
| 2005 | 28,685,664 | 25,973,520 ^c |
| 2006 | 28,985,040 | 25,853,401 |
| 2007 | 29,003,184 | 24,788,539 ^d |
| 2008 | 28,622,160 | 23,674,017 |
| 2009 | 26,317,872 | 22,714,122 ^e |
| 2010 | 26,544,672 | 21,741,734 ^e |
| 2011 | 26,544,672 | 20,756,870 |
| 2012 | 26,544,672 | 20,756,870 ^f |
| 2013 | 26,544,672 ^g | 20,756,870 ^f |
| 2014 | 26,544,672 ^g | 20,756,870 ^f |

^a Interpolated between 2000 and 2002 values.

^b Interpolated between 2002 and 2004 values.

^c Interpolated between 2004 and 2006 values.

^d Interpolated between 2006 and 2008 values

^e Interpolated between 2011 and 2008 values

^f Set equal to the 2011 value

^g Set equal to the 2012 value.

3.8. Methodology for Estimating Emissions from International Bunker Fuels used by the U.S. Military

Bunker fuel emissions estimates for the Department of Defense (DoD) were developed using data generated by the Defense Logistics Agency Energy (DLA Energy) for aviation and naval fuels. DLA Energy prepared a special report based on data in the Fuels Automated System (FAS) for calendar year 2014 fuel sales in the Continental United States (CONUS).⁶⁹ The following steps outline the methodology used for estimating emissions from international bunker fuels used by the U.S. Military.

Step 1: Omit Extra-Territorial Fuel Deliveries

Beginning with the complete FAS data set for each year, the first step in quantifying DoD-related emissions from international bunker fuels was to identify data that would be representative of international bunker fuel consumption as defined by decisions of the UNFCCC (i.e., fuel sold to a vessel, aircraft, or installation within the United States or its territories and used in international maritime or aviation transport). Therefore, fuel data were categorized by the location of fuel delivery in order to identify and omit all international fuel transactions/deliveries (i.e., sales abroad).

Step 2: Allocate JP-8 between Aviation and Land-based Vehicles

As a result of DoD⁷⁰ and NATO⁷¹ policies on implementing the Single Fuel For the Battlefield concept, DoD activities have been increasingly replacing diesel fuel with JP8 (a type of jet fuel) in compression ignition and turbine engines of land-based equipment. Based on this concept and examination of all data describing jet fuel used in land-based vehicles, it was determined that a portion of JP8 consumption should be attributed to ground vehicle use. Based on available Military Service data and expert judgment, a small fraction of the total JP8 use (i.e., between 1.78 and 2.7 times the quantity of diesel fuel used, depending on the Service) was reallocated from the aviation subtotal to a new land-based jet fuel category for 1997 and subsequent years. As a result of this reallocation, the JP8 use reported for aviation was reduced and the total fuel use for land-based equipment increased. DoD's total fuel use did not change.

Table A-163 displays DoD's consumption of transportation fuels, summarized by fuel type, that remain at the completion of Step 1, and reflects the adjustments for jet fuel used in land-based equipment, as described above.

Step 3: Omit Land-Based Fuels

Navy and Air Force land-based fuels (i.e., fuel not used by ships or aircraft) were omitted for the purpose of calculating international bunker fuels. The remaining fuels, listed below, were considered potential DoD international bunker fuels.

- **Aviation:** jet fuels (JP8, JP5, JP4, JAA, JA1, and JAB).
- **Marine:** naval distillate fuel (F76), marine gas oil (MGO), and intermediate fuel oil (IFO).

Step 4: Omit Fuel Transactions Received by Military Services that are not considered to be International Bunker Fuels

Only Navy and Air Force were deemed to be users of military international bunker fuels after sorting the data by Military Service and applying the following assumptions regarding fuel use by Service.

⁶⁹ FAS contains data for 1995 through 2014, but the dataset was not complete for years prior to 1995. Using DLA aviation and marine fuel procurement data, fuel quantities from 1990 to 1994 were estimated based on a back-calculation of the 1995 data in the legacy database, the Defense Fuels Automated Management System (DFAMS). The back-calculation was refined in 1999 to better account for the jet fuel conversion from JP4 to JP8 that occurred within DoD between 1992 and 1995.

⁷⁰ DoD Directive 4140.25-M-V1, Fuel Standardization and Cataloging, 2013; DoD Directive 4140.25, DoD Management Policy for Energy Commodities and Related Services, 2004.

⁷¹ NATO Standard Agreement NATO STANAG 4362, Fuels for Future Ground Equipments Using Compression Ignition or Turbine Engines, 2012.

- Only fuel delivered to a ship, aircraft, or installation in the United States was considered a potential international bunker fuel. Fuel consumed in international aviation or marine transport was included in the bunker fuel estimate of the country where the ship or aircraft was fueled. Fuel consumed entirely within a country's borders was not considered a bunker fuel.
- Based on previous discussions with the Army staff, only an extremely small percentage of Army aviation emissions, and none of Army watercraft emissions, qualified as bunker fuel emissions. The magnitude of these emissions was judged to be insignificant when compared to Air Force and Navy emissions. Based on this research, Army bunker fuel emissions were assumed to be zero.
- Marine Corps aircraft operating while embarked consumed fuel that was reported as delivered to the Navy. Bunker fuel emissions from embarked Marine Corps aircraft were reported in the Navy bunker fuel estimates. Bunker fuel emissions from other Marine Corps operations and training were assumed to be zero.
- Bunker fuel emissions from other DoD and non-DoD activities (i.e., other federal agencies) that purchased fuel from DLA Energy were assumed to be zero.

Step 5: Determine Bunker Fuel Percentages

It was necessary to determine what percent of the aviation and marine fuels were used as international bunker fuels. Military aviation bunkers include international operations (i.e., sorties that originate in the United States and end in a foreign country), operations conducted from naval vessels at sea, and operations conducted from U.S. installations principally over international water in direct support of military operations at sea (e.g., anti-submarine warfare flights). Methods for quantifying aviation and marine bunker fuel percentages are described below.

- **Aviation:** The Air Force Aviation bunker fuel percentage was determined to be 13.2 percent. A bunker fuel weighted average was calculated based on flying hours by major command. International flights were weighted by an adjustment factor to reflect the fact that they typically last longer than domestic flights. In addition, a fuel use correction factor was used to account for the fact that transport aircraft burn more fuel per hour of flight than most tactical aircraft. This percentage was multiplied by total annual Air Force aviation fuel delivered for U.S. activities, producing an estimate for international bunker fuel consumed by the Air Force.

The Naval Aviation bunker fuel percentage was calculated to be 40.4 percent by using flying hour data from Chief of Naval Operations Flying Hour Projection System Budget for fiscal year 1998 and estimates of bunker fuel percent of flights provided by the fleet. This Naval Aviation bunker fuel percentage was then multiplied by total annual Navy aviation fuel delivered for U.S. activities, yielding total Navy aviation bunker fuel consumed.

- **Marine:** For marine bunkers, fuels consumed while ships were underway were assumed to be bunker fuels. The Navy maritime bunker fuel percentage was determined to be 79 percent because the Navy reported that 79 percent of vessel operations were underway, while the remaining 21 percent of operations occurred in port (i.e., pierside) in the year 2000.⁷²

Table A-164 and Table A-165 display DoD bunker fuel use totals for the Navy and Air Force.

Step 6: Calculate Emissions from International Bunker Fuels

Bunker fuel totals were multiplied by appropriate emission factors to determine greenhouse gas emissions. CO₂ emissions from Aviation Bunkers and distillate Marine Bunkers are the total of military aviation and marine bunker fuels, respectively.

⁷² Note that 79 percent is used because it is based on Navy data, but the percentage of time underway may vary from year-to-year depending on vessel operations. For example, for years prior to 2000, the bunker fuel percentage was 87 percent.

The rows labeled “U.S. Military” and “U.S. Military Naval Fuels” in the tables in the International Bunker Fuels section of the Energy chapter were based on the totals provided in Table A-164 and Table A-165, below. CO₂ emissions from aviation bunkers and distillate marine bunkers are presented in Table A-168, and are based on emissions from fuels tallied in Table A-164 and Table A-165.

+ Indicates value does not exceed 0.05 million gallons.

^a Includes fuel distributed in the United States and U.S. Territories.

^b Intermediate fuel oil (IFO 180 and IFO 380) is a blend of distillate and residual fuels. IFO is used by the Military Sealift Command.

^c Prior to 2001, gasoline and diesel fuel totals were estimated using data provided by the Military Services for 1990 and 1996. The 1991 through 1995 data points were interpolated from the Service inventory data. The 1997 through 1999 gasoline and diesel fuel data were initially extrapolated from the 1996 inventory data. Growth factors used for other diesel and gasoline were 5.2 and -21.1 percent, respectively. However, prior diesel fuel estimates from 1997 through 2000 were reduced according to the estimated consumption of jet fuel that is assumed to have replaced the diesel fuel consumption in land-based vehicles. Datasets for other diesel and gasoline consumed by the military in 2000 were estimated based on ground fuels consumption trends. This method produced a result that was more consistent with expected consumption for 2000. Since 2001, other gasoline and diesel fuel totals were generated by DLA Energy.

^d The fraction of jet fuel consumed in land-based vehicles was estimated based on DLA Energy data as well as Military Service and expert judgment.

Note: Totals may not sum due to independent rounding.

3.9. Methodology for Estimating HFC and PFC Emissions from Substitution of Ozone Depleting Substances

Emissions of HFCs and PFCs from the substitution of ozone depleting substances (ODS) are developed using a country-specific modeling approach. The Vintaging Model was developed as a tool for estimating the annual chemical emissions from industrial sectors that have historically used ODS in their products. Under the terms of the Montreal Protocol and the United States Clean Air Act Amendments of 1990, the domestic U.S. consumption of ODS—chlorofluorocarbons (CFCs), halons, carbon tetrachloride, methyl chloroform, and hydrochlorofluorocarbons (HCFCs)—has been drastically reduced, forcing these industrial sectors to transition to more ozone friendly chemicals. As these industries have moved toward ODS alternatives such as hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs), the Vintaging Model has evolved into a tool for estimating the rise in consumption and emissions of these alternatives, and the decline of ODS consumption and emissions.

The Vintaging Model estimates emissions from five ODS substitute end-use sectors: refrigeration and air-conditioning, foams, aerosols, solvents, and fire-extinguishing. Within these sectors, there are more than 60 independently modeled end-uses. The model requires information on the market growth for each of the end-uses, a history of the market transition from ODS to alternatives, and the characteristics of each end-use such as market size or charge sizes and loss rates. As ODS are phased out, a percentage of the market share originally filled by the ODS is allocated to each of its substitutes.

The model, named for its method of tracking the emissions of annual “vintages” of new equipment that enter into service, is a “bottom-up” model. It models the consumption of chemicals based on estimates of the quantity of equipment or products sold, serviced, and retired each year, and the amount of the chemical required to manufacture and/or maintain the equipment. The Vintaging Model makes use of this market information to build an inventory of the in-use stocks of the equipment and ODS and ODS substitute in each of the end-uses. The simulation is considered to be a “business-as-usual” baseline case, and does not incorporate measures to reduce or eliminate the emissions of these gases other than those regulated by U.S. law or otherwise common in the industry. Emissions are estimated by applying annual leak rates, service emission rates, and disposal emission rates to each population of equipment. By aggregating the emission and consumption output from the different end-uses, the model produces estimates of total annual use and emissions of each chemical.

The Vintaging Model synthesizes data from a variety of sources, including data from the ODS Tracking System maintained by the Stratospheric Protection Division, the Greenhouse Gas Reporting Program maintained by the Climate Change Division, and information from submissions to EPA under the Significant New Alternatives Policy (SNAP) program. Published sources include documents prepared by the United Nations Environment Programme (UNEP) Technical Options Committees, reports from the Alternative Fluorocarbons Environmental Acceptability Study (AFEAS), and conference proceedings from the International Conferences on Ozone Protection Technologies and Earth Technologies Forums. EPA also coordinates extensively with numerous trade associations and individual companies. For example, the Alliance for Responsible Atmospheric Policy; the Air-Conditioning, Heating and Refrigeration Institute; the Association of Home Appliance Manufacturers; the American Automobile Manufacturers Association; and many of their member companies have provided valuable information over the years. In some instances the unpublished information that the EPA uses in the model is classified as Confidential Business Information (CBI). The annual emissions inventories of chemicals are aggregated in such a way that CBI cannot be inferred. Full public disclosure of the inputs to the Vintaging Model would jeopardize the security of the CBI that has been entrusted to the EPA.

The following sections discuss the emission equations used in the Vintaging Model for each broad end-use category. These equations are applied separately for each chemical used within each of the different end-uses. In the majority of these end-uses, more than one ODS substitute chemical is used.

In general, the modeled emissions are a function of the amount of chemical consumed in each end-use market. Estimates of the consumption of ODS alternatives can be inferred by determining the transition path of each regulated ODS used in the early 1990s. Using data gleaned from a variety of sources, assessments are made regarding which alternatives have been used, and what fraction of the ODS market in each end-use has been captured by a given alternative. By combining this with estimates of the total end-use market growth, a consumption value can be estimated for each chemical used within each end-use.

Methodology

The Vintaging Model estimates the use and emissions of ODS alternatives by taking the following steps:

1. *Gather historical data.* The Vintaging Model is populated with information on each end-use, taken from published sources and industry experts.

2. *Simulate the implementation of new, non-ODS technologies.* The Vintaging Model uses detailed characterizations of the existing uses of the ODS, as well as data on how the substitutes are replacing the ODS, to simulate the implementation of new technologies that enter the market in compliance with ODS phase-out policies. As part of this simulation, the ODS substitutes are introduced in each of the end-uses over time as seen historically and as needed to comply with the ODS phase-out and other regulations.

3. *Estimate emissions of the ODS substitutes.* The chemical use is estimated from the amount of substitutes that are required each year for the manufacture, installation, use, or servicing of products. The emissions are estimated from the emission profile for each vintage of equipment or product in each end-use. By aggregating the emissions from each vintage, a time profile of emissions from each end-use is developed.

Each set of end-uses is discussed in more detail in the following sections.

Refrigeration and Air-Conditioning

For refrigeration and air conditioning products, emission calculations are split into two categories: emissions during equipment lifetime, which arise from annual leakage and service losses, and disposal emissions, which occur at the time of discard. Two separate steps are required to calculate the lifetime emissions from leakage and service, and the emissions resulting from disposal of the equipment. For any given year, these lifetime emissions (for existing equipment) and disposal emissions (from discarded equipment) are summed to calculate the total emissions from refrigeration and air-conditioning. As new technologies replace older ones, it is generally assumed that there are improvements in their leak, service, and disposal emission rates.

Step 1: Calculate lifetime emissions

Emissions from any piece of equipment include both the amount of chemical leaked during equipment operation and the amount emitted during service. Emissions from leakage and servicing can be expressed as follows:

$$Es_j = (l_a + l_s) \times \sum_{i=1}^k Qc_{j-i+1} \quad \text{for } i = 1 \rightarrow k$$

where:

| | | |
|-------|---|--|
| Es | = | Emissions from Equipment Serviced. Emissions in year j from normal leakage and servicing (including recharging) of equipment. |
| l_a | = | Annual Leak Rate. Average annual leak rate during normal equipment operation (expressed as a percentage of total chemical charge). |
| l_s | = | Service Leak Rate. Average leakage during equipment servicing (expressed as a percentage of total chemical charge). |
| Qc | = | Quantity of Chemical in New Equipment. Total amount of a specific chemical used to charge new equipment in a given year by weight. |
| I | = | Counter, runs from 1 to lifetime (k). |
| j | = | Year of emission. |
| k | = | Lifetime. The average lifetime of the equipment. |

Step 2: Calculate disposal emissions

The disposal emission equations assume that a certain percentage of the chemical charge will be emitted to the atmosphere when that vintage is discarded. Disposal emissions are thus a function of the quantity of chemical contained in the retiring equipment fleet and the proportion of chemical released at disposal:

$$Ed_j = Qc_{j-k+1} \times [1 - (rm \times rc)]$$

where:

| | | |
|------|---|--|
| Ed | = | Emissions from Equipment Disposed. Emissions in year j from the disposal of equipment. |
| Qc | = | Quantity of Chemical in New Equipment. Total amount of a specific chemical used to charge new equipment in year $j-k+1$, by weight. |

| | | |
|-----------|---|--|
| <i>rm</i> | = | Chemical Remaining. Amount of chemical remaining in equipment at the time of disposal (expressed as a percentage of total chemical charge). |
| <i>rc</i> | = | Chemical Recovery Rate. Amount of chemical that is recovered just prior to disposal (expressed as a percentage of chemical remaining at disposal (<i>rm</i>)). |
| <i>j</i> | = | Year of emission. |
| <i>k</i> | = | Lifetime. The average lifetime of the equipment. |

Step 3: Calculate total emissions

Finally, lifetime and disposal emissions are summed to provide an estimate of total emissions.

$$E_j = Es_j + Ed_j$$

where:

| | | |
|-----------|---|---|
| <i>E</i> | = | Total Emissions. Emissions from refrigeration and air conditioning equipment in year <i>j</i> . |
| <i>Es</i> | = | Emissions from Equipment Serviced. Emissions in year <i>j</i> from leakage and servicing (including recharging) of equipment. |
| <i>Ed</i> | = | Emissions from Equipment Disposed. Emissions in year <i>j</i> from the disposal of equipment. |
| <i>j</i> | = | Year of emission. |

Assumptions

The assumptions used by the Vintaging Model to trace the transition of each type of equipment away from ODS are presented in Table A-169, below. As new technologies replace older ones, it is generally assumed that there are improvements in their leak, service, and disposal emission rates. Additionally, the market for each equipment type is assumed to grow independently, according to annual growth rates.

Table A-169: Refrigeration and Air-Conditioning Market Transition Assumptions

| Initial Market Segment | Primary Substitute | | | | Secondary Substitute | | | | Tertiary Substitute | | | | Growth Rate |
|--|--------------------|------------|---|----------------------------|----------------------|------------|---|----------------------------|---------------------|------------|---|----------------------------|-------------|
| | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | |

¹ DX refers to direct expansion systems where the compressors are mounted together in a rack and share suction and discharge refrigeration lines that run throughout the store, feeding refrigerant to the display cases in the sales area.

² DR refers to distributed refrigeration systems that consist of multiple smaller units that are located close to the display cases that they serve such as on the roof above the cases, behind a nearby wall, or on top of or next to the case in the sales area.

³ SLS refers to secondary loop systems wherein a secondary fluid such as glycol or carbon dioxide is cooled by the primary refrigerant in the machine room and then pumped throughout the store to remove heat from the display equipment.

⁴ The CFC-12 large retail food market for new systems transitioned to R-502 from 1998 to 1990, and subsequently transitioned to HCFC-22 from 1990 to 1993. These transitions are not shown in the table in order to provide the HFC transitions in greater detail.

⁵ HCFC-22 for new equipment after 2010 is assumed to be reclaimed material.

Table A-170 presents the average equipment lifetimes and annual HFC emission rates (for servicing and leaks) for each end-use assumed by the Vintaging Model.

Table A-170: Refrigeration and Air-Conditioning Lifetime Assumptions

| End-Use | Lifetime (Years) | HFC Emission Rates (%) |
|----------------------------------|------------------|------------------------|
| Centrifugal Chillers | 20 – 27 | 2.0 – 10.9 |
| Cold Storage | 20 – 25 | 15.0 |
| Commercial Unitary A/C | 15 | 7.9 – 8.6 |
| Dehumidifiers | 11 | 0.5 |
| Ice Makers | 8 | 3.0 |
| Industrial Process Refrigeration | 25 | 3.6 – 12.3 |
| Mobile Air Conditioners | 5 – 16 | 2.3 – 18.0 |
| Positive Displacement Chillers | 20 | 0.5 – 1.5 |
| PTAC/PTHP | 12 | 3.9 |
| Retail Food | 10 – 20 | 1.0 – 25 |
| Refrigerated Appliances | 14 | 0.6 |
| Residential Unitary A/C | 15 | 11.8 |
| Transport Refrigeration | 9 – 40 | 19.4 – 36.4 |
| Water & Ground Source Heat Pumps | 20 | 3.9 |
| Window Units | 12 | 0.6 |

Aerosols

ODSs, HFCs, and many other chemicals are used as propellant aerosols. Pressurized within a container, a nozzle releases the chemical, which allows the product within the can to also be released. Two types of aerosol products are modeled: metered dose inhalers (MDI) and consumer aerosols. In the United States, the use of CFCs in consumer aerosols was banned in 1978, and many products transitioned to hydrocarbons or “not-in-kind” technologies, such as solid deodorants and finger-pump hair sprays. However, MDIs can continue to use CFCs as propellants because their use has been deemed essential. Essential use exemptions granted to the United States under the Montreal Protocol for CFC use in MDIs are limited to the treatment of asthma and chronic obstructive pulmonary disease.

All HFCs and PFCs used in aerosols are assumed to be emitted in the year of manufacture. Since there is currently no aerosol recycling, it is assumed that all of the annual production of aerosol propellants is released to the atmosphere. The following equation describes the emissions from the aerosols sector.

$$E_j = Qc_j$$

where:

- E = Emissions. Total emissions of a specific chemical in year j from use in aerosol products, by weight.
- Qc = Quantity of Chemical. Total quantity of a specific chemical contained in aerosol products sold in year j , by weight.
- j = Year of emission.

Transition Assumptions

Transition assumptions and growth rates for those items that use ODSs or HFCs as propellants, including vital medical devices and specialty consumer products, are presented in Table A-171.

Table A-171: Aerosol Product Transition Assumptions

| Initial Market Segment | Primary Substitute | | | | Secondary Substitute | | | | Growth Rate |
|-------------------------------------|----------------------|------------|---|----------------------------|----------------------|------------|---|----------------------------|-------------|
| | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | |
| MDIs | | | | | | | | | |
| CFC Mix ^a | HFC-134a | 1997 | 1997 | 6% | None | | | | 0.8% |
| | Non-ODP/GWP | 1998 | 2007 | 7% | None | | | | |
| | CFC Mix ^a | 2000 | 2000 | 87% | HFC-134a | 2002 | 2002 | 34% | |
| | | | | | HFC-134a | 2003 | 2009 | 47% | |
| | | | | | HFC-227ea | 2006 | 2009 | 5% | |
| | | | | | HFC-134a | 2010 | 2011 | 6% | |
| | | | | | HFC-227ea | 2010 | 2011 | 1% | |
| | | | | | HFC-134a | 2011 | 2012 | 3% | |
| | | | | | HFC-227ea | 2011 | 2012 | 0.3% | |
| | | | | | HFC-134a | 2014 | 2014 | 3% | |
| | | | | HFC-227ea | 2014 | 2014 | 0.3% | | |
| Consumer Aerosols (Non-MDIs) | | | | | | | | | |
| NA ^b | HFC-152a | 1990 | 1991 | 50% | None | | | | 2.0% |
| | HFC-134a | 1995 | 1995 | 50% | HFC-152a | 1997 | 1998 | 44% | |
| | | | | | HFC-152a | 2001 | 2005 | 36% | |

^a CFC Mix consists of CFC-11, CFC-12 and CFC-114 and represents the weighted average of several CFCs consumed for essential use in MDIs from 1993 to 2008.

^b Consumer Aerosols transitioned away from ODS prior to 1985, the year in which the Vintaging Model begins. The portion of the market that is now using HFC propellants is modeled.

Solvents

ODSs, HFCs, PFCs and other chemicals are used as solvents to clean items. For example, electronics may need to be cleaned after production to remove any manufacturing process oils or residues left. Solvents are applied by moving the item to be cleaned within a bath or stream of the solvent. Generally, most solvents are assumed to remain in the liquid phase and are not emitted as gas. Thus, emissions are considered “incomplete,” and are a fixed percentage of the amount of solvent consumed in a year. The remainder of the consumed solvent is assumed to be reused or disposed without being released to the atmosphere. The following equation calculates emissions from solvent applications.

$$E_j = l \times Qc_j$$

where:

- E* = Emissions. Total emissions of a specific chemical in year *j* from use in solvent applications, by weight.
- l* = Percent Leakage. The percentage of the total chemical that is leaked to the atmosphere, assumed to be 90 percent.
- Qc* = Quantity of Chemical. Total quantity of a specific chemical sold for use in solvent applications in the year *j*, by weight.
- j* = Year of emission.

Transition Assumptions

The transition assumptions and growth rates used within the Vintaging Model for electronics cleaning, metals cleaning, precision cleaning, and adhesives, coatings and inks, are presented in Table A-172.

Table A-172: Solvent Market Transition Assumptions

| Initial Market Segment | Primary Substitute | | | | Secondary Substitute | | | | Growth Rate |
|----------------------------------|--------------------|------------|---|----------------------------|----------------------|------------|---|----------------------------|-------------|
| | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | |
| Adhesives | | | | | | | | | |

| | | | | | Non-ODP/GWP | 2005 | 2009 | 10% | |
| Metals | | | | | | | | | |
| CH ₃ CCl ₃ | Non-ODP/GWP | 1992 | 1996 | 100% | None | | | | 2.0% |
| CFC-113 | Non-ODP/GWP | 1992 | 1996 | 100% | None | | | | 2.0% |
| CCl ₄ | Non-ODP/GWP | 1992 | 1996 | 100% | None | | | | 2.0% |
| Precision | | | | | | | | | |
| CH ₃ CCl ₃ | Non-ODP/GWP | 1995 | 1996 | 99.3% | None | | | | 2.0% |
| | HFC-43-10mee | 1995 | 1996 | 0.6% | None | | | | |
| | PFC/PFPE | 1995 | 1996 | 0.1% | Non-ODP/GWP | 2000 | 2003 | 90% | |
| | | | | | Non-ODP/GWP | 2005 | 2009 | 10% | |
| CFC-113 | Non-ODP/GWP | 1995 | 1996 | 96% | None | | | | 2.0% |
| | HCFC-225ca/cb | 1995 | 1996 | 1% | Unknown | | | | |
| | HFE-7100 | 1995 | 1996 | 3% | None | | | | |

Non-ODP/GWP includes chemicals with zero ODP and low GWP, such as hydrocarbons and ammonia, as well as not-in-kind alternatives such as "no clean" technologies.

Fire Extinguishing

ODSs, HFCs, PFCs and other chemicals are used as fire-extinguishing agents, in both hand-held "streaming" applications as well as in built-up "flooding" equipment similar to water sprinkler systems. Although these systems are generally built to be leak-tight, some leaks do occur and of course emissions occur when the agent is released. Total emissions from fire extinguishing are assumed, in aggregate, to equal a percentage of the total quantity of chemical in operation at a given time. For modeling purposes, it is assumed that fire extinguishing equipment leaks at a constant rate for an average equipment lifetime, as shown in the equation below. In streaming systems, non-halon emissions are assumed to be 3.5 percent of all chemical in use in each year, while in flooding systems 2.5 percent of the installed base of chemical is assumed to leak annually. Halon systems are assumed to leak at higher rates. The equation is applied for a single year, accounting for all fire protection equipment in operation in that year. Each fire protection agent is modeled separately. In the Vintaging Model, streaming applications have a 12-year lifetime and flooding applications have a 20-year lifetime.

$$E_j = r \times \sum Q_{C_{j+i}} \text{ for } i=1 \rightarrow k$$

where:

- E* = Emissions. Total emissions of a specific chemical in year *j* for streaming fire extinguishing equipment, by weight.
- r* = Percent Released. The percentage of the total chemical in operation that is released to the atmosphere.
- Q_c* = Quantity of Chemical. Total amount of a specific chemical used in new fire extinguishing equipment in a given year, *j-i+1*, by weight.
- i* = Counter, runs from 1 to lifetime (*k*).

j = Year of emission.

k = Lifetime. The average lifetime of the equipment.

Transition Assumptions

Transition assumptions and growth rates for these two fire extinguishing types are presented in Table A-173.

Table A-173: Fire Extinguishing Market Transition Assumptions

| Initial Market Segment | Primary Substitute | | | | Secondary Substitute | | | | Growth Rate |
|-------------------------|--------------------------------|------------|---|----------------------------|----------------------|------------|---|----------------------------|-------------|
| | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | |
| Flooding Agents | | | | | | | | | |
| Halon-1301 | Halon-1301* | 1994 | 1994 | 4% | Unknown | | | | 2.2% |
| | HFC-23 | 1994 | 1999 | 0.2% | None | | | | |
| | HFC-227ea | 1994 | 1999 | 18% | FK-5-1-12 | 2003 | 2010 | 10% | |
| | Non-ODP/GWP | 1994 | 1994 | 46% | HFC-125 | 2001 | 2008 | 10% | |
| | Non-ODP/GWP | 1995 | 2034 | 10% | FK-5-1-12 | 2003 | 2010 | 7% | |
| | Non-ODP/GWP | 1998 | 2027 | 10% | None | | | | |
| | C ₄ F ₁₀ | 1994 | 1999 | 1% | FK-5-1-12 | 2003 | 2003 | 100% | |
| | HFC-125 | 1997 | 2006 | 11% | None | | | | |
| Streaming Agents | | | | | | | | | |
| Halon-1211 | Halon-1211* | 1992 | 1992 | 5% | Unknown | | | | 3.0% |
| | HFC-236fa | 1997 | 1999 | 3% | None | | | | |
| | Halotron | 1994 | 1995 | 0.1% | None | | | | |
| | Halotron | 1996 | 2000 | 5.4% | Non-ODP/GWP | 2020 | 2020 | 56% | |
| | Non-ODP/GWP | 1993 | 1994 | 56% | None | | | | |
| | Non-ODP/GWP | 1995 | 2024 | 20% | None | | | | |
| | Non-ODP/GWP | 1999 | 2018 | 10% | None | | | | |

*Despite the 1994 consumption ban, a small percentage of new halon systems are assumed to continue to be built and filled with stockpiled or recovered supplies.

Foam Blowing

ODSs, HFCs, and other chemicals are used to produce foams, including such items as the foam insulation panels around refrigerators, insulation sprayed on buildings, etc. The chemical is used to create pockets of gas within a substrate, increasing the insulating properties of the item. Foams are given emission profiles depending on the foam type (open cell or closed cell). Open cell foams are assumed to be 100 percent emissive in the year of manufacture. Closed cell foams are assumed to emit a portion of their total HFC content upon manufacture, a portion at a constant rate over the lifetime of the foam, a portion at disposal, and a portion after disposal; these portions vary by end-use.

Step 1: Calculate manufacturing emissions (open-cell and closed-cell foams)

Manufacturing emissions occur in the year of foam manufacture, and are calculated as presented in the following equation.

$$Em_j = lm \times Qc_j$$

where:

Em_j = Emissions from manufacturing. Total emissions of a specific chemical in year j due to manufacturing losses, by weight.

lm = Loss Rate. Percent of original blowing agent emitted during foam manufacture. For open-cell foams, lm is 100%.

Qc = Quantity of Chemical. Total amount of a specific chemical used to manufacture closed-cell foams in a given year.

j = Year of emission.

Step 2: Calculate lifetime emissions (closed-cell foams)

Lifetime emissions occur annually from closed-cell foams throughout the lifetime of the foam, as calculated as presented in the following equation.

$$Eu_j = lu \times \sum Qc_{j+i} \text{ for } i=1 \rightarrow k$$

where:

Eu_j = Emissions from Lifetime Losses. Total emissions of a specific chemical in year j due to lifetime losses during use, by weight.

lu = Leak Rate. Percent of original blowing agent emitted each year during lifetime use.

Qc = Quantity of Chemical. Total amount of a specific chemical used to manufacture closed-cell foams in a given year.

i = Counter, runs from 1 to lifetime (k).

j = Year of emission.

k = Lifetime. The average lifetime of foam product.

Step 3: Calculate disposal emissions (closed-cell foams)

Disposal emissions occur in the year the foam is disposed, and are calculated as presented in the following equation.

$$Ed_j = ld \times Qc_{j-k}$$

where:

Ed_j = Emissions from disposal. Total emissions of a specific chemical in year j at disposal, by weight.

ld = Loss Rate. Percent of original blowing agent emitted at disposal.

Qc = Quantity of Chemical. Total amount of a specific chemical used to manufacture closed-cell foams in a given year.

j = Year of emission.

k = Lifetime. The average lifetime of foam product.

Step 4: Calculate post-disposal emissions (closed-cell foams)

Post-disposal emissions occur in the years after the foam is disposed; for example, emissions might occur while the disposed foam is in a landfill. Currently, the only foam type assumed to have post-disposal emissions is polyurethane foam used as domestic refrigerator and freezer insulation, which is expected to continue to emit for 26 years post-disposal, calculated as presented in the following equation.

$$Ep_j = lp \times \sum Qc_{j-m} \text{ for } m=k \rightarrow k + 26$$

where:

Ep_j = Emissions from post disposal. Total post-disposal emissions of a specific chemical in year j, by weight.

lp = Leak Rate. Percent of original blowing agent emitted post disposal.

Qc = Quantity of Chemical. Total amount of a specific chemical used to manufacture closed-cell foams in a given year.

k = Lifetime. The average lifetime of foam product.

m = Counter. Runs from lifetime (k) to (k+26).

j = Year of emission.

Step 5: Calculate total emissions (open-cell and closed-cell foams)

To calculate total emissions from foams in any given year, emissions from all foam stages must be summed, as presented in the following equation.

$$E_j = Em_j + Eu_j + Ed_j + Ep_j$$

where:

E_j = Total Emissions. Total emissions of a specific chemical in year j , by weight.

Em = Emissions from manufacturing. Total emissions of a specific chemical in year j due to manufacturing losses, by weight.

Eu_j = Emissions from Lifetime Losses. Total emissions of a specific chemical in year j due to lifetime losses during use, by weight.

Ed_j = Emissions from disposal. Total emissions of a specific chemical in year j at disposal, by weight.

Ep_j = Emissions from post disposal. Total post-disposal emissions of a specific chemical in year j , by weight.

Assumptions

The Vintaging Model contains thirteen foam types, whose transition assumptions away from ODS and growth rates are presented in Table A-174. The emission profiles of these thirteen foam types are shown in Table A-175.

Table A-174: Foam Blowing Market Transition Assumptions

| Initial Market Segment | Primary Substitute | | | | Secondary Substitute | | | | Tertiary Substitute | | | | Growth Rate |

Table A-175: Emission Profile for the Foam End-Uses

| Foam End-Use | Loss at Manufacturing (%) | Annual Leakage Rate (%) | Leakage Lifetime (years) | Loss at Disposal (%) | Total ^a (%) |
|---|---------------------------|-------------------------|--------------------------|----------------------|------------------------|
| Flexible PU Foam: Slabstock Foam, Moulded Foam | 100 | 0 | 1 | 0 | 100 |
| Commercial Refrigeration | 6 | 0.25 | 15 | 90.25 | 100 |
| Rigid PU: Spray Foam | 15 | 1.5 | 56 | 1 | 100 |
| Rigid PU: Slabstock and Other | 37.5 | 0.75 | 15 | 51.25 | 100 |
| Phenolic Foam | 23 | 0.875 | 32 | 49 | 100 |
| Polyolefin Foam | 95 | 2.5 | 2 | 0 | 100 |
| Rigid PU: One Component Foam | 100 | 0 | 1 | 0 | 100 |
| XPS: Sheet Foam ^a | 40 | 2 | 25 | 0 | 90 |
| XPS: Boardstock Foam | 25 | 0.75 | 50 | 37.5 | 100 |
| Flexible PU Foam: Integral Skin Foam | 95 | 2.5 | 2 | 0 | 100 |
| Rigid PU: Domestic Refrigerator and Freezer Insulation ^a | 4 | 0.25 | 14 | 40.0 | 47.5 |
| PU and PIR Rigid: Boardstock | 6 | 1 | 50 | 44 | 100 |
| PU Sandwich Panels: Continuous and Discontinuous | 5.5 | 0.5 | 50 | 69.5 | 100 |

PIR (Polyisocyanurate)

PU (Polyurethane)

XPS (Extruded Polystyrene)

^a In general, total emissions from foam end-uses are assumed to be 100 percent, although work is underway to investigate that assumption. In the XPS Sheet/Insulation Board end-use, the source of emission rates and lifetimes did not yield 100 percent emission; it is unclear at this time whether that was intentional. In the Rigid PU Appliance Foam end-use, the source of emission rates and lifetimes did not yield 100 percent emission; the remainder is anticipated to be emitted at a rate of 2.0%/year post-disposal for the next 26 years.

Sterilization

Sterilants kill microorganisms on medical equipment and devices. The principal ODS used in this sector was a blend of 12 percent ethylene oxide (EtO) and 88 percent CFC-12, known as "12/88." In that blend, ethylene oxide sterilizes the equipment and CFC-12 is a diluent solvent to form a non-flammable blend. The sterilization sector is modeled as a single end-use. For sterilization applications, all chemicals that are used in the equipment in any given year are assumed to be emitted in that year, as shown in the following equation.

$$E_j = Qc_j$$

where:

E = Emissions. Total emissions of a specific chemical in year j from use in sterilization equipment, by weight.

Qc = Quantity of Chemical. Total quantity of a specific chemical used in sterilization equipment in year j , by weight.

j = Year of emission.

Assumptions

The Vintaging Model contains one sterilization end-use, whose transition assumptions away from ODS and growth rates are presented in Table A-176.

Table A-176: Sterilization Market Transition Assumptions

| Initial Market Segment | Primary Substitute | | | | Secondary Substitute | | | | Tertiary Substitute | | | | Growth Rate |
|------------------------|--------------------|------------|---|----------------------------|----------------------|------------|---|----------------------------|---------------------|------------|---|----------------------------|-------------|
| | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | Name of Substitute | Start Date | Date of Full Penetration in New Equipment | Maximum Market Penetration | |
| 12/88 | EtO | 1994 | 1995 | 95% | None | | | | | | | | 2.0% |
| | Non-ODP/GWP | 1994 | 1995 | 1% | None | | | | | | | | |
| | HCFC/EtO Blends | 1993 | 1994 | 4% | Non-ODP/GWP | 2010 | 2010 | 100% | None | | | | |

Model Output

By repeating these calculations for each year, the Vintaging Model creates annual profiles of use and emissions for ODS and ODS substitutes. The results can be shown for each year in two ways: 1) on a chemical-by-chemical basis, summed across the end-uses, or 2) on an end-use or sector basis. Values for use and emissions are calculated both in metric tons and in million metric tons of CO₂ equivalents (MMT CO₂ Eq.). The conversion of metric tons of chemical to MMT CO₂ Eq. is accomplished through a linear scaling of tonnage by the global warming potential (GWP) of each chemical.

Throughout its development, the Vintaging Model has undergone annual modifications. As new or more accurate information becomes available, the model is adjusted in such a way that both past and future emission estimates are often altered.

Bank of ODS and ODS Substitutes

The bank of an ODS or an ODS substitute is “the cumulative difference between the chemical that has been consumed in an application or sub-application and that which has already been released” (IPCC 2006). For any given year, the bank is equal to the previous year’s bank, less the chemical in equipment disposed of during the year, plus chemical in new equipment entering the market during that year, less the amount emitted but not replaced, plus the amount added to replace chemical emitted prior to the given year, as shown in the following equation:

$$BC_j = BC_{j-1} - Qd_j + Qp_j + E_e - Q_r$$

where:

| | | |
|--------|---|--|
| BC_j | = | Bank of Chemical. Total bank of a specific chemical in year j , by weight. |
| Qd_j | = | Quantity of Chemical in Equipment Disposed. Total quantity of a specific chemical in equipment disposed of in year j , by weight. |
| Qp_j | = | Quantity of Chemical Penetrating the Market. Total quantity of a specific chemical that is entering the market in year j , by weight. |
| E_e | = | Emissions of Chemical Not Replaced. Total quantity of a specific chemical that is emitted during year j but is not replaced in that year. The Vintaging Model assumes all chemical emitted from refrigeration, air conditioning and fire extinguishing equipment is replaced in the year it is emitted, hence this term is zero for all sectors except foam blowing. |
| Q_r | = | Chemical Replacing Previous Year’s Emissions. Total quantity of a specific chemical that is used to replace emissions that occurred prior to year j . The Vintaging Model assumes all chemical emitted from refrigeration, air conditioning and fire extinguishing equipment is replaced in the year it is emitted, hence this term is zero for all sectors. |
| j | = | Year of emission. |

Table A-177 provides the bank for ODS and ODS substitutes by chemical grouping in metric tons (MT) for 1990 to 2014.

Table A-177. Banks of ODS and ODS Substitutes, 1990-2014 (MT)

| Year | CFC | HCFC | HFC |
|------|---------|-----------|---------|
| 1990 | 699,504 | 281,676 | 872 |
| 1995 | 792,162 | 495,808 | 48,449 |
| 2000 | 667,205 | 921,390 | 181,369 |

Subject: RE: Intermittent-bleed pneumatic controllers
Date: Monday, September 22, 2014 at 8:39:34 AM Eastern Daylight Time
From: Mark D. Smith
To: David McCabe

Yes David. That is correct. We require all controllers to emit less than 6 scf/hr whether the controllers are continuous or intermittent bleed devices.

Subject: Intermittent-bleed pneumatic controllers

Hi Mark,

Thanks for discussing how the Wyoming Oil and Gas Production Air Permitting Guidance works with me yesterday.

As I understand it, Wyoming's P-BACT permitting requirements do not allow pneumatic controllers at new or modified facilities to emit more than 6 scfh, whether the controllers are continuous-bleed or intermittent bleed. Is that correct?

Best,

David

submitted via email to a-and-r-docket@epa.gov

**Ref.: Proposed Rulemaking – Oil and Gas Sector Regulations
Standards of Performance for New Stationary Sources: Oil and Natural Gas
Production and Natural Gas Transmission and Distribution;
National Emission Standards for Hazardous Air Pollutants from Oil and Natural
Gas Production Facilities; and
National Emission Standards for Hazardous Air Pollutants from Natural Gas
Transmission and Storage Facilities
(Docket ID No. EPA-HQ-OAR-2010-0505)**

Assistant Administrator McCarthy:

The American Petroleum Institute (API) is pleased to provide comment on the proposed rulemakings that will modify the New Source Performance Standards (NSPS) 40 CFR Part 60 Subparts KKK and LLL, create a new Subpart OOOO, and modify Part 63 National Emission Standards for Hazardous Air Pollutants (NESHAP) Subparts HH and HHH as a result of EPA's sector-based rulemaking for the oil and natural gas (O&G) industry. API represents more than 480 oil and natural gas companies, leaders of a technology-driven industry that supplies most of America's energy, supports 9.2 million U.S. jobs and 7.7 percent of the U.S. economy, and delivers more than \$86 million a day in revenue to our government. Most of our members will be directly impacted by these proposed regulations.

First, API commends the efforts that your staff has made to learn about the oil and natural gas production industry. With respect to the proposal, we have limited concern with the selected control technologies, which are emission control techniques developed by our industry over many years of operating experience. However, we are concerned about the broad applicability and the one-size-fits-all approach of the proposed rule to regulating an industry that varies greatly in the type, size and complexity of operations.

The following are critical concerns with the proposed rules:

- The proposed rule expands listed categories and applies NSPS to new affected facilities in unique and unprecedented ways that are outside the Agency's authority. There are NSPS sources included in the proposed rule that emit little to no regulated pollutant or are construction-related emissions sources that are temporary (i.e., not routine), neither of which should be included in the rule.
- EPA's schedule will not allow adequate time to review and analyze all stakeholder comments, develop necessary revisions to the rules, and complete internal and interagency reviews. Four months between close of the comment period and promulgation of a final rule is unrealistic and unacceptable for these significant rules impacting an industry as large and vital to the U.S. economy as the oil and gas industry.
- The equipment prescribed to conduct Reduced Emission Completions will simply not be available in time to comply with the current final rule schedule. We believe it will take years to manufacture sufficient specialized equipment and adequately train operators how to safely conduct these operations.
- EPA cost analyses are based on "average model facilities" that do not represent all equipment and compliance costs and, without proper variability analysis to represent the wide variety of operations in the O&G industry, fail to identify when the controls are no longer economic.
- The system of notifications, monitoring, recordkeeping, performance testing and reporting requirements for compliance assurance are overly burdensome for the small and/or temporary affected facilities that EPA is regulating. This is a waste of time and resources for both industry and the EPA.
- EPA has expanded an already conservative risk analysis to include "MACT allowable" emissions and wrongly concluded that additional requirements are needed. The modeling of *actual* emissions under the existing rules indicates that the public is protected with an ample margin of safety.

Therefore, API urges the Agency to:

1. Consult with State air pollution control agency representatives on the expansion of the source category for the new and unique affected facilities as required by CAA §111(f)(3) and re-propose certain new affected source regulations as necessary.
2. Extend the final rule deadline one year to April 5, 2013 to adequately address stakeholder comments.
3. Allow sufficient compliance time (varying from 60 days to at least 2 years) to comply with the equipment specific NSPS requirements following promulgation of the final rule (see technical comments).

4. Revise the economic analyses to include all compliance cost and operational variables. These revised analyses should be used to limit the emission controls applicability to operations where they are economically justifiable.
5. Significantly reduce the compliance assurance complexity and burden by replacing the general provisions notification, recordkeeping and reporting requirements with specific requirements in NSPS, Subpart OOOO. Monitoring and performance testing requirements should be appropriate for small, remote and dispersed sites in the O&G industry.
6. Maintain the existing NESHAP HH and HHH to reflect the low risk posed to the public from these sources.

To facilitate the review of our comments, we have summarized critical issues with the proposed rules in an Executive Summary followed by detailed technical comments. Additionally, we have attached a document with the regulatory language marked up to show how our comments could be accommodated in the regulatory text (Attachment C). Finally, additional attachments are included to document certain points made in our detailed comments.

API remains committed to helping the Agency promulgate a cost effective, clear regulation to reduce the impact of our operations on air quality and look forward to the opportunity to meet and discuss these comments with you and your staff.

We appreciate your consideration of our concerns. If you have any questions, please contact Matt Todd (202-682-8319; todd@api.org) or me.

Sincerely,

/s/

Howard J. Feldman

EXECUTIVE SUMMARY

As detailed in our comments, API has numerous concerns with EPA's proposed rulemaking for the Oil and Gas (O&G) sector. However, the control technologies selected in the proposed O&G New Source Performance Standard (NSPS) and revisions to the National Emissions Standards for Hazardous Air Pollutants (NESHAP) O&G regulations are not what cause the concerns. Instead, API's concerns come from the broad applicability of the proposed rule and the one-size-fits-all approach to regulating an industry that varies greatly in the type, size and complexity of operations. EPA has supported its regulations using economic studies on "average model facilities" without determining whether the resulting control requirements are appropriate for the entire range of sources included in the source category. The proposed rule applies NSPS in unique and unprecedented ways to categories and equipment not previously listed, using unsound legal justification and without consulting with the States as required by the CAA. The system of notifications, monitoring, recordkeeping, performance testing and reporting requirements are more burdensome than justified for the small and/or temporarily affected facilities that EPA is regulating. Finally, API is concerned with the pace of this rulemaking. Seven months between the published proposed rule and promulgating the final rule is an unrealistic schedule for issuing a complex rule with the concerns identified that is supposed to cover an industry as large as the O&G production industry. EPA has only four months to review all the submitted comments, analyze them, make appropriate revisions, and complete the necessary internal and interagency reviews.

Listed below in priority order are API's top issues with the proposed O&G rules. API has included a solution to address the issue raised and the rationale behind the solution, with a reference to the detailed comments.

Natural Gas is Not a Surrogate for Volatile Organic Compounds (VOC) and Regulating Low VOC Natural Gas is not Cost Effective and is Equivalent to Regulating Greenhouse Gases (GHG).

Issue – The proposed rule purports to not regulate GHGs, but rather to regulate emissions of natural gas. Many natural gas streams produced today contain little or no VOCs.

Solution – Restrict final rule applicability to streams that have a minimum VOC content to assure that NSPS are cost effective as required by the Clean Air Act.

Rationale – EPA calculated cost effectiveness based on natural gas that is 18% by weight VOC. The cost effectiveness (in dollars per ton of VOC reduced) approaches infinity as VOC content approaches zero. EPA must economically justify its regulations for not just for the average "model" facility, but for reasonably expected variations.

Economic Analysis of Emission Control Strategies Must Be Representative of Industry's Operations.

Issue – The "average model facilities" that EPA has used in the economic analysis do not represent the great variation seen across the U.S.

Solution – The applicability of the proposed regulations must be narrowed to operations in which the proposed emission control practices can be applied in a cost effective manner.

Rationale – Current economic analyses must include the full variety of conditions (i.e., VOC content) in the O&G industry for all of the costs of compliance with the proposed rule. API found

the cost effectiveness for tanks to vary from \$5,271/ton of VOC to \$1,519,667/ton of VOC (Section 16.6.6., Table 3). See Sections 4 & 5.

Expansion of NSPS Source Category is Arbitrary and is Not Allowed Without Consulting with States.

Issue – 42 USC 7411(f) requires consultation with State Governors air pollution control agencies before expanding the listed categories or promulgating new NSPS.

Solution – EPA should conduct the required consultations with the States with significant the oil and gas transportation and distribution sectors and revise the requirements for reduced emission completions requirements, storage vessels, pneumatic controllers, and compressors in NSPS, Subpart OOOO.

Rationale – The uniqueness of the new affected facilities (very small in cost and/or quantity of emissions or the non-routine, temporary construction nature) being justify consultation with states. States will see a massive increase in permitting burden with little to no environmental benefit. See Section 2.

Compliance Assurance Requirements for NSPS Are Overly Burdensome.

Issue – The notifications, monitoring, recordkeeping, testing and reporting requirements for a major source NESHAP regulation are overly burdensome for NSPS Subpart OOOO.

Solution – Specific O&G industry appropriate notification, recordkeeping, reporting, and performance testing sections requirements should be included in Subpart OOOO.

Rationale – The remote, dispersed and unmanned nature of facilities that lack electrical power, make the requirements logistically impractical, technically difficult and uneconomic. The use of NESHAP compliance requirements for storage vessels is confusing and unjustifiably stringent for NSPS. Comment Section 8.

Availability of Equipment and Experienced Operators for Reduced Emission Completions (REC) Requires Delayed Compliance Date.

Issue – The necessary equipment to comply with the REC requirements is currently not available and will require time to manufacture. Also, industry will have a shortage of experienced contractors or staff for safely doing “reduced emissions completions”.

Solution – Due to the limited availability of appropriate and safe equipment and experienced and trained personnel to perform REC's, API requests that compliance with the reduced emissions completions portion of the rule be delayed for 2 years to allow for manufacturing of equipment and training of operators. During the time period from the effective date to two years after the effective date, only the use of completions combustion devices should be required for reducing emissions.

Rationale - The proposed requirement to implement RECs immediately upon the effective date of the final rule does not constitute “the best system for emission reduction.” Comment Section 15.4

Legality of Reduced Emissions Completions Requirements.

Issue – Flowback immediately following hydraulic fracturing stimulation during well completions is not part of the normal operation of a well but is a construction-related activity that must be

accomplished for a well to begin producing and thereafter engage in normal operations. The proposal to regulate construction-related emissions is a significant and substantive departure in the Agency's prior interpretation and implementation of § 111.

Solution – EPA should remove the requirements for reduced emissions completions from the proposed regulation. If EPA chooses to proceed in regulating flowback immediately following hydraulic fracturing stimulation, EPA should repropose the requirements and include sufficient justification for their departure from not regulating construction-related emissions and present the legal basis for regulating non-routine emissions.

Rationale – EPA's failure to explain why the departure from not regulating construction-related emissions is justified and failure to present the legal basis for regulating non-routine emissions is arbitrary and capricious and plainly violates EPA's obligation to clearly set forth "the major legal interpretations and policy considerations underlying the proposed rule." CAA § 307(d)(3)(C). Comment Section 15.1.

EPA Should Not Prescribe the Equipment Required for Reduced Emissions Completions (REC).

Issue –API is requesting that the rule not require the use of specific equipment. The final rule should allow options to use other emission reduction techniques, not require routing liquids to a storage vessel, and recognize commercial viability.

Solution – API proposes that the rule text be greatly simplified to provide objectives for the control of VOCs, rather than specify methods.

Rationale – Section 111 of the Clean Air Act establishes a strong presumption against prescribing control technologies and section 111(h) allows work practice standards where "it is not feasible to prescribe or enforce a standard of performance." An underlying presumption of section 111 is that a standard of performance should allow the affected facility flexibility to meet a standard, rather than be required to use specific controls. Comment Section 15.2

Applicability for Storage Vessels [NSPS OOOO & NESHAP HH] Must Be Clarified.

Issue – Both NSPS OOOO and NESHAP HH, as proposed, are unnecessarily vague in specifying the storage vessels to which these rules apply.

Solution – Define storage vessels and specify applicability so as to limit applicability to:

- Storage vessels that are located in the oil and natural gas production sector,
- Which are continuously on site for more than 180 days,
- Storing crude oil or condensate,
- With emissions greater than 12 tpy [NSPS OOOO].

Rationale – EPA has a responsibility to clearly specify the sources to which a given rule applies. See Sections 16.1–16.6.

Allow 90 Days to Implement Storage Vessels [NSPS OOOO] Controls at New Production Sites.

Issue – A period of time is necessary to determine whether a new production site will flow at a rate that will trigger the control requirements for storage vessels, and then an additional period of time is necessary to install those controls.

Solution – Specify that applicability shall be determined on the basis of the first 30 days of production and, for sites that trigger controls for storage vessels, compliance shall be achieved within 60 days thereafter.

Rationale – If EPA fails to specify a reasonable compliance period, then storage vessels would potentially need to be equipped with controls at every new production site – just in case the production characteristics might trigger the control requirements. This would clearly result in installing controls at many sites for which controls would eventually be shown to have been neither required nor cost effective. See Section 16.7.

Control Device Requirements for Storage Vessels [NSPS OOOO & NESHAP HH] Must Be Clarified & Reasonable.

Issue – When vapors are required to be routed to a control device, the proposed requirements for the control device are unreasonably complicated and burdensome. For example, there are more than 50 recordkeeping requirements for storage vessels routed to a control device.

Solution – Revise the requirements for control devices for simplification and for suitability to production field operations, including the following:

- Include the “manufacturer certification” option for performance demonstration in NSPS OOOO (confirm the availability of this NESHAP HH option to NSPS OOOO),
- Specify requirements appropriate to an NSPS rule for VOCs in OOOO, rather than invoking the MACT requirements for HAPs from HH,
- Allow electronic ignition for flares, rather than requiring that a pilot flame is present at all times,
- Specify monitoring requirements that are appropriate for remote facilities that may not have an available power source,
- Limit reporting requirements to semi-annual reporting of exceedances, and
- Simplify the recordkeeping requirements.

Rationale – EPA has a responsibility to specify control requirements that are reasonable for the type of facilities found in a given source category. The proposed rule provisions fail to account for the remoteness of production field facilities, the types of technologies that would be most suitable for these facilities, or the volume of unnecessary paperwork that would be required. See Sections 16.10–16.12.

Regulating Small Sources or Construction Activities Using NSPS Is Not Justified by Cost Effectiveness or Legal Precedent.

Issue – EPA has historically regulated emissions during normal operations of a process unit (i.e., a tank, boiler, gas processing plant, etc.). The proposed rule regulate individual components (e.g., a single pneumatic controller) of a process control system and temporary construction emissions (e.g., hydraulic fracturing flowback emissions requiring REC) that have not previously been regulated by NSPS.

Solution – Subpart OOOO regulations for pneumatic controllers, compressors and REC should be revised so the source categories reflect sources that “contribute significantly” to the endangerment of “human health or the environment.”

Rationale – The NSPS general provisions and compliance assurance requirements proposed are not appropriate for the unique emission sources proposed in Subpart OOOO. See Section 2.

Definitions Do Not Represent the Activities of the Oil and Gas Industry.

Issue – The proposed definitions are inconsistent with the way they are used within the O&G industry activities, leading to confusion of which activities are regulated.

Solution – New definitions and revisions for existing definitions have been suggested that accurately describe O&G activities.

Rationale – A common understanding between the agency and regulatory communities of terms is required for a final rule that is clear and enforceable. See Section 6.

Best System of Emission Reduction Must Be Currently Available To Industry.

Issue – EPA has proposed BSER that is not currently available in sufficient quantities for compliance with the proposed rule (especially REC equipment and combustors).

Solution – EPA should phase in the proposed requirements to provide equipment manufacturers and the O&G industry sufficient time to obtain equipment required.

Rationale – Less than 25% of REC equipment needed to comply with the proposal is available. It will take two to seven years to manufacture the equipment. Sufficient combustors that have been tested by the manufacturer to meet the proposed rule requirements are not currently available. Comment Section 7.

Ability to Combust or Vent During Completions Is Needed.

Issue – Paragraphs 60.5375(a)(1) and (2) require “routing recoverable liquids to storage vessels and routing the recovered gas into a gathering line or collection system” and “all salable quality gas must be routed to the gas gathering line as soon as practicable.” API requests more clarity in the rule to address the many operational and safety constraints to routing all salable gas to gathering line

Solution – API proposes that the rule text be greatly simplified to provide objectives for the control of VOCs, rather than specify methods.

Rationale – Section 111 of the Clean Air Act establishes a strong presumption against prescribing control technologies and section 111(h) allows work practice standards where “it is not feasible to prescribe or enforce a standard of performance.” Comment Section 15.3

Relocation of an Existing Compressor Should Not Trigger NSPS Applicability.

Issue – EPA stating that a compressor is considered to have commenced construction on the date the compressor is installed at the facility.

Solution – Remove the last sentence in the applicability sections for centrifugal and reciprocating compressors.

Rationale – The sentence of concern is inconsistent with historical EPA decisions for other NSPS and Applicability Determination Index determinations. Comment Section 18.1.

Pneumatic Controller Affected Facility Should be Redefined as a Process Unit Affected Facility.

Issue – Pneumatic controllers are numerous, small, component level, and inexpensive pieces of equipment for which minor expenditures for routine maintenance, repair, or replacement may trigger

a reconstruction determination setting up the likelihood for unnecessary onerous recordkeeping and tens or hundreds of wasteful and time consuming annual reports per operator.

Solution – Redefine affected facility to “Continuous bleed gas-driven pneumatically controlled process unit” to include all the component parts of a pneumatic control system at a site. Further limiting to “continuous bleed gas-driven” restricts applicable controllers to only those with a weak stream bleed rate of regulated VOC in accordance with the way EPA correctly defines high and low bleed controllers.

Rationale – EPA uses a process unit approach in LDAR to prevent modification and reconstruction triggers for RMRR of fugitive components such as valves. Also, EPA set precedent for this approach in the preamble discussion of the NSPS Subpart YYY proposal [59 FR 46780, 09/15/94]. See Section 17.4.

Revising the MACT Floor Is Not Authorized by the CAA.

Issue – EPA set the MACT floor in the June 17, 1999 rulemaking. The CAA does not give EPA unfettered authority to revise the MACT floor as it desires.

Solution – EPA should not revise the applicability criteria or the control standards for either storage vessels or triethylene glycol dehydrators.

Rationale – CAA 112(d)(2)-(3) allows EPA to set the MACT floor only once. This MACT floor decision was not challenged or overturned by the Court. Revising this MACT floor due to the successful challenge of another category is both inappropriate and unauthorized by the CAA. CAA 112(d)(6) only authorizes the review of improvements in control technology for the revision of the MACT standard. See Comment Section 11.

Removal of 0.9 Mg/yr Benzene Alternative Emission Limitation is Based on Flawed Analysis.

Issue –For subparts HH and HHH, the EPA proposed to remove the 0.9 Mg/yr benzene alternative emission limitation for large dehydrators. In both subparts, there were errors in the analyses. For example, EPA estimated that the cancer MIR based on MACT allowable emissions was 400-in-1 million for subpart HH. Correction of the analysis results in a cancer MIR that is clearly in the range that EPA considers acceptable.

Solution – EPA must correct the errors in the analysis, which will lead to a different conclusion regarding the 0.9 Mg/yr benzene alternative for large dehydrators.

Rationale – Correction of the errors in the analysis result in risk-based outcomes that do not support EPA's proposed decision to eliminate the 0.9 Mg/yr benzene alternative. See Section 20.

Proposed Standards for Small Dehydrators are Unnecessary.

Issue – EPA identified small dehydrators as unregulated emission sources despite the fact that they are effectively subject to standards. In addition, EPA's proposed standards for both subparts HH and HHH are based on faulty MACT floor analyses.

Solution – Eliminate the proposed requirements for small dehydrators. Alternatively, if EPA elects to promulgate standards for small dehydrators, it must establish subcategories that appropriately account for fundamental differences among small dehydrators in determining the "classes, types, and sizes" of sources to be regulated and determine MACT floors for the subcategories.

Rationale – The dual use of 0.9 Mg/yr benzene as criteria for separating small and large dehydrators and as an emission limitation for large dehydrators effectively creates a situation where all dehydrators are subject to standards. This is consistent with the original MACT floor determination for dehydrators, which did not distinguish between dehydrator subcategories. Therefore, EPA should not promulgate any standards for small dehydrators.

If EPA does elect to move forward with promulgating standards for small dehydrators, EPA must take into account fundamental differences in dehydrators, most importantly the naturally occurring concentration of HAP in the gas stream, create appropriate subcategories, and determine MACT floors for each subcategory. See Section 20.

Equipment Leaks – Lowering the Leak Definition from 10,000 ppm to 500 ppm.

Issue – EPA proposes to lower the leak definition for valves at natural gas processing plants from 10,000 ppm to 500 ppm, which would not lead to any substantial VOC emissions reductions.

Solution – The leak definition for valves at gas plants should remain at 10,000 ppm. In lieu of imposition of 500 ppm leak definition, API recommends the valve LDAR program at gas plants includes the following two elements: 1) once meeting the requirement of no leak detected during monthly monitoring initially, all valves are, and continue to be, monitored on a quarterly basis with no skip periods ; and 2) the owner or operator would identify "chronic leaks" (i.e., valves that leak above 10,000 ppm in three of any consecutive four quarters), and designate these valves for refurbishing or replacement during the next process unit shutdown.

Rationale – EPA overestimated valve control-effectiveness, which is confirmed by the data provided by API member companies. The proposed leak definition for valves would be burdensome without achieving the VOC reduction as claimed by EPA. See Sections 19.1.1 and 19.1.6.

Equipment Leaks – Imposition of a Connector Program.

Issue – EPA proposes to require a leak detection and repair (LDAR) program for connectors at natural gas processing plants, with a leak definition of 500 ppm, while the existing rule only requires auditory, visual and olfactory (AVO) inspections.

Solution – API recommends that no new LDAR program for connectors be imposed at natural gas processing plants, and that connectors continue to be subject to the AVO requirements.

Rationale – EPA overestimated the emissions reduction and underestimated the cost of the proposed connector LDAR program, resulting in an overly inflated cost-effectiveness estimation. See Sections 19.1.2 and 19.1.6.

INTRODUCTION

On August 23, 2011, the US EPA proposed to modify the New Source Performance Standards (NSPS) 40 CFR Part 60 Subparts KKK and LLL, create a new Subpart OOOO, and modify Part 63 National Emission Standards for Hazardous Air Pollutants (NESHAP) Subparts HH and HHH. API has prepared the following detailed comments in response to this proposed sector-based rulemaking for the oil and natural gas (O&G) industry.

API appreciates the efforts that EPA has made to learn about the oil and natural gas production industry (O&G industry) and taking the time to tour production fields and request information on the industry. API was pleased to be able to offer presentations and white papers on various aspects of the O&G industry. Copies of these presentations and white papers have been included in Attachment A for your convenience.

EPA has requested comments on a wide variety of issues. API has tried to supply information on these requests throughout the document. Attachment B is provided to cross reference these request with sections where this information is located. API regrets that time during the comment period was insufficient to gather the type or quantity of information needed to properly answer EPA's questions. However, much of the information is simply not available. Surveys, studies and research would have to be commissioned to provide the information requested. EPA should have commissioned these events during the pre-proposal stage of the rulemaking. EPA simply did not invest the time and resources for a rulemaking of this magnitude.

Finally, EPA has requested during meetings that solutions be provided for the concerns being raised in these comments and that revised regulatory text be suggested to implement these solutions. Attachment C provides revised regulatory text in redline/strikeout format for this purpose with reference to the sections that discuss these revisions. While Attachment C has been prepared as a summary of API's suggested edits to the rule language, the markups shown in these comments should be taken as our preferred position in the event of any differences between these comments and Attachment C.

API remains committed to helping the agency promulgate a cost effective, clear regulation to reduce the impact of our operations on air quality and look forward to the opportunity to meet and discuss these comments soon.

GENERAL COMMENTS

1. EXTENSION OF COMMENT PERIOD AND FINAL RULE DEADLINE

1.1. Extension of Comment Period to 90 Days Remains Insufficient for Adequate Comments

API continues to believe that industry needed a full 120 days to provide an adequate set of comments to a rulemaking as broad, high impact, precedent setting, and complex as these proposed rules. However, API appreciates the additional 30 day extension that EPA provided. API has developed as complete a set of comments as time allowed. Much of the information EPA requested, as well as additional information API wanted to provide, is not included because of time limitations.

1.2. Insufficient Time for Agency to Review Comments and Revise and Finalize Rule

API also continues to believe that the revised final rule deadline of April 3, 2012 needs to be delayed a full year to allow EPA sufficient time to fully review and give reasoned responses to the comments as required by the Administrative Procedures Act (APA). Given the complexity of the issues, the many competing demands on Agency resources, and the time that will be needed to complete interagency review of the draft final rules, the agency is fully justified in extending the final rule promulgation date to February 28, 2013.

1.3. Consent Decree Does Not Require Promulgation of Rules for New Affected Facilities

It is worth noting in this regard that the settlement agreement itself does not dictate that EPA issue a final rule that is commensurate with the scope of the proposed rule. Indeed, EPA's proposal goes well beyond the scope even contemplated by the settlement agreement. With respect to Section 112, the settlement agreement provides that EPA was to propose and shall take final action under Sections 112(d)(6) and 112(f)(2). With respect to Section 111, the settlement agreement provides that EPA shall sign one or a combination of the following for the NSPS Subparts KKK and LLL:

- (a) a proposed rule containing revisions to the NSPS (in whole or in part) under CAA section 111(b)(1)(B); and/or
- (b) a proposed determination not to revise the NSPS (in whole or in part) under CAA section 111(b)(1)(B); and/or
- (c) a proposed or final determination not to review the NSPS (in whole or in part) under CAA section 111(b)(1)(B).

For final action, it commits EPA to "sign one or a combination of the following for NSPS Subparts KKK and LLL:

- (a) a final rule containing revisions to the NSPS (in whole or in part) under CAA section 111(b)(1)(B); and/or

- (b) a final determination not to revise the NSPS (in whole or in part) under CAA section 111(b)(1)(B); and/or
- (c) a final determination not to review the NSPS (in whole or in part) under CAA section 111(b)(1)(B).”

API believes that many of the proposed rule requirements have been inadequately proposed (especially the expansion of the Oil and Natural Gas Sector and addition of affected facilities) and a supplemental proposal is needed. If EPA cannot extend the comment period and final rule deadline as discussed above, then API recommends that EPA separate the portions of the rule required by the consent decree from the voluntary additions to the rulemaking, so appropriate consideration can be given to these unique provisions.

2. EXPANSION OF NSPS SOURCE CATEGORY

To date, EPA has established only two NSPS for the oil and gas production sector – Subpart KKK, applicable to VOC equipment leaks at gas processing plants, and Subpart LLL, applicable to sulfur dioxide emissions from gas processing plants. In the proposal, EPA would expand its NSPS regulations for the oil and gas production sector to include requirements for numerous additional source types; including completions of hydraulically fractured gas wells, VOC standards for gas-driven pneumatic devices, standards for centrifugal and reciprocating compressors, and tank standards. 76 Fed. Reg. at 52745-52746. These standards would apply throughout the sector, from production wells, to gas processing, to transmission to local distribution systems.

EPA asserts that it is authorized to expand the scope of the current rules because it “believe[s] that the currently listed Oil and Natural Gas source category covers all operations in this industry (*i.e.*, production, processing, transmission, storage and distribution).” *Id.* at 52745. Alternatively, EPA declares, “To the extent there are oil and gas operations not covered by the currently listed Oil and Natural Gas source category, pursuant to CAA section 111(b), we hereby modify the category list to include all operations in the oil and natural gas sector.” *Id.* As justification for such a modification, EPA explains only that “Section 111(b) of the CAA gives the EPA broad authority and discretion to list and establish NSPS for a category that, in the Administrator’s judgment, causes or contributes significantly to air pollution which may reasonably be anticipated to endanger public health or welfare” and, pursuant to this authority, “we are modifying the source category list to include any oil and gas operation not covered by the current listing and evaluating emissions from all oil and gas operation at the same time.” *Id.*

EPA is wrong on both counts.

2.1. Current source category does not cover all operations in this industry

As to the scope of the original listing of the “crude oil and natural gas production” source category, EPA made it clear that the category was listed to satisfy CAA § 111(f). 44 Fed. Reg. 49222 (Aug. 21, 1979). Section 111(f) required EPA to create a list of “categories of major stationary sources” that had not been listed as of August 7, 1977 under § 111(b)(1)(A) and to promulgate NSPSs for the listed categories according to a set schedule. EPA explained in the listing rule that its list included “major source categories,” which EPA defined to include “those categories for which an average size plant has the potential to emit 100 tons or more per year of any one pollutant.” *Id.*

While EPA provided no further explanation in its original listing decision as to what facilities it intended to regulate under the “crude oil and natural gas production” source category, there can be no doubt that the category originally included “stationary sources” (*i.e.*, “plants”) that typically have a potential to emit at least 100 tons per year of a regulated pollutant. This communicates two important limitations on the original listing decision. First, EPA was focused on discrete “plants” or “stationary sources.” Second, EPA was focused on large emitting plants or stationary sources.

As a result, the original listing decision cannot reasonably be interpreted to extend to the types of sources EPA seeks to regulate in the proposal. For example, typical production wells do not have the potential to emit major amounts of any regulated pollutant. Thus, they could not reasonably have been considered major-emitting plants at the time of the original listing decision. The same is true for compressors, tanks, and pneumatic devices scattered along gathering and transmission lines. EPA could not plausibly have considered such transportation and distribution sources to be major emitting plants.

Nevertheless, EPA claims that the source category should be construed broadly because, “In the [1979] notice that listed source categories (including Oil and Natural Gas) for promulgation of NSPS, we noted that there were discrepancies between the source category names on the list and those in the background document, and we clarified our intent to address all sources under an industry heading at the same time.” 76 Fed. Reg. at 52745. But, that is not what the Agency said in 1979. Rather, EPA explained in 1979 that the discrepancies were “a result of aggregation of sources which had been subcategorized for size classification and priority ranking analysis in the background document” and that “all source categories under a generic industry heading, such as non-metallic mineral processing, will be evaluated at the same time, although this does not necessarily imply that a single standard would apply to all sources within the listed category.” 44 Fed. Reg. at 49225. Nothing in this explanation suggests that EPA intended to regulate non-major sources under § 111 by “aggregating” them with major sources. In context, EPA was simply saying that categories or subcategories of stationary sources that otherwise met the listing criteria (*i.e.*, plants that typically are major emitting) were sometimes lumped together into a single category for listing purposes. Thus, EPA’s “aggregation” decisions do not lend support to an expansive interpretation of the “crude oil and natural gas production” source category.

It is telling that, when the Agency eventually established NSPS for this source category, it decided to only regulate natural gas processing plants – the closest thing to a major-emitting plant that can be found in this sector. Thus, EPA’s prior actions speak louder than its words in the current proposal.

2.2. EPA is not Authorized to Arbitrarily Expand a Source Category

EPA’s claim that it is authorized to expand the scope of the original source category “to include any oil and gas operation not covered by the current listing and evaluat[e] emissions from all oil and gas operation at the same time” is equally unavailing. EPA is authorized to regulate “a category” of stationary sources under § 111 only if, in the judgment of the Administrator, the category “causes, or significantly contributes to, air pollution which may reasonably be anticipated to endanger public health or welfare.” CAA § 111(b)(1)(A). For now, the “category” of stationary sources that EPA regulates in the oil and gas sector consists of natural gas processing plants. The additional types of

sources that EPA seeks to regulate in the proposal are distinctly different types of stationary sources than gas processing plants. For example, an oil or gas production well is a stationary source, but it clearly is not a processing plant. Similarly, compressors, tanks, and pneumatic devices are stationary sources, but they also are plainly not processing plants. Such sources might be *part* of a gas processing plant (and, therefore, possibly susceptible to regulation as part of a gas processing plant), but if they are not part of a gas processing plant, they constitute a different kind of stationary source.

Thus, EPA is authorized to regulate these additional source types if and only if it: (1) defines a discrete “category” of stationary sources; and (2) determines that emissions from the source category cause or significantly contribute to endangerment to health or the environment. Since EPA has not defined such additional source categories or made such endangerment/contribution findings, EPA is not authorized to “expand” the scope of the “crude oil and natural gas production” source category.

Even if EPA had such authority, it would be arbitrary and unreasonable to expand the source category as proposed. To begin, EPA makes no effort whatsoever to demonstrate that emissions from the additionally-regulated sources cause or contribute to endangerment to health or the environment. Instead, the Agency simply asserts that it may evaluate “emissions from all oil and gas operations at the same time.” 76 Fed. Reg. at 52745. This failure to investigate the key statutory listing criteria is patently arbitrary and plainly violates the § 307(d)(3) requirement to clearly set forth the basis and purpose of the proposal.

In essence, EPA appears to be arguing that, since it determined that certain types of stationary sources within an industry sector cause or significantly contribute to endangerment to health or the environment, it is free thereafter to amend the source category to include all manner of ancillary equipment and operations (regardless of the quantity of emissions) because a teaspoonful of additional emissions contributes to the previously-identified endangerment. This is not a reasonable interpretation of § 111(b)(1)(A) because such an interpretation would bestow virtually unlimited regulatory authority upon EPA – allowing EPA to evade the express listing criteria by creating loose associations of nominally related source types.

The proposal is a case in point. Oil and gas production wells are fundamentally different stationary sources than gas processing plants. Yet, EPA asserts that its long-ago decision to regulate gas processing plants under § 111 somehow enables the Agency to now regulate production wells because the wells are associated with gas processing plants by virtue of being in the same industry sector. Even worse, EPA employs the same rationale to claim authority to regulate pneumatic devices in the sector – including single devices located anywhere on a pipeline and not necessarily associated with a “plant” or “stationary source.” Guilt by association is not a reasonable interpretation of the Act and does not satisfy EPA’s threshold obligation to clearly define a category of stationary source and show that emissions from that category of sources causes or significantly contributes to endangerment to health or the environment.

Lastly, CAA § 111(f)(3) requires EPA to “consult with appropriate representatives of the Governors” prior to “promulgating any regulations under this subsection.” As explained above, EPA originally listed the “crude oil and natural gas production” source category pursuant to § 111(f)(3). Thus, EPA has a clear obligation to consult with the Governors and should do so prior to proposing the rule so that the public has an opportunity to know the views of the Governors and submit comments on the

record. EPA's failure to consult with the Governors prior to proposal is a fundamental procedural error.

2.3. Extremely Small Affected Facilities

EPA makes similar errors in asserting that single individual components (such as pneumatic devices, compressors, and tanks) and single activities (such as each well completion) constitute separate "affected facilities" under the rule. *See, e.g.*, 76 Fed. Reg. at 52746 ("We are proposing that each pneumatic device is an affected facility."). The clear purpose of this approach is to expand the universe of "new sources" that will become subject to the final rules. *See, e.g., id.* ("Accordingly, the proposed standards would apply to each newly installed pneumatic device (including replacement of an existing device)."). This proposal to finely parse the definition of affected facility in order to expand applicability of the rules is fundamentally flawed for three distinct reasons.

2.3.1. EPA Has Failed to Explain Legal Authority

First, EPA has completely failed to explain where it finds legal authority for such an approach. The closest that EPA comes is to state that individual pieces of equipment constitute an "apparatus" and to vaguely refer to "the definitions of "affected facility" and "construction" at 40 CFR 60.2." *See, e.g., id.* at 52761. This explanation is indecipherable and, thus, falls far short of EPA's obligation to include in the proposed rule "the major legal interpretations ... underlying the proposed rule." CAA § 307(d)(3)(C).

2.3.2. Affected Facility Must Match the Source Category

More importantly, the proposal is flawed because the statute simply does not confer authority on EPA to define a source category and then define a different "affected facility" for purposes of determining what constitutes a new source. As explained above, the statute unambiguously requires EPA to identify and regulate "categories of stationary sources." CAA § 111(b)(1)(A). Similarly, the statute defines the term "new source" to mean "any stationary source" that is constructed or modified after proposal of an applicable standard. *Id.* at § 111(a)(2). There can be no doubt that the "stationary source(s)" that is identified for listing purposes must be the same "stationary source" used to define what constitutes a new source. In other words, by defining a category of "stationary sources" to be regulated under § 111, EPA unavoidably identifies the "stationary source" that must be used in applying the definition of "new source."

To be sure, § 111 provides EPA with regulatory flexibility – the Agency clearly "may distinguish among classes, types, and sizes within categories of new sources for the purpose of establishing such standards." *Id.* at § 111(b)(2). However, the authority to parse a given category of stationary sources for purposes of standard setting is distinctly different from the asserted authority to redefine what constitutes a "new source" within the given source category. *Asarco Inc. v. EPA*, 578 F.2d 319, 327 n. 24 (D.C. Cir. 1978) ("This language on its face merely allows the Administrator to set different standards for different classes, types, and sizes of sources. It does not give the Administrator authority to rewrite the definition of a stationary source ..."). EPA has flexibility in defining in the first instance the stationary

sources to be regulated, but the act of defining the “stationary sources” fixes the “affected facility” for purposes of determining what constitutes a new source.

2.3.3. EPA Has Failed to Follow Established Criteria

Third, even assuming (for the sake of argument) that EPA has authority to designate portions of stationary sources as “affected facilities” for purposes of determining what constitutes a “new source,” EPA has failed to follow the analytical framework established in prior rules for making such designations. For example, in establishing the NSPS for VOC emissions from synthetic organic chemical manufacturing wastewater, EPA explained that a balancing must be done. A “narrower” definition of affected facility can be favorable because “a broader definition means that replacement equipment is less likely to be regulated under the NSPS.” 59 Fed. Reg. 46780, 46789 (Sept. 12, 1994). On the other hand, a “broader” definition may be appropriate upon consideration of “the relevant statutory factors (technical feasibility, cost, energy, and other environmental factors).” *Id.* In the case of this SOCM rule, EPA selected the process unit as the appropriate affected facility because it “allows for routine equipment replacement and minor changes or expansions in existing facilities without subjecting either single emission sources or entire plant sites to requirements of the proposed standards.” *Id.* at 46790. The failure to engage in reasoned assessment according to these established criteria renders the proposed rule arbitrary and capricious and not in accord with the law.

2.4. Temporary Emission Sources (Completions)

Emissions from well completions are fundamentally different than emissions regulated under any existing NSPS. It goes without saying that the purpose of gas wells is to produce natural gas. A well completion is not part of the normal operation of a well, in that completion activities do not continuously occur as a well is producing or, for that matter, are not repeated more than once or twice over the life of a well (a life that typically spans years and often spans decades). Instead, a well completion is a construction-related activity that must be accomplished for a well to begin producing and thereafter engage in normal operations. To the extent that a producing well must be “recompleted,” this activity constitutes maintenance of the well because it is needed to assure the ongoing proper operation and suitable productivity of the well.

To date, EPA has not sought to impose § 111 emissions limitations or standards on construction or maintenance activities at affected facilities. In fact, EPA has actively worked to exclude construction and maintenance activities from coverage by an NSPS. For example, the initial performance tests and compliance determinations for affected facilities typically are not required to be conducted until “within 60 days after achieving the maximum production rate at which the affected facility will be operated, but not later than 180 days after initial startup of such facility.” 40 C.F.R. §60.8(a). Similarly, performance test must be conducted under conditions reflecting “representative performance of the affected facility.” *Id.* at §60.8(c). Periods of source construction and maintenance have never been determined to be “representative” of normal source operation under the NSPS program.

With this as a backdrop, EPA's proposal to set standards for well completions and recompletions is unfounded. To begin, as discussed more fully in Section 15.1 of these comments, production wells

are a distinct type of stationary source that cannot rationally belong to the same source category as the other disparate elements of the oil and gas production industry (such as natural gas processing plants) that EPA seeks to regulate in the proposed rule. EPA has not previously found and has not proposed to find that emissions from production wells cause or significantly contribute to air pollution that may reasonably endanger health or the environment. Therefore, EPA is not authorized to list or regulate oil and gas production wells under § 111.

In addition, EPA has not explained why it has reversed a decades-long practice under § 111 of regulating only emissions from normal operation of affected facilities and expressly excluding construction-related emissions from regulation. The proposal to regulate construction-related emissions is a significant substantive departure in the Agency's prior interpretation and implementation of § 111. The failure to explain why this departure is justified and the failure to present the legal basis for regulating non-routine emissions is arbitrary and capricious and plainly violates EPA's obligation to clearly set forth "the major legal interpretations and policy considerations underlying the proposed rule." CAA § 307(d)(3)(C).

3. BOUNDARIES FOR THE OIL AND NATURAL GAS PRODUCTION SECTOR

3.1. Boundary Between the Production and Transportation Sectors

EPA, in the preamble to the proposed rules, presents a description of the oil and natural gas sector that would clearly expand the boundaries of the oil and natural gas production source category from that listed in 1979. The preamble states, "We consider the oil refinery sector separately from the oil and natural gas sector. Therefore, at the point of custody transfer at the refinery, the oil leaves the oil and natural gas sector and enters the petroleum refining sector" (76 FR 52744, bottom of middle column). This statement would expand the oil and natural gas sector to include all pipeline facilities all the way to the refinery fence, which is almost surely not the intent. Such an expansion of the oil and natural gas sector would overlap with the oil and natural gas pipeline transportation sector, which is already regulated by NESHAP Subparts HHH and EEEE (OLD MACT) and NSPS Subpart Kb.

Having Subpart HH coverage overlap Subparts HHH and EEEE is unreasonable and unlawful because sources are included in two source categories and regulated under two standards. Under the proposal, it would seem some sources currently regulated under subparts HHH and EEEE might no longer be subject to those rules and instead would be subject to subpart HH on the basis that only one NESHAP applies to any individual source. At a minimum, there would be significant confusion and compliance liability over which rules apply to such sources, whether rule applicability has been correctly assigned in the past and whether the MACT floor analyses for Subparts HHH and EEEE inappropriately included sources from the oil and natural gas production source category. At minimum, any change in Subpart HH applicability must be clearly identified in rule language as applying only from the date of proposal, rather than retroactively, and overlaps with Subparts HHH and EEEE must be specifically addressed.

The point of custody transfer where the hydrocarbon liquids enter the transportation industry has always been the demarcation of the end of the production sector and the beginning of the transportation sector. The current definition of custody transfer in Part 63 Subpart HH (below) is typical of the definitions in NSPS Subpart Kb and NESHAP Subparts HHH and EEEE, each of

which describe this point as being where oil or natural gas is transferred from production or producing operations to “pipelines or any other forms of transportation.”

§63.761

Custody transfer means the transfer of hydrocarbon liquids or natural gas: after processing and/or treatment in the producing operations, or from storage vessels or automatic transfer facilities or other such equipment, including product loading racks, to pipelines or any other forms of transportation. For the purposes of this subpart, the point at which such liquids or natural gas enters a natural gas processing plant is a point of custody transfer.

Although oil and natural gas are measured at and pass several “accounting transfers” (such as lease accounting for royalty purposes, and gathering and gas plant balance for product loss and shrinkage purposes), products often are not transferred from the production operator until the product is loaded onto trucks or into a pipeline to leave the field. Additionally, using the last point before the oil or natural gas leaves the production field allows the NSPS and NESHAP regulations to use the same regulatory demarcation between the production and transportation sectors, as specified in CAA section 112(c).

As EPA accurately points out, “hydrocarbon liquids can pass through several custody transfer points between the well and the final destination”. However, this is not a good reason to abandon the best point of physical demarcation between production and transportation sectors that the agencies and industry has found. This rulemaking should clearly define which point of custody transfer is intended for this dividing point. API recommends that this dividing point be the last point of custody transfer before the crude oil or condensate leaves the production field and enters the transportation industry. This would most closely match the original intent of the custody transfer definition in the final NSPS Subpart K of March 8, 1974 and the common practice of the oil and natural gas industry.

Furthermore, API feels it is inappropriate to include the natural gas transportation (transmission) sector in NSPS Subpart OOOO for the reasons discussed in Section 5.1 on the low VOC natural gas streams. EPA states that the purpose of this NSPS is to control emissions of VOC and SO₂. However, there is no SO₂ and very little VOC to control in the natural gas stream after the gas processing plant. EPA recognized this when they exempted residue gas (gas after the extraction of NGLs) from the provisions of NSPS Subpart KKK. In addition to inappropriately expanding the source category, including the natural gas transportation sector in NSPS Subpart OOOO ignores this fact and amounts to the “backdoor” regulation of greenhouse gases (GHGs) because methane is the only substance effectively regulated for low VOC natural gas streams.

If EPA feels there is a need to add new requirements for the transportation and distribution sectors, it should revise existing subparts that already apply to them (i.e., NSPS Subpart Kb for tanks) or create a new subpart if necessary. Adding these sectors as part of a review for the production sector inappropriately reduces the opportunity of the transportation and distribution sectors from commenting on the proposed rules.

API requests that EPA define the boundary of the Oil and Natural Gas Production sector as the last point of custody transfer before leaving the production field, as suggested below, and that the title of NSPS Subpart OOOO be edited to delete the reference to the transmission and distribution sectors.

Suggested Rule Text:**Subpart OOOO—Standards of Performance for Crude Oil and Natural Gas Production,
~~Transmission, and Distribution~~****§60.5365**

If you are the owner or operator of [a site prior to the point of custody transfer at which is located](#) one or more of the affected facilities listed in paragraphs (a) through (g) of this section that commenced construction, modification, or reconstruction after August 23, 2011 your affected facility is subject to the applicable provisions of this subpart. [Paragraphs §60.5365\(a\)-\(e\) apply only to affected facilities in VOC service or in wet gas service.](#) ~~For the purposes of this subpart, a well completion operation following hydraulic fracturing or refracturing that occurs at a gas wellhead facility that commenced construction, modification, or reconstruction on or before August 23, 2011 is considered a modification of the gas wellhead facility, but does not affect other equipment, process units, storage vessels, or pneumatic devices located at the well site.~~

§60.5430

[Custody transfer means the last point of custody transfer of crude oil, condensate, or natural gas before it leaves the production field or basin and enters pipelines or any other forms of transportation. Typical custody transfer points include truck loading facilities or pipeline metering stations for crude oil or condensate, and the tail gate of natural gas processing plants or pipeline metering stations for natural gas.](#)

These changes would render NSPS OOOO consistent with NESHAP HH and HHH, as those rule were originally promulgated. The rule text adjustments below are necessary to return the proposal language to the original intent.

NESHAP HH

Return to the original language qualifying the affected facility.

§63.760(a)(2) Facilities that process, upgrade, or store hydrocarbon liquids prior to the point [of custody transfer](#) ~~where hydrocarbon liquids enter either the Organic Liquids Distribution (Non-gasoline) or Petroleum Refineries source categories.~~

NESHAP HHH

No changes are required to NESHAP HHH, in that the proposed revisions leave the “point of custody transfer” qualifier in place.

3.2. Boundary Between the Transportation and Distribution Sectors

API supports the comments of the American Gas Association (AGA) regarding the boundaries for the natural gas distribution sector under Subpart OOOO. As in the case of the production sector, the boundaries of other sectors in our industry are also defined by the point where the hydrocarbons leave one sector and enter another. Natural gas local distribution utilities usually obtain their supply of natural gas from upstream interstate transmission pipelines. Some gas utilities also obtain pipeline

quality dry natural gas directly from local production or from another adjacent gas utility, without an intervening interstate pipeline. The boundary for the distribution sector occurs at the point where custody of the natural gas is transferred from an upstream interstate transmission pipeline or from local production to a local natural gas distribution utility company. Subsequent transfers of custody from one distribution utility to another would mark the boundary between the two utilities, but would occur within the distribution sector.

EPA uses the term “city gate” loosely in Subpart OOOO to indicate the boundary between distribution and upstream sectors, but the agency has not defined the term or proposed a clear definition of the boundary between the natural gas distribution sector and other sectors of the industry. Although EPA added distribution to the *description of the source category* for Subpart OOOO, we understand that EPA did not intend to apply any of the proposed *standards* on the low VOC natural gas streams in natural gas distribution. This makes it essential to define the boundary of natural gas distribution clearly. Using the term “city gate” will not serve this purpose. AGA notes in its comments that the term “city gate” does not have a consistent meaning within the distribution sector. It is used by different gas utilities in different ways to refer to a wide variety of different types of facilities.^A

Suggested Rule Text:

Accordingly, to avoid confusion, we agree with AGA that EPA should replace the term “city gate” with the term “custody transfer station” and should add the following definition to §60.5430:

§60.5430

Custody transfer station means a facility where custody of natural gas is transferred from an interstate transmission pipeline or local producer to a natural gas local distribution utility.

If this change is made, then the term city gate should be replaced wherever it appears in Part 60, Subpart OOOO with the term “custody transfer station.” This would avoid confusion that would otherwise arise from using the term “city gate.”

As noted in section 3.1 above, §60.5365 should be qualified to pertain to “a site prior to the point of custody transfer at which is located.” The definition of custody transfer suggested in section 3.1, would mark the division between production and “pipelines *or any other forms of transportation.*” This is intended to encompass transportation in distribution systems. In combination with the above revision to §60.5365, this would clearly exclude the natural gas distribution sector from the application of Subpart OOOO, which we understand is consistent with EPA’s intent.

4. ECONOMIC ANALYSIS FOR DETERMINING BEST SYSTEM OF EMISSION REDUCTION (BSER)

^A AGA had a similar concern with the Mandatory Greenhouse Gas Reporting Rule for Natural Gas Systems, 75 Fed. Reg. 74,458. In that rulemaking, EPA responded to AGA’s comment on the term “city gate” used in the GHG reporting rule by proposing to delete the term “city gate” and replacing it with a different defined term in its recently proposed technical revisions to 40 C.F.R. Part 98, Subpart W. See 76 Fed. Reg. 56,010, 56,028 (Sept. 9, 2011). See also AGA’s comments on the Subpart W Technical Revisions, filed Oct. 24, 2011 in Docket EPA-OAR-2011-0512.

The Clean Air Act (CAA) requires EPA to set NSPS at the BSER, considering economics, which have been adequately demonstrated. In performing the economic analysis, EPA created a model for each "affected facility" that was used to perform the required economic analysis. These models contain assumptions for a "typical" affected facility within the industry. One of API's primary concerns with the proposed rule centers around the lack of sufficient sensitivity analysis for these model affected facilities with the economic justification for each control strategy that was determined to be BSER.

4.1. Unique Conditions of the Oil and Gas Industry

The O&G industry differs from most other industrial sectors in that the naturally-occurring dynamic reservoir properties control how we produce and manage the oil and natural gas from the reservoir. Most industries purchase their feedstocks to a set specification and have significant control over each step of the process. When the O&G industry finds a petroleum reservoir, the composition of the petroleum, the temperatures, and pressures of the fluids are dictated by the reservoir. These properties start to slowly change as soon as oil and gas begin being withdrawn from the reservoir. The volume of petroleum withdrawn from the well decreases every year (referred to as depletion) as does the pressure it is produced at. The composition of the petroleum changes (e.g. the gas to oil ratio [GOR], the amount of propane, butane, etc. in the gas, the characteristics of the crude oil, etc.) as does the volume and quality of produced water that comes with it. The O&G industry is constantly required to adapt to these changes. New wells must be drilled to replace the loss of production volume as the well depletes. Compressors must be added to compensate for the loss of well pressure, etc.

Additionally, each reservoir has a completely separate set of properties. For example, "conventional wells" of the past might flow oil and/or gas as soon as the well is drilled. Some of these conventional wells produce a very heavy, thick crude oil (a.k.a. black oil or dead oil) that has no associated natural gas at all. Other conventional wells may produce very light hydrocarbon liquids (a.k.a. condensate) along with high amounts of natural gas. While conventional O&G reservoirs are still producing today, the majority of new reservoirs are typically referred to as "non-conventional" since the reservoir characteristics and storage mechanism can be very different from those of conventional reservoirs. Non-conventional wells include formations such as coal bed methane (CBM), tight sands, and shale. Each type of formation may have some similarities, but still can have wide variation. CBM typically are produced at low pressures and contains very high percentage of methane (often as high as 97% by volume) and almost no hydrocarbons heavier than ethane. However some geographic areas of CBM can produce some liquid hydrocarbons. Some tight sands behave like sand stone and can produce significant amounts of heavier hydrocarbons. Shale fields run the gamut from wells that produce nearly 100% methane to wells that produce significant quantities of hydrocarbons that are liquid at stock tank conditions. The definitions of the various types of reservoirs are very broad and the defining characteristics have little to do with the reservoir's potential to emit VOC or HAP.

4.2. Economic Models and Variability

From the conversation above, it is clear that there is no one-size-fits all model to describe the O&G industry. For example, EPA looked at natural gas compositions that had no VOC content at all up to 53 weight % VOC, but selected a single gas composition of 18 weight % VOC to conduct most of the economic analysis on emission control options. When EPA utilizes this analysis to justify

controls, controls on high VOC content gas will actually have much lower cost/ton of VOC than the average, while controls on low or no VOC in the gas will have cost effectiveness that will approach an infinite cost/ton. (See Section 5.1.2 for further details). It is clearly inappropriate to designate an emission control for the reduction of VOC as BSER for a gas that contains no VOC, but this is what EPA has done by utilizing a one-size-fits-all economic strategy.

However, it is not fair to say that EPA did not attempt to set minimum thresholds where controls are cost effective. EPA set two throughput volume thresholds (20 bbl/day for crude oil and 1 bbl/day for condensate) for storage vessels. EPA selected the two throughput thresholds using a flawed study (see Section 16.6.1.) that assumed the emissions rate is dependent upon throughput volume alone. However, as discussed in Section 16 the composition of the hydrocarbon liquid and the temperature and pressure of the production separator also have a significant impact on VOC emissions. In fact, all three of these must be known to determine the VOC flash emissions from a storage vessel. API believes that throughput alone is an inappropriate surrogate to assure that emissions controls are economical, and that only VOC flash emissions calculations can serve this function for the production sector. However, API has suggested an alternative to a throughput threshold that is based on conservative volatile condensate compositions, conservative separator temperature and a range of separator pressures. (See Tables 16-3, 16-4, and 16-5 in Section 16.6 for cost effectiveness calculations).

Each new emission control suffers from this one-size-fits-all economic justification concern. All of the emission controls proposed are occasionally cost effective in selected O&G operations. However, all of the proposed emission control options fail to be cost effective in other O&G operations. A consistent theme of API's comments is that the controls should be applied only in situations where they are economic, so it qualifies as BSER.

4.3. Completeness of Cost Estimations of Control Options

In most cases, the cost estimates that EPA provides for specific pieces of equipment appear reasonable for the central activity. However, in every case the items included in the economic analysis are incomplete and the costs for compliance assurance requirements of the rule are underestimated. Below are listed examples of cost that have been left out or underestimated.

- **Auxiliary Equipment Required for a Complete Control System.** EPA consistently included the primary equipment required for the control option being considered. However, often the cost of auxiliary equipment was overlooked. For example with storage vessels, EPA considered the cost of the control device (flare, combustor or VRU), but did not appear to include the closed vent system required to collect the vapors, assure condensed liquids do not "vapor lock" this very low pressure system, and separate any condensed liquids before it reaches the control device.
- **Monitoring Requirements.** EPA appeared to include some costs for monitoring where required (i.e. storage vessels and LDAR). However, this cost did not appear to consider the remote, dispersed and unmanned nature of the facilities. This is most evident in the CPMS flow monitoring requirements for storage vessels. The data quality standards for CPMS require that personnel be able to monitor the instrumentation on an hourly (or at least daily) basis. Since these sites are unmanned, remote data collection systems would be required that are typically

either totally unavailable or require expansion to meet the requirements. These costs often far exceed the cost of control equipment that data is being provided for. Additionally, the operational personnel that are routinely at production sites are not qualified to perform many of the tasks required by the proposed rule and may be required multiple times a month. Travel time to and from the site is typically averages an hour in each direction from the central office. These costs have not been included in the economic analysis.

- **Notification, Recordkeeping and Reporting Cost.** EPA appears to assume that the data required for notification, recordkeeping and reporting required by the rule is readily available in a central location or in coordination with other routine operations. This is an unrealistic assumption.

4.4. Cost Effectiveness Threshold

When deciding whether emissions controls are economically justified, some measure is required, typically a cost/ton of emissions reduced. EPA has not placed a numeric threshold on the cost/ton of pollutant reduced, preferring to leave that decision up to a case-by-case analysis. However, comparing the cost effectiveness numbers for the control strategies that were determined not to be BSER with those that were accepted as BSER gives a good representation of an appropriate threshold. The cost effectiveness decisions that EPA made in determining regulatory strategies for this proposed rule were extracted from the Technical Support Document (EPA-HQ-OAR-0505-0045). From this table a cost effectiveness of less than \$5,000/ ton of VOC reduced appears to be acceptable.

Table 4-1. Comparison of EPA Cost Effectiveness Decisions

| Emission Source Type | Control Option | VOC Cost Effectiveness (\$/ton) | EPA Decision |
|--|-----------------------|--|---------------------|
| Pneumatic Devices | Low Bleed | \$262 | Accepted |
| Centrifugal Compressors - Production | Dry Seals | \$595 | Accepted |
| Completions/Flowback | REC | \$1,516 | Accepted |
| Pneumatic Devices | Compressed Air | \$2,659 | Accepted |
| Storage Tanks | 95% Control with VRU | \$3,150 | Accepted |
| Equipment Leaks - Processing Plants | VVa LDAR | \$3,352 | Accepted |
| Centrifugal Compressors - Transmission | Dry Seals | \$3,495 | Accepted |
| Reciprocating Compressors - Other | Change Out Seals | \$3,700 | Accepted |
| Centrifugal Compressors - Production | Flare | \$5,300 | Rejected |
| Equipment Leaks - Well pads | VVa LDAR with AWP | \$5,364 | Rejected |
| Equipment Leaks - Gathering Boosting | Component VVa LDAR | \$6,079 | Rejected |
| Equipment Leaks - Well pads | VVa LDAR | \$6,934 | Rejected |
| Equipment Leaks - Gathering Boosting | VVa LDAR | \$8,174 | Rejected |
| Equipment Leaks - Gathering Boosting | VVa LDAR with AWP | \$8,685 | Rejected |
| Equipment Leaks - Well pads | Component VVa LDAR | \$15,063 | Rejected |
| Equipment Leaks - Transmission Storage | VVa LDAR with AWP | \$19,723 | Rejected |
| Equipment Leaks - Transmission Storage | VVa LDAR | \$19,769 | Rejected |
| Equipment Leaks - Transmission Storage | Component VVa LDAR | \$24,762 | Rejected |
| Centrifugal Compressors - Transmission | Flare | \$31,000 | Rejected |
| Reciprocating Compressors - Wellhead | Change Out Seals | \$84,000 | Rejected |

5. APPLICABILITY [NSPS OOOO]

The scope of the regulation should be defined in the applicability §60.5365, so that all stakeholders clearly know what is covered. This regulation like many others has expansion or limitations of the scope included in definitions, paragraph titles and other portions of the rule. API recommends the following changes be made to the applicability section of the rule.

5.1. Applicability to Low VOC Natural Gas Streams

In the summary of the proposed rule, EPA states that it is adding new source performance standards for VOCs. However, there are insufficient conditions in the proposed rule to limit the applicability to streams that have a significant quantity of VOC, resulting in a NSPS regulation that can be interpreted to apply to streams with no VOCs. In this proposed rule, the term “natural gas” is used in the titles of the category, plants and equipment descriptions, as well as a surrogate for VOCs. However, many natural gas streams are mainly methane and have little or no VOC content when it is produced from the reservoir (thus the terms “dry gas” and “coal bed methane” that are common in the industry). EPA has previously stated that it does not intend to regulate GHGs within this rule and thus has not provided the public with an opportunity to comment on the inclusion of methane. Without some minimum applicability threshold for VOCs, EPA is essentially regulating GHGs.

5.1.1. Natural Gas is not an Appropriate Surrogate for VOCs

A common thread running through the virtually all of the Subpart OOOO proposal is that natural gas can appropriately be assumed to have a fixed composition. EPA does recognize that produced gas typically has significantly different characteristics than gas being moved through transmission operations, and thus established different fixed compositions for production (*i.e.*, completions and recompletions) and transmission (*i.e.*, pneumatics, equipment leaks, compressors). See Memorandum from Heather P. Brown, PE, EC/R Inc., to Bruce Moore, EPA/OAQPS/SPPD, Composition of Natural Gas for Use in the Oil and Natural Gas Sector Rulemaking (July 28, 2011) (“EC/R Memo”). However, these compositions are the only compositions used for purposes of analyzing the regulatory alternatives and supporting the proposed rule. In addition, EPA would require applicability to effectively be based on these fixed-composition assumptions. In other words, the actual content of the natural gas produced or transmitted at an affected facility has no bearing on applicability of the rule – applicability is based solely on the act of producing, processing, or transporting natural gas.

This approach of assuming geographically, temporally, and geologically fixed compositions of VOCs and other regulated pollutants in natural gas is insupportable and arbitrary. EPA's own analysis demonstrates the problem. Table 7 of the EC/R Memo provides a sensitivity analysis of EPA's gas composition data for gas wells and hydraulically fractured wells (see EC/R Memo, page 10). This table shows that the minimum VOC content in EPA's database is 0 and the maximum is 29.6 volume percent. This means that certain “affected facilities” will be subject to the rule even though the gas they handle contains little or no VOCs, which is the pollutant ostensibly, being regulated by this rule (see Section 5.1.2 for further details

EPA acknowledges that this is a problem. In discussing the proposed standards for well completions, EPA notes that “gas composition” is one of the “variety of factors” that determine “the length of the flowback period and actual volume of emissions.” 76 Fed. Reg. at 52757. As a result, EPA admits that “[t]his variability means there will be some wells which emit more than the estimated emission factor and some wells that emit less.” More to the point, this “heterogeneity in well operations and costs” means that “while RECS may be cost-effective on average, they may not be for all operators.” *Id.* at 52758.

However, EPA fails to take this observation to its logical conclusion – that some wells will emit so little VOC that the proposed standards cannot be justified given that little or no reductions will be achieved in regulated pollutant emissions and the cost effectiveness of the proposed standards would be unreasonably high. Instead, EPA sets up a false choice – that EPA can either “require an operational standard” (such as the proposed REC requirement) or impose a “performance-based standard” (which is not defined, but in context appears to be some sort of numeric emissions limitation). EPA asserts that a performance standard cannot work “because we believe there are no feasible ways for operators to measure emissions with enough certainty to demonstrate compliance with a performance-based standard.” *Id.* Therefore, EPA decided to propose an “operational standard” applicable to all hydraulically fractured natural gas wells.

This makes no sense because EPA obviously has other regulatory alternatives. These include the possibility of setting a lower level VOC cut-off for natural gas that would target the proposed rule only on those who produce, process, or transport gas with more than a specified amount of VOCs (with the cut-off based on consideration of emissions reductions and costs). EPA's failure to consider such other approaches is arbitrary and capricious. And, its proposal to impose requirements that “may be cost-effective on average” but that “may not be [cost effective] for all operators” violates the Agency's obligation to “consider the representativeness of the test data relied upon in the development and justification of its standard.” *National Lime* at 451.

Notably, in the NESHAP part of the proposal, EPA abandons the fixed composition assumption in assessing control requirements for small dehydrators “due to variability of gas throughput and *inlet gas composition*.” *Id.* at 52768 (emphasis added). As a result, this element of the proposed rule is based on facility-specific data of “inlet natural gas BTEX concentration.” *Id.* This further demonstrates that EPA can and should take account of VOC content in determining the applicability of Subpart OOOO.

On a related note, the variability in the composition of natural gas also means that natural gas is not an appropriate surrogate for VOCs under the standard for pneumatic devices. *See id.* at 52800 (proposed §60.5390). The D.C. Circuit has made clear that EPA does have authority to regulate surrogate pollutants, but “only if it is reasonable to do so.” *Nat'l Lime Ass'n v. EPA*, 233 F.3d 625, 637 (D.C. Cir. 2000) (internal quotes and citations omitted). For the reasons discussed above, applying the pneumatic device standards to any device in natural gas service would cause the standard to apply to many devices that emit little or essentially no VOCs. As a result, natural gas is not an appropriate surrogate for VOCs because applicability of the rule is not reasonably focused on significant sources of VOCs.

Lastly, the proposed rule does – in a limited way – provide for a lower level VOC cutoff. Section 60.5430 defines “equipment” to include only components “in VOC service” and §60.5400 provides that compressors at onshore natural gas processing plants are covered only if they are “in VOC service.” 76 Fed. Reg. at 52809 (proposed definition of “equipment”; 52800 (proposed VOC standards for onshore natural gas processing plants). However, proposed §60.5400(f) requires that “[e]ach piece of equipment is *presumed* to be in VOC service ... unless an owner or operator demonstrates that the piece of equipment is not in VOC service.” *Id.* at 52801 (emphasis added). This presumption can be overcome

only if it is “determined that the VOC content can be reasonably expected never to exceed 10.0 percent by weight.” *Id.*

While a lower level VOC cutoff is appropriate and necessary (for the reasons discussed above), EPA is without authority to require that affected equipment and compressors must be assumed to be in VOC service unless it is proven that they are not. NSPSs apply to specified affected sources – in this case, equipment and compressors with the potential to emit VOCs in amounts that justify regulation. It is unreasonable and arbitrary for EPA to declare that equipment or compressors are covered by the rule when it has not been determined that the equipment or compressors handle gas of a composition that EPA has determined warrants regulation.

5.1.2. In VOC Service and In Wet Gas Service

API requests that EPA add a limitation to §60.5365 that this regulation applies only to streams that are “in VOC service” or “in Wet gas service” as discussed further below.

EPA has chosen to use average compositions of natural gas throughout the US and utilized a single average composition with VOC content of 18.28% by wt. to economically justify regulations for LDAR, natural gas compressors, and pneumatic controllers throughout the US (see EPA-HQ-OAR-0505-0084). This “one size fits all” approach ignores the fact that natural gas ranges in VOC content from 52.72% to 0.0% by wt for the gas compositions EPA listed in the docket. In fact the average VOC content for shale gas production, the fastest growing sector of the natural gas industry, is only 2.95% by wt. and the average VOC content is 2.35% by wt. for the natural gas transportation sector. In Attachment G, RIA Review for Completions, Table G-6, API has calculated the cost effectiveness for the compositions EPA included in the docket for determining an “average natural gas stream”. The cost effectiveness (in terms of \$/ton of VOC) was calculated to be \$4,814/ton at 17.95 wt % VOC, \$8,564 at 10.09 wt % VOC and \$16,552/ton at 4.81 wt % VOC. This means that the cost benefit approaches infinite \$/ton of VOC for gas with no VOC content (i.e. coal bed methane [CBM] and some of the shale gas fields). When compared to the other cost effectiveness decisions that EPA made in determining regulatory strategies in the Technical Support Document (EPA-HQ-OAR-0505-0045; see Section 4.4), restricting these regulations to streams “in VOC service”, as recommended below, seems very reasonable.

NSPS Subparts VV and GGG control equipment leaks for streams containing 10% or more VOC by weight, and API continues to believe that 10 % by weight of VOC is an appropriate threshold for the oil and natural gas production sector. However, when EPA promulgated NSPS Subpart KKK in the 1980s, EPA also decided to control streams in “wet gas” service. While historically most streams in “wet gas” service contained significant amounts of VOC, that is not the case today. Today, two “wet gas” streams commonly occur that were infrequent or non-existent when NSPS Subpart KKK was promulgated. The first is streams with high inert gas (carbon dioxide [CO₂] or nitrogen [N₂]) content from enhanced oil recovery gas flood projects. The inert gas content often becomes the majority of the “wet gas” stream and the VOC content becomes negligible. The wet gas is still processed at a natural gas processing plant, to remove the inert gas stream (typically recycled for enhanced oil recovery purposes) and natural gas liquids (NGLs) to make the remaining natural gas

salable. The second is non-conventional natural gas (coal bed methane [CBM], shale gas or tight sands) that may have little VOC content. These new low VOC content streams were not considered in the original Subpart KKK promulgation process.

API recommends that EPA retain consistency between the LDAR programs (i.e., Subparts VV, GGG and KKK). API proposes that EPA add a definition of "in VOC service" to Subpart OOOO, and use that term in the applicability provisions (See Section 19.4.2 for further information).

Suggested Rule Text:

§60.5365

If you are the owner or operator of [a site prior to the point of custody transfer at which is located](#) one or more of the affected facilities listed in paragraphs (a) through (g) of this section that commenced construction, modification, or reconstruction after August 23, 2011 your affected facility is subject to the applicable provisions of this subpart. [Paragraphs §60.5365\(a\)-\(e\) apply only to affected facilities in VOC service.](#) ~~For the purposes of this subpart, a well completion operation following hydraulic fracturing or refracturing that occurs at a gas wellhead facility that commenced construction, modification, or reconstruction on or before August 23, 2011 is considered a modification of the gas wellhead facility, but does not affect other equipment, process units, storage vessels, or pneumatic devices located at the well site.~~

§60.5400

This section applies to each compressor in VOC service ~~or in wet gas service~~ and the group of all equipment (as defined in §60.5430), except compressors, within a process unit.

* * * * *

(f) You must use the following provision instead of §60.485a(d)(1):

Each piece of equipment is presumed to be in VOC service ~~or in wet gas service~~ unless an owner or operator demonstrates that the piece of equipment is not in VOC service ~~or in wet gas service~~. For a piece of equipment to be considered not in VOC service, it must be determined that the VOC content can be reasonably expected never to exceed 10.0 percent by weight. ~~For a piece of equipment to be considered in wet gas service, it must be determined that it contains or contacts the field gas before the extraction step in the process.~~ For purposes of determining the percent VOC content of the process fluid that is contained in or contacts a piece of equipment, procedures that conform to the methods described in ASTM E169-63, 77, or 93, E168-67, 77, or 92, or E260-73, 91, or 96 (incorporated by reference as specified in §60.17) must be used.

§60.5430

Equipment means each pump, pressure relief device, open-ended valve or line, valve, compressor, and flange or other connector that is in VOC service ~~or in wet gas service~~, and any device or system required by this subpart.

In VOC service means that the piece of equipment contains or contacts a process fluid that is at least 10 percent VOC by weight.

However, if EPA continues to believe it is important to regulate “wet gas” streams that are not “in VOC service”, API believes EPA must still set a minimum VOC content and maximum inert gas content for “wet gas”. Without doing so, EPA is ignoring the important part that VOC content in the controlled stream plays in the cost effectiveness of its regulations. API realizes that setting a concentration below the current 10 wt % “in VOC service” threshold is somewhat arbitrary, since this is not considered cost effective as discussed above. However, API proposes that EPA set the wet gas threshold (X) no lower than 5% by weight VOC. Additionally, API recommends EPA exclude “wet gas” that is predominately (i.e. greater than 50 wt %) inert gases. Therefore, API recommends the following:

Alternative Suggested Rule Text:

§60.5365

If you are the owner or operator of one or more of the affected facilities listed in paragraphs (a) through (g) of this section that commenced construction, modification, or reconstruction after August 23, 2011 your affected facility is subject to the applicable provisions of this subpart. Paragraphs §60.5365(a)-(e) apply only to affected facilities *in VOC service or in wet gas service.* ~~For the purposes of this subpart, a well completion operation following hydraulic fracturing or refracturing that occurs at a gas wellhead facility that commenced construction, modification, or reconstruction on or before August 23, 2011 is considered a modification of the gas wellhead facility, but does not affect other equipment, process units, storage vessels, or pneumatic devices located at the well site.~~

§60.5430

In wet gas service means that a compressor or piece of equipment contains or contacts wet gas. ~~the field gas before the extraction step at a gas processing plant process unit.~~

Wet gas means field gas before the extraction step at a gas processing plant process unit that is >X% VOC by weight. Wet gas does not include gas streams that are >50% by weight inert gases (nitrogen or carbon dioxide).

[API recommends X be equal to or greater than 5]

5.2. Applicability to Liquid Streams

The regulatory analysis on liquid streams in storage vessels has obviously concentrated on crude oil and condensate from production wells, however nothing in this Subpart limits the applicability to these streams. Regulators could easily apply the storage vessel regulations to vessels storing chemicals, vehicle fuels, lubrication oils, produced water, etc.; however these storage vessels have not gone through the economic analysis necessary to justify the applicability of the proposed rule to these services. API requests that applicability of the rule to storage vessels, as specified at

§60.5365(e), be limited to condensate and crude oil liquid streams. See Sections 16.4 and 16.5 for further details.

5.3. Applicability Limitation to Sectors

Applicability paragraphs §60.5365 (d) & (e) for pneumatic controllers and storage vessels have no limitation on the range of facilities to which they apply. Thus, the standards could inappropriately be applied to a fuel tank in a residence, if you ignore the title of the Subpart. Even with that limitation, a pneumatic device on the fuel system of any commercial boiler could be considered to be regulated, since the ending of the distribution sector was never discussed in the proposed rule. API requests that EPA add text to §60.5365 that limits applicability to the oil and natural gas production sector.

5.4. Applicability to Wellheads and Reduced Emission Completion Operations

5.4.1. Affected Facility

EPA's proposal to regulate temporary construction emissions from well completion activities within an NSPS has created problems and confusion within the proposed regulatory text. As discussed in Section 2.4, construction emissions are not part of normal operations and have not been regulated previously within an NSPS. Additionally, the CAA authority for NSPS applies to "any building, structure, facility, or installation." Thus, EPA chose the only stationary physical structure available at the time a well completion is performed as the "affected facility," the wellhead. API is concerned that EPA's choice of the wellhead as the affected facility along with EPA's failure to accurately define the emissions regulated by the proposed rule will lead to confusion within the agency and industry for the life of Subpart OOOO. EPA should first clarify that the affected facility is a natural gas wellhead facility onshore "except for one that does not have flowback immediately following hydraulic fracturing stimulation."

5.4.2. Regulated Emissions

The emissions proposed to be regulated by the proposed rule come from the flowback immediately following hydraulic fracturing stimulation. Such flowback, post hydraulic fracture stimulation may occur in conjunction with new well completion, existing well recompletion, or workovers. However, the proposed rule regulates "each well completion operation with hydraulic fracturing." Well completion, as discussed in Section 15.8, means the process of making a new oil or natural gas well ready for production. It allows for the flow of petroleum or natural gas from newly drilled wells to expel drilling and reservoir fluids and test the reservoir flow characteristics and also involves connecting the well bore to the reservoir, which may include treating the formation or installing tubing, packer(s), or lifting equipment. This process may also include high-rate flowback of injected gas, water, oil, and proppant used to fracture stimulate and prop open new fractures in lower permeability reservoirs. Flowback is only a portion of the well completion operation with hydraulic fracturing stimulation. Flowback can also occur from a recompletion or workover with hydraulic fracturing stimulation. VOC air emissions only occur when there is gas containing VOCs in the flowback. Well completions, recompletions, and workovers are not directly associated with the emissions being regulated. API believes that well completions,

recompletions, and workovers should only be included in the definition of flowback to prevent confusion of what is being regulated.

5.4.3. Defining Applicability

The applicability of the proposed regulation to “flowback immediately following hydraulic fracturing stimulation at onshore gas wellhead facilities” should be clearly defined in §60.5365(a). Furthermore, as discussed in Section 15.6.1, API believes that the following portion of the text is unnecessary and should be eliminated.

“For the purposes of this subpart, a well completion operation following hydraulic fracturing or refracturing that occurs at a gas wellhead facility that commenced construction, modification, or reconstruction on or before August 23, 2011 is considered a modification of the gas wellhead facility, but does not affect other equipment, process units, storage vessels, or pneumatic devices located at the well site.”

However, API agrees that the text should clarify that other equipment, such as process units, storage vessels, pneumatic controllers, and compressors located at the well site are not affected by hydraulic fracture flowback operations. This text is needed because of the issues discussed in Sections 5.4.1 and 5.4.2 above.

Suggested Rule Text:

§60.5365

If you are the owner or operator of [a site prior to the point of custody transfer at which is located](#) one or more of the affected facilities listed in paragraphs (a) through (g) of this section that commenced construction, modification, or reconstruction after August 23, 2011 your affected facility is subject to the applicable provisions of this subpart. [Paragraphs §60.5365\(a\)-\(e\) apply only to affected facilities in VOC service.](#) ~~For the purposes of this subpart, a well completion operation following hydraulic fracturing or refracturing that occurs at a gas wellhead facility that commenced construction, modification, or reconstruction on or before August 23, 2011 is considered a modification of the gas wellhead facility, but does not affect other equipment, process units, storage vessels, or pneumatic devices located at the well site.~~

- (a) [An onshore natural gas wellhead affected facility](#), is a single natural gas well, ~~that has flowback immediately following hydraulic fracturing stimulation.~~ [VOC emissions from flowback immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore is the only activity regulated at this affected facility. For the purposes of this subpart, an existing onshore natural gas wellhead facility is considered modified if it meets the criteria of modification in §60.14. The modification of an existing natural gas wellhead affected facility does not affect the status of other equipment, process units, storage vessels, or pneumatic devices located at the well site.](#)

§60.5430

Flowback means the process of allowing fluids to flow from the well following a treatment, either in preparation for a subsequent phase of treatment or in preparation for cleanup and

returning the well to production. [Flowback immediately following hydraulic fracture stimulation may occur in conjunction with a well completion, recompletion, or fracture stimulation of the same zone in an existing well.](#)

5.5. Applicability to Sweetening Units

In several locations of the regulatory text, EPA states clearly that the standard applies to sweetening units located at onshore natural gas processing plants. However, this distinction is not made in the applicability provisions of §60.5365(g). Some examples of where EPA clearly states the standard applies only to sweetening units at onshore natural gas processing plants, include:

- In §60.5405, “What standards apply to sweetening units at onshore natural gas processing plants?”
- In §60.5406, “What test methods and procedures must I use for my sweetening units affected facilities at onshore natural gas processing plants?”
- In §60.5407, “What are the requirements for monitoring of emissions and operations from my sweetening unit affected facilities at onshore natural gas processing plants?”

Based on the examples above, API reviewed and commented on the proposed rule with the understanding that the requirements for sweetening units apply only to units located at onshore natural gas processing plants. In order to improve clarity on the applicability for sweetening units, API recommends the following revisions:

Suggested Rule Text:

§60.5365

(g) Sweetening units located at onshore natural gas processing plants that process natural gas produced from either onshore or offshore wells.

5.6. Applicability Limitations to Modification and Reconstruction

EPA needs to clarify the applicability of Subpart OOOO to equipment that could be considered modified or reconstructed. EPA appears to inappropriately apply the modification or reconstruction tests to capture some existing facilities (i.e., recompletions and compressor relocations) for regulation when the General Provisions tests would not have included them and such inclusion is in violation of the Clean Air Act provisions. Other low cost, component level affected facilities (i.e., pneumatic controllers) may technically undergo modifications and reconstruction per the text of the General Provisions, but not fit the intent of the original rulemaking.

API believes that including definition of modification in Subpart OOOO is unnecessary, adds confusion and improperly changes longstanding precedents that reflect the intent of Section 111 of the Clean Air Act. API recommends that the provisions of §60.14 continue to apply to all NSPS regulations, including Subpart OOOO.

Suggested Rule Text:**§60.5430**Preferred Option:

~~Modification means any physical change in, or change in the method of operation of, an affected facility which increases the amount of VOC or natural gas emitted into the atmosphere by that facility or which results in the emission of VOC or natural gas into the atmosphere not previously emitted. For the purposes of this subpart, each recompletion of a fractured or refractured existing gas well is considered to be a modification.~~

Alternative Option:

~~Modification means any physical change in, or change in the method of operation of, an affected facility which increases the amount of VOC or natural gas emitted into the atmosphere by that facility or which results in the emission of VOC or natural gas into the atmosphere not previously emitted. For the purposes of this subpart, each recompletion of a fractured or refractured existing gas well is considered to be a modification.~~

5.6.1. Relocated Compressors

The provisions of §60.5365(b) & (c) states that a “compressor is considered to have commenced construction on the date the compressor is installed at the facility.”

This violates, for no apparent reason, the §60.2 definition of “commenced”, which is “Commenced means, with respect to the definition of new source in section 111(a)(2) of the Act, that an owner or operator has undertaken a continuous program of construction or modification or that an owner or operator has entered into a contractual obligation to undertake and complete, within a reasonable time, a continuous program of construction or modification.” Under this definition, which is long established in Part 60 precedent, construction of a compressor occurs when the contractual obligation has been entered to purchase the compressor or for the project that purchases and installs the compressor.

In addition, this proposed language could be interpreted to mean that a compressor that has been relocated from one location to another is “new” (see Section 18.1). This is directly opposed to the provisions of §60.14(e)(6) that state “The relocation or change in ownership of an existing facility” by itself shall not be considered a modification. This same precedent has been followed in the NESHAP regulations where the relocation of an affected source does not affect the existing status of the source (see Background Information for Promulgated Standards for the final NESHAP General Provisions (EPA-453/R-02-002), page 3-62). Not following this precedent would lead to the illogical result that if an existing engine (regulated by either NSPS Subparts JJJJ or IIII or NESHAP Subpart ZZZZ) and compressor (regulated by the proposed NSPS Subpart OOOO) package was relocated, the engine would still be considered existing, but the compressor would be considered new. Additionally, for a new compressor package, two notices of construction would be required at different times, one for when the engine is ordered as required by Subpart JJJJ, and a second for when the compressor is installed. Other issues arise with the undefined phrase

“installed at the facility”. API requests that the last sentence of both §60.5365(b)&(c) be removed to resolve this issue.

5.6.2. Reduced Emission Completions

The proposed rule would define “modification” to include “each recompletion of a fractured or refractured existing gas well.” 76 Fed. Reg. at 52810 (definition of “modification” in proposed §60.5430). As a result, recompletion of an existing non-affected well would cause Subpart OOOO to apply to that well. This requirement is unfounded and unlawful.

EPA asserts “a completion associated with refracturing performed at an existing well” would be a modification “because a physical change occurs to the existing well resulting in emissions increase during the refracturing and completion operation.” *Id.* at 52745. More specifically, the “physical change, in this case, would be caused by the reperforation of the casing and tubing, along with the refracturing of the wellbore.” *Id.* at 52759. Additionally, the “increased “VOC emissions would occur during the flowback period following the fracturing or refracturing operation.” *Id.* While EPA asserts in the preamble that “a detailed discussion of this determination is presented in the Technical Support Document,” *id.* at 52745, that “detailed discussion” merely consists of the following:

In order to fracture an existing well during recompletion, the well would be re-perforated, causing physical change to the wellbore and casing and therefore a physical change to the wellhead, the affected facility. Additionally, much of the emissions data on which this analysis is based demonstrates that hydraulic fracturing results in an increase in emissions. Thus, recompletions using hydraulic fracturing result in an increase in emissions from the existing well producing operations. Based on this understanding of the work performed in order to recomplete the well, it was determined that a recompletion would be considered a modification under CAA section 111(a) and thus, would constitute a new wellhead affected facility subject to NSPS. [TSD at 4-27]

This “detailed discussion” adds nothing of substance to EPA’s recap in the preamble.

The term “modification” is defined in § 111(a)(4) to mean “any physical change in, or change in the method of operation of, a stationary source which increases the amount of any air pollutant emitted by such source or which results in the emission of any air pollutant not previously emitted.” Under this definition, a modification occurs only if two things happen: (1) there must be a “physical change or change in the method of operation”; and (2) the change must result in an emissions increase.

In the context of the New Source Review program, the D.C. Circuit has opined that “Congress’s use of the word “any” in defining a “modification” means that all types of “physical changes” are covered.” *New York v. EPA*, 443 F.3d 880, 890 (D.C. Cir. 2006). In addition, the court determined that “the plain language of the CAA indicates that Congress intended to apply NSR to changes that increase actual emissions instead of potential or allowable emissions.” *New York v. EPA*, 413 F.3d 3, 40 (D.C. Cir. 2005).

However, the Supreme Court concluded that the § 111 definition of modification – which is

cross referenced in the statutory PSD provisions and, thus, applied in both the NSPS and NSR programs – does not have to have the same meaning under both programs. *Environmental Defense v. Duke Energy Corp.*, 127 S.Ct. 1423, 1434 (2007) (“Nothing in the text or the legislative history of the technical amendments that added the cross-reference to NSPS suggests that Congress had details of regulatory implementation in mind when it imposed PSD requirements on modified sources; the cross-reference alone is certainly no unambiguous congressional code for eliminating the customary agency discretion to resolve questions about a statutory definition by looking to the surroundings of the defined term, where it occurs.”). Thus, EPA has latitude within the context of § 111 to implement different rules regarding modifications – and, indeed, has done so from the inception of the NSPS program in the early 1970s.

In particular, EPA's regulatory definition of “modification” under the NSPS program provides several categories of activities that “shall not, by themselves, be considered modifications under this part.” 40 C.F.R. §60.14(e). Among other things, excluded activities include “maintenance, repair, and replacement which the Administrator determines to be routine for a source category,” and “an increase in production rate that can be accomplished without a capital expenditure.” *Id.* at §60.14(e)(1), (2). The term “capital expenditure” is defined to mean “an expenditure for a physical or operational change to an existing facility which exceeds the product of the applicable “annual asset guideline repair allowance percentage” specified in the latest edition of the Internal Revenue Service (IRS) Publication 534 and the existing facility's basis, as defined by section 1012 of the Internal Revenue Code.” *Id.* at §60.2. These provisions have been included in the rules since the very beginning of the NSPS program in 1971. They reflect the fact that Congress established the NSPS program for “new” sources. Without these exclusions, even the most minor activities would convert an existing source into a “new source.” The premise behind characterizing these activities as not being “changes” is that they all contemplate that the plant will continue to be operated in a manner consistent with its original design and thus is not a “new” facility.

In addition, EPA has established a method of measuring emissions increases under the NSPS program that differs markedly from the approach used under the NSR program. Under §60.14(b), the emission rate must be expressed as kg/hr of any pollutant to which the standard is applicable. The rule specifies that emissions factors should be used, unless the Administrator determines the use of such factors will not clearly demonstrate that emissions will increase or decrease as a result of a change. In this case, material balances, continuous monitoring data, or manual emissions test may be used. Testing must be conducted under conditions based on representative performance of the facility. And, all operating parameters that may affect emissions must be held constant to the maximum feasible degree.

To be sure, EPA has authority to adopt rule-specific modification provisions that differ from these general provisions. *See, e.g., Id.* at §60.14(f) (“Special provisions set forth under an applicable subpart of this part shall supersede any conflicting provision of this section.”). However, EPA clearly has the burden of explaining how such “special provisions” comport with the statute and why such “special provisions” should be adopted in lieu of the general provisions. EPA has failed in both regards with respect to the Subpart OOOO definition of

“modification.”

EPA fails in the proposal to explain why a recompletion is a physical change that should automatically trigger the application of NSPS Subpart OOOO. EPA merely asserts that it is a modification without any explanation or justification on the record. This assertion is particularly unavailing in light of the longstanding routine maintenance and capital expenditure exclusions from the definition of modification. Routine maintenance, for example, is a multifactor analysis that tries to arrive at a “common sense” finding based on the specific facts of a particular affected facility. In Section 15.11, API estimates that there are 1205 completions per year nationwide. These recompletions can certainly vary in nature, extent and cost and should be assessed individually, rather than automatically assumed to be a modification. This failure to explain, in the first instance, why recompletions can not constitute excluded routine maintenance or production increases achieved without a capital expenditure are arbitrary and capricious and represent a critical failure to provide an adequate explanation of “the major legal interpretations ... underlying the proposed rule.” CAA § 307(d)(3)(C).

EPA also fails to provide a rational explanation as to why a recompletion must, in all cases, result in an emissions increase. First, this, assumes that there are actual emissions associated with a recompletion, which for reasons discussed in other parts of these comments, is not a correct assumption. Second, if there are emissions, there may not be an increase. In fact, the emissions estimates in the TSD show that recompletions should not be expected to cause an emissions increase at all. Table 4-2 of the TSD shows that uncontrolled emissions from “natural gas well completion with hydraulic fracturing” are expected to be 158.55 tons of methane, 23.13 tons of VOC, and 1.68 tons of HAP per event (TSD at 4-7). Table 4-2 also reports emissions estimates for the same pollutants for “natural gas well recompletion with hydraulic fracturing.” Notably, EPA presents information that the emissions estimates for recompletions *are exactly the same* as the estimates for completions; however, they are lower unless a new zone is fractured.

Even more fundamentally, EPA's general provisions require emissions to be measured based on the “representative performance of the facility,” with all relevant operating parameters held constant. In other words, an apples-to-apples comparison must be made of pre- and post-change emission rates. This raises two critical questions EPA has not addressed. First, why are emissions from completions relevant to the emissions analysis when it is clear that emissions from completions are not representative of the performance of the facility? As explained above, for the vast majority of its operating lifetime, the only emissions from a well come from fugitive leaks. The initial completion and periodic recompletions certainly are not representative of normal operations and, therefore, emission rates during these periods should not be used to characterize emissions from the wells.

Second, even if emissions from completions and recompletions are relevant to the NSPS modification analysis, an “apples-to-apples” analysis should be done – *i.e.*, the emission rate during a recompletion should be compared to the emission rate during the initial completion to determine whether the recompletion results in an increase in emission rate. As shown above, because EPA has determined that emissions from recompletions are the same as

emissions from completions, there can be no emissions increase attributed to recompletions. EPA's failure to investigate and explain its departure from these key aspects of the §60.14 definition of "modification" render the proposal arbitrary and violate EPA's obligations under § 307(d)(3)(C).

5.6.3. Leak Detection and Repair (LDAR).

LDAR process units often use the concept of "capital expenditure" to prevent the addition of a few minor components from triggering modification. API believes that EPA needs to clarify the meaning of "capital expenditure" for the purposes of NSPS Subpart OOOO. A detailed discussion of "capital expenditure" can be found in Section 19.4.4.

6. DEFINITIONS [NSPS OOOO]

Confusion has occurred in the past when definitions have been used to both describe the meaning of the term for clarity and additionally limit applicability of the regulation. While this is often convenient and efficient in terms of creating regulatory text, it can cause unintended consequences. The definitions suggested below have attempted to keep the definition restricted to the meaning of the term, if that term is used within industry. Some terms are unique to EPA regulations, such as "in VOC service". In these instances, efforts have made to be consistent with other regulations, to reduce confusion.

6.1. Petroleum Product Definitions

The definitions of "crude oil" and "condensate" should not be based on API Gravity; the difference in these two products is in their origin. Physical properties of the products overlap and are not good indicators of product type. Also, natural gas was an undefined term and should be clarified.

Suggested Rule Text:

§60.5430

Condensate. *Condensate* means a ~~hydrocarbon liquid separated from natural gas that condenses due to changes in the temperature, pressure, or both, and remains liquid at standard conditions, as specified in §60.2. For the purposes of this subpart, a hydrocarbon liquid with an API gravity equal to or greater than 40 degrees is considered condensate~~ natural gas liquid recovered from associated and non associated gas wells from lease separators or field facilities, reported in barrels of 42 U.S. gallons at atmospheric pressure and 60 degrees Fahrenheit.
[Definition from Energy Information Administration glossary]

Crude Oil. *Crude oil* means ~~crude petroleum oil or any other hydrocarbon liquid, which are produced at the well in liquid form by ordinary production methods, and which are not the result of condensation of gas before or after it leaves the reservoir. For the purposes of this subpart, a hydrocarbon liquid with an API gravity less than 40 degrees is considered crude oil.~~ a mixture of hydrocarbons that exists in the liquid phase in natural underground reservoirs and remains liquid at atmospheric pressure after passing through surface separating facilities. Crude oil may also include:

- Small amounts of hydrocarbons that exist in the gaseous phase in natural underground reservoirs but are liquid at atmospheric pressure after being recovered from oil well (casinghead) gas in lease separators, and that subsequently are commingled with the crude stream without being separately measured.
- Small amounts of non-hydrocarbons produced with the oil.
[Definition from Energy Information Administration glossary]

Natural Gas. Natural gas means a naturally occurring mixture of hydrocarbon and non-hydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane. LNG is not considered natural gas, since impurities such as VOCs and HAPs have been removed.

[Basis of definition is NSPS Subpart Da]

6.2. Low VOC Streams

The definitions below should be added or modified as discussed in Section 5.1.2. The "In VOC service" definition is needed, even though it is in the definitions section of NSPS Subpart VVa, because that section of NSPS Subpart VVa is not referenced from Subpart OOOO.

Suggested Rule Text:

§60.5430

In VOC Service. In VOC service means that the piece of equipment contains or contacts a process fluid that is at least 10 percent VOC by weight.

[Copied from NSPS Subpart VVa]

In Wet Gas Service. In wet gas service means that a compressor or piece of equipment contains or contacts ~~wet gas. the field gas before the extraction step at a gas processing plant process unit.~~

Wet Gas. Wet gas means field gas before the extraction step at a gas processing plant process unit that is >X% VOC by weight. Wet gas does not include gas streams that are >50% by weight inert gases (nitrogen or carbon dioxide).

[API recommends X be equal to or greater than 5; see Section 5.1.2]

6.3. Natural Gas Processing Plant

The term "natural gas processing plant" is important to the Equipment Leaks, Acid Gas Recovery, and Pneumatic Controllers Sections. The definition of "natural gas processing plant" should be revised to add "forced" before extraction to clarify which extraction processes are included. See Section 19.4.1 for additional details.

Suggested Rule Text:

§60.5430

Forced Extraction. *Forced extraction of natural gas liquids* means removal of ethane or higher carbon number hydrocarbons existing in the vapor phase in natural gas, by removing ethane or heavier hydrocarbons derived from natural gas into natural gas liquids by means of a forced extraction process. Forced extraction processes include but are not limited to refrigeration, absorption (lean oil), cryogenic expander, and combinations of these processes. Forced extraction does not include in and of itself; natural gas dehydration, or the collection or gravity separation of water or hydrocarbon liquids from natural gas at ambient temperature or heated above ambient temperatures, or the condensation of water or hydrocarbon liquids through passive reduction in pressure or temperature, or portable dewpoint suppression skids or fuel treatment skids.

[based on EPA's proposed definition in *Mandatory Reporting of Greenhouse Gases: Technical Revisions to the Petroleum and Natural Gas Systems Category of the Greenhouse Gas Reporting Rule* (76 FR 56050)]

Natural Gas Processing Plant. *Natural gas processing plant (gas plant)* means any processing site engaged in the forced extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both.

6.4. Modification

EPA should not redefine the term "modification" in Subpart OOOO. The definition of modification in §60.14 of NSPS General Provisions should apply to Subpart OOOO.

It is unnecessary and confusing to include increases in emissions of both VOCs and natural gas in the proposed definition of modification. On 76 FR 52756, EPA states "this proposed rule does not include standards for regulating the GHG emissions." Including natural gas in the definition of modification, without defining it as requested in Section 4.1, will result in regulation of natural gas streams that have little or no VOCs, such as coal bed methane.

As discussed in Section 5.6, EPA should rely on the Part 60 General Provisions for defining modification. However, if EPA chooses to define modification in this subpart, the references to natural gas and recompletions should be removed.

Suggested Rule Text:

§60.5430

Preferred Option:

~~*Modification* means any physical change in, or change in the method of operation of, an affected facility which increases the amount of VOC or natural gas emitted into the atmosphere by that facility or which results in the emission of VOC or natural gas into the atmosphere not previously emitted. For the purposes of this subpart, each recompletion of a fractured or refractured existing gas well is considered to be a modification.~~

Alternative Option:

Modification means any physical change in, or change in the method of operation of, an affected facility which increases the amount of VOC ~~or natural gas~~ emitted into the atmosphere by that

facility or which results in the emission of VOC ~~or natural gas~~ into the atmosphere not previously emitted. ~~For the purposes of this subpart, each recompletion of a fractured or refractured existing gas well is considered to be a modification.~~

6.5. Orphaned Definitions

EPA has defined the terms “pneumatic pump”, “plunger lift system”, “reduced emissions completions”, and “reduced emissions recompletion”. None of these terms are used anywhere in the proposed rule. These definitions should be eliminated.

7. COMPLIANCE DATE

The compliance date of the final rules should be delayed because of the following:

7.1. Congressional Review Act

The Congressional Review Act states that a major rule shall become effective 60 days after publication in the Federal Register (see 5 USC 801(a)(3)(A)(i); unless other processes take longer). 5 USC 804(2)(A) states that a major rule is one that has “an annual effect on the economy of \$100,000,000 or more”. EPA states that “this action is an “economically significant regulatory action” because it is likely to have an annual effect on the economy of \$100 million or more (see 76 FR 52794). Thus, the compliance dates of the final rule need to be extended to at least the effective date (60 days after the publication in the Federal Register) to comply with the Congressional Review Act.

7.2. NSPS Effective Date for Completions

42 USC 7411(a)(2) defines new sources as those commencing construction after the proposal date of the performance standard. Currently, the proposed rule triggers compliance on the date of publication of the final rule in the Federal Register. However, an unintended consequence of defining temporary/construction/maintenance activities as affected facilities (see Section 2.4) is that flowback immediately following hydraulic fracturing stimulation at gas wellhead facilities onshore commencing after August 23, 2011 will be defined as new affected facilities, but may be completed before the effective date of the rule. Some regulatory text makes it appear that compliance activities must be completed before the effective date of the rule (i.e., the control requirements of §60.5375 and the notification and recordkeeping requirement of §60.5420(a)(2) and (b)(2) respectively). The rule, of course, cannot impose requirements prior to its effective date. Moreover, it is not possible to impose, upon the effective date of the rule, control measures on activities that have been completed prior to the effective date of the rule.

This retroactive compliance was stated to not be intended by EPA personnel in conference calls and meetings. This intent needs to be made clear in the final rule text. Please see Section 15.5 of the completion section for more details.

7.3. Manufacturer Compliance

The compliance requirements for certain affected facilities (i.e., pneumatic controllers and vapor combustors for controlling storage vessels) are a part of the equipment design that is controlled by

the equipment manufacturer, not the owner/operator. It is difficult for the owner/operator to be assured that he is meeting the requirements of the regulation with the equipment he purchases and installs, unless EPA allows sufficient time for the manufacturer to review the equipment design and label it as complying with the regulatory requirements of this rule.

For example, there are currently few if any manufacturer "guarantees" that continuous bleed pneumatic controllers are "low bleed" as required by proposed §60.5410(d)(3). Additionally, there are few if any continuous bleed pneumatic controllers that are even capable of a bleed rate of less than six scfh under all operating conditions. Variability in operating conditions, such as increases in instrument gas supply pressure, complicates the ability of a manufacturer to guarantee continuous bleed pneumatic controller performance.

NSPS Subpart JJJJ recognized that the manufacturers needed time to design, certify and manufacture equipment, and thus required compliance only for new sources manufactured after given manufacture dates when that equipment could reasonably be available from the manufacturer in quantities to meet the demand.

The same type of allowance provided for in NSPS JJJJ is needed in Subpart OOOO. Thus, while API believes a design verification is more appropriate for pneumatic controllers than a guarantee, we recommend that any equipment design guarantee required for pneumatic controller manufacturers be delayed by two years from the effective date of the rule. For additional discussion of the "guarantee" issue for pneumatics, please refer to Section 17.10.

A similar scenario exists for the option to have the performance test of a control device conducted by the manufacturer. The requirements in NSPS OOOO for storage tank control devices cite the performance test requirements specified in §63.772(e) of NESHAP HH, which include a provision for the performance test to be conducted by the manufacturer as specified in §63.772(h). It will obviously require considerable lead time, however, before such "manufacturer certified" control devices are readily available. We request that the effective date of the storage tank requirements under NSPS OOOO be delayed for 3 years to allow time for the specified control devices to become available.

7.4. Availability of Equipment for Reduced Emissions Completions

The equipment required for Reduced Emission Completions (REC) is not "off the shelf" equipment, but is typically custom built by the owner/operator or service company to meet the anticipated reservoir properties. Additionally, service companies would have to hire and train sufficient personnel to operate the REC equipment to meet the regulatory requirements. EPA should specify a compliance period for implementing the REC requirements that realistically accounts for the limitations on availability of equipment and trained personnel needed for widespread use of REC. Please see Section 15.4 for more detailed information, and for specific recommendations on revisions to the regulatory language. Such a compliance period is well within EPA's authority and, under the circumstances, the REC requirement cannot be justified without it.

By defining each new well as an affected facility, the proposal would cause the requirement to implement RECs to become effective industry-wide upon the effective date of the final rule. As described in Section 15.4, this means that 1,300 sets of equipment would be needed to accommodate

without unreasonable delay the expected number of affected completions. Only 300 sets of equipment currently exist in the industry, which is far short of what would be needed under the proposed rule. From that point, industry can probably deliver about 50 sets per quarter, so about 7.5 years will be required to meet the anticipated demand. As a result, as proposed, the REC requirement simply cannot be implemented upon the effective date of the final rule without causing widespread delays in new well development and imposing the substantial business interruption costs associated with such delays.

This means that the proposed requirement to implement RECs immediately upon the effective date of the final rule does not constitute "the best system for emission reduction" (BSER) for three independent reasons. First, § 111(a)(1) requires that BSER must be "achievable." This requirement is not satisfied when the selected control measures (in this case RECs) are not available to a significant portion of affected facilities. Second, § 111(a)(1) requires that BSER must have been "adequately demonstrated." Implicit in this obligation is that the given control measure not only has been shown to be effective in controlling emissions from the given affected facility, but also that it is sufficiently available that it can be obtained and applied by all affected facilities that trigger the control requirement. In this respect, the REC requirement has not been adequately demonstrated. Third, EPA must demonstrate that BSER is cost effective. EPA has failed to account for the costs of delay in obtaining REC equipment, which renders invalid its determination that RECs constitute BSER.

EPA could easily rectify this problem by bifurcating its BSER determination for well completions such that: (1) BSER is no additional control for a period of two years after the effective date of the final rule; and (2) REC constitutes BSER for well completions beginning two years after the effective date of the final rule. Such an approach would require EPA to adopt a "future effective" BSER determination for well completions. EPA has definitively determined that it has such authority under § 111.

Specifically, the so-called "Clean Air Mercury Rule" ("CAMR") was a § 111 standard that implemented mercury control requirements for power plants in two phases. In adopting this rule, EPA provided a detailed explanation as to why it was authorized under the law to do so:

In *Portland Cement Association v. EPA* (486 F.2d 375) (DC Cir. 1973), the Court rejected the argument that the words "adequately demonstrated" in CAA section 111 meant that the relevant technology already must be in existence and that plants now in existence be able to presently meet the proposed standards. Rather, the CAA's requirement that the degree of emission limitation be "adequately demonstrated" means that a plant now in existence must be able to meet the presently-effective standards for existing units, but that insofar as new plants and future requirements are concerned, section 111 authorizes EPA to "look toward what may fairly be projected for the regulated future, rather than the state-of-the-art at present." The court said:

The Administrator may make a projection based on existing technology, though that projection is subject to the restraints of reasonableness and cannot be based on "crystal ball" inquiry. 478 F.2d at 629. As there, the question of availability is partially dependent on "lead time," the time in which the technology will have to be available. Since the standards here put into effect will control new plants immediately, as opposed to one or two

years in the future, the latitude of projection is correspondingly narrowed. If actual tests are not relied on, but instead a prediction is made, "its validity as applied to this case rests on the reliability of [the] prediction and the nature of [the] assumptions." (citation omitted).

See also *Lignite Energy Council v. EPA*, 198 F.3d 930 (DC Cir. 1999) (section 111 "looks toward what may fairly be projected for the regulated future, rather than the state of the art at present") (quoting *Portland Cement*). These cases address CAA section 111(b) standards for new sources, where achievement of the standards is mandated on a short-term basis....The cases make clear that while a determination about a technology or performance standard's achievability may not be based on "mere speculation or conjecture," a technology or standard that may not necessarily be considered "adequately demonstrated" at present nonetheless can be considered "adequately demonstrated" for a compliance date in the future.

While CAMR was vacated by the D.C. Circuit, the court did not address the CAMR future effective BSER determinations and the court's decision to overturn the rule was not grounded in any concern about these determinations. Thus, EPA's conclusion that it is authorized to make future effective BSER determinations still stands.

Given that EPA has definitively determined that it has authority to under § 111 to establish such future effective BSER determinations, and in light of the record evidence indicating that sufficient REC equipment will not be available upon the effective date of the final rule but can become available within two years after the effective date of the rule, EPA has ample legal and factual justification to defer the REC requirement.

7.5. Adding Control to Existing Tanks

If an exempt affected storage vessel exceeds the exemption level at some point in the future, the regulation should allow for some period of time after exceeding an exemption level to comply with the control requirements. For example, the additional throughput from bringing on a new well to an affected storage vessel may trigger control requirements for a previously exempt tank. Since the throughput exemption is an annual amount, sources might not know if the exemption was lost until the end of the year. An existing affected storage tank that triggers the control requirements after the effective date of the final rule would then have to meet the control requirements as soon as it no longer meets the exemption, which might not be apparent into; the end of the year. In order to avoid any compliance concerns, an owner/operator may be forced to reduce production to ensure the storage vessel continues to meet the exemption or shutdown production until the storage vessel is modified to meet the control requirements.

API therefore recommends EPA include in the final rule a provision to allow time after exceeding an exemption level to implement controls. The time should be sufficient for designing, ordering, and installing the equipment necessary to meet the control requirements. Although this type of scenario would not be a modification, EPA could use a similar approach used in §60.14(g) and allow 180 days to come into compliance with all the applicable standards. For reference, the language used in §60.14(g):

Within 180 days of the completion of any physical or operational change subject to the control measures specified in paragraph (a) of this section, compliance with all applicable standards must be achieved.

Furthermore, we recommend proposed §60.5395(a)(1) and (2) be clarified to state that the exemptions are based on calendar year annual averages. A calendar year basis is most appropriate because it avoids surprises from fluctuating operations and minimizes burdens by matching the time period used for emission estimating and other reporting, where tank throughput data is needed.

Suggested Rule Text:

§60.5370

- (a) You must be in compliance with the standards of this subpart no later than **60 days after** the date of publication of the final rule in the **Federal Register** or upon startup, whichever is later **except for the provisions of §60.5370(a)(1)-(5) below:**
- (1) Compliance with §60.5375 is required beginning [two years after the effective date]. From the [effective date] until [two years after the effective date] comply only with §60.5375(a)(1)(ii).
 - (2) Compliance with §60.5390 is required beginning [one year after the effective date], except for the following
 - (i) Compliance with §60.5410(d)(3) is required (for any new, modified, or reconstructed affected facility) beginning two years after the effective date
 - (ii) Compliance with §60.5410(d)(3) is required (for any new, modified, or reconstructed affected facility) beginning two years after the effective date
 - (iii) Compliance with §60.5420(c)(4)(iii) is required (for any new, modified, or reconstructed affected facility) beginning two years after the effective date
 - (3) Compliance with §60.5395 is required beginning [three years after the effective date].
 - (4) If your new or reconstructed process unit equipment is subject to §§60.5400, 60.5401, and 60.5402, you must be in compliance no later than 180 days after startup.
 - (5) If you become subject to §§60.5400, 60.5401 and 60.5402 due to modification under provisions of §60.14, the group of all equipment within that process unit must be in compliance with the work practice provisions of §§60.5400, 60.5401, and 60.5402 of this subpart no later than a year after the modification. If any equipment upgrade is required in order to achieve initial compliance (e.g., pump seal and pressure relief device upgrades), you must complete all equipment upgrades and comply with §§60.5400, 60.5401 and 60.5402 for that equipment no later than three years after the modification.

7.6. Compliance Dates for NESHAP Subparts HH and HHH

NESHAP Subparts HH and HHH have been revised. EPA has made allowances for new compliance dates for specific types of equipment that have new or revised compliance requirements because of the proposed revisions [§63.760(f)(7)-(10)]. However, other proposed revisions do not appear to have new compliance dates associated. This practice may have the unintended consequence that the

new text may be interpreted as having retroactive compliance requirements. The following list illustrates some of these unintended consequences.

7.6.1. Major Source Definition Changes

Changing Subpart HH to include all tanks in lieu of tanks “with the potential of flashing emissions” in the affected source will cause some facilities to become major sources. However, EPA has provided no beginning effective date for this change, has not provided any provisions for existing facilities to come into compliance with the newly applicable regulations, or even adequately made the regulated public aware that they need to recalculate their applicability to major per the new Subpart HH definitions and obtain compliance with major source requirements if necessary. API recommends that, consistent with §63.6(c)(5) of the Part 63 General Provisions, EPA allow such facilities 3 years to obtain compliance with these new requirements. Regulatory text will need to be added to §63.760(f) to add the new compliance time. Regulatory text revisions should also be added in the definitions of “associated equipment” and “major source” to indicate the effective dates of the changes take effect.

LDAR Requirements.

EPA revised the requirements for LDAR monitoring to a leak rate definition of 500 ppm within the text of §63.769(c). In doing so, it is not apparent that regulated facilities have not always been required to meet the 500 ppm leak rate definition. API believes (see Section 19 for further discussion) that EPA must clarify that compliance with the 500 ppm leak rate definition only applies after the compliance date established in this rulemaking.

EPA should allow new or reconstructed facilities 180 days and existing facilities at least a year to implement work practice requirements and 3 years to come into compliance with new requirements requiring investment after the effective date of this rule

7.6.2. SSM Events

The revisions around the SSM events have no start date associated. Without this, agency personnel without the knowledge of the regulatory history could try to enforce the provisions around affirmative defense and SSM events retroactively. If EPA continues with these revisions (see Sections above), regulatory text should be added/revised to make a clear distinction of when these provisions become effective.

7.6.3. Performance Testing

Many of the revisions to the control equipment requirements of §63.771 apply to equipment that is currently required. No provisions have been made to indicate when these requirements were changed. EPA should revise the proposed rule so that the new performance testing requirements apply only to control equipment installed for the purpose of complying with this subpart after the effective date of this rule.

8. NSPS COMPLIANCE REQUIREMENTS (NOTIFICATION, RECORDKEEPING, REPORTING, MONITORING, PERFORMANCE TESTING, AND THIRD PARTY VERIFICATION).

In most instances, EPA has followed the precedent of previous NSPS regulations for the proposed rule. However, this proposed rule is unprecedented in the number of affected facilities it will regulate, the average sizes of the sites, and the remote, dispersed and unmanned nature of these sites. The proposed NSPS imposes considerable administrative burden associated with compliance (permitting, recordkeeping, reporting obligations) including first-time regulation (e.g., triggering minor source NSR "facility" permitting in several states) for minor individual pneumatic controllers.

These sites lack the infrastructure of power, communication or even a simply found geographic address that are required to make many of the historic compliance assurance measures function. The proposed NSPS results in unnecessary burden for notifications, monitoring, recordkeeping and reporting without a commensurate benefit.

Implementation concerns, potential rule conflicts (e.g. §60.5 determination of construction or modification, §60.14 modification, §60.15 reconstruction), and issues resulting from selective adoption of the General Provisions (40 CFR 60, Subpart A; see Table 3 of Subpart OOOO) is problematic for the proposed rule and is unnecessarily complicated. API suggests that NSPS Subpart OOOO, Table 3 sections designate that §60.7 – Notifications and Recordkeeping and §60.8 Performance Testing do not apply and that the specific requirements are defined within this final rule.

8.1. Excessive Cost Burden

Defining a very small individual piece of equipment (i.e. component-level) as an affected facility is illogical and defies the common sense definition of "facility". Unnecessary burden for notifications, permitting, reporting and recordkeeping would be introduced without commensurate benefit. For example, regulation by an NSPS has implications under state air quality regulations – e.g., permitting may be mandated. Although Subpart OOOO includes a provision that precludes Title V permitting, many states require permitting of NSPS affected sources. This would incur significant burden from reporting and recordkeeping, and new permitting requirements would result in some states. While EPA may attempt to preclude state rules implementation burdens and costs from consideration, the rule costs incurred from state permit actions are significant, add compliance risk though unnecessary rule complexity, can be estimated, and should not be summarily dismissed, disregarded, or ignored.

In the preamble, EPA "estimate(s) that over 20,000 completions and recompletions annually will be subject to the proposed requirements [76 FR 52747]. These completions and recompletions likely correspond to approximately 100,000 new pneumatic devices, thousands of new storage vessels, and associated new compressors. Each of these will be a new "facility" and the totals provide an indication of the magnitude of the annual industry cost burden for notification, recordkeeping, reporting (initial and on-going annual), permitting, and management activities.

Table 8-1 provides a summary of the myriad of equipment and facility-specific notification, recordkeeping, and reporting requirements and burdens imposed by the proposed rule. This table illustrates the magnitude of effort to track and comply with these requirements and also highlights

potential cost impacts that have not been properly categorized or considered in the cost-benefit portion of the proposed rule.

Table 8-1. Summary of Recordkeeping and Reporting Requirements of Subpart OOOO^B

| Proposed Regulatory Provision | Requirement | Applies to: | Due Date: | Start Date: |
|--------------------------------------|---|---|--|--------------------|
| 60.5420(a)(1) | Submit written notification required in 60.7(a)(1) | Construction of all affected facilities except pneumatic controllers | 30 days after commencement of construction or reconstruction | 8/23/11 |
| | Submit written notification required in 60.7(a)(3) | Startup of all affected facilities except pneumatic controllers | 15 days after initial startup | 8/23/11 |
| | Submit written notification required by 60.7(a)(4) | Physical or operational change that increase emission rates to any affected facility except pneumatic controllers | 60 days prior to the commencement of change or as soon as practicable | 8/23/11 |
| 60.5410(a)(1); 60.5420(a)(2) | Advance notification of well completion operation; commencement date of well completion; lat/long of well. | Gas wellhead completions and recompletions | 30 days <u>prior</u> to commencement of well completion | 8/23/11 |
| 60.5410(a)(2) | Maintain a daily log for completion including compliance with REC and deviations per 60.5375(b) | Gas wellhead completions and recompletions | Daily during completion operations | 8/23/11 |
| 60.5410(a)(3); 60.5420(b)(1)-(2) | Initial annual report for wellhead affected facility (company name and address; list of affected facilities; reporting period; list of well completions; deviations; completion logs) | Gas wellhead affected facilities | 1 year after initial startup or 1 year after final rule publication, whichever is later; annually thereafter | 8/23/11 |
| 60.5420(b)(1) | Annual report (company name and address; list of affected facilities; reporting period) | All affected facilities | 1 year after initial startup or 1 year after final rule publication, whichever is later; annually thereafter | 8/23/11 |
| 60.5410(c)(1) | Continuously monitor number of hours of operation | Well completions | Annual reporting | 8/23/11 |

^B Start date associated with each requirement is August 23, 2011 except for compressor rod packing hour tracking under 60.5420(c)(3)(i)-(ii) that starts either the date of FR final rule or previous rod packing replacement, whichever is later.

| Proposed Regulatory Provision | Requirement | Applies to: | Due Date: | Start Date: |
|-------------------------------|---|--|--|-------------|
| 60.5420(b)(2) | For gas wellhead affected facilities, list of well completions, deviations, and completion logs | Gas wellhead affected facilities | 1 year after initial startup or 1 year after final rule publication, whichever is later; annually thereafter | 8/23/11 |
| 60.5420(b)(3) | For centrifugal compressors, documentation that each one is equipped w/ dry seals | Centrifugal compressors | 1 year after initial startup or 1 year after final rule publication, whichever is later; annually thereafter | 8/23/11 |
| 60.5420(b)(4) | For reciprocating compressors, documentation that rod packing is replaced at least every 24,000 hours, cumulative hours of operation as specified | Reciprocating compressors | 1 year after initial startup or 1 year after final rule publication, whichever is later; annually thereafter | 8/23/11 |
| 60.5420(b)(5) | Date, location and mfr specs; reason for high bleeds; documentation that each controller has 0 NG emissions. | Pneumatic controllers installed at PFs | 1 year after initial startup or 1 year after final rule publication, whichever is later; annually thereafter | 8/23/11 |
| | Date, location, mfr specs, mfr guarantee that bleed rate is <6scf/hr, | Pneumatic controllers not installed at PFs | 1 year after initial startup or 1 year after final rule publication, whichever is later; annually thereafter | 8/23/11 |
| 60.5420(b)(6)(i) | For storage vessels with condensate throughput >1 bbl/d and crude oil >21 bbl/d, records required by 63.774(b)(2)-(8) | Storage vessels | 1 year after initial startup or 1 year after final rule publication, whichever is later; annually thereafter | 8/23/11 |
| 60.5420(b)(6)(ii) | For storage vessels with condensate throughput <1 bbl/d and crude oil <21 bbl/d, documentation of throughput | Storage vessels | 1 year after initial startup or 1 year after final rule publication, whichever is later; annually thereafter | 8/23/11 |
| 60.5420(c) | [60.7(f)] Maintain records of continuous monitoring tests, calibrations, maintenance, etc. | All affected facilities | Maintain records | 8/23/11 |
| 60.5420(c)(1)(i) | Records of each completion operation during the reporting period | Gas wellheads | Maintain records | 8/23/11 |
| 60.5420(c)(1)(ii) | Records of any deviations in completion operation requirements | Gas wellheads | Maintain records | 8/23/11 |
| 60.5420(c)(1)(iii) | Logs for completion operations | Gas wellheads | Maintain records | 8/23/11 |

| Proposed Regulatory Provision | Requirement | Applies to: | Due Date: | Start Date: |
|-------------------------------|--|---------------------------|------------------|---|
| 60.5420(c)(1)(iii)(A) | Location of well, duration of flowback, recovery to sales line, combustion, venting; and reasons for venting | Non-delineation wells | Maintain records | 8/23/11 |
| 60.5420(c)(1)(iii)(B) | For delineation wells, all of the above except for duration of recovery to sales line + record the distance, in miles, to nearest gathering line | Delineation wells | Maintain records | 8/23/11 |
| 60.5420(c)(2) | Maintain records of type of seal system installed | Centrifugal compressors | Maintain records | 8/23/11 |
| 60.5420(c)(3)(i)-(ii) | Maintain records of (i) cumulative hours of operations as specified and (ii) date and time of rod packing replacement | Reciprocating compressors | Maintain records | Date of FR final rule or previous rod packing replacement, whichever is later |
| 60.5420(c)(4)(i) | Date, location, and mfr specs for each installed pneumatic controller | All pneumatics | Maintain records | 8/23/11 |
| 60.5420(c)(4)(ii) | Use of high bleed pneumatic is predicated and why | High bleed pneumatics | Maintain records | 8/23/11 |
| 60.5420(c)(4)(iii) | Mfr's guarantee that emissions are <6scf/hr | Pneumatics not at PFs | Maintain records | 8/23/11 |
| 60.5420(c)(4)(iv) | Documentation of use of only instrument air controllers | Pneumatics at PFs | Maintain records | 8/23/11 |
| 60.5420(c)(5)(i) | For storage vessels with condensate throughput >1 bbl/d and crude oil >21 bbl/d, records required by 63.774(b)(2)-(8) | Storage vessels | Maintain records | 8/23/11 |
| 60.5420(c)(5)(ii) | For storage vessels with condensate throughput <1 bbl/d and crude oil <21 bbl/d, documentation of throughput | Storage vessels | Maintain records | 8/23/11 |
| 60.5421(a) | Comply with requirements of 60.486a | NG Processing plants | Maintain records | 8/23/11 |
| 60.5421(a)(1) | When leak is detected, mark with visible identification until repaired | Pressure relief devices | Maintain records | 8/23/11 |

| Proposed Regulatory Provision | Requirement | Applies to: | Due Date: | Start Date: |
|-------------------------------|--|-------------------------|---|-------------|
| 60.5421(a)(2)(i)-(x) | Record leaks in log including instrument and operator id, date of leak and attempts to repair, repair methods, delay of repair information, signature of o/o who decided repair could not be made w/o process shutdown, expected date of repair, lift of id numbers for equipment designated for no detectable emissions | Pressure relief devices | Maintain records for 2 years | 8/23/11 |
| 60.5422(a) | [Vva] 60.487a(a)-(c)(2)(i)-(iv), (vii) - LDAR requirements for valves, pumps and compressors | Equipment components | 6 mos after startup; semi-annually thereafter | 8/23/11 |
| 60.5422(b) | Number of pressure relief devices in gas/vapor service subject to quarterly monitoring requirements | Pressure relief devices | 6 mos after startup; semi-annually thereafter | 8/23/11 |
| 60.5422(c) | Number of pressure relief devices in gas/vapor service for which leaks were detected and number of devices for which leaks were not repaired | Pressure relief devices | 6 mos after startup; semi-annually thereafter | 8/23/11 |
| 60.5423(a) | Retain records of calculations and measurements of 60.8 performance test | Sweetening units | Retain records for 2 years | 8/23/11 |
| 60.5423(b) | Excess emissions reports for any 24 hour period of excess sulfur emissions | Sweetening units | Semi-annually | 8/23/11 |
| 60.5423(c) | Certify exemption analysis that facility's design capacity is <2 LT/D of H ₂ S | Sweetening units | Retain records for life of facility | 8/23/11 |
| 60.5423(d) | Alternative compliance demonstration for sulfur removal efficiency for facilities with a design capacity <150 LT/D of H ₂ S | Sweetening units | Retain records for life of facility | 8/23/11 |

8.2. Stated Goal Is Inconsistent with Proposed Rule Text and Requirements

EPA's intent to simplify, streamline, and minimize the burden associated with notification, recordkeeping, and reporting has not been translated into rule text that accomplishes the stated goal and objectives. EPA has significantly underestimated the magnitude of the annual industry cost burden for notification, recordkeeping, reporting (initial and on-going annual), permitting, and management activities. For example the rule as proposed is requiring four notifications for every well completion operation following hydraulic fracturing or refracturing at a gas well head facility.

Based on EPA's estimate of 20,000 completions/recompletions per year, this would result in 80,000 notifications being filed annually.

EPA states in the preamble that they desire to minimize duplication of notification through incorporating KKK and LLL requirements into OOOO.

“In addition, we are proposing to incorporate the requirements in 40 CFR 60, Subpart KKK and 40 CFR 60, Subpart LLL into the new subpart OOOO so that **all requirements applicable to the new and modified facilities would be in one subpart**. This would **simplify and streamline** compliance efforts on the part of the oil and natural gas industry and **could minimize duplication of notification**, recordkeeping and reporting. [emphasis added]” FR Vol. 76, 52746

EPA also provides additional support for their intention to reduce the burden associated with notification and reporting requirements:

“Given the number of these operations, we believe that **notification and reporting must be streamlined** to the extent possible to **minimize undue burden** on owners and operators, as well as **state, local and tribal agencies**.” [emphasis added]” FR Vol. 76, 52747

While we agree with this goal, the overwhelming administrative burden that would be imposed by the proposed rule falls far short of achieving this outcome.

8.3. Notifications

Affected facilities are so small that all notifications should be eliminated or limited to a single notice coincident with the first annual report. The requirements as proposed could literally lead to daily notifications, as activities change.

Newly added rule administrative costs for notifications and compliance management have *not* been included in cost-effectiveness analyses. These exclusions impose a low bias on compliance costs for *all* emission sources. If EPA elects to retain multiple notification requirements, these obligations need to be streamlined into a single year end summary notice and the cost benefit analyses need to be revised to more accurately reflect actual burdens.

Upset notification in HH and OOOO within 2 days and documentation of affirmative defense is unnecessary and burdensome. As proposed, these notifications would be required for the smallest of emission exceedances with no reportable quantity threshold being set. This is contradictory to other EPA reporting rules such as those under CERCLA and EPCRA where reportable quantities are established for unauthorized releases. Requirements for immediate reporting of unauthorized releases of VOCs should be left to the states as they are best equipped to handle any response that might be required as a result of the release. Immediate reporting to the EPA serves no purpose (see Section 10.2.1 for further details).

8.3.1. Well Completions - Multiple Notification Requirements for Well Completions

The rule as proposed is requiring four notifications for every well completion operation following hydraulic fracturing or refracturing at a gas well head facility which include:

- Post-marked 30 days after construction [§60.7(a)(1)],
- Post-marked 15 days after initial startup [§60.7(a)(3)],
- Post-marked 60 days or as soon as practicable before the changed is commenced [§60.7(a)(4)], and
- 30 days of the commencement of the well completion operation [§60.5410(a)(1) or §60.5420(a)(2)].

Based on EPA's estimate of 20,000 completions/recompletions per year, this would result in 80,000 notifications being filed annually. The necessary additional staff to manage the notification requirements has not been included in the cost-benefit analysis.

API requests that all the §60.7(a) General Provisions notification requirements be eliminated since they are not appropriate for completions operations. The definitions of both "construction" and "initial start-up" do not apply to the flowback and cleanup portions of the well completions operations. Please see Section 15.7 for further discussion on the completions notifications.

8.4. Recordkeeping

Many of the recordkeeping requirements proposed are ambiguous and need further clarification. API requests the following clarifications to the recordkeeping requirements.

Suggested Rule Text:

§60.5420

- (c) *Recordkeeping requirements.* You must maintain the records identified as specified in §60.7(f) and in paragraphs (c)(1) through (c)(5) of this section.
- (1) The records for each gas wellhead affected facility as specified in paragraphs (c)(1)(i) through (c)(1)(iii).
- (i) Records identifying by API well number and date flowback ended, each flowback immediately following hydraulic fracturing stimulation at a natural gas wellhead facility ~~well completion operation for each gas wellhead affected facility~~ conducted during the reporting period;
- (ii) Record of deviations and reasons for the deviations in cases where ~~well completion operations with flowback immediately following~~ hydraulic fracturing stimulation at natural gas wellhead facilities onshore were not performed in compliance with the requirements specified in §60.5375.
- (iii) Records required in §60.5375(b) or (f) for each well completion operation conducted for each gas wellhead affected facility that occurred during the reporting period. ~~You must maintain the records specified in paragraphs (e)(1)(iii)(A) and (e)(1)(iii)(B) of this section. (A)~~ For each flowback immediately following hydraulic

fracturing stimulation at natural gas wellhead facilities onshore ~~gas wellheads affected facility~~ required to comply with the requirements of §60.5375(a), you must record: The location of the well; the duration of flowback; duration of recovery to the sales line; duration of combustion; duration of venting; and specific reasons for venting in lieu of capture or combustion including but not limited to wildcat, appraisal, or delineation wells or where production equipment or a natural gas gathering line is not reasonably available, and where combustion is not allowed due to fire hazard, conditions that may result in an explosion, gas is not combustible, or not allowed by state, tribal, or local requirement. The duration must be specified in hours of time.

~~(B) For each gas wellhead affected facility required to comply with the requirements of §60.5375(f), you must maintain the records specified in paragraph (c)(1)(iii)(A) of this section except that you do not have to record the duration of recovery to the sales line. In addition, you must record the distance, in miles, of the nearest gathering line.~~

* * * * *

- (4) For each continuous bleed gas-driven pneumatically controlled process unit ~~pneumatic controller~~ affected facility, you must maintain the records identified in paragraphs (c)(4)(i) through (c)(4)(~~iv~~iii) of this section.
- (i) Records of the date, and location ~~and manufacturer specifications~~ for each gas-driven pneumatic controller installed.
 - (ii) Records of the determination that the use of high bleed gas-driven pneumatic controllers ~~devices~~ is predicated and the reasons why.
 - ~~(iii) If the pneumatic controller affected facility is not located at a natural gas processing plant, r~~Records of the manufacturer's specifications. For low bleed pneumatic controllers, specifications must verify guarantee that the device is designed such that weak stream ~~natural gas~~ emissions are less than 6 standard cubic feet per hour.
 - ~~(iv) If the pneumatic controller affected facility is located at a natural gas processing plant, records of the documentation that only instrument air controllers are used.~~
- (5) For each storage vessel affected facility, you must maintain the records identified in paragraphs (c)(5)(i) and (c)(5)(ii) of this section.
- (i) If required to reduce emissions by complying with ~~§63.766, §60.5395(b)~~, maintain the following records ~~specified in §63.774(b)(2) through (8) of this chapter~~.
 - (A) A copy of the operating plan if using §60.5415(e)(1).
 - (B) A copy of manufacturer certification if using §60.5415(e)(2)
 - (C) A record of the measured values of the parameters monitored.
 - (ii) Records of the determination of the throughput, pressure, and emissions using the methods in §60.5395(c) to demonstrate emissions are below 12 TPY. ~~that the annual average condensate throughput is less than 1 barrel per day per storage vessel and~~

~~crude oil throughput is less than 21 barrels per day per storage vessel for the exemption under §60.5395(a)(1) and (a)(2).~~

8.5. Reporting

Proposed compliance assurance approaches, including electronic reporting, should be revised or excluded from the Final Rule.

8.5.1. Annual Report Timing

Annual NSPS Subpart OOOO reports at Title V Permitted facilities should be allowed to be combined and submitted with other Title V reports for the same facility. For non-Title V permitted facilities, the report should be submitted a year and 60 days after final publication of the rule in the federal register to allow for submittal of a single report for multiple facilities versus a year after the anniversary date of the initial startup date.

8.5.2. Exception Reporting

The rule as proposed requires that for every source category you must report all the records gathered. However, it is excessive and burdensome to both industry and the agencies to require reporting of all the records versus just deviations from the rule. Most of the NSPS regulations require only reporting of deviations such as in 40 CFR 60, Subpart J under §60.107(c) or 40 CFR 60, Subpart Kb under §60.115b. Requiring that all the records are reported will result in a great deal of work for industry to prepare the reports and for the agencies to review all the information supplied to find deviations. In order to reduce this unneeded burden on both industry and agencies, API recommends that only deviations be reported in the annual report.

Suggested Rule Text:

§60.5420

(b) *Reporting requirements.* You must submit annual reports containing the information specified in paragraphs (b)(1) through (b)(6) of this section to the Administrator. The initial annual report is due ~~1 year after the initial startup date for your affected facility or~~ 1 year and 60 days after the date of publication of the final rule in the Federal Register, ~~whichever is later, or with a Title V report the year after~~ publication of the final rule in the Federal Register. Subsequent annual reports are due on the same date each year as the initial annual report. If you own or operate more than one affected facility, you may submit one report for multiple affected facilities provided the report contains all of the information required as specified in paragraphs (b)(1) through (b)(6) of this section.

* * * * *

(2) For each gas wellhead affected facility, the information in paragraphs (b)(2)(i) ~~through and~~ (b)(2)(iii) of this section.

- (i) An identification by API well number and date flowback ended of each flowback immediately following hydraulic fracturing stimulation at natural gas wellhead facilities onshore ~~well completion operation, as defined in §60.5430, for each gas wellhead affected facility~~ conducted during the reporting period;
- (ii) A record of deviations and reasons for the deviations in cases where ~~well completion operations with~~ flowback immediately following hydraulic fracturing stimulation at gas natural wellhead facilities onshore were not performed in compliance with the requirements specified in §60.5375 for each gas well affected facility.
 - ~~(iii) Records specified in §60.5375(b) for each well completion operation that occurred during the reporting period.~~
- (3) For each centrifugal compressor affected facility installed during the reporting period, documentation ~~that if~~ the centrifugal compressor ~~is was not~~ equipped ~~with dry seals as specified in §60.5380(a).~~
- (4) For each reciprocating compressor affected facility, ~~the information specified in paragraphs (b)(4)(i) and (b)(4)(ii) of this section.~~
 - ~~(i) The cumulative number of hours of operation since initial startup, the date of publication of the final rule in the **Federal Register**, or since the previous reciprocating compressor rod packing replacement, whichever is later.~~
 - ~~(ii) Documentation that if~~ the reciprocating compressor rod packing was due for replacement according to one of the frequencies described in §60.5385(a), but was not replaced as specified ~~before the cumulative number of hours of operation reached 24,000 hours.~~
- (5) For each continuous bleed gas-driven pneumatically controlled process unit ~~pneumatic controller~~ affected facility, the information specified in paragraphs (b)(5)(i) through (b)(5)(~~iv~~iii) of this section.
 - (i) The date, site name, location and quantity of high bleed gas-driven manufacturer specifications for each pneumatic controllers installed.
 - (ii) ~~If applicable, d~~Documentation that the use of high bleed gas-driven pneumatic controllers devices is predicated and the reasons why.
 - (iii) For all low-bleed gas driven controllers installed, a statement certifying that each controller was designed to meet the emissions threshold of less than 6 standard cubic feet per hour. ~~For pneumatic controllers not installed at a natural gas processing plant, the manufacturer's guarantee that the device is designed such that natural gas emissions are less than 6 standard cubic feet per hour.~~
 - ~~(iv) For pneumatic controllers installed at a natural gas processing plant, documentation that each controllers has zero natural gas emissions.~~

- (6) For each storage vessel affected facility, the information in paragraphs (b)(6)(i) and (b)(6)(ii) of this section.
- (i) If required to reduce emissions by complying with paragraph §60.5395(a)(1), ~~the records specified in §63.774(b)(2) through (b)(8) of this chapter.~~ the API number of the location of the tank and date of installation.
- (ii) If exempt from §60.5395 in accordance with §60.5395(a), the API number of the location of the exempt tank and date of installation. ~~Documentation that the annual average condensate throughput is less than 1 barrel per day per storage vessel and crude oil throughput is less than 21 barrels per day per storage for meeting the requirements in §60.5395(a)(1) or (a)(2).~~

8.5.3. Electronic Reporting.

8.5.3.1 Electronic or Administrator Reporting Requirements in §63.775(g)

API is opposed to mandatory electronic reporting and supports voluntarily reporting at the operator's discretion. 40 CFR Part 63 Subpart HH, §63.775(g) requires electronic submittal of performance test results to EPA's Central Data Exchange (CDX) after January 1, 2012. API believes electronic reporting should not be mandatory and should only be voluntary. The electronic reporting tool (ERT) is used to electronically create and submit stationary source sampling test plans to regulatory agencies and, after approval, to calculate and submit the test results as an electronic report to the regulatory agency. Paper notification, test plans, and reports may still be required to satisfy individual state requirements. API does not advocate duplicate effort and until state requirements for redundant reporting have been eliminated it is premature to consider mandatory electronic performance test reporting. The added burden for preparing and inputting data into the ERT is cumbersome and the cost has not been adequately addressed.

Additionally, rule language is also unnecessarily vague with respect to test methods that need to be reported to the Electronic Reporting Tool (ERT). Specifically, of the 18 test methods referenced in Subpart HH, only six (6) methods (Methods 1, 2, 3A, 4, 10, and 25A) are compatible with the ERT. API submits that the ERT is still in its infancy and requires additional time to develop the remaining test methods, data elements, and incorporation of alternative emission calculation methodologies that are currently not included in this system. API recommends that the rule language be modified to indicate the following:

- Electronic reporting is voluntary (i.e., not mandatory);
- Test Methods 1, 2, 3A, 4, 10, and 25A are the test methods that can be reported to the ERT voluntarily; and
- Test results are due 90 days after the completion of a test, beginning with tests performed three (3) years after the publication of the final rule.

Reporting under multiple rules for a variety of purposes are likely to result in conflicting data and add a burden on operators to provide detailed emission assumptions and methodologies that are not well suited to rigidly defined data entry fields in electronic database reporting formats. For example, reporting VOC, NMHC, THC, GHGs, and HAP emissions under different programs is likely to result in confusion and misinform the public based on overlapping compounds, test method differences, and emission factor based approaches. Redundant reporting under different rules is unnecessary, burdensome, and not cost effective. For example, many state agencies require an annual emission inventory.

Experience with some existing EPA reporting tools indicate that they do not enhance reporting efficiency and require an inordinate amount of time to enter data, verify data entries, and tailor available data to the prescribed fields. Further, the security measures for data entry involve additional burden through time-consuming responses to multiple security questions for each entry.

Furthermore, based on the timetable associated with the current comment/response cycle for this rule, we do not anticipate that the rule will be finalized by the end of this year. However, §63.775(g) requires electronic submittal of performance test results after January 1, 2012. Given this language, EPA is effectively requesting that the data be submitted prior to the effective date of this rule. API does not believe that this is logical, rational, and strongly advocates a measured review process and an adequate beta test period for any electronic reporting tool, either voluntary or mandated.

EPA should also consider confidential business information or proprietary data limitations as this reporting requirement is reviewed and the cost burden is reassessed. EPA should examine the likely business impact from the disclosure of required data elements before they are reported and potentially subject to public availability. Any electronic reporting would likely burden owners/operators.

8.5.3.2 Requested Comments on Electronic Reporting for NSPS Subpart OOOO (V.D.3.).

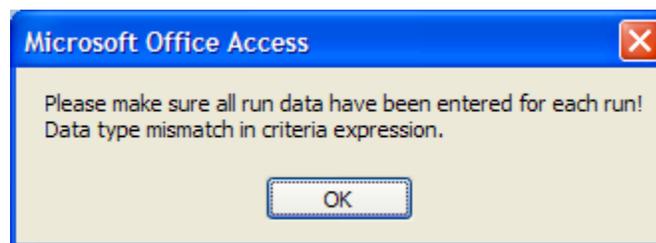

EPA has requested comment on electronic reporting. API believes electronic reporting should not be mandatory and supports only voluntary electronic reporting at the operator's. Electronic reporting is already required for many of these sources in the Mandatory Greenhouse Gas Reporting Rule (40 CFR, Part 98). Reporting conventions associated with VOC, NMHC, THC, and GHG emissions will result in conflicted data and add a burden on operators to provide detailed emission assumptions. Redundant reporting under different rules is unnecessary, burdensome, and not cost effective. If retained, the cost for duplicative reporting requirements should be addressed and justified. Any electronic reporting would burden owners/operators. Furthermore, experience with some existing EPA reporting tools indicate that they do not enhance reporting efficiency. Delays in the final version of the Electronic Greenhouse Gas Reporting Tool (e-GGRT) for the GHG MRR and the e-GGRT system for Subpart W show the difficulty in creating a

tool that is useful to both the EPA and industry. The experience with e-GGRT indicates that a more efficient system needs to be developed before requiring usage by industry. Another difficulty associated with electronic reporting is the reporting of new and/or alternative test methods that are slow to be incorporated into the system. Small companies could also be disproportionately burdened as they typically lack personnel specifically dedicated to environmental management issues.

8.5.4. EPA Should Not Require Use of the Electronic Reporting Tool (ERT)

While EPA continues to make improvements to the Electronic Report Tool (ERT), it still needs much more refinement before it is a useable tool by industry. Outlined below are some of the ongoing concerns with the ERT's ability to allow submittal of accurate, consistent and complete test data. EPA should resolve these issues before requiring its use in a regulatory program.

- a. The range of stack test methods which can be used in the ERT is narrow. Not only does the ERT lack the capability to accommodate all of EPA's test methods, there is only limited provision for use of other state, local or consensus standard methods. In the latest version (v4) EPA incorporated a "custom method" option; however, this is limited to methods which are analogous to EPA Method 5 (using extractive sampling and displacement gas volume meters) or instrumental methods like EPA 3A, 6C, 7E or 10. This feature allows one to enter a custom pollutant, but there is no provision to change the calculations or configure the data inputs to reflect different types of test instrumentation (e.g., for methods that use a rotameter or venturi and time to determine sample volume), different standard temperatures, blank corrections, etc.
- b. ERT has serious functional flaws that can cause calculation, printing and other errors. Error handling is very poor; error messages are not very helpful (e.g., see below), or the program may crash.

- c. Handling of detection limits is not integrated in a manner that would assure appropriate data calculations and data flagging in the test report. Entry of detection limits in comment fields and manual formatting of test data (e.g. [<3.2] for a result below detection limits at a detection limit of 3.2) almost assures that data will not be handled correctly or consistently.
- d. Analytical lab data can only be entered as a single net result for each sample fraction, rather than as individual values for each measured value. This requires testers or laboratories to make an intermediate calculation prior to data entry. For example, gravimetric results generally consist of two weights (tare and final) for each sample

fraction. Each weighing is the result of several replicate weights until the difference between two sequential weighings is less than a certain value (0.5 mg for Method 5). Method 5, for example, does not specify whether the first weight, the second weight or the average of the two weights should be reported, and different testers and labs use different conventions. Thus, there can be a total potential error of as much as 2 mg in the net weight of a Method 5 sample fraction, depending on convention. This can represent a large error compared to sample weights for many modern sources leading to inconsistent results and poor data comparability. As another example, many instances of incorrect intermediate calculations were found in the ICI Boiler and EGU ICRs. For example, many testers failed to correctly handle detection limits when summing values for the five analytical fractions comprising total mercury in EPA Method 29 measurements when some fractions were detected and some undetected. This introduces serious potential data quality issues for mercury measurements by this method. EPA states that one of the benefits of ERT is to improve consistency of results; however, this oversight allows one of the most significant sources of inconsistency to persist.

- e. Some state and local test methods use a different standard temperature than EPA's standard temperature of 20 C (68 F). Standard temperature is hard coded into ERT with no provision for the user to change it, neither in any of the current method templates nor in the custom method option. This limits the use of ERT for local reporting requirements, requiring the tester to prepare separate test reports for WebFIRE and for local use.
- f. Some state and local agencies have different protocols for handling undetected results (e.g., substitution of ½ detection limits or zero for undetected results). As noted above, ERT does not correctly flag undetected results in the test report nor allow for alternative detection limit protocols. Testers would need to prepare separate test reports for local use and WebFIRE use.
- g. There are numerous instances of ambiguous wording and nomenclature in ERT. For example, in Test Plan field 7b, a column is headed "Corrected analyte" and another is "Corrected %". If the intent is to list the diluent indicator (e.g., O₂ or CO₂) and diluent reference concentration, these should say so and the calculations should be handled accordingly.
- h. ERT does not allow for all common diluent corrections. O₂ diluent corrections embedded in ERT only work if the diluent is air. If a combustion source uses O₂ or nitrogen enrichment such that O₂ concentration in the diluent is not 20.9% by volume, the diluent-corrected test result would be incorrect.
- i. The laboratory(ies) performing sample analysis is not identified by name in the test report, unless the tester chooses to do so in a comment field. All organizations involved in the test program should be identified in the report.
- j. There doesn't appear to be a way to handle DGM (dry gas meter) volumes during non-sampling periods, e.g. leak checks.

- k. ERT can handle only three test runs. For some processes it is necessary to make more than three test runs to obtain representative emissions factors.
- l. The number format in the test report is not configurable so that values are reported with an appropriate number of significant digits. This generally gives a highly misleading impression of results precision. For example, the Emissions Summary page uses scientific notation with 3 significant figures (2 decimal places), while the Stack Data Results Summary and Stack Data Results Detail pages use decimal format. In one example, the mass of water gained in the impingers is reported to 11 significant figures (8 decimal places) and all average results are reported to three decimal places, ranging from 2 to 9 significant figures depending on the parameters. The appropriate number of significant figures will vary, depending on specific details of a given test and parameters.
- m. Some document control errors persist e.g. page count for one example test report was incorrect, resulting in last page numbered as "12 of 13".
- n. Data flags and comments entered on the lab data tab (e.g., ADL, BDL, DLL) are not carried forward to the results summary or detailed results report pages, presenting a misleading impression of high data quality.
- o. ERT does not include printing of all primary input data (e.g., point to point run data, lab data with flags and comments, impinger weights, etc.) among the report options. This is a key shortcoming for quality control review and auditing of test reports.
- p. Some formatting issues remain (e.g., in one example several pages of the printed test report had headers but no data).

8.6. Performance Test Methods and Compliance Monitoring Requirements

8.6.1. General

- a. The use of extensive cross referencing to a myriad of other rules and test methodologies renders the requirements in Subpart HH nearly impossible to follow, confusing to the extent that it unnecessarily adds to the compliance burden, and likely to lead to errors and misunderstanding.
- b. The test protocols, requirements, and methodologies specified in the rule are unnecessarily complex, likely not technically achievable in certain instances, and unnecessarily costly.
- c. The requirements for continuous monitoring of parameters to demonstrate continuous compliance are similarly unnecessarily complex, likely not technically achievable in certain instances, and unnecessarily costly.
- d. EPA should redraft the performance testing and continuous compliance monitoring requirements of the rule to:

- i. simplify requirements,
- ii. include only requirements appropriate for the large number and type of dispersed small sources which would be subject to the rule,
- iii. reduce the extensive cross referencing in the testing and monitoring requirements to reduce the confusing nature of the proposed rule and lessen the chance that the confusing construction of the rule will inadvertently lead to non-compliance incidents through misunderstanding, and
- iv. reduce the unnecessary economic burden.

8.6.2. Applicable to Subpart OOOO and Subpart HH/HHH

Requirements for using an enclosed combustion device for HAP or VOC control under NSPS Subpart OOOO or NESHAP Subpart HH or HHH are specified in §63.771.

- a. Paragraph 63.771(d)(1)(i) specifies that an enclosed combustion device must meet one of the following performance criteria:
 - (A) Reduces the mass content of either TOC or total HAP in the gases vented to the device by 95.0 percent by weight or greater as determined in accordance with the requirements of §63.772(e); or
 - (B) Reduces the concentration of either TOC or total HAP in the exhaust gases at the outlet to the device to a level equal to or less than 20 parts per million by volume on a dry basis corrected to 3 percent oxygen as determined in accordance with the requirements of §63.772(e); or
 - (C) For a control device that can demonstrate a uniform combustion zone temperature during the performance test conducted under §63.772(e), operates at a minimum temperature of 760 degrees C.
- b. Operational conditions in the oil and natural gas production sector are very different from those experienced at refineries or chemical plants. Conditions of intermittent, variable and turbulent flow and variable temperature and pressure make it infeasible to perform the test methods in the production field that are typically used in refineries or chemical plants. Coupled with the dispersed and remote nature of the small sources regulated under this rule, the proposed requirements are not appropriate and are unnecessarily burdensome. API requests:
 - i. The requirement in §63.771(d)(1)(i)(A) should be modified to require reduction of either TOC or HAP emissions by 95% on a volumetric concentration basis using a “carbon balance” methodology for analysis of the exhaust stack effluent from an “enclosed combustion device” being used as a control device to demonstrate reduction efficiency.

Methodologies 25A for TOC (calibrated to propane), 3A for CO₂ and O₂, and 10 for CO should be specified for testing of the stack effluent gas. The CO₂ measured

using Method 3A should be adjusted downward by the latest published atmospheric CO₂ concentration, as reported from the Mauna Loa monitoring site by NOAA’s Earth System Research Laboratory, multiplied by the ratio of O₂ measured in the stack effluent as compared to the ambient O₂ content of 20.8 volume %. (3A measured CO₂ (ppmv) – (Mauna Loa Concentration (ppmv) X (3A measured O₂ (ppmv)/208,000 (ppmv) ambient O₂ concentration).

Destruction efficiency of 95% would be demonstrated when the following equation yields a value of 95% or greater:

$$(CO_{2c} + CO)/(CO_{2c} + CO + (3 * TOC))$$

where:

CO_{2c} = CO₂ ppmv concentration measured in the stack via method 3A minus the ambient CO₂ ppmv concentration present in the stack determined as described above.

CO = CO concentration measured in the stack via method 10

TOC = Total Organic Carbon, expressed as propane, measured in the stack via method 25A

The following table shows this calculation and outcome for an assumed stack effluent composition:

| | | |
|---|---------|--|
| Outlet CO ₂ | 30,000 | Measured Value |
| Outlet CO | 100 | |
| Outlet TOC | 30 | |
| Outlet O ₂ | 150,000 | |
| Ambient O ₂ | 208,000 | |
| Ambient CO ₂ | 388 | |
| Outlet CO _{2c} from combustion | 29,720 | Outlet CO ₂ - ((Ambient CO ₂ X (Outlet O ₂ /Ambient O ₂)) |
| | | |
| Destruction Efficiency | 99.70% | (CO _{2c} + CO)/(CO _{2c} + CO + (3 * TOC)) |

The suggested carbon balance methodology is similar to that described in EPA’s Technical Report “EPA-AA-SDSB-80-05” “Carbon Balance and Volumetric Measurements of Fuel Consumption” used by EPA for vehicle testing and is identical to that described in the UNFCCC CDM methodology found at:

http://cdm.unfccc.int/filestorage/C/6/X/C6XWJCBZSTR2S0SQKE7ZFQYEDIBNPZ/Procedure%20to%20determine%20the%20flare%20efficiency%20based%20on%20the%20flame%20temperature%20in%20an%20enclosed%20flare.pdf?t=bmh8bHYyeTJ0fDAPxze0_d4bXBK2OcnA8D9I and also described on page 630 of the “John Zink Combustion Handbook” available for purchase from Amazon books.

- ii. Modify the requirement in §63.771(d)(1)(i)(B) of the proposed rule to demonstrate that TOC (as propane – method 25A) concentration in the stack exhaust from an enclosed combustion device is less than 200 ppmv corrected to 3% CO₂ in the stack. Using the carbon balance methodology described above a 200 ppmv TOC would correspond to slightly above 98% destruction efficiency which leaves a wide margin between the alternative of 95% destruction efficiency.

As proposed, the rule indicates an alternative control device exhaust concentration requirement of less than 20 ppm corrected to 3 percent oxygen. Typically, combustors have carbon dioxide concentrations of approximately 3% and oxygen concentrations of approximately 16%. 20 ppm corrected to 3 percent oxygen corresponds to an in-stack actual concentration of approximately 5 ppm which would likely correspond to a destruction efficiency approaching 100% (the alternative requirement is 95% destruction). API believes this is a simple mistake and the correct formulation would be corrected to 3 percent CO₂. For the type, small size, and number of sources subject to these requirements API believes a more appropriate formulation would be correction to 3% CO₂. This would be consistent with §§63.772(h)(6)(vi) and 63.772(h)(7)(i)(B), where the proposed rule indicates the concentration limits for the manufacturers of combustors conducting a performance test and specifies an exhaust concentration requirement of being less than 10 ppm corrected to 3 percent carbon dioxide. This appears inconsistent with the 3% oxygen correction stated in §63.771(d)(1)(i)(B), where it outlines the general field performance test requirements. As stated, the manufacturers of combustors would actually have a less restrictive limit than owners conducting a field performance test.

- iii. Modify the requirements in §63.772(h) to conform with the carbon balance test methodologies described above for field performance testing. The ppmv performance criteria stated in §63.772(h)(7)(i)(B) should be modified to 100 ppmv TOC (as propane) corrected to 3% CO₂ which corresponds to ~99% destruction efficiency and provides ample buffer between a manufacturers tests for certification and the required 95% destruction efficiency for field demonstration. As currently constructed, the manufacturers certification testing must show ~ 99.97% destruction which is unreasonable and certainly not supportable from the standpoint of rule cost effectiveness.
- iv. Remove §63.772(h)(7)(i)(C) to eliminate the consideration of CO concentration in the manufacturers certification testing. By imposing a CO concentration, EPA is effectively converting the destruction efficiency testing to combustion efficiency testing which is not required by nor appropriate for the proposed rule.
- v. Eliminate the requirements for measurement of inlet flow to an enclosed combustion device and outlet flow from an enclosed combustion device, as per §63.772(e)(3)(i)(A), or outlet flow from an enclosed combustion device, as per §63.772(e)(3)(i)(A). As described above, these measurements are unnecessary to accurately determine destruction and removal efficiency (DRE) for the control device.

Additionally, requiring Method 2, 2A, 2C, or 2D to determine volumetric inlet flow is not appropriate and likely not technically feasible for accurate measurement. The waste gas inlet stream to an enclosed combustion device being used for control for either a storage tank or a small or large dehydrator will be a low pressure (essentially atmospheric) low flow stream with very low velocity which is almost impossible to measure accurately using any of the specified methods. Rather than attempting to measure such a stream EPA should specify the use of E&P TANK or a process simulation model such as ProSim or HySys to determine the inlet flow and composition of a waste gas stream routed to an enclosed combustion device from a storage tank and GlyCalc 3.0 or higher dehydrator model or a process simulation model such as ProSim or HySys to determine the inlet flow and composition of a waste gas stream routed to an enclosed combustion device from either a small or large dehydrator. The problems with attempting to measure such a stream are more completely described in Attachment H which is incorporated in these comments by reference.

The outlet flow from a typical enclosed combustion device has the same low pressure, low velocity, and difficulty for measurement issues as the waste gas inlet. If EPA insists on a mass balance approach rather than the much simpler and accurate carbon balance approach, API recommends the rule enable the use of Method 2B to calculate outlet flow for the combustion device using the model output information discussed above to calculate inlet flow and composition to the combustion device.

- vi. Eliminate the proposed rule revisions that change the temperature monitoring device accuracy requirements from +/- 2 to +/- 1 percent of the temperature being monitored expressed in degrees C. In the preamble, EPA states:

"we are proposing to revise the temperature monitoring device minimum accuracy criteria ... to better reflect the level of performance that is required of the temperature monitoring devices. We believe that temperature monitoring devices currently used to meet the requirements of the NESHAP can meet the proposed revised criteria without modification."

However, EPA provides no data or analysis to support the need for a more stringent accuracy requirement. At typical incinerator temperatures, any change, in combustion efficiency and emissions caused by a temperature change represented by the difference between 1 and 2 percent accuracy is most likely not detectable. Further, EPA contradicts the need for the rule revision by stating that it believes that current temperature monitoring devices can meet the criteria without modification. If current devices are sufficiently accurate, why is there a need for a new accuracy standard? Absent data and analysis that demonstrate that the new accuracy requirements would provide better emissions control, there is no need to revise the existing accuracy criteria. The primary rule revision effect would be to unnecessarily burden operators to modify internal procedures and recalibrate select devices. Simply because a certain standard of accuracy can be attained is not sufficient to demonstrate that it should be required.

vii. Clarify that the requirements in §63.771(d)(1)(i) for enclosed combustion control devices for "sources except small glycol dehydration units" (i.e., large dehydration units and tanks) is correctly interpreted as:

- Operators may comply with the requirements to reduce HAP emissions in accordance with §§63.771(d)(1)(i) (A), (B), (C), or (D).
- Operators that comply with the requirement to reduce HAP emissions in accordance with §63.771(d)(1)(i)(C) are only required to conduct an initial performance test that demonstrates that the combustion zone profile has a minimum temperature of 760°C. "Uniform" should be deleted from §63.771(d)(1)(i)(C) because uniform is not defined in the rule and the complex interactions of flame zone reactions, mixing, and convective and radiative heat transfer preclude "uniform" combustion zone temperature profiles. Rather, it appears that EPA's intent is that the combustion zone profile must have a minimum temperature of 760°C such that there are no low temperature pathways for HAPs to escape destruction. API recommends the following rule revision:

§63.771

(d)(1)(i)(C) For a control device that can demonstrate a ~~uniform minimum~~ combustion zone temperature of 760°C during the performance test conducted under §63.772(e), ~~operates at a minimum temperature of 760 degrees C.~~

- In addition, the rule appears confused because the requirements for demonstrating "a uniform combustion zone temperature" are not specified in the performance testing section, nor otherwise discussed in the rule. Therefore, API recommends that the following initial performance testing requirements to determine a combustion zone profile be added as §63.772(e)(3)(vii):

§63.772

(e)(3)(vii) To determine compliance with the minimum combustion zone temperature of 760°C specified in §63.771(d)(1)(i)(C), the owner or operator shall profile the combustion zone temperature as follows:

(A) Method 1 or 1A, 40 CFR part 60, appendix A, as appropriate, shall be used for selection of the measurement sites in the combustion zone.

(B) The gas temperature at each measurement site shall be determined using a temperature monitoring device having a minimum accuracy of ±2 percent of the calibrated range expressed in °C, or ±2.5 °C, whichever is greater.

- Operators that comply with the requirements to reduce HAP emissions in accordance with §63.771(d)(1)(i)(D) are not required to conduct a performance test because this compliance option is an operating standard and does not have a numerical component.

8.6.3. Applicable to Subpart OOOO – Tanks controlled with an enclosed combustion device

- a. Specifying Subpart HH/HHH hazardous air pollutant requirements for testing and performance demonstration of VOC control from tanks is completely inappropriate, unnecessary, and yields unnecessary complexity, confusion, and burden.
- b. API requests that EPA include a separate performance demonstration and monitoring section which is specific to and appropriate for Subpart OOOO rather than simply referring to the requirements in Subpart HH/HHH. This separate performance demonstration and monitoring section should adapt the methodologies described above appropriately for VOC control using enclosed combustion devices. See Section 16.8 for suggested rule text to specify storage tank requirements within Subpart OOOO.

8.6.4. Applicable to Subpart HH/HHH – Dehydrators controlled with an enclosed combustion device

- a. §63.771(f)(1)(i) provides requirements for enclosed combustion control devices for small glycol dehydration units, and lacks compliance options parallel to §63.771(d)(1)(i) (C) and (D).
- b. API requests that compliance options parallel to options §63.771(d)(1)(i) (C) and (D) and appropriate for small dehydrators be added to §63.771(f)(1)(i).
- c. In §63.772(e)(3)(iii)(B)(4) the proposed rule refers to using GRI-GLYCalc 3.0 or higher for determining the mass emission rate of TOC and HAP at the inlet to a control device. It is confusing because it refers to GRI-GLYCalc 3.0 or higher but then later in the same paragraph it refers to EPA Methods 18 and 25A, which of course are testing methods.
- d. API requests that §63.772(e)(3)(iii)(B)(4) be modified to clearly allow use of GRI-GlyCalc to determine the mass emission rate of TOC and HAP at the inlet to a control device.

8.6.5. Other Comments

- a. It is not apparent that ASTM D6420–99 (2004) can be used for HAP measurements. The rule should clarify that ASTM D6420–99 (2004) - in addition to Method 18 in 40 CFR part 60, appendix A and any other method or data that have been validated according to the applicable procedures in Method 301, 40 CFR part 63, appendix A – are applicable for measuring benzene, BTEX, or total HAP emissions from any affected source.
- b. §63.772(f)(3) states: “For inlet gas flow rate, compliance with the operating parameter limit is achieved when the value is equal to or less than the value established under §63.772(h). However, §63.772(h) only applies to manufacturer performance tested combustion control devices and would not apply to dehydrators that are not equipped with manufacturer performance tested combustion control devices.

- c. §63.772(i)(1) requires the continuous monitoring of the inlet flow rate for manufacturer performance tested combustion control devices. The flowmeter is required to have an accuracy of +/- 2%.

As previously discussed, flowmeters for this type of low pressure low velocity stream application and service are not feasible and demonstration of flow to the enclosed combustion device should rely on appropriate models (E&P TANK or process simulation model for tanks, GlyCalc or process simulation model for dehydrators) to set volumetric operating parameters for conforming with a manufacturers range for a combustion device. For example, a process simulation model may be used to establish a lower and upper limit for oil throughput in a storage tank which corresponds with a manufacturers Btu operating range for a combustion device. An operator could then use their average production rates, as determined by normal production volume accounting methods and frequencies, to ensure they are within this range and demonstrate compliance.

API requests that EPA modify the proposed rule to eliminate continuous flow metering to control devices and enable the use of appropriate models to set limits on normally measured parameters to demonstrate compliance. Given the small size, dispersed nature, and large number of units affected by this rule, these changes would appropriately reduce burden while providing for compliance demonstration and monitoring.

- d. §63.772(i)(2) requires that a pilot flame be present at all times of combustion control device operation. This requirement is not applicable for combustion control devices equipped with electronic ignition systems. For combustion control devices equipped with electronic ignition systems, the rule should add a requirement that these be operational at all times of combustion control device operation.

API recommends the following revision to the rule language:

§63.772

- (i)(2) For combustion control devices equipped with pilot flames, a pilot flame shall be present at all times of operation. The pilot flame shall be monitored in accordance with §63.773(d)(3)(i)(H)(2). For combustion control devices equipped with electronic ignition systems, the electronic ignition systems shall be operational at all times of combustion control device operation.

API recommends the following revision to the rule language:

§63.773

- (d)(3)(i)(H) For a control device model whose model is tested under §63.772(h),²

~~(1) A continuous monitoring system that measures gas flow rate at the inlet to the control device. The monitoring instrument shall have an accuracy of plus or minus 2 percent or better.~~

~~(2) A~~ heat sensing or UV sensing (fire-eye) monitoring device equipped with a continuous recorder that indicates the continuous ignition of the pilot flame.

- e. §63.772(i)(3) requires monthly visible emissions tests using Method 22 of 40 CFR 60, Appendix A. Monthly testing is excessively burdensome and not needed to assure combustor compliance because continuous monitoring of combustion control ignition is already required and the materials being combusted are inherently combustible.

API recommends that the rule be revised to require testing every six months with an allowance for less frequent testing for units that routinely pass the visible emissions test. For example, for a unit that passes two consecutive emission tests, the next test would be required in 12 months. If EPA insists on retaining the onerous monthly testing requirement, then similar relaxed testing requirements for a compliant unit should be added. For example, for a unit that passes two consecutive monthly tests, the next test would be required in 2 months, and so forth until an annual testing schedule is achieved.

- f. §63.772(i)(4)(iii) requires the replacement of fuel nozzle(s) and burner tubes after one failed visible emissions test. EPA should *not* stipulate specific equipment replacement or maintenance practices that may be unnecessary and wasteful, or possibly not address the problem. The rule should delete these requirements and state that operators must perform maintenance and/or replace equipment as needed to restore combustion control device functionality.
- g. §63.773(b) requires semi-annual inspections of manufacturer performance tested combustion control devices. EPA should *not* stipulate a specific inspection frequency; rather inspection and maintenance practices should be based on manufacturer specifications and requirements as documented in the required inspection and monitoring plan.
- h. §63.773(d)(1)(iii) requires that the owner or operator conduct CPMS equipment performance checks, system accuracy audits, or other audit procedures specified in the site-specific monitoring plan at least once every 12 months. EPA should *not* stipulate a specific frequency for CPMS checks and audits. Rather, the appropriate frequency should depend on the monitoring parameters and equipment. API recommends that the frequency of CPMS checks and audits will be documented in the site-specific monitoring plan, and supported by manufacturer recommendations.
- i. §63.773(d)(3)(i)(A) in the redline version of the proposed rule states:

“For a thermal vapor incinerator that demonstrates during the performance test conducted under §63.772(e) that combustion zone temperature is an accurate indicator of performance, a temperature monitoring device equipped with a continuous recorder. The monitoring device shall have a minimum accuracy of ± 1 percent of the temperature being monitored in °C, or ± 2.5 °C, whichever value is greater. The temperature sensor shall be installed at a location representative in the combustion chamber downstream of the combustion zone temperature.”

This rule passage is poorly written and confusing. It infers that a thermal vapor incinerator performance test that does not demonstrate that combustion zone temperature is an accurate indicator of performance is not required to install a temperature monitoring device. Further, demonstration that “combustion zone temperature is an accurate indicator of performance” would require testing over a range of temperatures and correlating performance with temperature. This is not a performance testing requirement in the proposed rule nor should it be. In addition, the proposed rule does not define or discuss how to determine “a location representative of the combustion zone temperature.” To address these issues, API recommends the following revisions to the Federal Register version of §63.773(d)(3)(i)(A):

§63.773

(d)(3)(i)(A) For a thermal vapor incinerator ~~that demonstrates during the performance test conducted under §63.772(e) that the combustion zone temperature is an accurate indicator of performance~~, a temperature monitoring device equipped with a continuous recorder shall be installed at a location in the combustion chamber downstream of the combustion zone. The monitoring device shall have a minimum accuracy of ~~±12~~ percent of the calibrated range temperature being monitored in degrees C, or ±2.5 degrees C, whichever value is greater. The temperature sensor shall be installed at a location ~~representative of the combustion zone temperature~~ or downstream temperature measurement during the performance test.

The phrase “or downstream temperature” has been added to the recommended rule text because of the practical considerations associated with measuring combustion zone temperatures. The high temperatures and reactive chemical species rapidly degrade in-situ measurement devices. Equipment properly installed for downstream temperature measurements typically have a much longer operational life and provide an accurate indication of combustion conditions. As long as the compliance temperature is in the same location as the temperature measured during the performance test, that location provides compliance assurance.

- j. §63.773(d)(3)(i)(C) should clarify that a heat sensing monitoring device to indicate continuous ignition of the pilot flame is not required for flares equipped with electronic ignition systems.
- k. For boilers and heaters where the waste gas is not mixed with or used as the primary fuel, to address the temperature sensor location issue previously discussed for thermal vapor incinerators, API recommends the following revisions to the Federal Register version of §63.773(d)(3)(i)(D):

§63.773

(d)(3)(i)(D) For a boiler or process heater, a temperature monitoring device equipped with a continuous recorder shall be installed. The temperature monitoring device shall have a minimum accuracy of ~~±12~~ percent of the

calibrated range ~~temperature being monitored~~ in degrees C, or ± 2.5 degrees C, whichever value is greater. The temperature sensor shall be installed at a location representative of the combustion zone temperature or downstream temperature measurement during the performance test.

- l. The current rule flow meter accuracy requirement of $\pm 10\%$ for regenerative-type carbon adsorption systems should be retained in §63.773(d)(3)(i)(F)(1). EPA has not demonstrated the need for a revised flow meter accuracy requirement including how this revision will improve emission control, nor demonstrated that the additional cost to replace existing equipment and install more accurate flowmeters is justified.
- m. The checks of mechanical connections for leakage required by §63.773(d)(3)(i)(F)(1) should be performed every three months, rather than monthly, in concert with the required visual inspections. Absent moving parts, mechanical connections are extremely slow to develop leaks and more frequent checks add unnecessary labor and recordkeeping burden.

8.6.6. Complete Rewrite Required

API is not attempting to provide a full “mark-up” of the current proposed rule language due to the confusing complexity and extensive cross-referenced manner of its current construction. However, we would certainly be willing to draft, or work with EPA to draft, replacement testing and monitoring requirements and rule text. The replacement requirements must be appropriate for the large number of dispersed small sources subject to the rule with the rule text constructed in a straight forward and non-confusing manner with minimization of the use of cross-references. It is likely that cooperating on this issue will yield better results in a quicker time period.

8.7. Use of NESHAP Emission, Monitoring and Performance Testing Standards in NSPS

The proposed Subpart OOOO would impose a 95% control requirement on affected storage vessels. But, it would do so by incorporating by reference the Subpart HH MACT storage vessel control requirements. *See* 76 Fed. Reg. at 52800 (proposed §60.5395(a)). The preamble and TSD purport that the 95% control requirement is the product of an objective BDT analysis. *See, e.g., id.* at 52763-4; TSD at Section 7. And, EPA proposes that the consistency between the MACT and NSPS storage vessel requirements provides a coincidental opportunity for regulatory streamlining. *See* 76 Fed. Reg. at 52764 (“Because the controls used to achieve the 95-percent HAP reduction are the same as the proposed BSER for VOC reduction for storage vessels (*i.e.*, VRU and flare),” EPA proposes “that storage vessels subject to the requirements of subpart HH are exempt from the proposed NSPS for storage vessel in 40 CFR part 60, subpart OOOO.”).

But, on closer inspection, the storage vessel BDT determination was hard-wired to achieve the same level of control as Subpart HH – undermining the BDT determination and effectively (and unlawfully) extending Subpart HH major source MACT requirements to area source storage tanks. For example, in the BDT analysis, EPA explains that, “We identified two ways of controlling storage vessel emissions, both of which can reduce VOC emissions by 95 percent.” *Id.* at 52763; *see also* TSD at 7-12. EPA does not explain in the preamble or the TSD why other control efficiencies were

not examined or assessed – it simply begins the BDT analysis with the conclusion that 95-percent control is appropriate.

Having selected its preferred control techniques and control efficiencies, EPA is then forced to back-calculate vessel throughput levels that produce costs satisfying the statutory BDT cost criterion. 76 Fed. Reg. at 52763-4. Yet, this analysis precludes other potentially relevant regulatory alternatives – such as marginally less effective controls that might be applied to a broader range of storage vessels. The Agency's failure to consider other control techniques and other levels of control efficiency that might be achieved by its preferred techniques is arbitrary and capricious.

Even if the same control standard of 95% reduction is selected and economically justified, the more stringent monitoring and performance testing requirements required by the CAA in section 112 for HAPs are not required in section 111 for criteria pollutants. This is discussed in more detail in Sections 16.6 and 16.13 of these comments.

8.8. Third Party Verification

EPA asks for comment on the possibility of requiring affected facilities to provide “third party verification to assure compliance” with well completion requirements. 76 Fed. Reg. at 52750. According to EPA, assuring compliance with these requirements could be “very difficult and burdensome for state, local and tribal agencies and EPA permitting staff, inspectors and compliance officers” because “emission sources in the oil and natural gas sector, especially well completions, are widely geographically dispersed (often in very remote locations.” *Id.* A third party verification system could be used to “leverage compliance assurance efforts of the EPA and state, local and tribal agencies” by relieving them “of the burden of receiving thousands of paper or e-mail well completion notifications each year, yet still provide them quick access to the information.” *Id.* EPA also posits that such a system could benefit affected sources, for example by reducing the advance notice for well completions to “much less than 30-days” and eliminating the need for a 2-day follow up notification. *Id.*

There are several problems with this proposal. First, it is not clear what role third party verifiers would play. In part of the discussion of this issue, EPA suggests that the role would be limited to developing and maintaining a “clearinghouse” of information. EPA clearly envisions that such a “clearinghouse” would assist regulators (and the public) by providing easy access to well completion notifications. But, by establishing a clearinghouse, it does not seem that third-party verifiers would do more than the ministerial function of accepting notifications and putting them in an accessible database.

Alternatively, EPA describes the role of third party verifiers as substantive – *i.e.*, “verification of the data collection, compilation and calculations.” In addition, EPA suggests that the scope of third party verification might be extended to required electronic reporting using the ERT. The third party verifiers might assume the task of “review[ing] and verify[ing] that the information submitted to the EPA is truthful, accurate and complete.” *Id.* However, no further details about the scope and authority of the third party verifiers' substantive role is provided. For example, what happens if a third party verifier determines that a calculation error occurred. Would the verifier make the needed correction, or return the notification to the affected facility for correction and resubmission, or

perhaps report a potential violation to EPA? The proposal does not say. Similarly, would third party verifiers make field inspections to verify the information submitted in notifications and/or assess well completions determined not to be subject to Subpart OOOO? Again, the proposal does not say.

This lack of clarity is compounded by the fact that no proposed rule text is provided. As a result, commenters do not have adequate notice of how the third party verification system would work and cannot ascertain whether the regulatory text would faithfully implement the concept. To resolve these problems, EPA must repropose the third party verification requirement before finalizing it.

More fundamentally, EPA has not explained where it finds legal authority to impose a third party verification requirement. To be sure, EPA has broad authority to require such monitoring, recordkeeping, notification, and reporting requirements as are reasonably needed to assure compliance with Part 60 emissions standards. However, there is nothing on the face of the statute (and the statute cannot reasonably be construed as) authorizing EPA to require affected facilities to hire contractors to do EPA's work. EPA freely admits in the proposal that assuring compliance with the well completion requirements would be "very difficult and burdensome for state, local and tribal agencies and EPA permitting staff, inspectors and compliance officers." The clear purpose of the third party verification requirement would be for the third party verifiers to relieve this burden. Simply put, EPA does not have authority under the CAA to require affected facilities to hire contractors to do work on behalf of the Agency.

Moreover, such a requirement would run afoul of the Anti-Deficiency Act. A third party verification requirement clearly would circumvent the limited Congressional budget appropriation for EPA enforcement activity. Such circumvention violates the prohibition against authorizing expenditures "exceeding an amount available in an appropriation or fund for the expenditure." 31 U.S.C. § 1341(a)(1)(A).

For these reasons, even with a reproposal, EPA is without authority to impose a third party verification requirement.

8.9. Equipment Specific Notification, Recordkeeping and Reporting Requirements

8.9.1. Storage Vessels Monitoring

Installation and operation of a CPMS on each storage vessel control system is required under §60.5410(e)(4). The CPMS must be installed and operated in accordance with §63.773(d) requirements, which include hourly data collection/measurement and recording. At remote, unmanned locations, the required data collection would be difficult due to the lack of electrical power that would be needed for a continuous data system. Installing electrical generation equipment would be prohibitively expensive given the small size of these emission sources. Therefore, API recommends that the final rule allow manual data collection on a schedule that matches an owner's site visit schedule.

8.9.2. Sweetening Unit Recordkeeping and Reporting

Under §60.5365(g)(3) "Facilities that have a design capacity less than 2 long tons per day (LT/D) of hydrogen sulfide (H₂S) in the acid gas (expressed as sulfur) are required to

comply with recordkeeping and reporting requirements specified in §60.5423(c) but are not required to comply with §60.5405 through §60.5407 and paragraphs §60.5410(g) and §60.5415(g) of this subpart.”

Although these units are exempt from the standards and monitoring requirements, they remain subject to unnecessary recordkeeping and reporting requirements. API recommends a change to §60.5365(g)(3) as follows: “Facilities that have a design capacity less than 2 long tons per day (LT/D) of hydrogen sulfide (H₂S) in the acid gas (expressed as sulfur) are required to comply with recordkeeping and reporting requirements specified in §60.5423(c) but are not required to comply with §§60.5405 through §60.5407 and paragraphs §60.5410(g) and §60.5415(g) **and paragraphs §60.5423(a), (b), (d) or (e)** of this subpart.”

9. COMBUSTION DEVICE REQUIREMENTS

9.1. Flares - “Flame Present At All Times”

EPA has deferred to the general design requirement for flares in §60.18 and §63.11 if a flare is to be used as a control device. Since oil and gas operations are not always steady state, flares with continuously lit pilots (24/7) can sometimes unnecessarily burn and waste fuel gas for the pilot while causing unnecessary emissions when there is otherwise no emissions stream being burned. An example would be a flare installation used as a backup control device when a VRU is used. And in some cases, fuel gas has to be purchased where there is insufficient gas available from the production stream to fuel a flare pilot. EPA can resolve this issue in two ways.

9.1.1. Clarify What is Meant By “Flame Present At All Times”

Please clarify what is meant by “flame present at all times” by adding new regulatory text in §60.5415(i) and §63.769(c)(8) stating that “flame present at all times” in §60.18 and §63.11 refers to a pilot that must only be lit at all times while a VOC or waste stream is being sent to the flare for emissions destruction.

9.1.2. Allow Use of Electronic Flare Ignition Devices

In the Natural Gas STAR program, EPA published a Partner Recognized Opportunity (PRO) in PRO Fact Sheet No. 303. Presumably this was published because EPA approves of the design and recognizes its benefits and wanted to promote its use in industry. EPA should not lose the benefits of this control technology enhancement by disallowing its use in this rule. With this being an established and preferred technology in Natural Gas STAR, operators should not have to petition EPA for approval under its new control technology provision. See Sections 15.3.8 and 16.11.

9.2. “Completion Combustion Devices” Are Not Considered Flares

Section 60.5375(a)(3) provides that “You must capture and direct flowback emissions that cannot be directed to the gathering line to a completion combustion device, except in conditions that may result in a fire hazard or explosion. Completion combustion devices must be equipped with a reliable continuous ignition source over the duration of flowback.”

EPA appears to have chosen the term “completion combustion device” so that the pit flares, which the preamble states at p. 52758 are not a “traditional flare control device” would not be subject to §60.18. The preamble indicates that this is the case “because of the multiphase slug flow and intermittent nature of the discharge of gas, water and sand over the pit.” As a result, pit flares cannot comply with the technical requirements of this section.

However, Subpart OOOO also includes a definition of flare at §60.5430 which reads as “*Flare* means a thermal oxidation system using an open (without enclosure) flame.” This definition would include pit flares because they use an open flame to oxidize the gas portion of the flowback. Likewise, while pit flares are typically used and may not have been intended to be defined as flares, some operators may choose to use traditional flare devices or be required to do so by state or local rules. These would more clearly be subject to §60.18.

Suggested Rule Text:

§60.5430

Flare means a thermal oxidation system using an open (without enclosure) flame. [Completion combustion devices are not considered flares.](#)

9.3. Proper Cite for NSPS Flare Requirements is §60.18(b)

Subpart OOOO cites the requirements in the Part 60 General Provisions for flares, but the cite given is overly broad. The proper cite is §60.18(b), but the rule more generally cites §60.18.

Suggested Rule Text:

§60.5401

* * * * *

(f) Flares used to comply with this subpart must comply with the requirements of §60.18(b), [except as provided in §60.5415\(i\)\(1\) and \(2\).](#)

§ 60.5415

* * * * *

(i) [Flares used for compliance with this section must comply with §60.18\(b\), except as provided in §60.5415\(i\)\(1\) and \(2\).](#)

(1) [A “flame present at all times” as required in §60.18\(c\)\(2\) means that a pilot must be present at all times while a VOC or waste stream is being sent to the flare for emissions destruction, or](#)

[\(2\) thru the use of an electronic ignition device.](#)

9.4. Equipment Routing Vapors From Affected Facilities To Process Are Not Considered Control Devices

EPA has recognized that many of the emission reductions provided for in this rule may be able to be routed back into the process and sold as natural gas or petroleum products. In Subpart HH, at §63.761, EPA defines a “closed-vent system” such that “If gas or vapor from regulated equipment is routed to a process (e.g., to a fuel gas system), the conveyance system shall not be considered a closed-vent system.” EPA also included a definition of “routed to a process or route to a process” in the proposed rule text of §60.5430. API requests that EPA add a new provision in §60.5415 to exclude equipment that route the vapors back to the process and meet the definition provided in §60.5430 from being considered as control device or closed vent system for the purposes of this subpart.

Suggested Rule Text:

§60.5415

(j) For the purposes of this subpart if the vapors from the affected facility are routed back to process and meet the definition provided for *routed to process* in §60.5430 then this equipment is not considered a control device or closed vent system.

10. STARTUP, SHUTDOWN, AND MALFUNCTION PROVISIONS

Given that the SSM exemption in Part 63 Subpart A has been vacated by the courts, API supports EPA's edits to Table 2 of NESHAP Subpart HH that render SSM references in the General Provisions not applicable. API also supports EPA's proposal to address malfunctions as distinct from routine operating conditions, but we object to the manner in which EPA proposes to do so. API believes EPA is not authorized to subject malfunction events to an emissions standard for which EPA did not consider the emissions or costs of control associated with malfunctions. API endorses the comments submitted separately from the SSM Coalition on this issue (See Attachment D), particularly with respect to establishing an alternative emissions limitation for malfunctions. We address flaws in EPA's legal analysis below, followed by specific recommendations for a work practice as an alternative emissions limitation for malfunctions. In the comments on a work practice as a standard for malfunctions, Subpart HH references are given first, with Subpart OOOO references in brackets.

10.1. EPA's Legal and Technical Analyses of SSM Events are Fundamentally Flawed

10.1.1. Flawed Analysis of NESHAP SSM

EPA observes in the preamble that the startup, shutdown, and malfunction (“SSM”) provisions contained in the Part 63 General Provisions were vacated by the D.C. Circuit in *Sierra Club v. EPA*, 551 F.3d 1019 (D.C. Cir. 2008) (“*Sierra Club*”). 76 Fed. Reg. at 52787. The Agency then explains that “[w]e are proposing the elimination of the SSM exemption in the two oil and gas NESHAP” and that “[c]onsistent with *Sierra Club v. EPA*, the EPA is proposing to apply the standards in these NESHAP at all times.”

With regard to periods of startup and shutdown, EPA asserts that “operations and emissions do not differ from normal operations during these periods such that it warrants a separate standard.” *Id.* Consequently, “we have not proposed different standards for these periods.” *Id.* As to malfunctions, “EPA has determined that malfunctions should not be viewed as a

distinct operating mode and, therefore, any emissions that occur at such times do not need to be factored into development of CAA section 112(d) standards, which, once promulgated, apply at all times.” *Id.* However, EPA does propose to establish “an affirmative defense to civil penalties for exceedances of emission limits that are caused by malfunctions in both of the MACT standards,” which would be available if affected sources can prove by a preponderance of the evidence that qualifying criteria have been met. *Id.* at 52788.

The proposal to eliminate the SSM provisions in the two existing rules is not based on an accurate reading of *Sierra Club*, is not supported by any rational explanation as to why the elimination of the SSM provisions is justified, and is arbitrary and capricious given that EPA fails to provide any analysis of why affected sources reasonably can be expected to meet the emissions limitations and standards that the Agency proposes to apply during periods of SSM.

To begin, EPA's proposal “that the standards in these rules apply at all times” is not, as EPA claims, “[c]onsistent with *Sierra Club v. EPA*.” The decision in that case was grounded in the court's assertion that § 112 requires emissions standards to apply at all times. *Sierra Club* at 1027 (“Congress has required that there must be continuous section 112-compliant standards.”). Based on this, the court held the SSM General Provisions do not comport with § 112 because, in the eyes of the court, the SSM provisions are not “section 112-compliant” emissions standards. *Id.* at 1028 (“Because the general duty is the only standard that applies during SSM events — and accordingly no section 112 standard governs these events — the SSM exemption violates the CAA's requirement that some section 112 standard apply continuously.”). Notably, the court did not hold that EPA is prohibited from setting separate standards for periods of SSM. It simply held that standards for such periods must be developed according to the § 112(d) MACT process.

Thus, the proposal to eliminate the SSM provisions from the two source categories (Subparts HH and HHH) subject to this proposal is not “consistent” with *Sierra Club* because there is nothing in that case that supports the conclusion that vacatur of the Part 63 General Provisions necessarily requires “the established standards in these rules [to] apply at all times.” EPA's flawed legal analysis provides no support for the proposal to eliminate the SSM provisions in the two rules.

This fundamental legal flaw is magnified by the Agency's failure to provide any explanation whatsoever as to why it is appropriate to now apply the existing emissions standards to periods of SSM. For example, EPA made no effort to obtain emissions information from the two source categories for periods of SSM and provides no other evidence or analysis supporting its assertion that it is appropriate to apply the existing standards to periods of SSM. Moreover, EPA fails to investigate the record data developed during the promulgation of the existing standards to assess whether those data are characteristic and representative of emissions during periods of SSM. In short, the Agency simply asserts with no record basis that the existing standards should apply to periods of SSM. This unsupported assertion provides no basis for extending the existing standards to periods of SSM – the failure to seek relevant data, assess existing data, and investigate whether the existing standards should appropriately apply to periods of SSM is facially arbitrary and capricious and provide wholly

inadequate support for the Agency's proposal.

With regard to malfunctions, EPA's proposal to provide an affirmative defense for periods of malfunction is without merit. Comments recently submitted by the "SSM Coalition" on EPA's proposed standards for Sewage Sludge Incinerators explain in detail that: (1) EPA must take malfunctions into account when setting § 112 emissions standards; (2) the proposed affirmative defense is not a permissible substitute for setting emissions standards for periods of malfunction; and (3) the proposed affirmative defense is unreasonable and impracticable. *See* Letter to EPA Docket Center (EPA/DC) from the American Chemistry Council, *et al.*, Comments on Proposed Standards of Performance for New Stationary Sources and Emission Guidelines for Existing Sources: Sewage Sludge Incineration Units, Docket ID No. EPA-HQ-OAR-2009-0559, at 6-20 (Nov. 29, 2010). We incorporate these comments by reference.

A further flaw in EPA's reasoning is that it has failed to account for the costs of a standard that does not accommodate malfunctions. To assure continuous compliance, affected facilities have only two choices – install redundant processing and pollution control equipment so that operations can continue during a malfunction, or shut down the affected facility until the malfunction can be rectified. In either case, affected facilities would incur substantial costs directly attributable to the standard that have not been accounted for in the formulation of the rule.

For these reasons, EPA should set aside the proposed affirmative defense for periods of malfunction and, instead, set a work practice standard for such periods.

10.1.2. Flawed analysis of NSPS SSM

Consistent with its proposed approach to the oil and gas NESHAPs, "EPA is proposing standards in [the Part 60] rule that apply at all times, including during periods of startup or shutdown, and periods of malfunction." 76 Fed. Reg. at 52766. EPA claims that it "has taken into account startup and shutdown periods" in the proposed Part 60 standards. *Id.* And, EPA proposes "to add an affirmative defense to civil penalties for exceedances of emission limits that are caused by malfunctions." *Id.* To qualify for the affirmative defense, an affected source "must prove by a preponderance of the evidence that it has met" specified criteria. *Id.*

With regard to applying the proposed standards to periods of startup and shutdown, EPA has failed to provide record evidence as to how it has "taken into account startup and shutdown periods" in the proposed rules. Thus, EPA's assertion that the standards accommodate emissions during periods of startup and shutdown is unsupported and fundamentally arbitrary. EPA further undermines its position by asserting that "any comments that contend that sources cannot meet the proposed standard during startup and shutdown periods should provide data and other specifics supporting their claim." *Id.* In essence, EPA is trying to remake the law by asserting that its unsupported conclusions will be adopted *unless* commenters prove these unsupported conclusions to be wrong. This cannot be. EPA unambiguously has the obligation to support its proposed standards with substantial evidence

and must include in the proposed rule “the factual data on which the proposed rule is based.” CAA § 307(d)(3)(A). EPA has failed on both counts with regard to its unsupported assertion that the proposed standards should apply to periods of startup and shutdown.

EPA's proposal to provide an affirmative defense for malfunctions is equally flawed. EPA begins its analysis by asserting that it “has determined that malfunctions should not be viewed as a distinct operating mode and, therefore, any emissions that occur at such times do not need to be factored into development of CAA section 111 standards.” 76 Fed. Reg. at 72766. In support of this assertion, EPA first cites *Weyerhaeuser v. Costle*, 590 F.2d 1011, 1058 (D.C. Cir. 1978) for the proposition that “nothing in CAA section 111 or in case law requires that the EPA anticipate and account for the innumerable types of potential malfunction events in setting emission standards.” 76 Fed. Reg. at 52766.

Yet, *Weyerhaeuser* is inapposite – it is a Clean Water Act case that has no bearing on EPA's authorities and responsibilities under CAA § 111. More directly relevant cases – those decided under § 111 itself – tell a very different story. As explained in the SSM Coalition's comments (Attachment D), the courts have long recognized that a “technology based standard discards its fundamental premise when it ignores the limits inherent in technology.” *NRDC v. EPA*, 859 F.2d 156, 208 (D.C. Cir. 1988). For example, the D.C. Circuit recognized, in *Portland Cement Ass'n v. Ruckelshaus*, 486 F.2d 375, 398 (D.C. Cir. 1973), a decision reviewing standards under CAA section 111, that “‘start-up’ and ‘upset’ conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated.” *Id.* at 399. Similarly, in *Essex Chem. Corp. v. Ruckelshaus*, 486 F.2d 427, 432 (D.C. Cir. 1973), *cert. denied*, 416 U.S. 969 (1974), another section 111 case, the court held that SSM provisions are “necessary to preserve the reasonableness of the standards as a whole.” *Id.* at 433. In *National Lime Ass'n v. EPA*, 627 F.2d 416 (D.C. Cir. 1980), another case reviewing emission standards promulgated under CAA section 111, the court held CAA technology-based standards must be capable of being met “under most adverse circumstances which can reasonably be expected to recur,” such as during periods of SSM. 627 F.2d at 431 n.46. Thus, the relevant case law makes clear that EPA is authorized and obligated to account for periods of malfunction when setting Part 60 standards.

Nevertheless, EPA presses on by arguing that “it is reasonable to interpret CAA section 111 as not requiring the EPA to account for malfunctions in setting emissions standards” because “[t]he ‘application of the best system of emission reduction’ is more appropriately understood to include operating units in such a way as to avoid malfunctions.” 76 Fed. Reg. at 52766. This rationale makes no sense because EPA effectively is defining BDT as an affected facility that does not malfunction. EPA has asserted no record basis for such a determination and could not if it tried because malfunctions are inevitable, notwithstanding best efforts. In any event, as explained above, EPA has failed to estimate and take account of the added costs associated with a rule that requires compliance during malfunctions (*i.e.*, the costs of installing redundant equipment or the business interruption costs of shutting down).

EPA lastly asserts that “even if malfunctions were considered a distinct operating mode, we

believe it would be impracticable to take malfunctions into account in setting CAA section 111 standards for affected facilities” because “it would be difficult to set a standard that takes into account the myriad different types of malfunctions that can occur across all sources in the category.” *Id.* Four decades of operating under the existing Part 60 malfunction provision belie this claim. A work practice requiring best efforts to minimize emissions during malfunction events consistent with the application of good air pollution control practices is a tried and true way to “account for the myriad different types of malfunctions that can occur.” EPA’s failure to explain why such an approach cannot continue to be successfully applied represents a critical flaw in its conclusion that standards cannot and should not be developed for malfunction events.

10.2. Notifications and Reports for Malfunctions

Proposed paragraph §63.762(d)(2) [§60.5415(h)(2)] would require a notification of a malfunction to be submitted within 2 business days after the initial occurrence of the malfunction in order to preserve an affirmative defense. This paragraph would additionally require a report within 45 days after the malfunction. These deadlines are arbitrary, unrealistic, and unwarranted.

10.2.1. The Proposed 2-Day Notification is Unrealistic and Unnecessary

The provisions of §63.762(d)(1)(i)-(ix) [§60.5415(h)(1)(i)-(ix)] would specify a 9-step procedure for determining whether a given malfunction event qualifies for the affirmative defense. In most cases, it would not be realistic to complete this determination process within 2 days following the occurrence of the event. Facilities might therefore tend to routinely submit the 2-day notification in order to preserve the potential for an affirmative defense, even in cases which subsequently are determined to not qualify. Furthermore, there is no environmental benefit that would accrue from this notification, and similar provisions in refinery consent decrees do not require it. The result of this unrealistic and unnecessary requirement, then, would be to burden both the facility and the regulatory agency having jurisdiction with the processing of paperwork that has no associated environmental benefit. As proposed, these notifications would be required for the smallest of emission exceedances with no reportable quantity threshold being set. This is contradictory to other EPA reporting rules such as those under CERCLA and EPCRA where reportable quantities are established for unauthorized releases. Requirements for immediate reporting of excess emissions of VOCs should be left to the states as they are best equipped to handle any response that might be required as a result of the release. Immediate reporting to the EPA serves no beneficial purpose. However, if EPA insists on a notification requirement, the rules should allow at least 15 business days following the occurrence of the event for this notification to be submitted.

10.2.2. Malfunction Reports Should Be Submitted with the Semi-Annual Reports

The rule already requires, at §63.775(e) [§60.5423(b)], the submission of excess emissions reports on a semi-annual basis, and EPA has established the semi-annual basis as being appropriate for all compliance-related reporting through numerous rulemakings. In fact, EPA promulgated the Recordkeeping and Reporting Burden Reduction Rule for the

expressed purpose of simplifying and unifying reporting schedules. EPA stated this intent in the preamble to that rule:

“The Agency now believes that the semiannual reporting frequencies contained in recently promulgated NSPS and NESHAP regulations and proposed in this rulemaking for all types of information are generally appropriate. . . EPA sees no reason to retain different reporting frequencies in the NSPS and NESHAP General Provisions compared to the reporting frequencies contained in recently promulgated rules.”^C

As noted by EPA, there is no reason to require a reporting frequency that differs from the semi-annual basis adopted by the agency. It would be contrary to the agency's own assessment of an appropriate reporting frequency to arbitrarily require malfunction reports to be submitted within 30 days.

10.3. EPA Has No Mandate To Impose SSM Requirements in NSPS Rules.

EPA states that “In proposing the standards in this rule, the EPA has taken into account startup and shutdown periods” (see 76FR52766). However, API has found nothing in the Docket to support such a statement for the NSPS Subpart OOOO standards. In particular, the Technical Support Document (EPA-OAQR-0505-0045) does not have any statement about startup, shutdown emissions. The only reference to malfunctions is in a discussion about workovers being performed to address malfunctions of downhole pumps and this type of equipment mechanical malfunction has no emissions to atmosphere. EPA has predominately added work practices (i.e. compressor seal change and RECs). Although an SSM event could potentially cause the owner/operator to exceed the requirements of a work practice, it is unclear how the exceedance of a work practice would be tied to an “emission exceedance”. It is also not clear how an SSM event would cause “emission exceedance” in the case of a design standard such as the proposed requirements for pneumatic controllers. Finally, even though the sulfur recovery standard is an emission standard, it is simply a strengthening of the standard promulgated in the mid-1980s. No consideration of SSM events was found in the Technical Support Document as discussed above.

EPA has no mandate by the Court to cover periods of SSM in NSPS emission standards. In fact, EPA would have an obligation to show that covering such SSM periods within the NSPS emission standard was cost effective. Simply stating that SSM events have been considered is insufficient. By definition, SSM events have emissions in excess to the standard. API has not found any instance where EPA has defined what the SSM events are, the emission associated with the event, the control required obtain the emission standard and the cost effectiveness of requiring that control. The Clean Air Act (CAA) does not contain any provision allowing EPA to ignore cost effectiveness when setting NSPS and SSM events are no different. For these reasons, API recommend that EPA remove all references to SSM provisions from NSPS Subpart OOOO. If EPA continues to impose the emission standards at all times (including during SSM events), EPA must identify the SSM events, the controls required to maintain the emission standard and justify the cost impact of including the emission standard during the SSM event.

^C 61 Federal Register 47840-47852, September 11, 1996; page 47844, first two columns.

10.4. §63.762(d)(1)(i)-(ix) [§60.5415(h)(1)(i)-(ix)] Should Constitute a Work Practice for Compliance

For the reasons set forth in the comments above on the legal analysis, the steps specified in §63.762(d)(1)(i)-(ix) [§60.5415(h)(1)(i)-(ix)] should be specified as a work practice for compliance in the event of a malfunction, rather than being specified as a basis for an affirmative defense. In the preamble to the proposed rulemaking, EPA presents numerous reasons for not accounting for malfunctions in the setting of emission standards for routine operating conditions, yet proposes to apply these emission standards to malfunction events. This is logically inconsistent and statutorily inappropriate. If the standards are to apply to malfunction events, then the emissions and costs of control associated with malfunction events should have been included in the evaluation of the standards. As explained by EPA, however, not only was this not done – it would not be feasible to do so.

On the one hand, then, EPA is obligated to set standards that are “achievable” under section 112(d)(2) of the Clean Air Act. On the other hand, it is not feasible to develop an emission standard that governs malfunction periods. This scenario is expressly addressed in section 112(h) of the Clean Air Act, which allows EPA to set work practice standards for situations where “it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard . . .” Malfunctions fit within the situations described in the definition of “not feasible to prescribe or enforce an emission standard” as any situation where “the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.” Consequently, EPA should set work practice requirements to address periods of malfunction. The steps set forth in §63.762(d)(1)(i)-(ix) [§60.5415(h)(1)(i)-(ix)] would constitute an appropriate work practice standard for malfunctions, in which case the notifications specified in §63.762(d)(2) [§60.5415(h)(2)] should be replaced by a semi-annual reporting requirement.

10.5. Address Weather and System Outage Issues

Excess emissions can result from weather conditions or gathering system/processing plant outages that are beyond the control of the operator. Many well sites are remotely located and most are unmanned facilities. Inspection and maintenance visits occur on average anywhere from weekly to twice per month, depending on the location and time of year. In some areas, winter weather makes it difficult to visit sites causing extended periods between site visits. Although telemetry is often utilized for new production well sites to optimize the need for operator attention, weather conditions can affect not only the control device (flare flameout) but can also affect telemetry which would catch and report such discrepancies. System outages to the gathering system, gas treating plants, or gas processing plants occur infrequently but can occur several times during the year. These outages immediately result in a stop in production. Wells that are equipped to automatically shut down, do so. However, most wells must be visited manually in order to shut in the well and associated equipment. Once the system is restored and open to production flow, operators must begin the process of visiting the wells to open them back to production and restore associated operating equipment and control devices. EPA should specify how they would consider weather and “system” outages that are beyond the control of the upstream operator in a malfunction work practice.

10.6. Provide an Allowance for Reasonable Periods of Maintenance

EPA should provide an allowance for a reasonable period of routine maintenance for the control device. Proper operation of a control device includes periodic routine maintenance, and manufacturers of control devices typically recommend preventive maintenance on a semi-annual basis. EPA has stipulated in other rulemakings^D that standards do not apply during planned routine maintenance, other than a work practice standard that such periods shall not exceed 240 hours per year and records must be maintained to document such periods.

11. REVISING THE MACT FLOOR

Once EPA establishes a MACT standard for a particular source category, the Agency has the authority under § 112(d)(6) to “review and revise as necessary (taking into account developments in practices, processes, and control technologies), emissions standards promulgated under this section no less often than every 8 years.” In other words, EPA does not have unfettered discretion to revisit a prior MACT determination once that determination has been issued. Rather, EPA may revise a prior determination only “as necessary” according to explicit statutory criteria. *Cf. New Jersey v. EPA*, 517 F.3d 574, 582 (D.C. Cir. 2008) (Thus, EPA can point to no persuasive evidence suggesting that [the statute’s] plain text is ambiguous. It is therefore bound by [the statute] because “for [] EPA to avoid a literal interpretation at *Chevron* step one, it must show either that, as a matter of historical fact, Congress did not mean what it appears to have said, or that, as a matter of logic and statutory structure, it almost surely could not have meant it,” *Engine Mfrs. Ass’n v. EPA*, 88 F.3d 1075, 1089 (D.C. Cir. 1996), showings EPA has failed to make.”).

In the proposal, EPA explains that, “Pursuant to CAA sections 112(d)(2) and (3), we are proposing MACT standards for subcategories of glycol dehydrators for which standards were not previously developed.” 76 Fed. Reg. at 52746. Similarly, EPA states that, “We are also proposing MACT standards for storage vessels that are currently not regulated under the Oil and Natural Gas Production NESHAP.” *Id.* These statements make it clear that EPA is not invoking § 112(d)(6) as the authority for the new proposed standards – indeed, the preamble provides no analysis of “developments in practices, processes, and control technologies” to justify the proposed standards, as would be required if EPA were relying on § 112(d)(6). And, there is no mention of § 112(d)(6) in relation to the proposed new standards. EPA unambiguously drives home this point – “For both the Oil and Natural Gas Production and the Natural Gas Transmission and Storage source categories, we are proposing no revision to the existing NESHAP pursuant to section 112(d)(6) of the CAA.” 76 Fed. Reg. at 52747. Instead, the Agency is invoking §§ 112(d)(2) and (3) directly, as if MACT standards for these source categories do not already exist.

EPA does not have such authority. As explained above, once EPA makes a MACT determination for a particular category, § 112(d)(6) provides the only authority for the Agency to later review and possibly revise the determination. Section 112(d)(6) expressly authorizes EPA to review existing determinations and provides specific criteria to guide and constrain the review. The existence of this express authority forecloses the Agency’s ability to directly invoke §§ 112(d)(2) and (3) for a given source category when a MACT determination has already been issued for the source category.

Notably, even if the Agency had invoked § 112(d)(6) as authority for revising the existing MACT standards, it still would not have authority to regulate the emissions points for which standards were not established in the first round of MACT rulemaking. Prior MACT determinations may be revised only “as necessary (taking into account developments in practices, processes, and control technologies).” Perceived “gaps” in the

^D Examples of regulatory provisions for maintenance of the control device include §60.102a(f)(3) and §63.119(e)(3) & (4).

original MACT determinations are not “practices, processes, and control technologies” that are properly within the scope of a § 112(d)(6) review.

In any event, it is not a reasonable exercise of authority to establish new emissions limitations under existing MACT standards when there is no significant risk associated with emissions from sources in the given source category. As explained in Section 20 of these comments, the available data overwhelmingly show that the current standards protect public health with an ample margin of safety. Establishing new standards under these circumstances is patently unreasonable and cannot be justified under § 112(d)(6) because the so-called regulatory “gaps” in the current rules clearly are not contributing to unacceptable risk. This is regulation for the sake of regulation and, as such, contradicts Congress’s clear intent that an ample margin of safety is an appropriate stopping point for emissions limitations under § 112.

12. CHANGE IN THE PROTOCOL FOR DETERMINING RESIDUAL RISK FOR NESHAP

As noted in the Federal Register (FR) announcement, EPA is required under section 112(f) of the Clean Air Act (CAA) to evaluate the risk to public health that remains after implementation of the technology-based national emission standards for hazardous air pollutants (MACT standards). EPA proposes, in this rulemaking, to change the manner in which this “residual risk” is evaluated. API has several concerns with respect to these proposed changes. Please see Attachment E which contains the Residual Risk Coalition letter commenting on this issue.

12.1. Lack of Statutory Authority for the Changes

As EPA notes, the process that the agency has followed for residual risk evaluations was established in accordance with a protocol mandated by the CAA, including preparation and submission to Congress of the methods to be employed. These methods include the two-step process described in the FR announcement. The first step in this process is to determine whether the maximum individual lifetime cancer risk (MIR) exceeds a presumptive limit of approximately 1-in-10 thousand. When the MIR is determined to be below this limit, the residual risk is deemed to be acceptable and the analysis moves to the second step. The second step, for situations in which the MIR is above 1-in-1 million, is to determine whether the standard provides an “ample margin of safety” to protect human health. EPA has established certain metrics for the determination of ample margin of safety through both the agency’s report to Congress and an extensive history of subsequent rulemaking.

API believes that EPA lacks statutory authority to make significant and substantive changes unilaterally to this procedure that has been established in accordance with CAA mandates, vetted with Congress, and ratified by precedent. There has been no indication from Congress or experience which indicates that the established procedure for evaluating residual risk has failed to be protective of human health. API objects to arbitrary changes which are unnecessary and unauthorized, and which needlessly add further uncertainty and complexity to a process that is already unduly burdensome.

12.2. Inappropriateness of the Changes

The new measures which EPA proposes to apply to the determination of acceptable risk and ample margin of safety are inappropriate. These new measures include:

- “total facility” consideration; consideration of risk from the total facility (facility-wide risk), rather than from only the portion of the facility subject to the rule,
- “demographic” consideration; consideration of risk across selected social, demographic, and economic groups within the population living near the facility, and
- “allowable emissions” consideration; consideration of the hypothetical risk associated with the level of emissions allowed by the MACT standard (versus the actual emissions from the facility).

Each of these considerations is discussed below and in Attachment E.

12.2.1. The “Total Facility” Approach to Conducting Risk Assessment Exceeds EPA’s Authority Under §112(f)

EPA explains in the proposal that, “To put the source category risks in context, we also examined the risks from the entire ‘facility,’ where the facility includes all HAP-emitting operations within a contiguous area and under common control.” 76 Fed. Reg. 52774. Because the CAA requires residual risk determinations to be conducted on a category by category basis, EPA does not have authority to consider the combined emissions from entire facilities when making a § 112(f) risk assessment for a given source category.

Section 112(f)(2)(A) unambiguously requires EPA, within 8 years after adopting a MACT standard for a given source category or subcategory, to “promulgate standards for such category or subcategory if promulgation of such standards is required in order to provide an ample margin of safety to protect public health.” Section 112(f)(2)(A) further dictates that, “Emissions standards promulgated under this subsection shall provide an ample margin of safety to protect public health.” It is not reasonable to construe these provisions as authorizing EPA to consider emissions from entire facilities in conducting risk assessments and potentially revising the underlying rule for the simple reason that the Congress clearly envisioned that full implementation of the MACT program would take longer than 8 years. Consequently, it would be impossible for EPA to fulfill its unambiguous obligation for § 112(f) standards to protect public health with an ample margin of safety in cases where facilities contain sources in a category where the 8 year deadline for conducting the § 112(f) risk review precedes the adoption of MACT standards for other sources at the facilities.

This is not mere hypothetical conjecture. The standards under review in this proposal provide a case in point. Certain of the facilities containing sources affected by one of the standards under review in this proposal also contain industrial boilers that will be subject to the MACT standard for industrial boilers. As a result, EPA currently is without authority to conduct a § 112(f) risk assessment for co-located industrial boilers because those boilers are not yet subject to a MACT standard due to the stay of the final rule. Thus, it is impossible for EPA to assure an ample margin of safety from total facility emissions for sources affected by the standards covered by this proposal. This demonstrates why the statute cannot be interpreted to allow consideration of emissions from entire facilities when conducting a § 112(f) risk review.

In addition, § 112(f)(2)(A) further provides that, “If standards promulgated pursuant to subsection (d) of this section and applicable to a category or subcategory of sources emitting a pollutant (or pollutants) classified as a known, probable or possible human carcinogen do not reduce lifetime excess cancer risks to the individual most exposed to *emissions from a source in the category or subcategory* to less than one in one million, the Administrator shall promulgate standards under this subsection for such source category” (emphasis added). This provision unambiguously requires the § 112(f) risk assessment to be focused exclusively on “emissions from a source in the category or subcategory.” For this reason alone, EPA does not have authority to consider emissions from any sources other than those in the source category or subcategory under review at that time.

12.2.2. Demographics May Not be Considered in Conducting Risk Assessments Under §112(f).

EPA explains that, “To examine the potential for any environmental justice (EJ) issues that might be associated with each source category, we performed a demographic analysis of population risk.” 76 Fed. Reg. at 52774. Although EPA conducted an “environmental justice” assessment for the two rules covered by this proposal, EPA determined that those analyses do not provide a basis for imposing additional control measures in order to assure an ample margin of safety.

Because the term “public health” cannot reasonably be interpreted to include consideration of environmental justice in the § 112(f) context, EPA’s proposal to consider demographic analyses in conducting risk reviews under § 112(f) is not a proper exercise of Agency authority. Section 112(f)(2)(A) expressly instructs EPA to impose additional emissions controls if needed to provide an ample margin of safety “to protect public health.” The term “public health” is not defined in § 112 or in EPA’s Part 63 regulations.

In the context of EPA’s national ambient air quality program (“NAAQS”), the Supreme Court has observed that the “primary definition of the term” should be applied – *i.e.*, public health means “the health of the public.” *Whitman v. American Trucking Associations, Inc.*, 531 U.S. 457, 465 (2001). This conclusion emphasizes that the scope of the term “public health” should be dictated by the meaning of the word “public.” In relevant part, Websters Free Dictionary defines the adjective “public” to mean “of, relating to, or affecting all of the people or the whole area of a nation or state” and “of or relating to people in general.” These definitions emphasize that the word “public” should be construed expansively as describing the people as a whole, and not particular demographic segments.

EPA’s established approach to assessing potential impacts on public health under the NAAQS program is consistent with this meaning. EPA reasonably interprets the term “public health” to include consideration not only of potential impacts to the population as a whole, but also to sensitive subpopulations – recognizing that the objective is to protect the group rather than any particular individual in the group. *See, e.g.*, 71 Fed. Reg., 61144, 61145 fn. 2 (Oct. 17, 2006). But, sensitive subpopulations are identified according to their particular health-based sensitivities (*e.g.*, asthmatics) rather than demographic classifications

unrelated to particular health-based sensitivities (e.g., population without a high school diploma).

With this backdrop, it is not reasonable to construe the term “public health” as used in § 112(f) as allowing consideration of demographic classifications that bear no relationship to the potential health effects presented by the HAPs at issue for the given source category or subcategory. EPA’s proposal would unreasonably inject racial, ethnic, and other policy considerations into a program designed to provide protection for the public at large. For example, EPA suggests that the population without a high school diploma should receive extra scrutiny, yet does not afford the same scrutiny to other reasonably definable educational groups, such as those with a high school diploma, those with college degrees, and those with advanced degrees. There is simply no principled way to identify and define those groups that should receive extra scrutiny from those that do not. In short, EPA’s approach would inappropriately cause arbitrary policy and political considerations to trump objective scientific analysis. This is patently unreasonable and, as such, is not a supportable interpretation of § 112(f).

12.2.3. EPA Fails to Provide a Rational Basis for Using Allowable Emissions in Conducting Risk Assessments Under §112(f).

EPA uses the term “MACT allowable” emissions in the preamble to mean “the highest emission level that could be emitted by the facility without violating the MACT standards.” 76 Fed. Reg. at 52770. The Agency asserts that considering MACT allowable emissions in determining residual risk under § 112(f) “is inherently reasonable since these risks reflect the maximum level sources could emit and still comply with national emission standards.” *Id.* Without further explanation as to why it might be appropriate to determine and apply MACT allowable emissions in § 112(f) risk assessments, the Agency goes on to explain that it developed a ratio method of estimating MACT allowable emissions and applied these ratios in the risk assessment. Based on this analysis, EPA proposes to find that the “risks are unacceptable” under the current Subpart HH “due to MACT-allowable emissions” and, therefore, EPA proposes “to eliminate the 0.9 Mg/yr compliance alternative for dehydrators.” *Id.* at 52780.

EPA cannot lawfully use MACT allowable emissions in the proposed risk assessments and residual risk determinations because the Agency has failed to provide any reasoned explanation for why risk assessments based on actual emissions estimates are inadequate. It is noteworthy that § 112(f)(1)(A) required EPA to report to Congress on “methods of calculating the risk to public health *remaining, or likely to remain*, from sources subject to regulation under this section after the application of standards under subsection (d) of this section” (emphasis added). Section 112(f)(1)(B) required EPA also to report on “the *actual health effects* with respect to persons living in the vicinity of” affected sources” (emphasis added). These requirements clearly signal that Congress expected EPA to focus on actual risk and not hypothetical risk in implementing the requirements of § 112(f). Thus, it is not reasonable in the first instance for EPA to construe § 112(f) as authorizing the Agency to conduct risk assessments based on hypothetical “MACT allowable” emissions.

Moreover, the Agency's risk assessment methodology already is rife with conservative assumptions. For example, health benchmarks, such as acute reference doses, typically incorporate two to three orders of magnitude of conservatism to account for uncertainties, such as the extrapolation of animal toxicity testing data to humans. Similarly, the dispersion models used to predict off-site ambient HAP concentrations attributable to emissions from affected sources incorporate numerous conservative assumptions to simplify the analysis of highly complex factors, such as meteorology and atmospheric chemistry. In addition, risk assessments assume exposure to the most exposed individual on a continuous basis for an entire lifetime.

In light of the conservatism that already is inherent to EPA's risk assessment methodology, it makes no sense to apply yet another layer of conservatism – this time based on the hypothetical assumption that affected sources should be expected to emit more than the actual data indicate – to § 112(f) risk assessments. EPA has provided no data or analyses indicating that its current methodology results in negative bias. EPA has provided no data demonstrating that affected sources actually do emit at levels significantly higher than the actual data show for any significant period of time. In short, EPA's proposal to use hypothetical emissions levels in § 112(f) risk assessments is justified on nothing more than the bald assertion that sources *might* emit at these higher levels. The failure to provide a reasoned explanation as to why this approach is justified and the failure to provide any record evidence supporting the use of MACT allowable emissions render this proposal insupportable under the law.

13. AFFECT OF PROPOSED REGULATIONS ON STATES

13.1. Direct Regulatory Burden to State Environmental Regulatory Agencies.

The proposed rule will add tens of thousands of affected facilities annually. These affected facilities will result in a flood of notifications for new affected facilities that will each result in the submittal of annual reports, primarily into the State air pollution control agency. For this reason, API believes that consultation with the “appropriate representatives of the Governors and of State air pollution control agencies” of oil and natural gas producing states, as required by 42 USC 7411(f), is particularly important. The experience of these agencies is necessary to insure that only the notification and report information that is most beneficial to the agency is required to be submitted. API believes that the notification and recordkeeping requirements included in the proposed rule will flood the agencies with paperwork and effectively hide the useful information. API has made recommendation for the reduction of compliance assurance documentation below. However, EPA needs to recognize that these burdens are not only shouldered by industry, but the regulatory agencies as well.

13.2. Minor New Source Review (NSR) Permitting Programs

As discussed in Section 2, the proposed rule regulates affected facilities (i.e., individual pneumatic controllers and compressors, as well as RECs) that have not typically been regulated in an NSPS or NESHAP regulation in the past. Many states have developed minor source NSR permitting programs that go far beyond the requirements of the PSD (Prevention of Significant Deterioration) NSR or Title V Operating permitting programs. These programs typically have annual mass

emission thresholds similar to those included in the recent Tribal Lands FIP for Minor Sources (76 FR 38747, July 1, 2011; see Table 1, 76 FR 38792-3 for thresholds). However, some states also have an overriding requirement to permit facilities that contain NSPS or NESHAP affected facilities. This could result in a constant stream of permit revisions for very minor equipment activity (i.e., routine change out of equipment that occurs frequently). This unintended consequence of the proposed rule will bring a great burden to states that have this type of requirements and the O&G industry that operates within them for no environmental benefit. The NSPS/NESHAP programs are self implementing, thus do not require a permit to codify their requirements to make them enforceable. We recognize that EPA has already stated that the proposed regulation will not trigger Title V permitting requirements but we recommend that EPA expand this to include a recommendation in the preamble that "NSPS/NESHAP applicability alone should not trigger minor source NSR permitting requirements". We realize that such a statement will not bind the States, but it will be helpful in addressing this issue with the States

14. OFF-SHORE FACILITIES

API has found no evidence in the docket that EPA has considered the impact of the proposed rules on the offshore facilities that are under the EPA's jurisdiction for air quality issues. Offshore operations have unique and significant issues that directly impact the cost of compliance such as space on the platform for emission control equipment, weight allowance for additional equipment on the platform, remoteness of the platform, etc. Because of the unique circumstances around drilling and producing from offshore platforms and exploration vessels, complying with requirements designed for onshore activities is much more difficult and the costs are significantly higher when applying those same requirements to offshore facilities. For example, performing reduced emission completions on a new well completed on an existing offshore platform would most likely require a special separate installation to accommodate the additional REC equipment. The space on an offshore rig or platform is limited and designed to hold the equipment normally associated with drilling or necessary to manage the fluids expected during production. In addition, any recovered gas not meeting sales quality and capable of being flared, would be controlled using an existing flare typically designed as an emergency or safety control device. The flares used offshore are not designed to meet the §60.18 requirements. In Alaska, the vessels used for exploration are often foreign owned and operated and many times not designed to meet EPA stationary source standards. If the NSPS apply to offshore activities, drilling and subsequent production in Alaska will be significantly delayed until exploration rigs meeting the NSPS can be secured and moved to Alaska. With specific consideration of these issues for each of the standards EPA has proposed, API believes that the cost benefit requirement of the NSPS has not been satisfied. It is inappropriate for EPA to apply these standards to offshore facilities because of omission. API request that EPA specifically exempt offshore operations from the new standards it has proposed, as it has previously done in Subparts LLL and KKK.

TECHNICAL COMMENTS

15. WELL COMPLETIONS – NSPS SUBPART OOOO

API and its member companies are fully supportive of EPA's goals of minimizing VOC emissions from flowback immediately following hydraulic fracturing stimulation and have been among the earliest companies to adopt reduced such measures. Reduced emissions completions make sense in many scenarios, though not all. However, API does not support the manner in which EPA is proposing to regulate reduced emissions completions as discussed below in Section 15.1. Also, if EPA chooses to proceed in regulating reduced emissions completions, several issues must be addressed, as discussed in the rest of Section 15.

15.1. Legality of Regulation

Emissions from flow back immediately following hydraulic fracturing stimulation during well completions are fundamentally different than emissions regulated under any existing NSPS. It goes without saying that the purpose of gas wells is to produce natural gas. A well completion is not part of the normal operation of a well, in that completion activities do not continuously occur as a well is producing or, for that matter, are not repeated more than once or twice over the life of a well (a life that typically spans years and often spans decades). Instead, a well completion is a construction-related activity that must be accomplished for a well to begin producing and thereafter engage in normal operations. To the extent that a producing well must be "recompleted," this activity constitutes maintenance of the well because it is needed to assure the ongoing proper operation and suitable productivity of the well.

To date, EPA has not sought to impose § 111 emissions limitations or standards on construction or maintenance activities at affected facilities. In fact, EPA has actively worked to exclude construction and maintenance activities from coverage by an NSPS. For example, the initial performance tests and compliance determinations for affected facilities typically are not required to be conducted until "within 60 days after achieving the maximum production rate at which the affected facility will be operated, but not later than 180 days after initial startup of such facility." 40 C.F.R. §60.8(a). Similarly, performance test must be conducted under conditions reflecting "representative performance of the affected facility." *Id.* at §60.8(c). Periods of source construction and maintenance have never been determined to be "representative" of normal source operation under the NSPS program.

With this as a backdrop, EPA's proposal to set standards for well completions and recompletions is unfounded. To begin, as discussed more fully in Section 2 of these comments, production wells are a distinct type of stationary source that cannot rationally belong to the same source category as the other disparate elements of the oil and gas production industry (such as natural gas processing plants) that EPA seeks to regulate in the proposed rule. EPA has not previously found and has not proposed to find that emissions from flowback immediately following hydraulic fracturing stimulation cause or significantly contribute to air pollution that may reasonably endanger health or the environment. Therefore, EPA is not authorized to list or regulate flow back immediately following hydraulic fracturing stimulation at gas wellhead facilities onshore under § 111.

In addition, EPA has not explained why it has reversed a decades-long practice under § 111 of regulating only emissions from normal operation of affected facilities and expressly excluding construction-related emissions from regulation. The proposal to regulate construction-related emissions is a significant substantive departure in the Agency's prior interpretation and implementation of § 111. The failure to explain why this departure is justified and the failure to present the legal basis for regulating non-routine emissions is arbitrary and capricious and plainly violates EPA's obligation to clearly set forth "the major legal interpretations and policy considerations underlying the proposed rule." CAA § 307(d)(3)(C). EPA should remove the requirements for reduced emissions completions from the proposed regulation. If EPA chooses to proceed in regulating flowback immediately following hydraulic fracturing stimulation, EPA should repropose the requirements and include sufficient justification for their departure from not regulating construction-related emissions and present the legal basis for regulating non-routine emissions, under § 111, as discussed in Section 2. Furthermore, there are several issues that EPA needs to address which are discussed in the remainder of Section 15.

15.2. EPA Should Not Prescribe the Equipment Required for Reduced Emissions Completions

If EPA chooses to proceed in regulating flowback immediately following hydraulic fracturing stimulation, API is concerned with the prescriptive nature of the rule proposal for gas wellhead affected facilities. Section 60.5375(a) establishes three separate and prescriptive work practices, each of which must be followed in order to comply with the rule:

- Minimization of venting and routing recovered gases to the gas gathering line
- Use of specified equipment to maximize resource recovery^E and minimize releases to the environment
- Direction of flowback emissions that cannot be sent to a gathering line to a completion combustion device

Section 111 of the Clean Air Act establishes a strong presumption against prescribing control technologies:

CAA section 111(b)(5) "Except as otherwise authorized under subsection (h), nothing in this section shall be construed to require, or to authorize the Administrator to require, any new or modified source to install and operate any particular technological system of continuous emission reduction to comply with any new source standard of performance."

Section 111(h) allows work practice standards where "it is not feasible to prescribe or enforce a standard of performance," API concurs that it is not feasible to prescribe a standard of performance for gas wellhead.

However, an underlying presumption of section 111 is that a standard of performance should allow the affected facility flexibility to meet a standard, rather than be required to use specific controls. Likewise, the NSPS rules are directed at criteria pollutants, which for the gas wellhead affected

^E The maximization of resource recovery is not a proper subject of regulation in a New Source Performance Standard under the Clean Air Act. Such considerations are appropriate only under RCRA.

facilities are VOCs. For this reason, we propose that the rule text be greatly simplified to provide objectives for the control of VOCs, rather than specify methods. This proposed rule text also reflects the complexity of completions and the variability of conditions that can be encountered in natural reservoirs. If EPA chooses to regulate flowback immediately following hydraulic fracturing stimulation, API proposes that EPA adopt a management system approach to well completions rather than trying to specify methods that may work well in one well or region, but be wholly unsuited in another. EPA has used this approach in many rules, such as Part 68, but has also used this approach in NSPS Ja for flares.

15.2.1. The Rule Should Not Specify Use of Specific Equipment

Paragraph 60.5375(a)(2) states that “You must employ sand traps, surge vessels, separators, and tanks during flowback and cleanout operations”. Any one of these pieces of equipment may not be necessary for any given flowback and cleanout operation, or not necessary for the entire time, so it is not appropriate to mandate it. Industry should be allowed to determine what equipment is required to safely minimize emissions.

15.2.2. The Rule Needs To Be Expanded To Allow For Use of Other Emission Reduction Techniques

Currently the proposed rule presumes a very simplistic understanding of completions - that all wells are simply flowed back using the reservoir energy to pits or flowback tanks. As structured, the rule precludes the use of other completion techniques which may be necessary to clean out a well and which may have equally low emissions in comparison to reduced emission completions. For instance reverse circulation completions have been utilized in a number of areas/wells with good success and low emissions. Reverse circulation completions have been presented in several Natural Gas STAR workshops and should not be ignored or precluded by the rule as proposed. In the future, new completion techniques and options may be developed which adequately clean-up the reservoir while providing for reduced emissions when compared to an uncontrolled “normal” flow-back. The rule, as proposed, would stifle this innovation and effectively preclude progress in better reservoir clean-up and reduced emissions.

15.2.3. The Rule Should Not Require Routing Liquids to a Storage Vessel

Sometimes flowback contains sands and other injection fluids that can damage storage vessels and make the condensate not salable; therefore, some of the flowback may get sent to a pit versus a storage vessel. The ability to flowback to a pit should be allowed.

15.2.4. The Rule Should Recognize Commercial Viability

The rule should recognize that installation of a collection line, to enable gas sales and REC's, prior to drilling or completing a well is only justifiable from an economic and surface disturbance/habitat disturbance perspective when the probability of a commercially successful well is almost assured. This is typical only for well developed areas with very well-known reservoir extent and productivity where the new wells are “in-fill” between existing wells. Although EPA attempted to deal with this uncertainty by excluding

exploration and delineation wells from the REC requirements the exclusion is not broad enough. API requests that EPA broaden this exclusion to include any well which the owner determines does not have a very high probability of success. The operator would be required to document their evaluation of wells probability of commercial success.

Suggested Rule Text: In order to address these concerns and others in later sections of these comments, API proposes two options. The preferred option would be to require the development and implementation of a management plan of how you will minimize VOC emissions associated with flowback immediately following hydraulic fracturing stimulation at gas wellhead facilities onshore instead of requiring specific equipment. The alternative option that API is proposing to replace requiring specific equipment would be to “*Route salable natural gas to a natural gas gathering line if available when deemed safe and practicable by the operator. When the well head pressure (in absolute units) immediately following perforation is four times the static sales meter pressure then the operator is obligated to flow the well to an available sales line or document the reasons for failing to flow to sales.*” This would specify when it would even be feasible when gas can be routed to the sales line which is discussed further in Section 15.3.2.

Preferred Option:

§60.5375

If you are the owner or operator of a gas wellhead affected facility, you must comply with paragraphs (a) through (g) of this section.

- (a) Except as provided in paragraph (f) of this section, for flowback immediately following ~~with~~ hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore, as defined in §60.5430, you must control emissions by the operational procedures found in paragraphs (a)(1) ~~through and~~ (a)(32) of this section.
- (1) You must minimize the VOC emissions associated ~~with venting of hydrocarbon fluids and gas over the duration of~~ with flowback immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore, as defined in §60.5430, utilizing one or more of the following options routing the recovered liquids into storage vessels and routing the recovered gas into a gas gathering line or collection system:
- (i) Route salable natural gas to a natural gas gathering line if available when deemed safe and practicable by the operator.
- (ii) Capture and route VOC emissions associated with flowback immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore that cannot be directed to the gathering line to a completion combustion device except when conditions may result in a fire hazard, conditions may result in an explosion, gas is not combustible, or not allowed by state, tribal, or local requirement. Completion combustion

devices must be equipped with a reliable ignition source over the duration of flowback but are not subject to §60.18.

(iii) Other method that minimizes VOC emissions associated with flowback immediately following hydraulic fracture stimulation.

~~(2) You must employ sand traps, surge vessels, separators, and tanks during flowback and cleanout operations to safely maximize resource recovery and minimize releases to the environment. All salable quality gas must be routed to the gas gathering line as soon as practicable.~~ Develop and implement a management plan for each basin for how you will minimize VOC emissions associated with flowback immediately following hydraulic fracturing stimulation at a natural gas wellhead facilities onshore utilizing the options in §60.5375(a)(1). The plan must include:

(i) Methods and techniques to enhance direction of gas during the flowback immediately following hydraulic fracturing to the natural gas gathering system.

(ii) Equipment to be used.

(iii) Operating procedures

(iv) Definition of roles and responsibilities for implementation of the plan.

(v) Review of the effectiveness of the plan in minimizing VOC emissions every 2 years.

~~(3) You must capture and direct flowback emissions that cannot be directed to the gathering line to a completion combustion device, except in conditions that may result in a fire hazard or explosion. Completion combustion devices must be equipped with a reliable continuous ignition source over the duration of flowback.~~

(b) You must maintain a log records for each well completion operation at each gas wellhead affected facility. ~~The log must be completed~~ on a daily basis and must contain the information records specified in §60.5420(c)(1)(iii).

(c) You must demonstrate initial compliance with the standards that apply to gas wellhead affected facilities as required by §60.5410.

(d) You must demonstrate continuous compliance with the standards that apply to gas wellhead affected facilities as required by §60.5415.

(e) You must perform the required notification, recordkeeping, and reporting as required by §60.5420.

- (f) For wells meeting the criteria for wildcat, appraisal, or delineation wells or where production equipment or a natural gas gathering line is not reasonably available, each well completion operation with hydraulic fracturing at a gas wellhead affected facility must reduce emissions by using a completion combustion device meeting the requirements of paragraph (a)(~~3~~)(1)(ii) of this section. ~~You must also maintain records specified in §60.5420(e)(1)(iii) for wildcat or delineation wells.~~
- (g) The provisions of this section notwithstanding, a gas wellhead affected facility that commenced construction, modification, or reconstruction after August 23, 2011 but flowback immediately following hydraulic fracturing at a natural gas wellhead facility onshore that ends prior to [two years after the effective date] shall not be required to comply with §60.5375 (a) through (f)

Alternative Option:

§60.5375

If you are the owner or operator of a gas wellhead affected facility, you must comply with paragraphs (a) through (g) of this section.

- (a) Except as provided in paragraph (f) of this section, for ~~flowback of each well completion operation with~~ immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore, as defined in §60.5430, you must control emissions by the operational procedures found in paragraphs (a)(1) ~~through (a)(3)~~ of this section.
- (1) You must minimize the VOC emissions associated ~~with venting of hydrocarbon fluids and gas over the duration of~~ flowback duration of immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore, as defined in §60.5430, utilizing one or more of the following ~~options: by routing the recovered liquids into storage vessels and routing the recovered gas into a gas gathering line or collection system.~~
- (i) Route salable natural gas to a natural gas gathering line if available when deemed safe and practicable by the operator. When the well head pressure (in absolute units) immediately following perforation is four times the static sales meter pressure then the operator is obligated to flow the well to an available sales line or document the reasons for failing to flow to sales.
- (ii) Capture and route flowback emissions that cannot be directed to the gathering line to a completion combustion device except when conditions may result in a fire hazard, or explosion, gas is not combustible, or not allowed by state, tribal, or local requirement. Completion combustion devices must be equipped with a reliable ignition source over the duration of flowback but are not subject to §60.18. For wells meeting the criteria for wildcat, appraisal, or delineation wells or where production equipment or a natural gas gathering line is not reasonably available, reduce emissions by

using a completion combustion device when not precluded by one of the conditions described above.

(iii) Other methods that minimize VOC emissions associated with flowback immediately following hydraulic fracture stimulation.

~~(2) You must employ sand traps, surge vessels, separators, and tanks during flowback and cleanout operations to safely maximize resource recovery and minimize releases to the environment. All salable quality gas must be routed to the gas gathering line as soon as practicable.~~

~~(3) You must capture and direct flowback emissions that cannot be directed to the gathering line to a completion combustion device, except in conditions that may result in a fire hazard or explosion. Completion combustion devices must be equipped with a reliable continuous ignition source over the duration of flowback.~~

- (b) You must maintain a log records for each well completion operation at each gas wellhead affected facility. ~~The log must be completed~~ on a daily basis and must contain the information records specified in §60.5420(c)(1)(iii).
- (c) You must demonstrate initial compliance with the standards that apply to gas wellhead affected facilities as required by §60.5410.
- (d) You must demonstrate continuous compliance with the standards that apply to gas wellhead affected facilities as required by §60.5415.
- (e) You must perform the required notification, recordkeeping, and reporting as required by §60.5420.
- (f) For wells meeting the criteria for wildcat, appraisal, or delineation wells or where production equipment or a natural gas gathering line is not reasonably available, each well completion operation with hydraulic fracturing at a gas wellhead affected facility must reduce emissions by using a completion combustion device meeting the requirements of paragraph (a)(~~3~~) (1)(ii) of this section. ~~You must also maintain records specified in §60.5420(c)(1)(iii) for wildcat or delineation wells.~~
- (g) The provisions of this section notwithstanding, a gas wellhead affected facility that commenced construction, modification, or reconstruction after August 23, 2011 but flowback immediately following hydraulic fracturing ends prior to [two years after the effective date] shall not be required to comply with §60.5375 (a) through (f).

15.3. Need Ability to Combust or Vent

Paragraphs 60.5375(a)(1) and (2) require “routing recoverable liquids to storage vessels and routing the recovered gas into a gathering line or collection system” and “all salable quality gas must be routed to the gas gathering line as soon as practicable.” API appreciates that EPA is trying to provide flexibility in the proposed rule language, but additional clarity is needed in the rule to

address the many operational and safety constraints to routing all salable gas to gathering line. There are several operational and safety constraints that limit the ability to meet these requirements. These constraints include but are not limited to:

15.3.1. Lack of Availability of a Natural Gas Gathering Line and Production Equipment

Unless a well's probability of commercial productivity is almost assured, natural gas gathering lines and production equipment may not be installed prior to completion and it is unreasonable and not cost effective to require that they be installed to enable REC's. This limits the "footprint" as well as the financial risk associated with a well that may never produce. Non-producing wells are known as "dry holes". According to the US Energy Information Administration (EIA), in 2010 8.9% of total wells drilled were dry holes^F and approximately 39.2% of total exploration wells drilled were dry holes^G. Commercial viability of the well must be considered when requiring to route gas to a natural gas gathering line. The Wyoming Department of Environmental Quality "Oil and Gas Production Facilities Chapter 6, Section 2 Permitting Guidance" revised March 2010^H only applied to concentrated development areas and the Jonah Pinedale Development Area of Wyoming, not to smaller development areas where reservoir extent, productivity, compositions, and pressures are not well established. Furthermore, in these concentrated development areas current development is "in-fill" drilling where the probability of success is almost assured, there is already sufficient natural gas production to justify the installation of a natural gas gathering line and the main gas gathering line/system is already in place. Permitting, designing, and installing a natural gas gathering system (including pipelines, compression, gas plant) takes a great amount of time and money. Sufficient natural gas production in the area is required to justify the cost and burden for permitting, designing, and building the natural gas gathering system. Companies may drill multiple wells prior to determining whether an area can be economically produced and justify the investment necessary. An exemption from sending natural gas to a natural gas gathering line should be extended to wells where commercial viability is not assured prior to installation of equipment and pipelines.

Before natural gas production can be sent to natural gas gathering line, all of following must be done:

- **A natural gas gathering line/system must be permitted, installed and operational in the area.** Permits are required for right-of-way, installation, compressor site air quality, etc. for the natural gas gathering line/system before it is installed which take much longer than getting a permit to drill a well. Designing and installing a natural gas gathering system (including a pipelines, compression, gas plant to send the gas to, etc) takes considerable time and money. Furthermore, designing and installing a gas

^F <http://www.eia.gov/totalenergy/data/annual/showtext.cfm?t=ptb0407>

^G <http://www.eia.gov/totalenergy/data/annual/showtext.cfm?t=ptb0406>

^H Wyoming Department of Environmental Quality, Oil and Gas Production Facilities Chapter 6, Section 2 Permitting Guidance, Revised March 2010, <http://deq.state.wy.us/aqd/Oil%20and%20Gas/March%202010%20FINAL%20O&G%20GUIDANCE.pdf>

gathering line depends on having enough natural gas production to justify the exceptional cost and burden for the gas gathering system.

- **A contractual right to flow into the gas gathering system with the company that owns the gathering line.** In most cases the company owning the well is different from the company that owns the gathering system. Therefore, contracts must be put in place to allow for flow to the gathering system. The company owning the gas gathering system must determine if the pipeline has the capacity to accept the additional well or wells being added.
- **Acquire necessary permits and right-of-way for the pipeline from the well site to the natural gas gathering system.** Permits and right-of-way are required for installation of the pipeline to connect to the natural gas gathering system. Sometimes obtaining the necessary right-of-way can be difficult and require a court decision.
- **The natural gas must meet the specifications of the natural gas gathering line.** Contracts with the gathering company include specifications for entering the gas gathering line including concentrations of inert gases such as carbon dioxide or nitrogen, and H₂S. Carbon dioxide and nitrogen are often used to energize well stimulations to assist with flowback and cleanup. The carbon dioxide and nitrogen flowback and can not be routed to the pipeline because they make the gas not salable. The natural gas gathering system operator ultimately controls when an operator can send gas to sales.
- **There must be adequate reservoir pressure to flow into the natural gas gathering line to clean up the well and not choke it.** This has been discussed in further detail under Section 15.3.2 below and Attachment F (Reservoir Performance) which is incorporated in these comments by reference.
- **The natural gas gathering line must be operational at the time of the completion.** Natural gas gathering lines can be down for a multitude of reasons including but not limited compressor maintenance or repair, line maintenance, line inspection, the gas plant being shut down, etc.

Furthermore, there are many reasons to complete a well and flowback without a natural gas gathering line or production equipment in place including but not limited to:

- **Avoiding lease jeopardy by establishing production in paying quantities.** Mineral leases contain expiration clauses tied to specific milestones to encourage the development of a lease hold in a timely fashion. One of the typical milestones is performance of a well completion. If the date is missed, the lease expires, causing the rights owner not only to lose the cost of the lease, but the investment in assessing the lease and preparing to drill it. It is common for operators in a low-price natural gas environment to drill and complete a well prior to acquiring surface equipment or contracting for gathering system space. Delays due to unavailability of REC equipment create an additional risk that the operator could fail to live up to steps in the contract and negate the contract causing the operator to lose their rights to the minerals.

- **Waiting for the necessary permits for installing the pipeline or the production equipment.** For major sources and minor sources in some states or on Tribal land, a permit for installing the production equipment must be obtained prior to construction of the source. Due to lease requirements, the well may have to be drilled within a certain time period as discussed above. If the air permit for collection system compression or the well site (if required) has not been obtained in time, the well could have to be drilled due to performance provisions in the lease agreement before the production equipment can be constructed. Furthermore, permits are needed to install the pipeline to connect to the natural gas gathering system. Time for approval of permits depends on the agency reviewing them and is out of the control of the company owning the well.
- **Not knowing the composition of gas limiting ability to design the production equipment or pipeline.** In some areas, the production equipment and pipeline are not installed until the composition of the gas is known in order to design the equipment to handle the gas and condensate, particularly for sour gas fields where the level of H₂S is critical for the design requirements. This is particularly significant in areas where the reservoir and properties are not well known and delineated.
- **Getting the surface rights for installing production equipment.** In many cases the owners of the mineral rights are different from the surface rights; therefore, surface rights must be obtained for construction of a pad to drill a well and subsequently install the production equipment. These surface rights are size/area limited and in many cases not sufficient to have in place both the completions equipment and the production equipment at the same time so companies wait to install the production equipment until after the drilling and completions equipment are gone. This also limits the “footprint” of surface disturbance to the area.

API requests that any well that does not have production equipment or a natural gas gathering line reasonably available based on when the well is flowed back should be able to be treated the same as a delineation or wildcat well under the rule and be able to combust or vent the natural gas. At a minimum, we would appreciate concurrence that the issued discussed above are conditions in which routing to a sales line are not practicable.

15.3.2. Pipeline Pressure

When each stage of a stimulation program is initially completed, the pressure of the gas may not be high enough to overcome pipeline pressure and maintain adequate velocity to clean-up the well and reservoir. Any time this occurs, the well must be flared or vented until enough flowing pressure is available to send gas to the sales pipeline. This allows clean up of the well bore and is critical to minimize the potential for formation damage. It is possible that sensitive zones can lose productivity due to increased clean-up time required if back pressure is added to the well because of the line pressures. Once a fracture stimulation is pumped, flowback and cleanup must proceed regardless of sufficient pressure to enable sales or severe and permanent reservoir damage is likely. Adding compression to overcome line pressure on low energy wells has been tried several times and found to be not feasible for technical reasons. Furthermore it adds additional emissions for engines to power the compressors while greatly increasing the cost.

The Colorado Oil and Gas Commission requirements under 805(b)(3) are written to apply only to “on oil and gas wells where reservoir pressure, formation productivity, and wellbore conditions are likely to enable the well to be capable of naturally flowing hydrocarbon gas in flammable or greater concentrations at a stabilized rate in excess of five hundred (500) MCFD to the surface against an induced surface backpressure of five hundred (500) psig or sales line pressure, whichever is greater.” Based on conversations with industry and agency participants in the rule making, the threshold of 500 psig was based on ensuring the reservoir pressure was high enough to overcome the line pressure, clean out the well, and not choke the well based on the reservoir and line pressures within Colorado. Based on the wide range of variability across the US in reservoir and line pressures, setting a specific pressure threshold would be difficult. API recommends that any well whose reservoir pressure (measured at the wellhead immediately after perforation) is less than 4 times (in absolute units) line pressure measured at the flow meter would be exempt from any requirement to flow to sales during the flowback period. Please see Attachment F (Reservoir Performance) which is incorporated into these comments by reference for additional information.

15.3.3. Drilling Fracture Plugs and Running Tubing

Nitrogen may be added to the fluid stream when drilling fracture plugs to help assist flowback and debris removal. The nitrogen content prevents the gas from meeting pipeline specifications and may render the gas unable to support combustion. A well must be flowed while drilling out plugs to remove cuttings/debris and prevent “pack off” around the tubing which is likely to result in stuck tubing. Flow may be sent to a pit or flow-back tank and atmospheric pressure rather than sales to reduce back pressure to enable fracture-plug debris and sand to be more efficiently removed from the well. Furthermore, higher back pressures which may occur if “pack off” around the tubing occurs, may result in cross flow from high pressure zones to low pressure zones, which results in the inefficient cleanup of low pressure zones and may cause irreparable formation damage.

15.3.4. Hydrates and Maintenance

Pressure drops across a flow-back choke can initiate hydrate formation. The additional equipment and piping associated with flareless completions creates an even greater opportunity for hydrates (which form at elevated temperatures while the stream is at elevated pressure). Hydrate formation can plug the pipeline, wellhead equipment, or production equipment. If any of the components must be taken out of service, the well may be routed to the flare until the hydrate problems are solved and the system is back on line. Cold weather operations need additional flexibility to flare to prevent hydrates during clean-up operations.

15.3.5. Depressuring High Pressure Wells

Routing initial flow from a high pressured well to the sales line can create a safety issue. When there is a large difference between the well pressure and the sales line pressure, the decrease in pressure results in a significant temperature drop. This cold gas stream can cause the equipment to freeze up. Initial well flow after drilling or shut-in will be flared until the gas is warm enough to be routed to sales safely. Some companies require the use of a line heater to prevent freezing and choking the well.

15.3.6. Exempt Appraisal Wells from Going to Sales.

The proposed Subpart OOOO does not require reduced emissions completions for “wildcat” and “delineation” wells because such wells are “generally not in close proximity to a gathering line.” 78 FR 52745. These two terms are defined as follows:

Delineation well means a well drilled in order to determine the boundary of a field or producing reservoir.

Wildcat well means a well outside known fields or the first well drilled in an oil or gas field where no other oil and gas production exists

These terms probably work reasonably well in conventional oil and gas reservoirs to define the early stages in field development where a gathering system would not be expected to be present.

However, unconventional reservoirs such as shale gas reservoirs present different issues in determining whether infrastructure investment in gathering systems is appropriate. The issue is related to understanding well performance and ultimate well recovery. The decline of wells in unconventional reservoirs is not as well understood and most of the 'new' shale plays have only limited production history. It often takes several wells and significant production history before enough production data exists to properly characterize the well and area potential. Aside from the lesser degree of production history, shale plays have two other characteristics that may delay infrastructure investment:

- Horizontal wells are more costly to drill and prepare than typical conventional wells, so that good production history is important to determine if more wells are economically viable
- Shale reservoirs often have gradual gradients from oil to gas. Oil remains more valuable as a commodity than natural gas, so that one function of field appraisal is to find the economically viable areas of a shale reservoir, not its technical geologic boundary

API recommends adding “Appraisal wells” as a third category of well that is exempt from the REC requirements of §60.5375(a). The suggested definition shown below has been drawn from definitions used by the Energy Information Agency and other federal agencies such as the USGS and SEC.¹

Because the term “proved reserve” has an important regulatory and financial reporting meaning, companies have a very strong incentive to accurately report areas and amounts of proved reserves.

We believe this additional definition better reflects the universe of wells for which a gas gathering system will not be available. It also avoids a potential “chicken before the egg” problem where a shale play appraisal well system is effectively compelled to install a

¹ http://www.eia.gov/dnav/ng/TblDefs/ng_enr_shalegas_tbldef2.asp

gathering line system before the wells are determined to be economically viable, in order to assure compliance with NSPS Subpart OOOO.

Suggested Rule Text:

§60.5430

Appraisal well means a well drilled in an area where the reservoir has not been classified for that area as containing proved reserves of natural gas.

Proved reserves of natural gas are reserves which analysis of geological and engineering data demonstrate with reasonable certainty to be recoverable in future years from known reservoirs under existing economic and operating conditions. Reservoirs are considered proved if economic producibility is supported by actual production or conclusive formation test (drill stem or wire line), or if economic producibility is supported by core analyses and/or electric or other log interpretations. The area of a gas reservoir considered proved includes: (1) that portion delineated by drilling and defined by gas -- oil and/or gas -- water contacts, if any; and (2) the immediately adjoining portions not yet drilled, but which can be reasonably judged as economically productive on the basis of available geological and engineering data. In the absence of information on fluid contacts, the lowest known structural occurrence of hydrocarbons is considered to be the lower proved limit of the reservoir.

15.3.7. Allow for Venting Versus Flaring

The rule allows for venting in “conditions that may result in a fire hazard or explosion.” However, there are also times when the gas may not be burnable due to low BTU content from use of nitrogen or CO₂ in the fracturing operation which would require venting. Also, there are areas of the country that do not allow for the use of a combustion device due to fire hazard such as San Juan County, CO or areas where burn bans are put in place.

15.3.8. Allow For Electronic Igniters

The rule currently requires a completion combustion device with a “reliable continuous ignition device.” In many cases electronic igniters are used instead of a continuous ignition device. API requests that the rule be modified to explicitly allow the use of electronic igniters. (See Section 9.1.2 of general comments for more details.)

15.3.9. Completion Combustion Device Not Subject to §60.18

Section 60.5375(a)(3) provides that “You must capture and direct flowback emissions that cannot be directed to the gathering line to a completion combustion device, except in conditions that may result in a fire hazard or explosion. Completion combustion devices must be equipped with a reliable continuous ignition source over the duration of flowback.”

EPA appears to have chosen the term “completion combustion device” so that the pit flares, which the preamble states at p. 52758 are not a “traditional flare control device” would not be subject to §60.18. The preamble indicates that this is the case “because of the multiphase

slug flow and intermittent nature of the discharge of gas, water and sand over the pit.” As a result, pit flares cannot comply with the technical requirements of this section.

However, Subpart OOOO also includes a definition of flare at §60.5430 which reads as “*Flare* means a thermal oxidation system using an open (without enclosure) flame.” This definition would include pit flares because they use an open flame to oxidize the gas portion of the flowback. While pit flares are often used, some operators may choose to use temporary portable “field flare” flare devices or be required to do so by state or local rules. These temporary portable “field flares” may or may not be capable of meeting the full requirements of §60.18 and API requests that they receive the same exclusion from the requirements of §60.18 that are afforded to pit flares.

Suggested Rule Text:

§60.5430

Flare means a thermal oxidation system using an open (without enclosure) flame. [A completion combustion device is not a flare.](#)

Suggested Rule Text: Please see suggested rule text for §60.5375 under Section 15.2.

15.4. Availability of Equipment and Experienced Operators

Paragraph 60.5370(a) requires that “You must be in compliance with the standards of this subpart no later than the date of publication of the final rule in the Federal Register or upon startup, whichever is later.” EPA is required to complete the final rules by February 28, 2012 which is the deadline established in the consent decree EPA negotiated with WildEarth Guardians and San Juan Citizens Alliance. Obtaining the necessary equipment and experienced staff for reduced emissions completions (REC) is a significant issue as discussed below. The processes and equipment used for doing reduced emissions completions have taken industry over 10 years to develop and vary greatly depending on the reservoir type, gas composition, hydraulic fracturing medium used, etc. Currently most of the larger operators are employing REC where it makes economic sense; however, the majority of smaller and independent operators are not currently doing REC. As written, every gas well hydraulically fractured would require REC as discussed further in Attachment G (RIA Review), which is incorporated into these comments by reference.

Due to the limited availability of appropriate and safe equipment and experienced and trained personnel to perform REC's, API requests that compliance with the reduced emissions completions portion of the rule, except for routing gas to a completion combustion device, be delayed for 2 years to allow for manufacturing of equipment and training of operators. This delayed compliance date is necessary to ensure the implementation of safe equipment and practices and enable the ability of companies to comply with the proposed requirements. Under 40 CFR 60 Subpart A, Ja, AA, JJJ, and KKKK, EPA allowed for an effective date for compliance with the rule after the final rule was published in the federal register. The Wyoming Department of Environmental Quality allowed over a year from the time their “Oil and Gas Production Facilities Chapter 6, Section 2 Permitting

Guidance" revised March 2010^J was approved until permits were issued for reduced emissions completions to give all companies time to acquire the needed equipment and train operators on doing the completions for only part (concentrated development areas and the Jonah Pinedale Development Area) of the State of Wyoming. With the nationwide coverage of Subpart OOO the magnitude of the gap between current availability and necessary equipment and experienced personnel will be much larger and a longer delay will be required.

15.4.1. Availability of Equipment

With implementation of the rule required so quickly after the rule is finalized, equipment will not be available to meet these requirements. There is already a shortage of the specialty equipment required due to the recent WYDEQ BACT Policy and the expansion of the rule to all of the US will make this shortage unmanageable. It will take a significant amount of time for the vessel/equipment manufacturers to expand their capacity to manufacture adequate equipment which meets API and pressure-vessel code specifications in the quantities required to comply with the rule. Maintaining the current aggressive rule implementation schedule will force one of two outcomes:

- (1) The pace of drilling of new wells and recompletion of existing wells will be sharply reduced which will result in job losses, supply disruption, higher natural gas prices, and higher electricity prices.
- (2) In order to comply, companies will be forced to use or quickly manufacture/modify equipment which may not meet fabrication codes and standards and could be less safe to use.

In short, the current schedule contemplated by the rule is very likely to unnecessarily create unsafe conditions and operations or supply disruptions and job losses.

Today there is something on the order of 300 sets of REC equipment in existence. This equipment has the ability to process approximately 4,000 wells a year. To allow 20,000 wells to flow to sales in a year would require about 1,300 additional sets of equipment. This equipment is fairly specialized, the shops licensed to make it are limited, and some of the components require a long lead time. It should be expected with today's demand for other pressure vessels that it will be on the order of one year before the first set of additional equipment can be delivered. From that point, industry can probably deliver about 50 sets per quarter, so about 7.5 years will be required to meet the anticipated demand. For this reason, API also requests that the applicability be further limited and that the specific equipment not be specified as discussed further below. As discussed in Section 7.4, if the equipment is not available it does not constitute "the best system of emission reduction."

A related problem with meeting the equipment demand is the availability of capital to fund the necessary new equipment given the current economic conditions and credit availability. Manufacture of a single set of high-pressure code compliant REC equipment is expected to

^J Wyoming Department of Environmental Quality, Oil and Gas Production Facilities Chapter 6, Section 2 Permitting Guidance, Revised March 2010, <http://deq.state.wy.us/aqd/Oil%20and%20Gas/March%202010%20FINAL%20O&G%20GUIDANCE.pdf>

cost about \$467,000 per set. With the estimated 1,300 additional sets necessary this implies a capital investment in excess of \$600 MM to manufacture the equipment. The majority of the pressure vessel manufacturers are not large companies and will likely not commit the capital and effort to expanding the equipment base until the rule is finalized and detailed requirements are known. Even when the rule is finalized, detailed requirements known, and manufacturers chose to construct additional equipment they may not be able to access the funding required. This could further extend the time required for the necessary suite of equipment to be manufactured and deployed.

The current flowback language requires that this equipment must be available prior to stimulation even if it is known that the reservoir pressure/energy, pipeline pressure, and prior well behavior in an area preclude or make highly unlikely that a well can flow to sales. Requiring equipment on site even when it is known that REC's cannot be reasonably accomplished will unnecessarily exacerbate the equipment and personnel shortage problems with zero benefit while imposing unnecessary costs on the operators and ultimately the public. This unnecessary requirement will exacerbate the likely reduced well activity with the consequent job loss, lowering of gas supply, and raising of natural gas and electricity prices.

An additional potential economic harm is the requirements included in mineral leases. If the spud date of a well is delayed by very many months due to equipment availability, then there is a real risk that companies can find themselves in violation of leasing agreements that allow those agreements to be cancelled by the mineral owner. This "lease jeopardy" situation is a real danger in oil & gas operations and production companies take special pains to avoid it where possible. Requirements of REC will create a real risk that companies will lose leases that otherwise would have represented substantial value.

15.4.2. Availability of Experienced Operators

An additional significant concern with requiring implementation of the rule so quickly after the rule is finalized is that industry will have a shortage of experienced contractors or staff for complying with §60.5375(a) or doing "reduced emissions completions". Reduced emissions completions are very complicated and involve many safety issues/concerns with unique risks. The high pressure flow rates of fluids and sand can be quite dangerous. Inexperienced staff will not have adequate knowledge to properly manage the unique risks and prevent incidents from occurring. Industry will not have time to adequately train contractors or staff on how to safely do "reduced emissions completions" which again is likely to create unsafe conditions and operations.

Suggested Rule Text:**§60.5370**

- (a) You must be in compliance with the standards of this subpart no later than 60 days after the date of publication of the final rule in the **Federal Register** or upon startup, whichever is later: ~~except for the provisions of §60.5370(a)(1)-(5) below:~~
- (1) Compliance with §60.5375 is required beginning [two years after the effective date]. From the [effective date] until [two years after the effective date] comply only with §60.5375(a)(1)(ii).

15.5. Timing of Requirements

EPA has stated during conference calls on the rule and at a meeting with API that it was EPA's intent that well completions at gas wellhead affected facilities commenced after the August 23, 2011 proposal date for NSPS OOOO where the completion was commenced before the effective date of the final NSPS OOOO ("Proposal Period Wells") did not require compliance with the emissions control requirements of §60.5375(a). This appears to be consistent with section 111(e) of the Clean Air Act, which reads as follows:

(e) After the effective date of standards of performance promulgated under this section, it shall be unlawful for any owner or operator of any new source to operate such source in violation of any standard of performance applicable to such source.

If the completion work is commenced before the effective date of the final rule, the owner or operator of an affected natural gas wellhead facility will not be operating the well in violation of the requirements of §60.5375 (or other provisions of Subpart OOOO that apply) after the effective date of the final rule. Thus, the requirements of Subpart OOOO do not apply to Proposal Period Wells. However, the applicability section of the rule is written as follows:

§60.5365 Am I subject to this subpart? If you are the owner or operator of one or more of the affected facilities listed in paragraphs (a) through (g) of this section that commenced construction, modification, or reconstruction after August 23, 2011 your affected facility is subject to the applicable provisions of this subpart.

This can be read to require that Proposal Period Wells comply with the emissions control requirements of §60.5375. This concern is magnified by the recordkeeping requirements in §60.5420(c).

§60.5420 (c) Recordkeeping requirements. You must maintain the records identified as specified in §60.7(f) and in paragraphs (c)(1) through (c)(5) of this section

- (1) The records for each gas wellhead affected facility as specified in paragraphs (c)(1)(i) through (c)(1)(iii).
- (i) Records identifying each well completion operation for each gas wellhead affected facility conducted during the reporting period;

- (ii) Record of deviations in cases where well completion operations with hydraulic fracturing were not performed in compliance with the requirements specified in §60.5375.
- (iii) Records required in §60.5375(b) or (f) for each well completion operation conducted for each gas wellhead affected facility that occurred during the reporting period. You must maintain the records specified in paragraphs (c)(1)(iii)(A) and (c)(1)(iii)(B) of this section.

In particular, subparagraph §60.5420(c)(ii) appears to state that it is a “deviation” (i.e. a violation of Subpart OOOO) if Proposal Period Wells are not completed in accordance with the requirements specified in §60.5375(a)

To clarify the applicability of Subpart OOOO to Proposal Period Wells, API recommends that Section §60.5375 be amended to add a new paragraph (g):

Suggested Rule Text:

§60.5375

(g) The provisions of this section notwithstanding, a gas wellhead affected facility that commenced construction, modification, or reconstruction after August 23, 2011 but flowback immediately following hydraulic fracturing ends prior to [two years after the effective date] shall not be required to comply with §60.5375 (a) through (f).

Most of the recordkeeping provisions applicable to gas wellhead affected facilities are tailored to documentation of compliance with §60.5375(a). We are suggesting recordkeeping requirements for Proposal Period Wells which require documenting that the well is not required to comply with emissions control requirements in §60.5375(a). We have also suggested that owners and operators have until two years after publication of the final rule in the federal register or worst case 60 days after publication of the final rule in the federal register to comply with these reporting and recordkeeping obligations, so that owners and operators have a reasonable compliance period to provide these notifications and ensure that proper exemption documentation relating to Proposal Period Wells is in place after the effective date.

API believes that neither section 111(e) (set forth above) nor section 111(a)(2)^K prevent EPA from allowing Proposal Period Wells additional time after the effective date of NSPS OOOO to comply with reporting, recordkeeping and notification requirements^L. That is because these requirements are not standards of performance as that term is defined in section 111:

Section 111(a) For purposes of this section:

^K (2) The term "new source" means any stationary source, the construction or modification of which is commenced after the publication of regulations (or, if earlier, proposed regulations) prescribing a standard of performance under this section which will be applicable to such source.

^L This comment is not intended to suggest that EPA lacks authority under Section 111 as a general matter to allow for compliance dates after the effective date of an NSPS rule. Other sections of API's comments discuss other requirements for which API believes additional time should be allowed for compliance after the effective date of NSPS OOOO.

- (1) *The term "standard of performance" means a standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction.*

Thus, it is only the standard for emissions of air pollutants that is referenced in section 111(e). Reporting, recordkeeping and notification requirements are not, therefore, standards of performance so that section 111(e) need not be read to require compliance with these requirements on the effective date of NSPS OOOO. This appears to a distinction already recognized by EPA as general matter, since EPA already allows time after the effective date of rules to submit reports and notifications for other new sources.

15.6. Applicability Issues

Further clarity is needed in various parts of the rule text as to where reduced emissions completions applies.

15.6.1. §60.5365(a)

As discussed in Section 5.6.2 (modification) of the comments, §60.5365 states, “For the purposes of this subpart, a well completion operation refracturing that occurs at a natural gas wellhead facility that commenced construction, modification, or reconstruction on or before August 23, 2011 is considered a modification of the natural gas wellhead facility, but does not affect other equipment, process units, storage vessels, or pneumatic devices located at the well site.” First, this general section is the wrong location for this text. It only adds confusion. At a minimum, it needs to be moved to §60.5365(a) which discusses the affected source. More importantly, it adds to the confusion of what the affected source is or should be. As discussed in Section 5.4.1, the affected source has been defined as the wellhead, when the emissions being regulated are emissions from the flowback immediately following hydraulic fracture stimulation. API believes that this contradiction will lead to decades of confusion and disagreements by regulators and industry alike. API believes that this contradiction must be eliminated by the consultation and supplemental proposal previously discussed. However, if EPA refuses to do so, then EPA should clarify its intent through a series of definitions and regulatory text revisions that makes its intent much more clear than does the proposed rule.

Currently, there is no time limit placed on “following” hydraulic fracturing or refracturing. Thus, as written, once a well has been hydraulically fractured, any subsequent well work could be subject to the reduced emissions completions requirements. Furthermore, it does not limit the applicability to the flowback immediately following hydraulic fracturing at a natural gas wellhead facility onshore. Also, EPA mistakenly states that the rule applies “before” August 23, 2011.

Suggested Rule Text: See suggested rule text for §60.5365 under Section 5.4.3

15.6.2. §60.5375

Under §60.5375, it states that “for each well completion operation with hydraulic fracturing” the operational procedures of reduced emissions completions applies. However, as with §60.5365, there is no time limit placed on “with hydraulic fracturing or refracturing” and could be interpreted that any subsequent well work could be subject to reduced emissions completions. Also, it does not limit the applicability to the flowback immediately following hydraulic fracturing. Furthermore, “gas wellhead” is never mentioned which could be interpreted that all hydraulically fractured wells, gas and oil, would be subject to these requirements.

Suggested Rule Text: See suggested rule text for §60.5375 under Section 15.2.4.

15.6.3. Definition of Modification

As discussed earlier in the comments, a “modification” should apply to flowback of a recompletion immediately following hydraulic fracturing that has a reasonable expectation to be greater than the original completion. Wells that are recompleted within the same reservoir/zone that was previously hydrofractured will necessarily have fewer emissions than previously experienced due to the depletion of reservoir pressure. However, a well that is recompleted in new reservoir may have more or less emission than in original completion operations. By including recompletion in the definition of modifications, EPA has exceeded the intent of the CAA. The definition of modification should remain under §60.14. However, if EPA chooses to define modification in this subpart, the recompletions portion of the definition of modification should be removed.

Suggested Rule Text:

§60.5430

Preferred Option:

~~Modification means any physical change in, or change in the method of operation of, an affected facility which increases the amount of VOC or natural gas emitted into the atmosphere by that facility or which results in the emission of VOC or natural gas into the atmosphere not previously emitted. For the purposes of this subpart, each recompletion of a fractured or refractured existing gas well is considered to be a modification.~~

Alternative Option:

~~Modification means any physical change in, or change in the method of operation of, an affected facility which increases the amount of VOC or natural gas emitted into the atmosphere by that facility or which results in the emission of VOC or natural gas into the atmosphere not previously emitted. For the purposes of this subpart, each recompletion of a fractured or refractured existing gas well is considered to be a modification.~~

15.6.4. Gas Wellhead Applicability Only

Based on EPA's discussion in Section 4 of the Technical Support Document, it appears the EPA's intent is to require reduced emissions completions only for natural gas wells. However, the rule needs to include "natural gas" versus "gas" throughout as API has proposed for clarity. API supports that EPA applied reduced emissions completions only to natural gas wellhead facilities and excluded oil wellhead facilities and other types of gas wells which have little or no VOC emissions. As shown on page 4-13 on Table 4.4 "Nationwide Baseline Emissions from Uncontrolled Oil and Gas Well Completions and Recompletions" of the Technical Support Document, there are only 134 TPY of VOCs emissions from oil well completions and recompletions for the entire U.S., which is not worth regulating.

15.6.5. Offshore Applicability.

Based on the Technical Support Document and preamble for the proposed rule, it was clear that EPA did not assess the feasibility and cost for doing reduced emissions completions offshore. Without a pipeline being available nor space for the specified reduced emission completions equipment, it is not feasible to do REC offshore. Furthermore, many offshore rigs are often foreign flagged and will not necessarily be designed to accommodate or achieve US regulatory requirements. Therefore, API request that reduced emissions completions only apply to onshore facilities.

Suggested Rule Text : See suggested rule text for §60.5365 under Section 5.4.3, for §60.5375(a) under Section 15.2.4, and for the definition of a modification under Section 15.6.3 above.

15.7. Multiple Notification Requirements

The rule as proposed is requiring four notifications for every well completion operation following hydraulic fracturing or refracturing at a gas well head facility which include:

- Post-marked 30 days after construction [§60.7(a)(1)],
- Post-marked 15 days after initial startup [§60.7(a)(3)],
- Post-marked 60 days or as soon as practicable before the changed is commenced [§60.7(a)(4)], and
- 30 days of the commencement of the well completion operation [§60.5410(a)(1) or §60.5420(a)(2)].

Furthermore, EPA requested comment on a "follow-up notification one or two days before an impending completion via telephone or by electronic means" which would mean five notifications for every completion operation. EPA predicted 20,000 hydraulic fracturing and refracturing events per year resulting in greater than 100,000 notifications per year. These multiple notifications will be excessively burdensome on both the Administrator and industry with no benefit to air quality. Industry would need full time employees to just do all these notification and re-notifications. EPA

solicited many comments on the notifications for completions on pages 52749-52750 of the Federal Register. In response to EPA's questions, API proposes the following changes.

15.7.1. Remove Subpart A Notifications

API requests that all the §60.7(a) notifications be removed since they are not appropriate for completions operations. The definitions of both "construction" and "initial start-up" do not apply to the flowback immediately following hydraulic fracturing. The flowback is a temporary operation that lasts only "3-10 days" as discussed in the preamble. Furthermore, predicting 60 days in advance of doing a completion operation is not possible. Even drilling of the well would not necessarily have even been started 60 days prior to the completion operation so predicting when the completions event would begin is even more difficult to predict. The timing for the flowback portion of the completions operation depends on the drilling schedule, availability of the drilling equipment, the time to drill the well, the schedule for the completion, the availability of the equipment for casing the well and running tubing, the schedule for casing the well and running tubing, the schedule for fracturing, the availability of the hydraulic fracturing equipment, the time to fracture the well, the number of fracture stages (individual or multi-stage), etc.

15.7.2. Remove the Notification to EPA 30 Days Prior to a Well Completion Operation or Change as Proposed

Paragraph 60.5420(a)(2) requires that you must submit a notification to the Administrator within 30 days of the commencement of the well completion operation. The notification must include the date of commencement of the well completion operation, the latitude and longitude coordinates of the well in decimal degrees to an accuracy and precision of five (5) decimals of a degree using the North American Datum of 1983." Based on the preamble and discussions with EPA, it is API's understanding that the intent was that notification be given to EPA 30 days prior to the doing a completion so that the Administrator could attend. Predicting a completion 30 days prior to its occurrence is extremely difficult as discussed above. In many cases the well may not have begun to be drilled. The actual date of the flowback depends on a multitude of factors as discussed above. EPA acknowledged this issue in the preamble stating "We also solicit comment on provisions for a follow-up notification one or two days before an impending completion via telephone or by electronic means, since it is difficult to predict exactly when a well will be ready for completion a month in advance" (pg. 52749-52750 of the FR). API requests that this notification requirement either be removed or reduced to a monthly report of the well completions scheduled to occur during the upcoming month. The notification could provide the tentative scheduled date for the start of the flowback immediately following hydraulic fracturing that will occur in the following month. The Administrator could contact the company with questions to request or more up-to-date timing of the flowback operations if needed. This would minimize the burden for reporting for each flowback operation for operators and give the Administrator a plan of the operations for the month ahead. Follow-up notification two days in advance seems excessive. With operations lasting 3-10 days, this should allow the Administrator sufficient time to attend part of the flowback operation.

Suggested Rule Text:

§60.5410

- (a) You have achieved initial compliance with standards for each well completion operation conducted at your gas wellhead affected facility if you have complied with paragraphs (a)(1) and (a)(2) of this section.
- (1) You have notified the Administrator monthly of all the well flowbacks immediately following hydraulic fracturing stimulation that are scheduled to occur at any gas wellhead facilities onshore during the upcoming month in which you have one or more hydraulic fractures scheduled, including within 30 days of the commencement of the well completion operation, the tentative scheduled start date of the well flowback and commencement of the well completion operation, the latitude and longitude coordinates of the well in decimal degrees to an accuracy and precision of five (5) decimals of a degree using the North American Datum (NAD) of 1983.

§60.5420

- (a) You must submit the notifications required ~~in §60.7(a)(1), (a)(3) and (a)(4), and~~ according to paragraphs (a)(1) and (a)(2) of this section, if you own or operate one or more of the affected facilities specified in §60.5365. ~~For the purposes of this subpart, a workover that occurs after August 23, 2011-2011 at each affected facility for which construction, reconstruction, or modification commenced on or before August 23, 2011 is considered a modification for which a notification must be submitted under §60.7(a)(4).~~

* * * * *

- (2) If you own or operate a gas wellhead affected facility, you must submit a notification to the Administrator monthly of all the well flowbacks immediately following hydraulic fracturing stimulation that are scheduled to occur at any gas wellhead facilities onshore during the upcoming month in which you have one or more hydraulic fractures scheduled~~within 30 days of the commencement of the well completion operation~~. The notification must include the tentative scheduled start date of the well flowback and commencement of the well completion operation, the latitude and longitude coordinates of the well in decimal degrees to an accuracy and precision of five (5) decimals of a degree using the North American Datum (NAD) of 1983.

15.8. Clearer Definitions

The definitions for gas well, crude oil, well completions, well completions operation, and hydraulic fracturing in the rule are unclear and inconsistent with common industry understanding. Also, the definition of flowback should be edited as discussed in Section 5.4.2, and a definition should be added for well recompletion.

15.8.1. Definition of Gas Well

The definition of a gas well is unclear. “*Gas well means a well, the principal production of which at the mouth of the well is gas.*” The phrase “mouth of the well” is not a term used or defined in the industry, by the EIA, or commonly understood. For consistency with 40 CFR 98 Subpart W of the GHG Mandatory Reporting Rule and the EIA definition of a “gas well”, API recommends using the definition of a gas well from 40 CFR 98.238 (which is based on the EIA definition) of “*Gas well means a well completed for production of natural gas from one or more gas zones or reservoirs. Such wells contain no completions for the production of crude oil.*”

Suggested Rule Text:

§60.5430

Gas well means a well, ~~the principal production of which at the mouth of the well is gas.~~ completed for production of natural gas from one or more gas zones or reservoirs. Such wells contain no completions for the production of crude oil.

15.8.2. Definition of Crude Oil

The definition of crude oil that EPA uses in the proposed rule conflicts with the definition of crude oil used in the Greenhouse Gas Mandatory Reporting Rule 40 CFR 98 Subpart W, by the EIA, and most states. The API gravity is not known for a well at the time a well is completed; therefore, with the definition of a gas well including crude oil and the definition of a gas well determining applicability for REC, the definition of crude oil should not contain an API gravity. API, therefore, recommends that EPA use the definition of crude oil from the EIA^M. This definition is also consistent with the definition of crude oil used in the Greenhouse Gas Mandatory Reporting Rule 40 CFR 98 Subpart W.

Suggested Rule Text:

§60.5430

Crude oil means ~~crude petroleum oil any other hydrocarbon liquid, which are produced at the well in liquid form by ordinary production methods, and which are not the result of condensation of gas before or after it leaves the reservoir. For the purposes of this subpart, a hydrocarbon liquid with an API gravity less than 40 degrees is considered crude oil.~~ a mixture of hydrocarbons that exists in the liquid phase in natural underground reservoirs and remains liquid at atmospheric pressure after passing through surface separating facilities. Crude oil may also include:

- Small amounts of hydrocarbons that exist in the gaseous phase in natural underground reservoirs but are liquid at atmospheric pressure after being recovered from oil well (casinghead) gas in lease separators, and that subsequently are commingled with the crude stream without being separately measured.
- Small amounts of non-hydrocarbons produced with the oil.

^M http://www.eia.gov/dnav/pet/TblDefs/pet_crd_pres_tbldef2.asp

15.8.3. Definition of Well Completions

Under §60.5430 a well completion is defined as “the process that allows for the flow of petroleum or natural gas from newly drilled wells to expel drilling and reservoir fluids and tests the reservoir flow characteristics, steps which may vent produced gas to the atmosphere via an open pit or tank. Well completion also involves connecting the well bore to the reservoir, which may include treating the formation or installing tubing, packer(s), or lifting equipment.” Flowback of the well after hydraulic fracturing is potentially part of a well completion but a well completion may involve other activities such as perforating the production casing, stimulating the reservoir, and installing wellbore equipment such as tubing, packers, or liquid-lift tools.

API suggests the following definitions for well completion and well completion operations:

Suggested Rule Text:

§60.5430

Well Completions means the process ~~that allows for the flow of petroleum or natural gas from newly drilled wells to expel drilling and reservoir fluids and tests the reservoir flow characteristics, steps which may vent produced gas to the atmosphere via an open pit or tank. Well completion also involves connecting the well bore to the reservoir, which may include treating the formation or installing tubing, packer(s), or lifting equipment~~ of making a new oil or natural gas well ready for production. It allows for the flow of petroleum or natural gas from newly drilled wells to expel drilling and reservoir fluids and test the reservoir flow characteristics and also involves connecting the well bore to the reservoir, which may include treating the formation or installing tubing, packer(s), or lifting equipment. This process may also include high-rate flowback of injected gas, water, oil, and proppant used to fracture stimulate and prop open new fractures in lower permeability reservoirs.

Well Completion Operation means any well completion ~~or well workover~~ occurring at a gas wellhead affected facility onshore.

15.8.4. Definition of Hydraulic Fracturing

The definition used for hydraulic fracturing is inconsistent with standard industry understanding. API recommends the following definition that is based on the definition of hydraulic fracturing in the Schlumberger Oilfield Glossary^N.

Suggested Rule Text:

§60.5430

Hydraulic fracturing means ~~process of directing pressurized liquids, containing water, proppant, and any added chemicals, to penetrate tight sand, shale, or coal formations that~~

^N <http://www.glossary.oilfield.slb.com/>

~~involve high rate, extended back flow to expel fracture fluids and sand during completions and well workovers~~ [a stimulation treatment routinely performed on oil and gas wells in low-permeability reservoirs. Specially engineered fluids are pumped at high pressure and rate into the reservoir interval to be treated, causing a fracture\(s\) to open. The wings of the fracture extend away from the wellbore in opposing directions according to the natural stresses within the formation. Proppant, such as grains of sand of a particular size, is mixed with the treatment fluid to keep the fracture open when the treatment is complete. Hydraulic fracturing creates high-conductivity communication with a large area of formation and bypasses any damage that may exist in the near-wellbore area.](#)

15.8.5. Definition of Flowback

As discussed in Section 5.4.2, to help prevent confusion of what is being regulated under §§60.5365(a) and 60.5375, API recommends that discussions of well completions and recompletions should only be included in the definition of flowback to prevent confusion of what is being regulated.

Suggested Rule Text:

§60.5430

Flowback means the process of allowing fluids to flow from the well following a treatment, either in preparation for a subsequent phase of treatment or in preparation for cleanup and returning the well to production. [Flowback immediately following hydraulic fracture stimulation may occur in conjunction with a well completion, well recompletion, or fracture stimulation of the same zone in an existing well.](#)

15.8.6. Add Definition for Well Recompletion

The current proposed rule does not define *well recompletion*. This term has been included in the suggested revisions to the rule text. Therefore, API suggests the following definition for well recompletion be added to the proposed rule text.

Suggested Rule Text:

§60.5430

[Well Recompletion means completing a well again. See the definition of well completion.](#)

15.9. Remove the Requirement to Record the Distance to the Nearest Gathering Line

Paragraph 60.5420(c)(1)(iii)(B) requires that “For each gas wellhead affected facility required to comply with the requirements of §60.5375(f) “you must record the distance, in miles, of the nearest gathering line.” This could take an excessive amount of work to determine and provides no benefit to air quality. Before natural gas production can be sent to natural gas gathering line, all of following must be done as discussed in more detail under Section 15.3.1:

- A natural gas gathering line system must be permitted, installed and operational in the area a reasonable distance from the well.
- A contractual right to flow into the gas gathering system with the company that owns the gathering line must be in place.
- The necessary permits and right-of-way for the pipeline from the well site to the natural gas gathering system must be obtained.
- The natural gas must meet the specifications of the natural gas gathering line.
- There must be adequate reservoir pressure to flow into the natural gas gathering line to clean up the well against the pipeline pressure without lowering the flow and velocity to the point where the well will not adequately clean-up.
- The natural gas gathering line and system must be operational at the time of the completion.

Suggested Rule Text:**§60.5420**

~~(c)(1)(iii)(B) For each gas wellhead-affected facility required to comply with the requirements of §60.5375(f), you must maintain the records specified in paragraph (c)(1)(iii)(A) of this section except that you do not have to record the duration of recovery to the sales line. In addition, you must record the distance, in miles, of the nearest gathering line.~~

15.10. Emission Rates and Economics Are Unrealistic

Based on API's analysis, the data presented by the EPA for the cost effectiveness of reduced emissions completions does not take in account great variability of the VOC content of the gas, the flow rate of the gas, equipment needed for reduced emissions completions, etc. to adequately address requiring reduced emissions completions for all hydraulically fractured wells. Due to the vast variability, determining a threshold for cost effective reduced emissions completions is extremely difficult. EPA has looked at small subset of wells for the RIA which does not fully represent the diversity of wells across the US that are hydraulic fractured. Please see Attachment G (RIA Review) for more details. API estimates that the average cost per ton of VOCs without sales is \$33,748 versus EPA's estimate of \$1,516 and cost per ton of VOCs with sales is \$27,579 versus EPA's net gain of \$99. The overall cost to the industry for doing REC in 2015 would be \$782.6 Million versus EPA's benefit estimate of \$20.2 million.

15.10.1.EPA's Overestimate of Completions Emissions

In the preamble EPA stated "we estimate that uncontrolled well completion emissions for a hydraulically fractured gas well are approximately 23 tons of VOC, where emissions for a conventional gas well completion are around 0.12 tons VOC." Many of the formations currently being developed have very low concentrations of VOCs in the gas, particularly for some shale gas and coal bed methane formations.

An article published in *Oil & Gas Journal* March 9, 2009 titled "Compositional variety complicated processing plans for US shale gas" written by Keith A Bullin and Peter E Kroushop both of Bryan Research and Engineering had a series of tables that are summarized below:

Table 15-1. Average Compositions of US Shale Gas

| Area | C1 | C2 | C3+ | CO2 | N2 |
|---------------------------|-------|-------|------|------|------|
| Barnett Average | 86.8% | 6.7% | 2.0% | 1.7% | 2.9% |
| Marcellus Average | 85.2% | 11.3% | 2.9% | 0.4% | 0.3% |
| Fayetteville Average | 97.3% | 1.0% | 0.0% | 1.0% | 0.7% |
| New Albany Average | 89.9% | 1.1% | 1.1% | 7.9% | 0.0% |
| Haynesville Shale Average | 95.0% | 0.1% | 0.0% | 4.8% | 0.1% |
| Shale Gas Average | 90.8% | 4.0% | 1.2% | 3.1% | 0.8% |

One API member furnished an average VOC content for coal bed methane wells (1,190 analyses) in the SW Colorado (Durango area) San Juan Basin area which indicates the following composition:

Table 15-2. Average VOC Concentrations of Coal Bed Methane Wells in SW Colorado

| | C1 | C2 | C3 | IC4 | NC4 | IC5 | NC5 | C6 | CO2 | N2 |
|-----------------|--------|-------|-------|-------|-------|-------|-------|-------|--------|-------|
| Mole % | 94.694 | 0.332 | 0.062 | 0.010 | 0.009 | 0.002 | 0.001 | 0.002 | 4.330 | 0.280 |
| Weight % | 87.694 | 0.576 | 0.159 | 0.034 | 0.031 | 0.009 | 0.006 | 0.010 | 11.027 | 0.453 |

As these data illustrate, the variability of VOC content is broad and EPA's assumption of "average" VOC content is both high and does not reflect many of the producing areas. Consequently, EPA's analysis of cost per ton of VOC emissions controlled is both high and does not reflect the reality of gas compositions. For example, a 3 day flow-back period for a well with the Durango area average composition and EPA's assumed flow-back volume of ~9,175 mscf of gas would reduce VOC emissions by about 900 lbs at an EPA estimated risked cost of \$33,237 (~\$72,500 per ton) with no condensate recovery and a more likely maximum recovery of ~70%. With a 70% recovery the VOC reduction would be ~ 0.36 tons with an EPA estimated cost of \$33,237 and a total product sales revenue of ~ \$25,692 or a net cost of ~\$21,163/ton of VOC reduced which is clearly economically unreasonable. Given that API's analysis predicts sharply higher costs, lower overall volumes, and lower (<90%) recovery than EPA's estimate the costs of applying REC's to a well in the Durango area would approach \$500,000 per ton.

API requests that the final regulation include an applicability cut-off of 10% VOC by weight as discussed in Section 5.1.2. Actual data shows emissions range from 0 to 156 tons per flowback depending on the volume of the gas in the flowback, the VOC concentration, etc. (see Attachment G (RIA Review) for more details). However, the average emissions for shale gas wells are only 5.334 Tons of VOC per flowback. As the Tons of VOCs per

flowback drops to zero, the cost for doing reduced emissions completions per ton goes to infinity.

15.10.2. Cost of “Reduced Emissions Completions”

The estimated cost per well to do reduced emissions completions ranges from ~\$30,000 - \$200,000 per well according to an API survey depending on whether equipment is rented or owned, the equipment required, the time need for having the equipment on site, etc. (see Attachment G for details). In the preamble, EPA stated that, “Typical well completions last between 3 and 10 days and costs of performing REC are projected to be between \$700 and \$6,500 per day, including a cost of approximately \$3,523 per completion event for the pit flaring equipment.” This grossly underestimates the cost. The cost estimate per day in the RIA is reasonably close to the numbers reported in the API survey reported in Attachment G, but the RIA assumes that the equipment rental begins the very first day that it is needed and ends the last day of the flowback. This is unrealistic. The manpower and equipment required for completion events represent valuable resources that are in short supply. It is not normal practice to have stimulation equipment and personnel waiting for equipment installation. The respondents to the survey place the elapsed time for REC rental at 30 days more or less. So, for \$5,000/day a 30 day rental represents a \$150,000 outlay. Further, work around an active well site is very expensive. The respondents in the API survey estimated that mobilization/demobilization and operations of REC equipment adds approximately \$30,000 to the cost of the flowback. API estimates that a REC evolution to sales would add \$180,000 to the cost of the well. For low VOC wells, this additional cost represents a cost effectiveness that can be hundreds of thousands of dollars per ton. On CBM wells and those shale gas wells with very low VOC, the cost effectiveness can approach infinity. Production companies may have economic incentives to flow the well back to sales, but those incentives do not include a cost-effectiveness of VOC emission avoidance. A detailed economic analysis will be submitted later; however, the preliminary results indicate that the cost is much higher than EPA estimated.

15.11. Over Estimate of Number Re Completions per Year

In the TSD, EPA states that “10 percent of the wells being re-fractured annually (as previously assumed in Subpart W’s Technical Supporting Document³). From anecdotal information, API understands that this 10% re-fracture frequency per year was originally from work underlying the National Inventory and was developed based on one paper which evaluated the post re-stimulation performance of five (5) wells in the Barnett shale area which was then extrapolated to the population of unconventional wells nationwide. Obviously relying on extrapolation of somewhat unrelated information on five (5) wells in one area and one formation to the nationwide population of unconventional wells is completely unsupportable. API requests that EPA fully and completely explain the derivation of the 10% re-stimulation frequency per year rather than simply referencing the technical support document for Subpart W which simply makes the 10% assumption with no explanation or backup information. As the largest single reduction category in the proposed rule, this explanation is necessary to reasonably support EPA’s analysis.

According to a 1996 study by the Gas Research Institute (GRI)^O, only 2-3% of wells are refractured. This study found that only 15% of the well populations are potentially high potential restimulation candidates which should be subjected to additional analysis. Another study done in 1999 that was presented in a paper at a Society of Petroleum Engineers conference^P, showed that further analysis must be done to determine whether these 15% would actually benefit from restimulation. This paper presented an analysis of some 300 tight sand wells which had originally been hydraulic fracture stimulated, high-graded the top 15% of candidate wells for further evaluation and ultimately reduced the wells recommended for restimulation to five (5) of which 2 had been restimulated at the time the paper was written. In other words, only a small number (~2% of the total wells) of the top 15% candidate wells would actually be economic to restimulate anytime in their life. Other developing information suggests the percentage of wells refractured annually is less than 1%. Applying a 1% re-stimulation rate per year rather than a 10% would reduce the projected number of affected units to ~1,205 rather than 12,050 (90% reduction) and reduce the emissions reductions by the same magnitude.

16. STORAGE VESSELS

16.1. Applicability

There is considerable ambiguity under both Subpart OOOO and Subpart HH as to the population of storage vessels to which these rules are intended to apply. API requests EPA clarify that the boundaries listed below apply to the storage vessel provisions. Each of these issues is discussed more fully in the paragraphs that follow.

- **Storage vessel properly defined.** That is, defined as stationary vessels constructed of non-earthen materials, and which are distinct from process tanks.
- **Located in the oil and gas production source category.** That is, located upstream of the point of custody transfer between the production field and the liquid distribution pipeline.
- **Storing crude oil or condensate.** That is, storing only produced petroleum liquids.
- **Containing the regulated pollutant.** That is, storing liquids from which the regulated pollutant is emitted at greater than de minimis levels.
- **Having emissions above a cost-effective threshold.** That is, regulating emissions only for those storage vessels for which the controls would be above a cost-effective threshold under Subpart OOOO.

16.2. Storage Vessel Definition [OOOO & HH]

The term “storage tank” or “storage vessel” should be defined in a manner that is consistent with other rules, while acknowledging the particular scenarios unique to the oil and gas production sector. Existing EPA regulations establish several features that distinguish a storage vessel (tank):

- The function of a storage vessel is storage, which distinguishes storage vessels from process vessels or tanks.
- A storage vessel is stationary, which distinguishes storage vessels from containers, vessels attached to mobile vehicles, and other vessels that are placed temporarily.
- A storage vessel is constructed of non-earthen materials, which distinguishes storage vessels from surface impoundments and underground caverns.

16.2.1. Process Tank

Activities identified as process functions in other regulations include:

- Reactions and blending.^Q
- Collection of material discharged from a process prior to transfer to other equipment within the process or to a storage vessel.^R
- Surge control.^S
- Bottoms receiver.^T
- Knock-out.^U

16.2.2. Stationary

The stationary aspect of a storage vessel is typically addressed by EPA in terms of whether or not it is reasonably portable. One issue in the consideration of portability is the size of the vessel, which is sometimes addressed by EPA in regulations pertaining to storage vessels.

Another criterion specified by EPA in several regulations is that “vessels permanently attached to motor vehicles” are not storage vessels, and EPA has issued a determination^V that this exemption extends to tanks “equipped with a permanently attached wheel assembly and a truck hitch.” This renders most so-called frac tanks, Baker tanks, ISO tanks, *etc.* exempt from the storage tank provisions when this form of definition is used.

API recognizes, however, that such tanks sometimes become effectively “stationary” in oil and gas production operations, and that it may be appropriate to apply a time limitation to

^Q From the definition of a Process Tank, 40 CFR 60.111b, added to Subpart Kb Standards of Performance for Volatile Organic Liquid Storage Vessels with the October 15, 2003 rule amendments.

^V U. S. Environmental Protection Agency, letter from George T. Czerniak to Ken Comey, Flint Hills Resources L.P., September 2, 2004.

this exemption. We therefore suggest that storage vessels should be deemed stationary if they remain at a given site for more than 180 consecutive days, consistent with the period of time allowed under §60.14(g) to achieve compliance after a modification. As a point of comparison, the definition of non-road engines in 40 CFR 89.2 states:

“(2)(iii) the engine otherwise included in paragraph (1)(iii) of this definition remains or will remain at a location for more than 12 consecutive months or a shorter period of time for an engine located at a seasonal source. A location is any single site at a building, structure, facility, or installation. Any engine (or engines) that replaces an engine at a location and that is intended to perform the same or similar function as the engine replaced will be included in calculating the consecutive time period. An engine located at a seasonal source is an engine that remains at a seasonal source during the full annual operating period of the seasonal source. A seasonal source is a stationary source that remains in a single location on a permanent basis (i.e., at least two years) and that operates at that single location approximately three months (or more) each year. This paragraph does not apply to an engine after the engine is removed from the location.”

Given this precedent for the term stationary to not apply until a source has remained in place for at least 12 consecutive months, API's request that stationary not apply to a storage tank at an oil and gas production site until it remains in place for only 180 days is a modest and reasonable request.

Finally, cost effectiveness of the proposed control measures has been evaluated under the assumption that storage vessels remain in place for the useful life of the control equipment, and thus the control costs are amortized over a period of years. The cost per ton of emission reductions would obviously be much higher if the controls were applied to a tank that is only on site temporarily, in that the total cost of controls would be applied to emission reductions achieved over only 180 days, rather than over a period of years. It is clear, then, that a cost-effectiveness analysis for permanent storage tanks would not be valid for temporary storage tanks, and thus the control requirements for permanent storage tanks are not justified for temporary storage tanks.

16.2.3. Non-earthen

This is self-explanatory. Certain EPA regulations add the phrase “such as wood, concrete, steel, fiberglass, or plastic”^W as a parenthetical explanatory clause.

Suggested Rule Text:

We request that the following definition of “storage vessel” be used in both OOOO and HH:

§60.5430 and §63.761

[Storage vessel or Tank means a stationary unit that is constructed primarily of nonearthen materials \(such as wood, concrete, steel, fiberglass, or plastic\) which provide structural support](#)

^W U.S. Environmental Protection Agency, “National Emission Standards for Storage Vessels (Tanks)–Control Level 2,” 40 CFR Part 63, Subpart WW.

and is designed to hold an accumulation of liquids or other materials. Storage vessel or Tank does not include:

(1) Vessels with a design capacity less than or equal to 472 barrels^X storing a volatile organic liquid with maximum true vapor pressure less than 11.1 psia.

(2) Process tanks, including vessels used for a process function such as reactions, blending, or separation, vessels such as sumps used to collect discharged material such that it can be transferred to a process or to storage, vessels used for surge control, and vessels used as knockouts,

(3) Vessels storing wastewater,

(4) Pressure vessels designed to operate without emissions to the atmosphere,

(5) Subsurface caverns and porous rock reservoirs, and

(6) Vessels that do not remain at a given site for more than 180 consecutive days.

16.3. Located in the Oil and Natural Gas Production Source Category

As discussed in Section 3, there is unnecessary ambiguity in the applicability of the proposed rules with respect to storage vessels. The rules need to clearly specify the boundaries of the source category, identify the affected facilities within that source category, and specify which of the affected facilities are subject to the control requirements. Part 60 Subpart Kb and Part 63 Subparts HH, HHH, and EEEE each describe the boundary between the oil and natural gas production sector and the transportation sector as being where oil or natural gas is transferred from production or producing operations to “pipelines or any other forms of transportation.”

It is evident that the oil and natural gas production sector has been historically understood as being distinct from the transportation sector, but Subpart OOOO fails to delineate the sector to which the storage vessel provisions apply. Furthermore, EPA has proposed removing the distinction of “prior to custody transfer” from NESHAP HH, thereby unnecessarily obscuring the boundaries that had been previously established. These ambiguities should be addressed by restoring the source category boundaries to the manner in which they have been historically understood.

16.3.1. NSPS OOOO – Storage Tank Location

While the Subpart OOOO provisions for several types of emission points specify the locations at which the rule applies (e.g., applicability to compressors is specified as being between the well head and the city gate, both of which are defined terms), the applicability section contains no such language to stipulate boundaries for the storage vessel provisions.

^X A capacity threshold of 75 cubic meters (472 barrels) is specified in 40 CFR Part 63 Subpart BBBBBB—National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Distribution Bulk Terminals, Bulk Plants, and Pipeline Facilities, 40 CFR Part 63 Subpart R—National Emission Standards for Gasoline Distribution Facilities (Bulk Gasoline Terminals and Pipeline Breakout Stations), and 40 CFR Part 60 Subpart Kb—Standards of Performance for Volatile Organic Liquid Storage Vessels (Including Petroleum Liquid Storage Vessels) for Which Construction, Reconstruction, or Modification Commenced after July 23, 1984.

In fact, the provisions simply specify that they apply to storage vessels, with no discussion of what industry sector the storage vessels may be located in.

Paragraph §60.5395(b) addresses overlap of Subpart OOOO with Subpart HH, and the definition of a storage vessel makes reference to a well site, so it might be inferred that applicability of the rule is limited to the production field, but the language is simply not clear. The definition of a storage vessel in Subpart OOOO limits the applicability for storage vessels that are not manifolded together to those located at a single well site. But there is no such qualifier for storage vessels that are manifolded together. Furthermore, the terms “manifolded together” and “single well site” are not defined, and their meaning is not evident.

API requests that EPA clarify the population of storage vessels to which NSPS OOOO is applicable as those located in the production field, prior to the point of custody transfer to the liquids distribution system. This may be accomplished by:

- Replacing the definition of “storage vessel” with the language suggested above (see below for mark-up of EPA’s proposed rule language), and
- Clearly specifying the intended applicability of the storage vessel provisions in the description of the affected facility, at §60.5365(e). This paragraph should specify that applicability is to storage vessels located prior to the point of custody transfer to pipelines or other forms of transportation.

Suggested Rule Text:

§60.5430

Custody transfer means the last point of custody transfer of crude oil, condensate, or natural gas before it leaves the production field or basin and enters pipelines or any other forms of transportation. Typical custody transfer points include truck loading facilities or pipeline metering stations for crude oil or condensate, and the tail gate of natural gas processing plants or pipeline metering stations for natural gas.

Storage vessel or Tank means a stationary ~~vessel or series of stationary vessels that are either manifolded together or are located at a single well site and that have potential for VOC emissions equal to or greater than 10 tpy.~~ unit that is constructed primarily of nonearthen materials (such as wood, concrete, steel, fiberglass, or plastic) which provide structural support and is designed to hold an accumulation of liquids or other materials.
Storage vessel or Tank does not include:

(1) Vessels with a design capacity less than or equal to 472 barrels storing a volatile organic liquid with maximum true vapor pressure less than 11.1 psia.

(2) Process tanks, including vessels used for a process function such as reactions, blending, or separation, vessels such as sumps used to collect discharged material such that it can be transferred to a process or to storage, vessels used for surge control, and vessels used as knockouts.

- [\(3\) Vessels storing wastewater,](#)
- [\(4\) Pressure vessels designed to operate without emissions to the atmosphere,](#)
- [\(5\) Subsurface caverns and porous rock reservoirs, and](#)
- [\(6\) Vessels that do not remain at a given site for more than 180 consecutive days.](#)

§60.5365

* * * * *

- (e) A storage vessel affected facility, which is defined as a single storage vessel [storing condensate or crude oil and located prior to the point of custody transfer.](#)

16.3.2. NESHAP HH – Storage Tank Location

As noted above, the original version of Subpart HH specifies that applicability is limited to storage vessels located prior to the point of custody transfer to pipelines or other forms of transportation. The proposed revisions to §63.760(a)(2), however, would remove that point of demarcation, and instead specify that the rule applies to facilities “prior to the point where hydrocarbon liquids enter either the Organic Liquids Distribution (Nongasoline) or Petroleum Refineries source categories.” While this wording has the apparent intent of preserving the boundary between the production field and the liquids distribution system, the reference becomes circular in that the Organic Liquids Distribution MACT rule (Part 63 Subpart EEEE) specifies that it excludes facilities subject to Part 63 Subpart HH (see §63.2334(c)(1)). Thus the revisions to Subpart HH would result in each rule excluding the affected facilities of the other, but neither rule defining the boundary between the source categories. In order to preserve a specified boundary, the wording of §63.760(a)(2) should continue to specify the point of custody transfer as the demarcation between the production field and transportation sectors. Further clarity would be achieved by replacing the former definition of “custody transfer” with the suggestion shown below (as suggested for NSPS OOOO above).

Suggested Rule Text:

§63.761

[Custody transfer means the last point of custody transfer of crude oil, condensate, or natural gas before it leaves the production field or basin and enters pipelines or any other forms of transportation. Typical custody transfer points include truck loading facilities or pipeline metering stations for crude oil or condensate, and the tail gate of natural gas processing plants or pipeline metering stations for natural gas.](#)

§63.760

- (a)(2) Facilities that process, upgrade, or store hydrocarbon liquids prior to the point of custody transfer ~~where hydrocarbon liquids enter either the Organic Liquids Distribution (Non gasoline) or Petroleum Refineries source categories.~~

16.4. Storing Crude Oil or Condensate

API believes that EPA intends the storage vessel requirements to apply only to tanks storing crude oil or condensate, but this intent is not adequately specified in the regulations.

16.4.1. NSPS OOOO – Crude Oil and Condensate

It seems, from the preamble, that EPA intends for these rules to apply only to tanks storing crude oil or condensate. However, the rules do not expressly specify the stored liquids to which the rules are applicable. On the one hand, one might infer from §60.5395(a) that Subpart OOOO applies only to tanks storing crude oil or condensate. On the other hand, the language could be construed to extend applicability to any storage vessel storing any liquid whatsoever, unless the vessel is storing crude oil or condensate and the throughput is below the specified cutoffs (in that the language does not address the situation if the vessel is storing something other than crude oil or condensate). API requests clarification that the storage vessel provisions of Subpart OOOO are applicable only to tanks storing crude oil or condensate.

Suggested Rule Text: See suggested rule text for §60.5365(e) under Section 16.3.1.

16.4.2. NESHAP HH – Crude Oil and Condensate

The MACT Floor memo for Subpart HH, in the discussion of storage tanks, indicates that the EPA survey was representative of “tanks that have the potential for air emissions to occur.” It then states, “Significant HAP emissions can occur due to flashing, and due to breathing and working losses from tanks containing volatile organic liquids such as condensates or volatile oils.”^Y The “volatile oil” produced in the oil and natural gas production source category is, of course, crude oil. It seems readily evident, then, that the storage vessels in this source category are those located in the production field which store condensate or crude oil. API requests clarification that the storage vessel provisions of Subpart HH are applicable only to tanks storing crude oil or condensate.

Suggested Rule Text:

§63.760

(b)(1)(ii) Each storage vessel [storing condensate or crude oil and located prior to the point of custody transfer](#);

16.5. Containing the Regulated Pollutant

EPA's authority to extend applicability of a regulation to a given facility is predicated on that facility being reasonably considered a source of the regulated pollutant. EPA has recognized this by use of the term “in VOC service” with respect to NSPS regulations, and “in organic HAP service” or “in

^Y Memorandum from G. Fitzsimons and G. Viconovic, EC/R, to M. Smith, EPA, “Recommendation of MACT Floor Levels for HAP Emission Points at Major Sources in the Oil and Natural Gas Production Source Category,” September 23, 1997, page 9, section 3.2, third paragraph.

VHAP service” for NESHAP regulations. This is not a matter of requesting an exemption for facilities that are sources of the regulated pollutant, but rather it is a matter of recognizing that below certain *de minimis* thresholds of concentration, a facility is not reasonably deemed a source of that pollutant and thus is not part of the source category.

16.5.1. In VOC Service [NSPS OOOO]

Subpart OOOO, at §60.5400(f), specifies “For a piece of equipment to be considered not in VOC service, it must be determined that the VOC content can be reasonably expected never to exceed 10.0 percent by weight.” The same statutory authority applies to other types of emission sources as to “equipment,” and thus this requirement of being “in VOC service” should qualify applicability of the rule to every type of emission source. We note, however, that this qualifier would be moot if EPA were to clarify that Subpart OOOO is applicable only to storage vessels storing crude oil or condensate, in that those liquids would always exceed the 10% threshold.

16.5.2. In VHAP Service [NESHAP HH]

Similarly, Subpart HH defines the term “in VHAP service” as involving a total volatile HAP concentration equal to or greater than 10% by weight. Subpart HH presently applies this term only to ancillary equipment and compressors. API requests that this term also be applied in the determination of applicability of Subpart HH to storage vessels, in that EPA is not required to regulate *de minimis* sources of HAPs.

Revision of the rule language to clarify that the rule is applicable to storage vessels that are “in VHAP service” would ensure that applicability of the rule is practicable and effective. As with the issue of “in VOC service” noted above, however, this comment on “in VHAP service” would likely be rendered moot if EPA were to clarify that Subpart HH is applicable only to storage vessels storing crude oil or condensate.

16.6. Having Emissions Above a Cost-Effective Threshold [NSPS OOOO]

EPA has proposed thresholds for applicability of the Subpart OOOO storage vessel provisions on the basis of cost effectiveness. However, both the use of throughput as a surrogate for VOC emissions and EPA's cost-effectiveness analysis are flawed. Also, while we endorse the concept of limiting applicability to tanks that emit more than 10 tpy, we believe that this limit should be specified in the storage vessel provisions rather than in the definitions, and the limit should be 12 tpy (as documented below).

16.6.1. EPA's Emission Rate versus Throughput is Not Credible.

In the preamble VI.B.4.d, EPA states that the emission factors used to establish thresholds for requiring storage vessel controls are from a Texas Environmental Research Consortium (TERC) study. This study H051c, *VOC Emissions from Oil and Condensate Storage Tanks*, calculated emission factors based on observations made during three summer months in 2006 of 11 crude oil tanks and 22 condensate tanks in East Texas. The report calculated an

emission rate as a function of throughput of 33.3 lb/bbl +/- 24.3 lb/bbl for the condensate tanks and 1.6 lb/bbl +/- 1.6 lb/bbl for the crude oil tanks.

We believe the methodology used in the report is flawed for the following reasons.^Z

- A. It is obvious that gross errors in measurements occurred for tank battery #25. Both the reported vent gas molecular weight of 89 and the VOC fraction of 0.99 are impossible values for gas flashed from condensate at a natural gas production site. The calculated VOC flash emissions of 215 lb/bbl would require that 82% of the condensate flashed when reduced in pressure from 200 psig. This is not possible at this separator pressure. Rejecting this data point and recalculating the average VOC emissions from the remaining tank batteries would give a factor of 24.2 lb/bbl, 73% of 33.3 lb/bbl.
- B. For tank battery #17, the calculated VOC flash emissions of 145 lb/bbl would require that 55% of the condensate flashed when reduced in pressure from 200 psig. This is not possible at this separator pressure. Since the other measured data for the vented gas (molecular weight of 36.6 and VOC fraction of 0.65) are reasonable, the error is most likely due to the low condensate production rate of 2 bbl/day used in the calculations. Rejecting this data point and recalculating the average VOC flash emissions from the remaining 19 tank batteries would give a factor of 17.8 lb/bbl, 53% of 33.3 lb/bbl.
- C. Throughput was not accurately determined, because the researchers did not follow their experimental design. Section B1 (Experimental Design), states "VOC emission rates will be measured by sampling the tank vent gas for compositional analysis and measuring the vent gas flow rate. Measurements of separator gas vented to the atmosphere will also be made. The concentration of each C1-C6 gas component in the sample, plus benzene, toluene, ethyl benzene, xylene (BTEX) and other C6+ VOC will be multiplied by the flow rate (averaged over 24-hours) to produce measurements of mass emission rates for each of the reported gas constituents and other C6+ VOC in units of pounds per hour. The mass emission rates will then be divided by the number of barrels produced during the 24-hour flow measurement period to produce emission factors in units of pounds per barrel. Critical measurements for this approach include the following:
 - Vent gas composition;
 - Vent gas flow rate; and
 - Oil or condensate production rate"

On the same page, when discussing selection of well sites to be tested, one of the stated criteria is that "The oil or condensate production rate is at least 2 barrels per day."

^Z The comments in this section are taken in large part from various comments submitted by Dr. Ed Ireland, Executive Director of the Barnett Shale Energy Education Council (BSEEC) to the Texas Commission on Environmental Quality (TCEQ) regarding various regulatory proceedings.

Lastly, Section B5 (Quality Control) states “The greatest source of uncertainty in the calculated emission factors is likely to be the estimation of oil or condensate produced over the sampling period. The accuracy of the emission factors derived from these tests will be limited to how accurately the production volumes can be determined during the sampling episode. While such production information is readily available on a monthly or annual basis from the Texas Railroad Commission, accurate production data over a 24-hour period is generally not available (emphasis added), and will have to be estimated from reading the tank level gauges (if present), manually gauging the tank level, or from production meters at the site if available. The specific methods and instruments used to estimate daily throughput will be recorded in the field sampling log; however, the sensitivities of these devices to oil or condensate throughput over 24-hours is unknown.”

1. Obtaining data from a well site that is producing only 2 barrels of condensate per day is very inaccurate when the goal is to calculate VOC emissions based on a 24-hr test period. Using emissions data based on this low amount of production lends itself to large sampling errors that can result in large variability in reported numbers (which is exactly what occurred). In addition, page 1 of Section B2 (Sampling and Measurement Methods), states that “The liquid production rates will be determined during the test period either by reading the level gage on the tanks (if present at the site), or by manually gauging the tanks. The manual tank readings will be adjusted to account for any unloading of the tanks into tank trucks during the test.”

The smallest capacity storage tank found in the report was 300 barrels. Even if one assumes a tank height of 20 feet (most likely the height would be 12 feet), the storage capacity of the tank would be around 15 bbl per foot. To gauge a 24-hr production rate of 2 barrels would mean taking two measurements to obtain a difference of about 1 ½ inches. For a tank height of 12 feet, measurement of a difference of 1 inch would be necessary. In addition, all of the sites had at least two tanks. Therefore, to measure 2 barrels of production would take two measurements to obtain a difference of 1/2 to 3/4 of an inch. It is easy to see that this technique would lead to large errors in assumed condensate production rate, and in fact, it appears that the researchers abandoned this concept at some point (see Item 2).

2. Our greatest concern is with the methodology used to estimate condensate production rates for the 24-hr test periods. Evidently, the researchers rightly determined that an accurate measurement of condensate production during the test periods from tank gauging was not feasible based on the concerns described above. It appears that, in place of measured condensate production, the researchers substituted 2005 daily average condensate production numbers for each tested site obtained from the RRC database (footnote “f” for Table 3-3 on page 3-4 “Daily average condensate production for 2005 from www.rrc.state.tx.us/interactive_data.html”). Using daily average condensate production numbers from a historical database, for which only monthly and yearly totals are reported, to calculate a VOC emissions factor from actual 24-hr test data for a specific tank battery can introduce large errors in the calculation of the flash VOC emissions factor as evidenced by the results from tank battery #17.

- D. Excluding tank batteries with a throughput of 2 bbl/day or less would give average VOC flash emissions of 14.9 lb/bbl. This is more in line with the results from the CDPHE study (cited in Section 1.2 of the report), which gave a range of 10.0 to 13.7 lb/bbl for different condensate producing regions, and with the simulation results discussed below

16.6.2. Variability of Flashing Emissions

A database that is more representative of nationwide emission rates from production field tanks than the data in the TERC study is available from the Geographical Database Option of the E&P TANK^{AA} program. For the 103 geographic sites across the U.S. for which E&P TANK results were tabulated in the Geographical Database Option, the average emission rate for condensate tanks (if condensate is defined as API gravity of 40 degrees or greater) is 11.4 lb/bbl and for crude oil tanks 1.1 lb/bbl. But, even with this larger sample, the variability in emissions per throughput barrel is large.

Under d. NSPS for Storage Vessels on page 52763 of the preamble, EPA correctly states “Flash losses occur when a liquid with dissolved gases is transferred from a vessel with higher pressure to a vessel with lower pressure, thus, allowing dissolved gases and a portion of the liquid to vaporize or flash. In the oil and natural gas production segment, flashing losses occur when live crude oils or condensates flow into a storage tank from a processing vessel operated at a higher pressure. Typically, the larger the pressure drop, the greater the flash emissions will occur in the storage stage. Temperature of the liquid also influences the amount of flash emissions. The amount of liquid entering the tank during a given time, commonly known as throughput, also affects the emissions rate, with higher throughput tanks having higher annual emissions, given that other parameters are the same.” However, EPA did not mention the other very important parameter, the volatility of the liquid, which can be indicated by API gravity but is more accurately a function of the composition of the high pressure separator liquid.

Flashing emissions determined using the E&P TANK low pressure oil option with a pressurized liquid sample are summarized in Table 16-1 for 7 sites in Texas and Louisiana. This table shows that, among sites with the same throughput, VOC emissions vary by three orders of magnitude (from 0.072 lb/bbl to 20.72 lb/bbl). This clearly establishes that throughput correlates very poorly to emissions.

Table 16-1 Variability of Flashing Emissions for Constant Throughput

| Location | API Gravity | Throughput (bbl/day) | Pressure (psi) | Temperature (°F) | GOR | VOC Emissions (lb/bbl) |

16.6.3. Specify an Applicability Threshold for Storage Tanks Based on Estimated Emissions

Given the variability of emissions as a function of site-specific conditions, we request that the rule specify an emissions threshold for storage tanks, and allow facilities to perform emissions estimates to determine whether a given storage tank is subject to the control requirements of the rule. As indicated by both EPA^{BB} and TCEQ^{CC}, appropriate methods of estimating flashing emissions include process simulation software and E&P TANK.

16.6.4. Allow Use of Default Emission Rates as a Function of Throughput and Separator Pressure

As an alternative to a site-specific estimate of flashing emissions, the rule should allow an estimate of flashing emissions to be obtained from a table that accounts for both throughput and separator pressure.

Figure 16-1 shows a graph of flashing emissions (in lb/bbl) as a function of separator pressure (in psi). This graph shows emissions estimated from three simulation methods. The results labeled "API Flash Factor" were obtained using ProMax^{DD} (includes two very volatile high API gravity condensates), the results labeled "TX & LA sites" were obtained using E&P TANK, and the results labeled "Anadarko well" were obtained using HYSYS^{EE}. For comparison, the TERC study average (33.3 lb/bbl) and the average of the E&P TANK Geographical Database Option with simulated results for 103 wells nationwide (11.4 lb/bbl) are also shown.

The TERC estimate is greater than the simulation results for any level of pressure, which

^{BB} STAPPA/ALAPCO/EPA, "Preferred and Alternative Methods for Estimating Air Emissions from Oil and Gas Field Production and Processing Operations," Emission Inventory Improvement Program, Volume II: Chapter 10, September 1999.

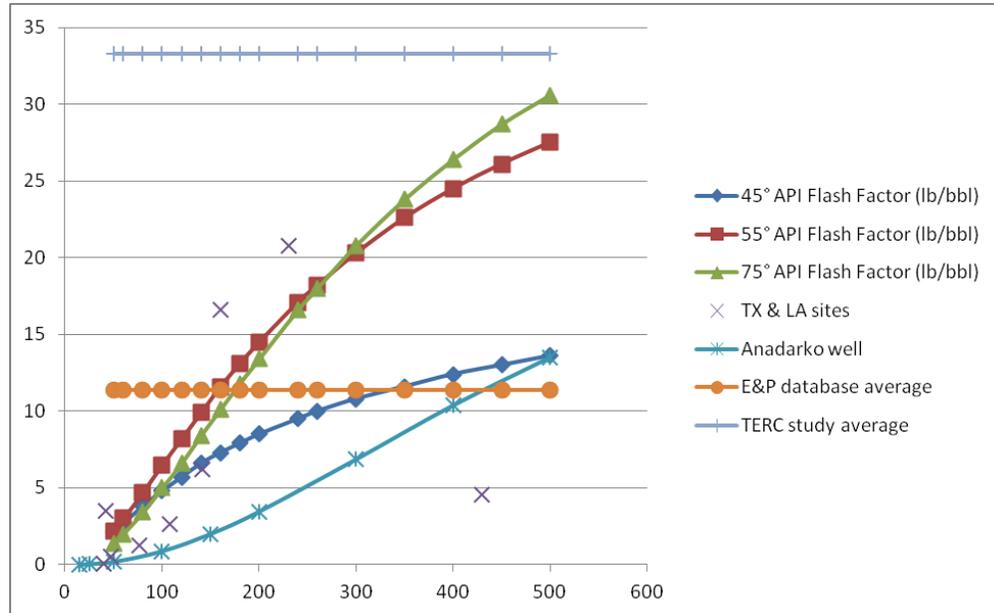

^{CC} Texas Commission on Environmental Quality, Air Permits Division, "Calculating Volatile Organic Compounds (VOC) Flash Emissions from Crude Oil and Condensate Tanks at Oil and Gas Production Sites," Air Permit Reference Guide APDG 5942, v2, September 2009.

^{DD} ProMax, Bryan Research & Engineering, Inc.

^{EE} AspenTech HYSYS 2006.5, Aspen Technology, Inc.

further suggests that it is not a credible value. However, as noted previously, a value of 14.9 lb/bbl is obtained from the TERC study when the most problematic data are removed from the data set. This value appears to be much more in line with simulation results using site-specific data. Also, the average value of 11.4 lb/bbl from the E&P TANK database falls reasonably within the simulation results. But the evident variability as a function of pressure shows that a simple average is not an appropriate indicator of flashing emissions.

Figure 16-1 Emissions (lb/bbl) vs. Separator Pressure (psi)

A throughput-based factor for estimating flashing emissions should be expressed as a function of pressure drop, rather than applying a simple average value as a function of throughput. This could be done by means of a lookup table.

The results of the ProMax simulations for the volatile condensates graphed in Figure 16-1 are tabulated in Table 16-2, along with results from a 38° API Gravity crude oil, showing the relationship between emissions, throughput, and separator pressure at multiple levels of API Gravity. In the simulations, the last separator temperature was set at 60°F, which is conservative since a higher temperature (which is typical for most sites with a heater-treater) lowers the amount of VOC flashed at the storage tank. Table 16-2 shows that emissions are highly influenced by pressure and, to a lesser extent, by API Gravity.

It is evident from Table 16-2 that an applicability threshold based on throughput should also account for separator pressure.

Table 16-2 VOC Flash Factors vs. Separator Pressure

| Separator Pressure (psig) | 38° API Crude Oil Flash Factor (lb/bbl) | 45° API Condensate Flash Factor (lb/bbl) | 55° API Condensate Flash Factor (lb/bbl) | 75° API Condensate Flash Factor (lb/bbl) |

16.6.5. Basis for Determining Throughput

Under §60.5410(e)(5)(i), EPA requires "You have installed and operated a flow meter to measure condensate or crude oil throughput in accordance with the manufacturer's procedures or specifications." Flow of condensate from a production separator to a storage vessel is intermittent and short duration. Every flow meter has a "latency period" that provides unreliable data for some period of time after flow begins. This unreliable period of time can range from a few seconds to several minutes depending on the technology. The "short duration" part of the equation is compounded by the latency period. It is frequent for a common technology like a turbine meter to over-range (i.e., spin faster than the magnetic revolution counter can count) for several seconds when it first opens in dump service. Often, by the time it has slowed to begin reporting reasonable values, the dump is beginning to close. It is common for either a turbine meter or a magnetic meter in dump service to report values that are 5-10 times higher than sales volumes that are eventually reported to accounting systems. There is no technology that will allow a 1 bbl/day condensate stream (or a 20 bbl/day oil stream for that matter) to accurately record flow volume into a storage

tank. API strongly recommends that the preferred method of quantifying liquid hydrocarbons throughput in the regulation be changed to “based on Lease Automatic Custody Transfer (LACT) meter, haul records (run tickets), sales tickets, or other sales documentation to show the amount transferred to a truck or liquids pipeline.” See Attachment H for background on technical issues pertaining to metering.

16.6.6. Variability of Cost Effectiveness

Using EPA's estimated annual cost for controls of \$18,983 and 95% control effectiveness, the cost effectiveness of controls for the sites shown in Table 16-1 is shown in Table 16-3. Table 16-3 shows that, when emissions are determined for a throughput of 1 bbl/day of condensate on a site-specific basis, the cost of controls varies from about \$5,300 to over \$1.5 million per ton. These costs are much higher than EPA's estimate of \$3,228/ton given in EPA's background technical support document (TSD) Table 7-10, because these costs are based on site-specific emission estimates rather than on a flawed study purporting to determine an average emissions rate as a function of throughput, which itself is an inaccurate indicator of emissions.

Table 16-3 Cost Effectiveness of Controls Using the TSD Cost Analysis.

| Location | API Gravity | Throughput (bbl/day) | Pressure (psi) | Temperature (°F) | VOC Emissions (ton/ yr) | Emission Reductions (ton/ yr) | Annual Cost (\$/yr) | Cost Effectiveness (\$/ton) |
|----------------------|-------------|----------------------|----------------|------------------|-------------------------|-------------------------------|---------------------|-----------------------------|
| Robertson Co. TX | 36 | 1 | 42 | 60 | 0.6399 | 0.6079 | \$18,983 | \$ 31,226 |
| Shelby Co. TX | 53 | 1 | 40 | 75 | 0.0131 | 0.0124 | \$18,983 | \$1,519,667 |
| Panola Co. TX | 45 | 1 | 76 | 90 | 0.2235 | 0.2123 | \$18,983 | \$ 89,392 |
| Claiborne Parish, LA | 62 | 1 | 160 | 75 | 3.0287 | 2.8773 | \$18,983 | \$ 6,598 |
| La Salle Parish, LA | 32 | 1 | 47 | 114 | 0.0964 | 0.0916 | \$18,983 | \$ 207,227 |
| Upsher Co. TX | 56 | 1 | 230 | 60 | 3.7913 | 3.6017 | \$18,983 | \$ 5,271 |
| Rusk Co. TX | 47 | 1 | 108 | 98 | 0.4865 | 0.4622 | \$18,983 | \$ 41,072 |
| Average | 49 | 1 | 141.5 | 81.5 | 1.1390 | 1.0821 | \$18,983 | \$ 17,543 |

16.6.7. Corrected Cost Analysis

As noted above, the TSD used an annual cost of \$18,983 for controlling a tank. This cost, however, is inconsistent with the EPA Air Pollution Control Cost Manual^{FF} (EPA Cost Manual), which addresses enclosed combustors in Section 3.2. Using the method prescribed in the EPA Cost Manual, the annual cost of controls is \$55,207, as detailed below. This cost

^{FF} U.S. Environmental Protection Agency, “EPA Air Pollution Control Cost Manual,” EPA/452/B-02-001, Sixth Edition, January 2002. <http://www.epa.gov/ttn/catc/dir1/cs3-2ch1.pdf>

is conservative in that it includes no costs for data management required by the proposed rule, and it does not adjust for inflation since calendar year 2000.

| 20 | 19.00 | \$55,207 | \$ 2,906 |

16.6.8. Requested Emissions Threshold

EPA concluded in the TSD that a cost of \$5,300 per ton was not cost effective. On this basis, Table 16-5 shows that a threshold of 11 tpy would not be cost effective, but a threshold of 12 tpy would be cost effective. API therefore requests a level of 12 tpy of VOC emissions as the threshold above which controls are required for a storage vessel under NSPS OOOO.

EPA proposed throughput thresholds pegged to 6 tpy of emissions in the storage tank provisions of §60.5395(a), as well as a 10 tpy emissions threshold in the definition of a storage vessel at §60.5430. These thresholds do not determine whether or not a given structure is a storage vessel, but rather they are criteria for determining whether a given storage vessel is subject to the control requirements of the rule. As such, the more appropriate location for them in the rule is at §60.5395, rather than in the definitions. API therefore requests that EPA move the emissions threshold from the storage vessel definition at §60.5430 to the storage vessel standard at §60.5395, and specify a threshold of 12 tpy.

16.6.9. Look-up Table Alternative

As we noted above, the regulations should specify that the owner or operator may estimate emissions to determine whether a given storage vessel would exceed the 12 tpy threshold, using E&P TANK or other process simulation software to account for flashing emissions. The rule should also include a look-up table as an alternative approach to determining applicability.

Despite EPA's recognition of severable variables affecting the rate of VOC flash emissions, the agency chose a single VOC flash emissions factor of 33 lb/bbl for condensate and 1.6 lb/bbl for crude oil. Our previous comments demonstrate that the emission factors for condensate are based on faulty test data and data analysis, as well as the faulty premise that flashing emissions can be reasonably predicted as a simple function of throughput.

We agree that a throughput exemption threshold is convenient for operators in many situations; however, a "one-size-fits-all" throughput number is not appropriate due to the many variables that can affect emissions. Of those variables, last separator pressure and throughput are the most important. We therefore suggest a look-up table that is a function of these two variables as an alternative to estimating emissions to evaluate the applicability threshold.

The VOC flash factors from Table 16-2 may be converted to throughput thresholds corresponding to an emissions threshold of 12 tpy as follows:

$$Q = 12.00 \text{ tpy} * 2,000 \text{ lb/ton} * 1/365 \text{ d/yr} * 1/FF = 65.75/FF$$

where:

Q is the throughput, in barrels per day, and

FF is the flash factor, in pounds per barrel.

Using this approach, the flash factors from Table 16-2 have been converted to an applicability look-up table in Table 16-6. The flash factors given for condensate in Table 16-6 are based on the worst case at each level of separator pressure from the condensate cases given in Table 16-2. The flash factors given for crude oil in Table 16-6 are based on the 38° API Gravity crude oil from Table 16-2. In that 38° API Gravity is a very light crude oil, it is expected that these factors are conservative (*i.e.*, likely to overestimate VOC emissions for heavier crude oils). We request that EPA include this look-up table in NSPS OOOO as an alternative to estimating emissions to determine applicability.

**Table 16-6 Throughput Exemption Thresholds vs. Separator Pressure.
(corresponding to 12 tpy VOC emissions per tank)**

| Separator Pressure (psig) | Crude Oil Throughput Threshold (bbl/day) | Condensate Throughput Threshold (bbl/day) |
|---------------------------|--|---|
| 10 | 330 | 330 |
| 20 | 130 | 130 |

| | | |
|-----|-----|------|
| 30 | 73 | 66 |
| 40 | 50 | 41 |
| 50 | 39 | 30 |
| 60 | 31 | 22 |
| 80 | 23 | 14 |
| 100 | 19 | 10.0 |
| 120 | 16 | 8.0 |
| 140 | 15 | 6.6 |
| 160 | 14 | 5.7 |
| 180 | 13 | 5.0 |
| 200 | 12 | 4.5 |
| 240 | 11 | 3.8 |
| 260 | 10 | 3.6 |
| 300 | 10 | 3.2 |
| 350 | 9.0 | 2.8 |
| 400 | 8.7 | 2.5 |
| 450 | 8.3 | 2.3 |
| 500 | 8.0 | 2.1 |

16.6.10. Allowance for Production Decline.

In that oil field production declines over time, storage vessels that initially emit more than 12 tpy may eventually fall below 12 tpy of emissions. EPA should specify that controls are no longer required after a storage vessel no longer emits more than 8 TPY similar to the WYDEQ Best Available Control Technology (BACT) Policy^{GG}. EPA has allowed boilers that are derated below 100 TPY to no longer be subject to NSPS Subparts D, Da, Db, and Dc. Attachment I contains applicability determinations given by EPA allowing boilers to no longer be subject to NSPS D, Da, Db, and Dc. Furthermore, the cost effectiveness analysis above shows that controls at 8 tpy are not cost effective.

16.7. Compliance Schedule for New Production [NSPS OOOO]

The rule should allow time to evaluate the throughput, pressure, and emissions before the control must be installed and then time to install the control. For instance WYDEQ bases control on the first 30 days of production multiplied by a decline factor, and then control must be installed 60 days later.^{HH} WYDEQ allows the use of the first 30 days production multiplied by a decline factor for determining applicability of the rule because it is very difficult to predict the actual production for a well before the well is producing. This method gives operators a chance to estimate what the annual

^{GG} Wyoming Department of Environmental Quality, Oil and Gas Production Facilities Chapter 6, Section 2 Permitting Guidance, Revised March 2010, <http://deq.state.wy.us/aqd/Oil%20and%20Gas/March%202010%20FINAL%20O&G%20GUIDANCE.pdf>

^{HH} Wyoming Department of Environmental Quality, Oil and Gas Production Facilities Chapter 6, Section 2 Permitting Guidance, Revised March 2010, <http://deq.state.wy.us/aqd/Oil%20and%20Gas/March%202010%20FINAL%20O&G%20GUIDANCE.pdf>

production and emissions could be and then allows time to install a control if the emissions were to exceed the specified threshold.

16.8. Compliance Requirements [NSPS OOOO]

Suggested Rule Text:

§60.5365

If you are the owner or operator of a site prior to the point of custody transfer at which is located one or more of the affected facilities listed in paragraphs (a) through (g) of this section that commenced construction, modification, or reconstruction after August 23, 2011 your affected facility is subject to the applicable provisions of this subpart. Paragraphs §60.5365(a)-(e) apply only to affected facilities in VOC service. ~~For the purposes of this subpart, a well completion operation following hydraulic fracturing or refracturing that occurs at a gas wellhead facility that commenced construction, modification, or reconstruction on or before August 23, 2011 is considered a modification of the gas wellhead facility, but does not affect other equipment, process units, storage vessels, or pneumatic devices located at the well site.~~

* * * * *

- (e) A storage vessel affected facility, which is defined as a single storage vessel storing condensate or crude oil and located prior to the point of custody transfer.

§60.5395

You must comply with the standards in paragraphs (a) through (eg) of this section for each storage vessel affected facility.

- (a) You must comply with the standards for storage vessels storing condensate or crude oil specified in ~~40 CFR part 63, subpart HH, §63.766(b) and (c) paragraph (b) of this section,~~ except as specified in paragraph (bd) of this section. ~~Storage vessels that meet either one or both of the throughput conditions specified in paragraphs (a)(1) or (a)(2) of this section are not subject to the standards of this section.~~ Storage vessels with annual average VOC emissions less than 12 tons per year, estimated according to paragraph (c)(3) of this section, are exempt. A storage vessel that has been subject to this standard becomes exempt when the uncontrolled emissions of VOC drop below an annual average of 8 tons per year.

~~(1) The annual average condensate throughput is less than 1.5 barrel per day per storage vessel.~~

~~(2) The annual average crude oil throughput is less than 20 barrels per day per storage vessel.~~

- (b) Within 90 days of the first date of production the owner or operator shall equip the affected storage vessel closed vent system and control device meeting the following specifications:

(1) The closed vent system shall be designed to collect all VOC vapors and gases discharged from the storage vessel and operated with no detectable emissions.

(2) The control device shall be designed and operated to reduce inlet VOC emissions by 95 percent or greater.

(c) The annual average daily throughput and pressure and the annual emissions for a new well shall be determined as follows:

(1) First 30 days of throughput after the first date of production divided by 30 times the average decline factor for the reservoir based on Lease Automatic Custody Transfer (LACT) meter, haul records (run tickets), sales tickets, or other sales documentation to show the amount transferred to a truck or liquids pipeline.

(2) Pressure of separator prior to the tank averaged over the first 30 days after the first date of production.

(3) Calculated using either methods (i) or (ii) using the average annual throughput calculated under (c)(1) and the average pressure calculated under (c)(2) for demonstrating compliance with (a)(1):

(i) E&P TANK or an appropriate flashing model.

(ii) Interpolating from the table below:

| <u>Separator Pressure (psig)</u> | <u>Crude Oil Throughput Threshold (bbl/day)</u> | <u>Condensate Throughput Threshold (bbl/day)</u> |
|----------------------------------|---|--|
| <u>10</u> | <u>330</u> | <u>330</u> |
| <u>20</u> | <u>130</u> | <u>130</u> |
| <u>30</u> | <u>73</u> | <u>66</u> |
| <u>40</u> | <u>50</u> | <u>41</u> |
| <u>50</u> | <u>39</u> | <u>30</u> |
| <u>60</u> | <u>31</u> | <u>22</u> |
| <u>80</u> | <u>23</u> | <u>14</u> |
| <u>100</u> | <u>19</u> | <u>10.0</u> |
| <u>120</u> | <u>16</u> | <u>8.0</u> |
| <u>140</u> | <u>15</u> | <u>6.6</u> |
| <u>160</u> | <u>14</u> | <u>5.7</u> |
| <u>180</u> | <u>13</u> | <u>5.0</u> |
| <u>200</u> | <u>12</u> | <u>4.5</u> |
| <u>240</u> | <u>11</u> | <u>3.8</u> |
| <u>260</u> | <u>10</u> | <u>3.6</u> |
| <u>300</u> | <u>10</u> | <u>3.2</u> |
| <u>350</u> | <u>9.0</u> | <u>2.8</u> |
| <u>400</u> | <u>8.7</u> | <u>2.5</u> |
| <u>450</u> | <u>8.3</u> | <u>2.3</u> |
| <u>500</u> | <u>8.0</u> | <u>2.1</u> |

- (bd) This standard does not apply to storage vessels already subject to and controlled in accordance with the requirements for storage vessels in 40 CFR part 63, subpart HH, §63.766(b)(1) or (2).
- (ee) You must demonstrate initial compliance with standards that apply to storage vessel affected facilities as required by §60.5410.
- (df) You must demonstrate continuous compliance with standards that apply to storage vessel affected facilities as required by §60.5415.
- (eg) You must perform the required notification, recordkeeping, and reporting as required by §60.5420.

§60.5410

You must determine initial compliance with the standards for each affected facility using the requirements in paragraphs (a) through (g) of this section. The initial compliance period begins on the date of publication of the final rule in the **Federal Register** or upon initial startup, whichever is later, and ends on the date the first annual report is due as specified in §60.5420(b).

* * * * *

- (e) You have demonstrated initial compliance with emission standards for your storage vessel affected facility if you are complying with paragraphs (e)(1) through (e)(7) of this section.
 - (1) You have equipped the storage vessel with a closed vent system ~~that meets the requirements of §63.771(e) connected to a~~ and a control device that meets the conditions specified in ~~§63.771(d)~~ §60.5395(b).
 - ~~(2) You have conducted an initial performance test as required in §63.772(e) within 180 days after initial startup or the date of publication of the final rule in the **Federal Register** and have conducted the compliance demonstration in §63.772(f).~~
 - ~~(3) You have conducted the initial inspections required in §63.773(e)~~
 - ~~(4) You have installed and operated continuous parameter monitoring systems in accordance with §63.773(d)~~
 - ~~(5) If you are exempt from the standards of §60.5395 according to §60.5395(a)(1) or (a)(2), you have determined the condensate or crude oil throughput, pressure, and emissions according to §60.5395(c), as applicable, according to paragraphs (e)(5)(i) or (e)(5)(ii) of this section and demonstrated to the Administrator's satisfaction that your annual average condensate throughput is less than 1 barrel per day per tank and your annual average crude oil throughput is less than 20 barrels per day per tank.~~
 - ~~(i) You have installed and operated a flow meter to measure condensate or crude oil throughput in accordance with the manufacturer's procedures or specifications.~~
 - ~~(ii) You have used any other method approved by the Administrator to determine annual average condensate or crude oil throughput.~~

(63) You have submitted the information in paragraphs (e)(1) through (e)(5) of this section in the initial annual report for your storage vessel affected facility as required in §60.5420(b).

§60.5415

* * * * *

(e) ~~For each storage vessel affected facility, continuous compliance is demonstrated according to 40 CFR part 63, subpart HH, §63.772(f).~~ The owner or operator of each source that is equipped with a closed vent system and control device as required in §60.5395(b) shall meet the requirements of either (1) or (2) below.

(1) Develop and maintain an operating plan containing the information listed below and operate the closed vent system and control device and monitor the parameters of the closed vent system and control device in accordance with the operating plan submitted to the Administrator in accordance with paragraph (2)(i) of this section, unless the plan was modified by the Administrator during the review process. In this case, the modified plan applies.

(i) Documentation demonstrating that the control device will achieve the required control efficiency during maximum loading conditions. This documentation is to include a description of the gas stream which enters the control device and manufacturer's design specifications for the control device. If the control device or the closed vent capture system receives vapors, gases, or liquids other than fuels from sources that are not designated sources under this subpart, the efficiency demonstration is to include consideration of all vapors, gases, and liquids received by the closed vent capture system and control device. If an enclosed combustion device with a minimum residence time of 0.5 seconds and a minimum temperature of 760 °C is used to meet the 95 percent requirement, documentation that those conditions will exist is sufficient to meet the requirements of this paragraph.

(ii) A description of the parameter or parameters to be monitored to ensure that the control device will be operated in conformance with its design and an explanation of the criteria used for selection of that parameter (or parameters).

(2) A control device that has been certified by the manufacture with a performance test to demonstrate the device meets the requirements of §60.5395(b) and parameters limits needed to meet the requirements of §60.5395(b) to measure. Monitor the parameters of the control device to demonstrate the control device is operating within the parameter limits specified by the manufacture.

§60.5420

* * * * *

(b) **Reporting requirements.** You must submit annual reports containing the information specified in paragraphs (b)(1) through (b)(6) of this section to the Administrator. The initial annual report is due 1 year after the initial startup date for your affected facility or 1 year

after the date of publication of the final rule in the Federal Register, whichever is later. Subsequent annual reports are due on the same date each year as the initial annual report. If you own or operate more than one affected facility, you may submit one report for multiple affected facilities provided the report contains all of the information required as specified in paragraphs (b)(1) through (b)(6) of this section.

* * * * *

(6) For each storage vessel affected facility, the information in paragraphs (b)(6)(i) and (b)(6)(ii) of this section.

- (i) If required to reduce emissions by complying with paragraph §60.5395(ab), ~~the records specified in 40 CFR part 63, subpart §63.774(b)(2) through (b)(8) the API number of the location of the tank and date of installation.~~
- (ii) ~~If exempt from §60.5395 in accordance with §60.5395(a), the API number of the location of the exempt tank and date of installation. Documentation that the annual average condensate throughput is less than 1 barrel per day per storage vessel and crude oil throughput is less than 21 barrels per day per storage for meeting the requirements in §60.5395(a)(1) or (a)(2).~~

(c) **Recordkeeping requirements.** You must maintain the records identified as specified in §60.7(f) and in paragraphs (c)(1) through (c)(5) of this section

* * * * *

(5) For each storage vessel affected facility, you must maintain the records identified in paragraphs (c)(5)(i) and (c)(5)(ii) of this section.

- (i) If required to reduce emissions by complying with ~~§63.766~~ §60.5395(b), maintain the following records ~~specified in §63.774(b)(2) through (8) of this chapter.:~~

(A) A copy of the operating plan if using §60.5415(e)(1).

(B) A copy of manufacturer certification if using §60.5415(e)(2)

(C) A record of the measured values of the parameters monitored.

- (ii) Records of the determination of the throughput, pressure, and emissions using the methods in §60.5395(c) to demonstrate emissions are below 12 TPY. ~~that the annual average condensate throughput is less than 1 barrel per day per storage vessel and crude oil throughput is less than 21 barrels per day per storage vessel for the exemption under §60.5395(a)(1) and (a)(2).~~

§60.5430

Condensate means a ~~hydrocarbon liquid separated from natural gas that condenses due to changes in the temperature, pressure, or both, and remains liquid at standard conditions, as specified in §60.2. For the purposes of this subpart, a hydrocarbon liquid with an API gravity equal to or greater than 40 degrees is considered condensate.~~ natural gas liquid recovered from

associated and non associated gas wells from lease separators or field facilities, reported in barrels of 42 U.S. gallons at atmospheric pressure and 60 degrees Fahrenheit.

First Date of Production means the date permanent production equipment is in place and product is consistently flowing to sales lines, gathering lines or storage tanks. Production occurring during well completion activities which is routed to temporary production equipment is considered to occur prior to the First Date of Production. If extended periods of time pass between zone completions but production from initially completed zones is consistently flowing to permanent production equipment, the First Date of Production is the date when production from the initial zones began consistently flowing to the permanent production equipment, even though more zones will be completed later.

Alternative Rule Text (if EPA insists on citing to Subpart HH):

The requirements in NSPS OOOO for storage tank control devices cite the performance test requirements specified in §63.772(e) of NESHAP HH, which include a provision for the performance test to be conducted by the manufacturer as specified in §63.772(h). While the intent appears to allow the manufacturer’s certification specified in §63.772(h) for NSPS OOOO, it would be helpful if NSPS OOOO were to explicitly say so. API requests that EPA clarify this intent by editing §60.5410 to read as follows:

§60.5410

(e)(2) You have conducted an initial performance test as required in §63.772(e) of this chapter, or you have a copy of the performance test results for a performance test conducted by the manufacturer as specified in §63.772(h), within 180 days after initial startup or the date of publication of the final rule in the **Federal Register** and have conducted the compliance demonstration in §63.772(f).

16.9. Capacity and Vapor Pressure [NSPS OOOO]

Every EPA regulation with provisions for storage vessels has capacity and vapor pressure thresholds below which the specified control measures are not required – even rules for the storage of gasoline and benzene. It is certainly unreasonable, then, to not have capacity and vapor pressure cutoffs for vessels storing crude oil and condensate. The cutoffs in NSPS Subpart Kb have already been determined by EPA as appropriate for storage vessels, and thus would seem appropriate for NSPS OOOO as well. However, we recognize that the oil production sector has the unique situation of potential for flash emissions, and thus it would be reasonable to remove the minimum capacity threshold in Subpart Kb when applying these thresholds to Subpart OOOO. The Subpart Kb cutoffs are presented in Table 16-7, with suggested adjustment for Subpart OOOO.

Table 16-7 Capacity and Vapor Pressure Cutoffs

| Subpart Kb | Subpart OOOO |
|---|---|
| Controls are not required if a storage vessel has: | Controls are not required if a storage vessel has: |
| a capacity of less than 75 m ³ (472 bbl) regardless of the vapor pressure; | a capacity of less than 75 m ³ (472 bbl) And true vapor pressure less than 11.1 psia |

| | | |
|--|-----|--|
| or | | |
| a capacity of less than 151 m ³ (950 bbl) | and | true vapor pressure less than 4.0 psia; |
| or | | |
| a capacity greater than 151 m ³ (950 bbl) | and | true vapor pressure less than 0.75 psia; |

| | | |
|--|-----|--|
| or | | |
| a capacity of less than 151 m ³ (950 bbl) | and | true vapor pressure less than 4.0 psia; |
| or | | |
| a capacity greater than 151 m ³ (950 bbl) | and | true vapor pressure less than 0.75 psia; |

16.10. Infrequent Use [OOOO & HH]

EPA’s capacity and vapor pressure thresholds are based on emissions that would be expected if these tanks were in continuous operation. However, tanks such as blowdown tanks, emergency tanks, and dehydrator drip tanks are used only infrequently. EPA should specify a threshold for storage vessels in infrequent use, and specify a work practice for such tanks. There is precedent for this in the Gasoline Distribution area source rule. EPA must allow for open-top blow down tanks. A well cannot be blown down to a closed top tank. The conventional set up is to route the gas associated with a blow down to the produced water tank to allow for entrained liquid to be contained during the event. Knocking out this entrained liquid will be a critical step in flaring this stream as well. However, the tanks are only rated to around 10-12 oz with thief hatch seals set at approximately 6 oz of pressure to protect tank integrity. The majority of tanks in the field are not designed to take the back pressures anticipated by the piping changes. These tanks are typically “atmospheric” tanks/vessels designed to operate at pressures not exceeding 15 psig (per mechanical design codes defined by the American Society of Mechanical Engineers). The relief valves and seals are designed and operate accordingly. Piping system for the combustion device will provide too much back pressure during a blow down event and the safety devices will vent the tanks as they should.

The EPA needs to recognize that implementation of this requirement is far more complicated than connecting up existing tanks to combustors. The entire tank system would need to be evaluated and possibly replaced with a “code stamped” pressure vessel/tank and appropriately sized and designed safety valves, hatches, and gas piping. Accordingly, the EPA needs to fully recognize the associated costs which are substantially more. Furthermore, infrequently used tanks such as blowdown tanks, emergency tanks, and dehydrator drip tanks were not considered in EPA’s cost effectiveness analysis.

16.11. Flare Pilot Flame [OOOO & HH]

The requirement in §60.18(c)(2) and §63.11(b)(5) for a flare to be operated “with a flame present at all times,” referenced by NSPS OOOO [§60.5401(f)] and NESHAP HH [§63.771(d)(1)(iii)] respectively, is not appropriate in light of current technology. This issue is discussed in more detail in Section 9.1 of the general comments.

16.12. Performance Test Methods [OOOO & HH]

See Section 8.6 of the general comments for API’s recommendations with respect to performance tests.

16.13. MACT-Level Requirements for NSPS

EPA has referenced the full MACT requirements in NESHAP HH for NSPS OOOO, rather than craft cost-effective requirements tailored for storage tanks with relatively low annual VOC emissions and generally located in remote areas. The capital cost of the control device is trivial in comparison to the cost of the performance tests, monitoring, recordkeeping, etc. for complying with NESHAP HH. These ongoing operating and maintenance costs were not adequately considered by EPA in the cost effectiveness determination for NSPS OOOO. This is illustrated in the cost discussion above, where annual costs determined from EPA's Cost Manual are shown to be nearly 3 times the cost that EPA presented in the TSD. Furthermore, NSPS OOOO applies to dispersed locations that do not have electricity or automation, and with limited remote transmitting unit (RTU) space. Although it may be appropriate to evaluate control devices similar to those found in NESHAP HH, it is not appropriate to arbitrarily invoke requirements intended for the maximum control of hazardous air pollutants (HAPs) as the standard for an NSPS regulation for the control of volatile organic compounds (VOCs). See Section 8.7 of these comments.

Examples of the inappropriateness of invoking MACT requirements for NSPS include but are not limited to:

- **§63.773(d) Control Device Monitoring requirements [Continuous Parameter Monitoring System (CPMS)].** EPA did not include the cost for installing, maintaining, and operating a CPMS. Most affected storage tanks will be located in remote areas without available electricity or limited remote transmitting unit (RTU) space. In addition, a programmable logic controller (PLC) is often needed to record, average, and analyze the large amounts of data to determine if a parameter is exceeded, resulting in activation of a control system or signal for site visit evaluation. The calibration, maintenance, and repair of a CPMS requires specialized crafts knowledgeable in instrumentation and controllers. This work can not be performed by lease operators during normal inspection visits.
- **§63.772 Test Methods, Compliance Procedures, Compliance Demonstrations.** EPA should reference test methods specific to VOCs. Many of the methods reference HAPs or comparison of a performance test to a HAP emission limit. This causes confusion in understanding how to apply the requirements to a VOC standard. EPA should reference test methods, compliance procedures, and compliance demonstrations that are specific to VOCs and the type of control device being used to control VOCs.
- **§63.774(b)(2) through (8) Recordkeeping Requirements.** The proposed recordkeeping requirements result in more than 56 different records to be maintained for a single tank (see Attachment J). These overwhelming and burdensome recordkeeping requirements are unreasonable and unjustified.

16.14. Floating roof option [OOOO & HH]

Other regulations governing storage tanks allow floating roofs as an alternative to routing vapor to a control device. Consideration should be given to providing a floating roof control option under these rules. While floating roofs are not viable for tanks with the potential for flash emissions or for very small tanks, they may be suitable for larger production field tanks storing stabilized crude oil, and

thereby avoid roof fitting leak tightness requirements. API requests that EPA revise both NSPS OOOO and NESHAP HH to specify that a storage vessel storing a volatile organic liquid with a maximum true vapor pressure of less than 11.1 psia may be equipped with a floating roof, in lieu of routing vapors to a control device. We suggest that EPA specify the floating roof requirements in the same manner as in Table 1 of the Gasoline Distribution area source rule.ⁱⁱ

16.15. EPA's Estimate of the Number of Affected Storage Vessels

See FR page 52789, Preamble VIII.A. EPA predicts that a very small fraction of the production field tank population will be affected by this rulemaking. While we have not yet evaluated these numbers, we believe for the reasons stated below that the total cost impact of the rule will be dramatically greater than projected by EPA.

16.15.1.NESHAP HH

The proposed changes to the definition of an affected facility will likely cause some existing sites that were not previously major sources to become major sources, due to the expansion of emission points that EPA proposes to include in the major source determination. Tanks at these facilities would then become subject to NESHAP HH controls, but EPA does not appear to have taken these tanks into account when evaluating the impact of the proposed rule revisions.

16.15.2.NSPS OOOO

EPA apparently evaluated the existing well population, which is dominated by old wells that have declined to very low production rates (sometimes known as stripper or marginal wells), and assumed that the production rates of these stripper wells would be characteristic of new wells. On this basis, EPA assumed that very few new wells would have sufficient flow to trigger applicability for storage tanks under NSPS OOOO. This is a fundamentally flawed assumption, in that companies do not purposely drill low producing wells. New wells would not be drilled unless there was an expectation of flow significantly greater than EPA's proposed throughput thresholds, and thus virtually all new wells would likely trigger NSPS OOOO applicability for the associated storage tanks.

16.16. Permit Limits

Under the MACT rules, a facility can avoid major source status if it has federally enforceable permit conditions that preclude emitting above the major source threshold (i.e., synthetic minor status). Similarly, if EPA sets an emissions-based applicability threshold for tanks under NSPS OOOO, the rule should specify that legally effective PTE limits (such as those issued through state minor NSR permits) are one means that may be used to manage applicability of the rule. EPA has ample legal authority to define the applicability of an NSPS. Such an approach would be a reasonable exercise of that authority. In addition, such an approach would be consistent with similar approaches taken in prior NSPSs. For example, the NSPS for Bulk Gasoline Terminals applies to facilities with a throughput greater than 75,700 liters/day. The gasoline throughput of a facility "shall be the

ⁱⁱ 40 CFR Part 63 Subpart BBBB—National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Distribution Bulk Terminals, Bulk Plants, and Pipeline Facilities

maximum calculated design throughput as may be limited by compliance with an enforceable condition under Federal, State or local law and discoverable by the Administrator and any other person.” 40 C.F.R. § 60.501 (definition of “bulk gasoline terminal”).

17. PNEUMATIC CONTROLLERS

API supports the use of intermittent vent, electro-pneumatic, and low bleed pneumatic controllers where feasible, however, certain key language in the proposal is unclear with regard to applicability, is unnecessarily restrictive, and creates burdensome, and needless recordkeeping and reporting requirements.

API supports comments regarding pneumatic controllers provided to EPA by the Gas Processors Association (GPA). We are in agreement that the only regulated sources should be high bleed gas-driven pneumatic controllers. We would add that EPA should only regulate high bleed gas-driven controllers in VOC service as we argue numerous times throughout this comment document for affected facilities with natural gas emissions. As well, limiting regulation to controllers in VOC service would markedly reduce the recordkeeping and reporting burden in the proposal.

Before continuing review of our comments and suggested rule text changes API recommends that EPA reviewers read the pneumatic controller technical paper in Attachment K and Kimray, Inc.'s technical bulletin Y09201 “Pilot Bleed Rate” in Attachment L^{JJ}. Both of these papers are excellent references that clarify the terminology and technology of pneumatic controllers.

From our review of the preamble, proposal, TSD, and Natural Gas STAR documentation, EPA appears to have an inconsistent understanding of the design and operation of pneumatics. For example, in the preamble EPA incorrectly states: “(1) Continuous bleed devices (high or low-bleed) are used to modulate flow, liquid level or pressure and gas is vented at a steady state rate; (2) actuating/intermittent devices (high or low-bleed) perform quick control movements and only release gas when they open or close a valve or as they throttle the gas flow...” indicating that both high and low bleed controllers can be either continuous or intermittent vent. However, in the proposed rule language and TSD, EPA correctly categorizes high and low bleed controllers as continuous bleed controllers only. The result of this inconsistency is an affected facility that effectively includes all pneumatic controllers when intermittent vent controllers are considered neither high nor low bleed, but rather no-bleed controllers that have no weak stream vent. As a result, intermittent vent controllers are not defined in the proposal, but should be exempted from this rulemaking. A fundamental and consistent understanding of pneumatic terminology, design, and operation is essential to providing an effective regulatory framework that works for both industry and EPA alike.

API provides suggested changes to proposed rule language in Attachment C that limits requirements to continuous bleed gas-driven controllers, clarifies both intent and compliance requirements, and simplifies the recordkeeping and reporting requirements. The underlying premise of our comments is that this rule needs to be clearly limited to “continuous bleed gas-driven pneumatic controllers,” but grouped as pneumatically controlled process unit affected facilities. Additionally, pneumatic controllers driven by compressed air, or other medium that does not contain VOC, cannot be affected facilities since there are no regulated emissions associated with them. In no other NSPS subpart do definitions of affected facilities include those with no regulated emissions. The following discussion explains in detail the issues and recommendations identified by API.

^{JJ} <http://kimray.com/LinkClick.aspx?fileticket=WvoYfx11%2f6E%3d&tabid=215&mid=811>

17.1. Problem with High-Bleed/Low-Bleed Classification

The proposed rule sets a threshold of 6 SCF/hr to classify continuous “high bleed” and “low bleed” controllers and EPA seeks to regulate both. There is no discussion in the proposed rule or in the TSD that explains how this threshold was derived. Instead, there is only a footnote on page 5-3 in the TSD that says this classification originated from a PG&E/GRI report in 1990, titled “Unaccounted for Gas Project Summary Volume” that EPA adopted for a 1993 report to Congress titled “Opportunities to Reduce Anthropogenic Methane Emissions in the United States”. EPA has failed to include this 1990 PG&E report in the docket. API, via email to EPA staff, also requested background documentation addressing how the 6 scfh threshold was derived. No reply was received. Without needed documentation being made available, API is unable to review and comment on the validity of this threshold classification.

From the 1993 congressional report, this 6 scfh threshold carried forward into EPA's definition of a low bleed controller for the Natural Gas STAR (NGS) program. However, NGS was a voluntary program. The 6 scfh dividing line for low bleed/high bleed became an acceptable threshold by EPA declaration that wasn't subjected to the needed scrutiny required for rulemaking and regulatory compliance obligations. Using this threshold declared by EPA fiat since 1993 in a non-regulatory environment does not satisfactorily justify its use in rulemaking. Not being able to review the 1990 PG&E report, API has no way of knowing under what conditions bleed rates for continuous bleed controllers were determined to set this threshold.

EPA has set a performance standard without making available its own independent BSER technical review for continuous bleed pneumatic controllers. In addition to not having access to the 1990 PG&E report, the TSD data is incomplete, and does not include details of the data collected from their vendor surveys. API has asked for this data in emails to EPA staff, but did not receive a response to this request. With this data unavailable for review, API cannot conduct its own quality assurance analysis (QA) of the data and comment on the results.

Concurrent with an incomplete demonstration of BSER, without the needed background documentation in the docket, EPA has not “adequately demonstrated” that less than 6 scfh bleed rate is practically “achievable” as BDT for continuous bleed controllers as required by CAA §111(a)(1). The issues with BSER and BDT can be remedied by re-proposing these requirements with inclusion of the necessary background documentation placed in the docket.

Without the appropriate technical documentation available for stakeholder review and comment, API is not supportive of the 6 scfh threshold for continuous high bleed controllers. API believes the 6 scfh threshold is too low for defining the high bleed/low bleed boundary for continuous bleed pneumatic controllers. Only a few models advertised as continuous low bleed controllers operating at < 6 scfh are available in the marketplace. And those that advertise low bleed rates, base it on operating at a low supply gas pressure such as 20 psi or less though the devices are designed for and frequently operate at higher pressures. Guarantees of a constant low bleed rate of < 6 scfh are not reasonable as operating variables in the field dictate controller bleed rates. These variables can include dependence on a supply pressure required by the actuator that is higher than that advertised by a manufacturer for low bleed controller performance.

As pointed out in the technical paper in Attachment K, a 6 scfh dividing line between high bleed and low bleed will effectively mean most operators will choose between continuous high bleed and intermittent vent controllers that are no-bleed, which should be considered a desirable outcome. The reason for this is that most continuous bleed controllers will require a pilot orifice so small, that reliability of the controller will be an issue. Plugging of the orifice will be a major concern as will controller response time. Also, if the controller is part of a pneumatic system where the valve actuator requires a higher pressure to operate than the advertised supply pressure for low bleed rate performance, the "low bleed" controller operating at a lower pressure than required could very well result in sluggish end-device performance and increase the risk of liquid spills and uncontrolled gas releases. Since intermittent vent controllers have no continuous bleed rate, in most cases where feasible, this will be the choice for operators that do not want to be subject to the requirements for high bleed controllers and want to be exempt from the rule.

From the TSD, EPA recognizes there are intermittent vent pneumatic controllers that are no-bleed. EPA correctly refers to snap acting controllers as no-bleed, and acknowledges that intermittent vent rates are dependent on valve actuation volume and frequency which cannot be regulated. Hence, snap acting controllers appear to be exempt from the rule. However, as illustrated in the API technical paper in Attachment K and EPA's 1996 report "Methane Emissions from the Natural Gas Industry," Vol. 12^{KK}, throttling controllers can also be intermittent vent. Likewise, continuous bleed controllers can also be converted to intermittent vent no bleed controllers by replacing the pilot valve with a Mizer type no-bleed pilot. As with snap acting controllers, all other intermittent vent controllers should be exempt from the rule.

17.2. Definitions

The subject of pneumatic controllers is highly technical and has been the province of a very narrow subset of industry experts. Unfortunately, key terminology and definitions have never been standardized which adds complexity to this rulemaking. Consequently, one of the results of this problem has led to inadequate definitions in the proposal. For example, the proposed definition of pneumatic controller in Subpart OOOO is "Pneumatic controller means an automated instrument used for maintaining a process condition such as liquid level, pressure, delta pressure and temperature". A more appropriate definition would be "Pneumatic controller means an instrument that is able to sense the state of a process variable and send a pressure signal to an end device to affect a change in that process variable". With EPA's proposed definition, an incorrect conclusion can be made that the end-device such as a control valve that actually maintains the process condition or variable is being regulated instead of the controller. API is recommending language for definitions needing clarity which apply to pneumatic controllers and recommending definitions for additional terms not currently in the proposal.

17.2.1. Revised Definitions

For clarity API recommends EPA's proposed definitions for pneumatic controllers be revised to read as follows:

^{KK} U.S. Environmental Protection Agency, "Methane Emissions from the Natural Gas Industry – Volume 12: Pneumatic Devices," EPA/600/R-96-0801, June 1996.

§60.5430

Pneumatic controller means an ~~automated~~ instrument that is able to sense the state of a process variable and send a pressure signal to an end device to affect a change in that process variable.~~used for maintaining a process condition such as liquid level, pressure, delta pressure and temperature.~~

Gas-driven pneumatic controller means a pneumatic controller that directs a signal to an end device using pressurized natural gas.~~powered by pressurized natural gas.~~

Non gas-driven pneumatic controller ~~device~~ means a pneumatic controller that directs a signal to an end device in a medium other than natural gas. The signal can include compressed air, electric power, or hydraulic power. ~~means an instrument that is actuated using other sources of power than pressurized natural gas; examples include solar, electric, and instrument air.~~

Low-bleed pneumatic controller means a continuous bleed pneumatic controller which controls pressurized gas that has the ability to vent the weak stream to the atmosphere at a rate equal to or less than six standard cubic feet per hour.~~automated flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents continuously (bleeds) to the atmosphere at a rate equal to or less than six standard cubic feet per hour.~~

High-bleed pneumatic controller means a continuous bleed pneumatic controller which controls pressurized gas that has the ability to vent the weak stream to the atmosphere at a rate greater than six standard cubic feet per hour.~~automated, continuous bleed flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents continuously (bleeds) to the atmosphere at a rate in excess of six standard cubic feet per hour.~~

The definition changes API proposes remove ambiguity, and help clarify the rule. These changes in definition are especially important to the rule text revisions API recommends in Attachment C. In particular, API's revisions add "weak stream" to the definitions of low and high bleed controllers. Weak stream is added as a new definition in the next section, but this is a critically important term to unambiguously distinguish which stream in a continuous bleed controller is being regulated. Our recommended rule text revisions are based on use of these definition revisions.

17.2.2. New Definitions

In addition to revising existing proposed definitions, API recommends five new definitions to help with rule clarity and recommendations to rule text. The list of terms API recommends to be defined are:

§60.5430

Continuous bleed pneumatic controller means a pneumatic controller that does not have a mechanical barrier between the pressure source and the end device and controls the signal to the end device by adjusting the magnitude of the flow rate of the bleed gas to the atmosphere (weak stream) through an adjustable port.

Intermittent vent pneumatic controller means a pneumatic controller that has an internal mechanical barrier between the source of gas pressure and the end device. In response to an input signal, these devices will shut the vent and open the mechanical barrier to send gas pressure to the end device. When the input signal has been satisfied it shuts the mechanical barrier and opens a vent to remove pressure from the end device.

Weak stream means the stream of gas that is vented when the end device is “at rest” in its idle position (e.g., when the end device is shut on a pressure-to-open system).

Pneumatically controlled process unit means the group of equipment required to operate all pneumatically controlled valves that regulate the flow, pressure, or temperature of gas and liquids located at a single site such as a well site, tank battery, or compressor station. This group of equipment includes instrument gas supply lines, pressure regulators, pneumatic controllers, valve actuators, and valves.

Continuous bleed gas-driven pneumatically controlled process unit means the group of equipment required to operate all pneumatically controlled valves that regulate a process variable (such as flow, fluid level, pressure, or temperature of gas and liquids) located at a single site such as a well site, tank battery, or compressor station. This group of equipment includes instrument gas supply lines, filters, pressure regulators, floats and switches, continuous bleed gas-driven pneumatic controllers, valve actuators, and valves.

Again, these new terms are important to the rule text changes API is recommending. The “continuous bleed pneumatic controller and “continuous bleed gas-driven pneumatically controlled process unit” are new terms vitally important to API’s recommendation for changes in §60.5365(d) for the affected facility discussed below in section 17.4. “Weak stream” requires definition because in the rule text revisions in Attachment C, API frequently recommends use of this term to clearly define which controller vent stream is being regulated. “Weak stream” is also used in suggested rule text changes for pneumatic controllers. As recommended previously, EPA may refer to the technical paper in Attachment K, for a more detailed discussion of the “weak stream” and “intermittent vent pneumatic controller”.

17.3. Inconsistent Terminology

Another problem with definitions and the proposal in general is inconsistent terminology when referring to pneumatic controllers. The terms “pneumatic device” and “pneumatic controller” are used interchangeably throughout the proposal. Examples are the definitions of “high bleed pneumatic devices” and “low bleed pneumatic controller”. API recommends that all instances of the

term "pneumatic device" be replaced with "pneumatic controller". Pneumatic device is a general nonspecific term, and even though it is meant to be synonymous with pneumatic controller, it could create uncertainty with regard to applicability.

17.4. Pneumatic Controller Affected Facility

From both the discussion of pneumatic controllers in Section 5.0 of the Technical Support Document (TSD) and the definitions provided in Subpart OOOO §60.5430 for high bleed and low bleed controllers, EPA clearly shows that the rulemaking was intended to apply to "continuous bleed" pneumatic controllers in natural gas service. From Section 5.1 of the TSD, EPA states: "Since actuation emissions serve the device's functional purpose and can be highly variable, the emissions characterized for high-bleed and low-bleed devices in this analysis (as described in Section 5.2.2) account for only the continuous flow of emissions (i.e., the bleed rate) and do not include emissions directly resulting from actuation." The continuously bleeding stream referred to both in the preceding quote from the TSD and in the proposed definitions for high and low bleed controllers is also known as the "weak stream". API agrees if pneumatic controllers are to be regulated, it is only the weak stream that should be regulated.

Additionally, pneumatic controllers are small, component level, and inexpensive pieces of equipment for which minor expenditures for routine maintenance, repair, or replacement (RMRR) may trigger a reconstruction determination. Consequently, the pneumatic controller affected facility definition needs to be redefined as a process unit to address the collection of all equipment used to pneumatically control an end device such as a valve using continuous bleed gas-driven pneumatic controllers in VOC service.

17.4.1. Include Continuous Bleed Only

As alluded to in this section's introduction, due to inaccuracies in the discussion of pneumatic controller design and operation in the preamble, and the nonspecific definition of a pneumatic controller affected facility in §60.5365(d), a high level of confusion exists over EPA's intention of what is meant by a "pneumatic controller affected facility". Snap acting and other intermittent vent controllers have no weak stream that continuously bleeds, and as EPA correctly points out in the TSD, the intermittent vent rate is dependent on the necessary cycling frequency of the controller. Consequently, a narrower, more specific definition of pneumatic controller affected facility that limits applicability to continuous bleed controllers is needed to clarify both EPA's intent and the type of controller being regulated.

17.4.2. Include Gas-Driven Only

In addition, the proposed rule includes all pneumatic controllers regardless of the medium used to drive the controller. As EPA correctly points out in the proposal, compressed air or "instrument air" or other inert gas is frequently used as the driver for pneumatic controllers. However, since neither air nor inert gas driven controllers produce regulated emissions, these controllers should not be affected facilities.

As in other NSPS Subparts for source categories, a method of documented applicability determination can be employed by operators. Subpart Kb for example, defines applicability

based on the design capacity of the tank and vapor pressure of the fluid being stored. Equivalently, one of the design criteria for pneumatic controllers at a site is the medium used to drive the controller. Since compressed air and inert gas drivers have no regulated emissions, a design to operate controllers without using a natural gas driver should exempt these controllers as affected facilities. As a result, in addition to narrowing the affected facility to continuous bleed controllers, the affected facility needs to be further limited to a natural gas-driven pneumatic controller in VOC service.

17.4.3. Modification/Reconstruction Must Not Apply to Individual Controllers

As discussed in Section 2.3, pneumatic controllers are an unprecedented small affected source. In fact, a pneumatic controller is not even a piece of operating equipment on its own, but only a component that sends a control signal to another piece of equipment. The concept of reconstruction was developed to trigger when "the Administrator will consider, on a case-by-case basis, technical and economic parameters in determining 'whether a substantial portion of a facility has been replaced'" (see 39 FR 36946). The types of affected facilities being considered in the 1970's when this concept was developed were large boilers, tanks, and waste incinerators. The "50 percent of the fixed capital cost that would be required to construct a comparable entirely new facility" [§60.15(b)(1)] threshold for reconstruction did not consider affected facilities where the "entirely new facility" would cost just a few hundred to a few thousand dollars. In fact, pneumatic controllers would have been only one small component of an affected source being regulated until this rulemaking.

API believes that neither modification, reconstruction, nor the total replacement of a pneumatic controller should be subject to the provisions of NSPS OOOO. At most, only the installation of a new pneumatic controller on a newly constructed process unit should be regulated. API recommends that §60.5365(d) be revised to group all equipment used for gas-driven pneumatically controlled valves into a single "continuous bleed gas-driven pneumatically controlled process unit." This removes the individual pneumatic controller as an affected facility, and more appropriately treats it as a component of a process unit. If EPA refuses to group pneumatic controllers within a process unit, then EPA should explicitly exempt pneumatic controllers from having to undergo modification and reconstruction determinations as a result of RMRR.

To illustrate this point, consider the following example. It is determined that a single existing low bleed controller installed sometime before this rule was proposed, requires pilot replacement because of problems with plugging. With a larger orifice pilot, the bleed rate increases slightly. This change causes an insignificant increase in emissions, but is still a modification. This simple repair now has to be documented and reported in an annual report, even though it still meets the criteria for a low bleed controller. Repairs must also be evaluated for reconstruction, since it doesn't take much in the way of parts replacement to achieve the 50% threshold. Making this determination for frequently occurring simple repairs that do not require any advanced planning and contracting as is done for large facilities in other source categories cannot be done with any reliability or accuracy. Maintenance personnel are not equipped or trained to make this evaluation, and simple repairs could be delayed if a complete reconstruction analysis was performed for each

occurrence of repair.

When considering the relatively low emissions of a single pneumatic controller combined with the impractical approach of having to determine modification and reconstruction for each instance of controller maintenance, the pneumatic controller affected facility needs to be redefined as a process unit that groups all controllers at a single site.

17.4.4. Proposal for New Definition of Affected Facility

To summarize, from the above discussions, the pneumatic controller affected facility needs to be redefined to limit the category to continuous bleed gas-driven pneumatic controllers, grouped together at each site as a process unit affected facility thereby creating a single source that lowers the exposure to the methodology for determining modifications and reconstruction. API recommends that section §60.5365(d) be changed to read:

§60.5365

* * * * *

- (d) A continuous bleed gas-driven pneumatically controlled process unit ~~pneumatic controller~~-affected facility, which is defined as a single continuous bleed gas-driven pneumatically controlled process unit in VOC service. ~~pneumatic controller.~~

The recommended definition of a “continuous bleed gas-driven pneumatically controlled process unit” is then:

§60.5430

Continuous bleed gas-driven pneumatically controlled process unit means the group of equipment required to operate all pneumatically controlled valves that regulate a process variable (such as flow, fluid level, pressure, or temperature of gas and liquids) located at a single site such as a well site, tank battery, or compressor station. This group of equipment includes instrument gas supply lines, filters, pressure regulators, floats and switches, continuous bleed gas-driven pneumatic controllers, valve actuators, and valves.

Precedent for this approach is found in the preamble discussion of the NSPS Subpart YYY proposal [59 FR 46780, 09/15/94], in which EPA states:

Defining the affected facility on a process unit basis avoids the problems associated with having multiple individual collection and treatment system equipment components classified as affected facilities, and it also provides a definition sufficiently narrow in scope so as not to preclude the possibility that existing sources will become subject to the NSPS through the modification and reconstruction provisions. Most importantly, defining an affected facility as a process unit reflects industry construction practices. Almost all new construction, reconstruction, and modification in the SOGMI is carried out by process unit.

After carefully considering each of the above alternatives, the EPA selected process

units as the basis for defining affected facilities for the proposed NSPS. This definition allows for routine equipment replacement and minor changes or expansions in existing facilities without subjecting either single emission sources or entire plant sites to requirements of the proposed standards.

The last sentence of the first paragraph quoted from 59 FR 46780 above is certainly applicable to pneumatic controllers. A new controller is not constructed by itself, as it would have no function. It is constructed as part of a whole unit construction where each component in our recommended unit definition is a necessary part for a pneumatically controlled valve to operate.

Accepting the arguments above, the pneumatic control process unit affected facility should then be defined as a single continuous bleed gas-driven pneumatically controlled process unit in VOC service.

Accepting the process unit approach, specifying an emissions rate for low bleed controllers, §60.5390(c) is recommended to read:

§60.5390

* * * * *

- (c) Each [weak stream vent from a continuous bleed gas-driven pneumatically controlled process unit](#) ~~pneumatic controller~~ affected facility [in VOC service](#) not located at a natural gas processing plant (as defined in §60.5430) must have natural gas emissions no greater than 6 standard cubic feet per hour. [Compliance with this emissions standard must occur according to the schedule in paragraph \(c\)\(1\) or \(c\)\(2\).](#)

17.4.5. Alternative Proposal for a Process Unit Affected Facility

If EPA refuses to aggregate all pneumatic controllers and associated equipment at a site into a single process unit affected facility, as discussed above in Section 17.4.4, then API alternatively suggests that a pneumatic controller process unit be defined in terms of all of the equipment utilized in a single control loop. This alternative can be implemented by simply amending the definitions of a “pneumatically controlled process unit” and “continuous bleed gas-driven pneumatically controlled process unit” recommended in Section 17.2.2 to:

[Pneumatically controlled process unit means the group of equipment required to operate a single pneumatically controlled valve that regulates a process variable \(such as flow, fluid level, pressure, or temperature of gas and liquids\). This group of equipment includes instrument gas supply lines, filters, pressure regulator, float and switch, pneumatic controller, valve actuator, and valve.](#)

[Continuous bleed gas-driven pneumatically controlled process unit means the group of equipment required to operate a single pneumatically controlled valve that regulates a process variable \(such as flow, fluid level, pressure, or temperature of gas and liquids\).](#)

[This group of equipment includes instrument gas supply lines, filters, pressure regulator, float and switch, continuous bleed gas-driven pneumatic controller, valve actuator, and valve.](#)

17.4.6. Benefits of Using a Pneumatically Controlled Process Unit as the Affected Facility

The above recommended change to the pneumatic controller affected facility would mitigate four issues. First, it would alleviate the inherent problem of a single pneumatic controller potentially triggering modification or reconstruction, but would preserve this trigger if major changes were made to the unit as a whole requiring a higher bleed rate. RMRR of a component of an affected facility is not likely to trigger reconstruction since the cost of the entire affected facility is the denominator in the cost analysis.

Second, there would be a significant reduction in the burdensome recordkeeping and reporting requirements which as currently proposed provides a disincentive to voluntarily replacing existing high bleed controllers with new low bleed controllers.

Third, and important to ozone nonattainment areas, using a process unit affected facility would preserve the ability for operators to capture offsets if they voluntarily change existing pneumatic controllers from high bleed to low bleed or intermittent vent. Changing out the controller would be changing a component part of the process unit affected facility but would not be the replacement of an affected facility that would otherwise trigger a new affected facility subject to this rule.

Fourth, defining pneumatic controllers as individual facilities could result in some states requiring that each continuous bleed pneumatic controller to be permitted prior to new construction, modification, or reconstruction for minor or major sources. By changing the affected facility definition to a pneumatically controlled process unit, permitting of individual controllers is not required if installation or replacement of an affected facility component occurs that might otherwise trigger modification or reconstruction. If API's recommendation to define pneumatics as a process unit is rejected, we request a note in the preamble to the effect that EPA does not intend that the installation of a single pneumatic controller would trigger permitting requirements. While this is ultimately a State issue, it would be helpful to have such a statement from EPA.

17.4.7. Continuous Bleed Gas-Driven Pneumatically Controlled Process Unit

Finally, assuming EPA agrees with API's recommendations, for consistency and clarity, every reference to "pneumatic controllers" used in the proposed rule for the affected facility should be changed to "continuous bleed gas-driven pneumatically controlled process unit".

17.5. Sitewide Applicability by Driver Medium

To complement affected facility applicability by the driver medium, which API recommends to be gas-driven only, determination of an affected facility for pneumatic controllers or pneumatic process units can be made on a sitewide basis, rather than by each individual controller. This will be much

less burdensome to an operator, as individual records of each controller are unnecessary. When compressed air is available to drive pneumatic controllers at any oil and gas site, it will be available to drive all controllers.

17.5.1. Natural Gas Processing Plants Have No Affected Facilities

In the proposal, EPA regulates pneumatic controllers with no emissions at natural gas processing plants due to the requirement for plants to use compressed air as the pneumatic driver to achieve zero emissions of natural gas. Recordkeeping and reporting is required for individual controllers which will be extremely burdensome. API knows of no precedent where a facility with no emissions of a regulated pollutant is regulated by an NSPS or other rule under the CAA. It would be much simpler if EPA prohibited the use of gas-driven controllers in VOC service. A plant using instrument air could then easily prove inapplicability to the rule by a single demonstration of the driver gas used to operate pneumatic controllers.

One exception is needed, however. Some operators may choose to use natural gas as the pneumatics driver for emergency and isolation valves, or switch instrument air to natural gas in the event of an emergency. If an emergency exists during a power outage, electric drive air compressors may not be functional to dependably supply needed compressed air to close emergency isolation valves. Operators need the flexibility to use natural gas as the driver, since it will be a dependable supply of gas available for emergency use.

17.5.2. Remote, small facilities

There are several categories of facilities such as Dew Point Suppression Facilities that are remote, unmanned, and have no available power, but meet the §60.5430 definition of a "Natural gas processing plant". Consequently, they do not have a method for meeting the §60.5410(d)(2) requirement of emitting zero natural gas. There is not always a cost-effective way of providing a reliable source of compressed air to be used as the driver for the pneumatic controller, so natural gas must be used. API's recommendation is either to accept API's proposed definitions for natural gas processing plant (gas plant) and forced extraction of natural gas liquids (see Section 6.3), or to exempt these remote facilities from the requirements of §60.5410(d)(2).

17.5.3. Use of Instrument Air at Other Oil and Gas Sites

While it is true that oil and gas sites are frequently remote and do not have access to reliable power supplies, it is not universally true. If a site does have access to reliable power, and if an operator decides that his process requires a high-bleed controller, he should have the option of installing instrument air if he decides that the combination of high-bleed controller and an air compressor provides a better process result. EPA's proposed rule language does not anticipate or allow this zero-emissions option. API provides rule text language in Attachment C that addresses this issue as paragraph §60.5390(c)(2). Switching to instrument air should be encouraged since it will reduce emissions from all controllers at a site. However, API recommends allowing 180 days for this to occur due to the extra time it takes to order and construct an air compressor.

17.6. Natural Gas is Not a Valid Surrogate for VOC

As discussed in General Issue section 5.1.1, there is no basis for the statement in §60.5390 to use natural gas as a surrogate for VOC. EPA assumed that natural gas contains 18% VOC, but the content varies widely. In fact, most unconventionally produced coal bed methane and shale gas has little if any measureable VOC. Additionally, natural gas downstream of an NGL fractionation or extraction gas plant has little or no VOC as VOCs are removed by processing. Further, gas analysis of process streams used for instrument gas are readily available and it is not difficult to use a VOC threshold directly. As stated in Section 5.1, pneumatics not in VOC service should be exempt from the rule.

17.7. Administrator's Approval for Use of High Bleed Pneumatic Controllers

Both §60.5390(a) and §60.5410(d)(1) state: "You have demonstrated, to the Administrator's satisfaction, the use of a high bleed gas-driven pneumatic controller device is predicated..." This suggests that prior approval from the EPA is required before high bleed pneumatic controllers are installed. If this is the intent, then it is a completely unworkable requirement. Construction and maintenance of pneumatic controllers cannot wait weeks or months for agency review and approval, as this would be very costly in terms of lost production while waiting to commence construction or maintenance. As well, EPA would be inundated with requests for approval if this is the expectation, and could not possibly process them in a timely manner.

Our suggested rule text changes in Attachment C delete use of the term "Administrator's satisfaction." If EPA deems use of the term necessary, then API requests clarification that prior approval is not the intent for its use and recommends that rule text in both section be changed to:

"You have maintained adequate records to support your decision that the use of high bleed gas-driven..."

17.8. Annual Reporting Requirements for Pneumatic Controllers

With an estimated 20,000 new gas and oil wells per year and an average of 3 controllers per well, there will be approximately 60,000 new pneumatic controllers installed each year. Additionally, according to EPA's own estimate pneumatic controllers have a 7-year service life^{LL}. This means approximately 1/7th of existing controllers will need replacement annually. There are approximately 3 controllers per well and 1 million existing wells so 1/7th of the controllers is 429,000 controllers. There are approximately 3 controllers per well and 1 million existing wells so 1/7th of the controllers is 429,000 controllers. If even 1/3 of that number is "continuous bleed, gas-driven pneumatic controllers" then 20,000 new controllers and 143,000 replacement controllers will create 163,000 new potentially affected facilities and reports each year. The administrative burden to industry will be overwhelming, just as it will be to state agencies and the EPA. It does not seem possible to demonstrate the benefit of these reports for such small sources, especially when agencies will be unable to review them. API is not supportive of a third party verification system, an idea raised in the preamble. see Section 8.8

^{LL} Page 2-16 of EPA 430-R-93-012, October, 1993 "Opportunities to Reduce Anthropogenic Methane Emissions in the United States"

If EPA refuses to exempt pneumatic controllers from the reporting requirements, then adopting API's recommendation for redefining the affected facility as a continuous bleed gas-driven pneumatically controlled process unit, will provide significant relief to the reporting burden. An initial annual report for each site that constructs a new, modified, or reconstructed process unit using one or more high bleed gas-driven controllers would be all that is necessary. Such a report would only need to include an explanation of why high bleed controllers are being used. Replacement and repair of controllers for existing facilities would normally not require additional reporting since modification or reconstruction would be seldom triggered.

17.9. Recordkeeping

API recommends that only records sufficient to demonstrate compliance with the rule be required. These records would include a sitewide applicability determination by documenting the medium for the pneumatic driver (e.g., air or gas). If the pneumatic driver is air or other gas not in VOC service, then that is the only record needed.

For sites with gas-driven pneumatics, records of controller make and model should then be sufficient but only for process unit affected facilities newly constructed, modified, or reconstructed after the proposal date. Knowing the make and model of controllers is sufficient to validate design specification to demonstrate compliance with the rule.

Records of installation dates are not possible for existing controllers as these are small components for which operators have not had any historical reason to track installation date. Furthermore, controllers are not date stamped with any manufacturing information. Only new controllers installed after Aug. 23, 2011 can be determined, since this proposal is the first time operators have had a demonstrated need to track this kind of information. These records can be made available by agency request or during a site inspection.

17.10. Time Extension for Manufacturer's Guarantee

The requirement in §60.5410(d)(3) specifies that "manufacturer's design specifications guarantee..." establishes a design standard. Currently, there is not a consistent manufacturing-industry practice to label pneumatic controllers or provide documentation with a bleed rate for the weak stream or to correctly specify if a controller is "high bleed" or "low bleed" based on the weak stream constant bleed rate. Since there is no industry standard, this leads to inconsistency amongst manufacturers in how they represent the performance of their products. If it is EPA's intention to establish regulations that require equipment manufactures to standardize the performance representation of their products so that performance is guaranteed, and to have them produce specific labeling, specific documentation, and/or specific performance parameters, then that intention needs to be a requirement directed to the equipment manufacturers. Other NSPS regulations have been accompanied with a grace period to allow manufacturers to conduct meaningful testing, develop necessary documentation, and alter required equipment name plates. API recommends that this grace period be 2 years. If it was not EPA's intent to require a manufacturer guarantee or certification, then API recommends that the term "guarantee" in §60.5410(d)(3) be replaced with "verify" (and the rule text be changed as recommended in Attachment C for §60.5420(b)(5)(iii) and §60.5420(c)(4)(iii)) to avoid confusion and misinterpretation.

17.11. Extend Compliance Date for Pneumatic Controllers by One Year

Unlike the large emission sources regulated in other NSPS Subparts, operators, manufacturers, and suppliers keep inventories of extra pneumatic controllers in stock as they are relatively inexpensive, and malfunctions require quick repair or replacement to maintain production. A compliance date of only 60 days after promulgation will make large inventories of high bleed controllers potentially unusable. Time is needed for manufacturers, suppliers, and operators to make inventory adjustments to adapt to the new requirements. Consequently, API requests the effective date of this rule for pneumatic controllers be delayed for one year past the promulgation date to allow companies to make inventory adjustments. Additionally, a one year extension will also give operators time to switch to instrument air, if feasible as an alternative control strategy. Switching to instrument air, where practicable, should be a desired outcome of this rule proposal since it will eliminate emissions of natural gas.

18. COMPRESSORS

GENERAL COMPRESSORS

18.1. Does Moving Compressors from One Location to Another Trigger Construction (i.e., Installation)?

In §60.5365, EPA states clearly that affected facilities listed in paragraphs (a) through (g) that commenced construction, modification, or reconstruction after August 23, 2011 are subject to the applicable provisions. However, in paragraphs §§60.5365(b) and (c), EPA includes confusing and unnecessary language for determining when a compressor is considered an affected facility. The specific sentences are bolded below:

§60.5365(b) A centrifugal compressor affected facility, which is defined as a single centrifugal compressor located between the wellhead and the city gate (as defined in §60.5430), except that a centrifugal compressor located at a well site (as defined in §60.5430) is not an affected facility under this subpart. **For the purposes of this subpart, your centrifugal compressor is considered to have commenced construction on the date the compressor is installed at the facility.**

§60.5365(c) A reciprocating compressor affected facility, which is defined as a single reciprocating compressor located between the wellhead and the city gate (as defined in §60.5430), except that a reciprocating compressor located at a well site (as defined in §60.5430) is not an affected facility under this subpart. **For the purposes of this subpart, your reciprocating compressor is considered to have commenced construction on the date the compressor is installed at the facility.**

If you breakdown the sentence for when a facility becomes an affected facility, then four clarifying words are important and discussed in detail in the General Provisions under the Definition section (§60.2), the Modification section (§60.14), and the Reconstruction section (§60.15). In §60.2, commenced construction is sufficiently defined as:

Commenced means, with respect to the definition of *new source* in section 111(a)(2) of the Act, that an owner or operator has undertaken a continuous program of construction or modification or that an owner or operator has entered into a contractual obligation to undertake and complete, within a reasonable time, a continuous program of construction or modification.

Construction means fabrication, erection, or installation of an affected facility.

As you can see from the definitions above, commenced construction includes installation and is based on when the operator enters a contractual obligation to construct or modify an affected facility. Therefore, the last sentences in §60.5365(b) and (c) are unnecessary and could be incorrectly interpreted to apply to existing compressors that are relocated from one location and installed at another without being modified or reconstructed according to the criteria of §60.14 or §60.15.

In addition to removing the confusing reference to "installed" as it relates to commenced construction, EPA should include in the response to comment that the historical position of relocation has not changed for facilities under NSPS OOOO. Some of the rationale and historical decisions are:

- Air pollution controls are generally more effective and less costly when designed as part of the original production facility, rather than retrofitted to an existing facility. Thus, the Clean Air Act amendments established the New Source Performance Standards (NSPS), which requires technology-based emission limitations on "new" sources of air pollution in certain designated industrial categories. It makes little sense in the context of section 111 of the Clean Air Act, to treat as new sources, equipment that was designed and built before the proposal date of an NSPS rule, because it is much less cost effective to retrofit these existing sources. For this reason, EPA appears to have adopted the rule that relocation of an existing source does not trigger NSPS. For this same reason, the installation date should not be used as a trigger for NSPS application to existing equipment. This is consistent with other actions taken by EPA, such as in the RICE and CI NSPS rules:

§60.4208 (h) The requirements of this section do not apply to owners or operators of stationary CI ICE that have been modified, reconstructed, and do not apply to engines that were removed from one existing location and reinstalled at a new location.

The engine and compressor are typically a package unit. When an engine is relocated, the associated compressor is relocated at the same time. If a relocated engine is not considered a modification or reconstruction under NSPS JJJJ or IIII, then EPA should also not consider a compressor relocated with the engine as a modification or reconstruction. Maintaining consistency between the NSPS's will avoid the confusion of having differing NSPS applicability for portions of a packaged unit being relocated to another location.

- Several EPA ADI's have clearly determined that relocation without a modification or reconstruction does not trigger NSPS. Refer to the following ADI's for more details on EPA's historical policy:
 - K003 (1978) – "EPA policy is that relocation of existing facilities does not constitute a modification under 40 CFR 60.14."

- 0900067 (2008) – "Relocation in and of itself does not trigger applicability."

To avoid the confusion and maintain consistency with the NSPS general provisions and historical position, API recommends EPA remove the last sentence from each section. The recommended change is reflected below:

Suggested Rule Text:

§60.5365

* * * * *

- (b) A centrifugal compressor affected facility, which is defined as a single centrifugal compressor in VOC service located between the wellhead and the point of custody transfer city gate (as defined in §60.5430), except that a centrifugal compressor located at a well site (as defined in §60.5430) and prior to the natural gas processing plant is not an affected facility under this subpart. ~~For the purposes of this subpart, your centrifugal compressor is considered to have commenced construction on the date the compressor is installed at the facility.~~
- (c) A reciprocating compressor affected facility, which is defined as a single reciprocating compressor in VOC service located between the wellhead and the point of custody transfer city gate (as defined in §60.5430), except that a reciprocating compressor located at a well site (as defined in §60.5430) is not an affected facility under this subpart. ~~For the purposes of this subpart, your reciprocating compressor is considered to have commenced construction on the date the compressor is installed at the facility.~~

18.2. Applicable Provisions for Compressor Located at an Onshore Natural Gas Process Plant

Clarify the applicable provisions for compressors located at an onshore natural gas processing plant. In §60.5365(b) & (c), compressors between the wellsite and the city gate are affected facilities, which are subject to the standards in §60.5380 and §60.5385. In §60.5365(f), compressors and equipment at onshore natural gas processing plants are an affected facility. Affected facilities under §60.5365(f) are subject to the VOC control requirements found in §60.5400, §60.5401, and §60.5402, which reference the LDAR requirements in NSPS VVa. Although NSPS VVa contains requirements for compressors, EPA did not reference the compressor standards found in VVa. The inclusion of compressors in both affected facility descriptions causes confusion as to the applicable requirements under NSPS OOOO. In Chapter 6 of the technical support document (TSD), EPA includes compressors located in the processing category (natural gas processing plants) in the regulatory options evaluation under §60.5380 and §60.5385. In Chapter 8 of the TSD (Equipment Leaks), page 8-21, EPA states "Compressors are not included in this LDAR option and are regulated separately." Therefore, it appears EPA intends to regulate affected compressors under §60.5380 and §60.5385 and not under the LDAR requirements for natural gas processing plants. To avoid confusion as to the appropriate requirements for the compressor affected facility, API recommends the following changes to the applicability section in §60.5365:

Suggested Rule Text:**§60.5365**

* * * * *

(f) ~~Compressors and~~ Equipment (as defined in §60.5430) located at onshore natural gas processing plants.

~~(1) Each compressor in VOC service or in wet gas service is an affected facility.~~

~~(2)~~(1) The group of all equipment, ~~except compressors~~, within a process unit is an affected facility.

RECIPROCATING COMPRESSORS**18.3. Rod Packing Change Out****18.3.1. Extend the Time Period to 43,800 Hours or the Option for Every 5 Years**

EPA's cost-benefit analysis does not account for the cost of downtime. EPA assumes the rod packing replacement is completed during a normally scheduled maintenance shutdown. Major maintenance and overhauls are typically completed on a 5 year cycle. In addition, packing sets are either "continuous" or "split ring". Split ring packing allows for replacement without removing the pistons from the cylinders, but is more prone to leak and some companies do not allow the use of a split ring packing for that reason. Continuous packing is less prone to leakage, but replacement requires pulling the piston and rod out of the cylinder which is a major effort that is only done on major compressor overhaul cycles generally every 5 years. Therefore, the rod packing replacement schedule should be changed to allow the option for every five years or 43,800 hrs in order to meet EPA's intent of not including downtime in the cost-benefit analysis and to coincide with a common frequency for major maintenance. Allowing the option for a set 5 year frequency will simplify the recordkeeping and eliminate the need to track operating hours. For owner/operators having a method to track operating hours, the option to replace the packing every 43,800 hours may be a preferable option.

18.3.2. Tracking Hours of Operation

The requirements of §60.5385(a) imply that the hours of operation of reciprocating compressors must be continuously monitored beginning upon the initial start-up, the date of publication of the final rule, or the date of the previous rod packing replacement. Although not specifically stated as a requirement, it could be interpreted that a "hour meter" be installed on all "engine-compressor" sets to continuously monitor runtime hours. There are other methods of monitoring runtime, such as "telemetry and periodic downloads associated databases", that do a reliable job of tracking hours of operation. EPA should clarify that hours of operation can be monitored using a runtime meter, telemetry and associated database, or other system (maintenance logs, PM databases, or work order tracking system) used to track preventative maintenance schedules.

18.3.3. Option for Preventative Maintenance and Inspection Programs

EPA should include an option for Owner or Operator to rely on preventative maintenance programs for determining a leak from the rod packing, subsequently requiring replacement. The maintenance plan typically contains normally scheduled rod packing frequencies changes to coincide with major preventive maintenance performed during a shutdown. Many owner or operators have a preventative maintenance programs that include periodic inspections and maintenance to ensure the compressor and engine driver are operating properly for maximum reliability. An example of an inspection that is sometimes performed to verify the condition of the rod packing seal, is to conduct a quarterly ultrasound measurements for indications of leak. If a leak is detected, the compressor is scheduled for shutdown and repair. The expert opinion of several reciprocating compressor engineers is that the replacement should be based on inspection/measurements to determine the compressor condition (including rod packing seals) and should not be based on time alone. New packing has a break-in period where the leakage can be higher than it would be for older packing. In addition, the failure of new seals due to installation problems or manufacturing defects is not uncommon. If you also account for the additional emissions that are likely to be released when preparing the compressor for maintenance, a time-based replacement program would probably result in higher emissions than a condition based program. For an engine subject NSPS JJJJ, the owner or operator is required to have a maintenance plan to ensure the engine is maintained and operated in a manner consistent with good air pollution control practice for minimizing emissions. Since many of the affected compressors under NSPS OOOO will be associated with an engine subject NSPS JJJJ, EPA should be consistent between the standards and allow for the option to use a preventive maintenance plan under NSPS OOOO.

18.3.4. Suggested Rule Text

§60.5385

You must comply with the standards in paragraphs (a) through (d) of this section for each reciprocating compressor affected facility.

- (a) You must replace the reciprocating compressor rod packing before the compressor has operated for [a period longer than one of the limits listed in paragraphs \(a\)\(1\) through \(a\)\(3\) of this section](#) ~~26,000 hours~~. The number of hours [or years](#) of operation must be ~~continuously~~ monitored beginning upon initial startup of your reciprocating compressor affected facility, or [60 days from](#) the date of publication of the final rule in the **Federal Register**, or the date of the previous reciprocating compressor rod packing replacement, whichever is later. [If monitoring the number of hours of operation, the hours can be monitored using an associated engine runtime meter, telemetry and associated database, or other system \(maintenance logs, PM databases, or work order tracking system\) used to track preventative maintenance and schedules.](#)

[\(1\) 43,800 hours; or](#)

(2) five years; or

(3) a frequency specified by the owner or operator in a preventative maintenance plan designed to maximize the reliability of the reciprocating compressor and minimize VOC emissions.

§60.5415

(c)(2) You have replaced the reciprocating compressor rod packing before the total number of hours of operation reaches the limit selected by the owner or operator from §60.5385(a)(1) through (a)(3) ~~26,000 hours.~~

§60.5420

(b)(4) For each reciprocating compressor affected facility, ~~the information specified in paragraphs (b)(4)(i) and (b)(4)(ii) of this section.~~

~~(i) The cumulative number of hours of operation since initial startup, the date of publication of the final rule in the **Federal Register**, or since the previous reciprocating compressor rod packing replacement, whichever is later.~~

~~(ii) Documentation that if the reciprocating compressor rod packing was due for replacement according to one of the frequencies described in §60.5385(a), but was not replaced as specified before the cumulative number of hours of operation reached 24,000 hours.~~

18.3.5. Ownership

The compressor owners (i.e. rental companies) should be responsible for rod packing change outs and recordkeeping.

18.4. Exclude Reciprocating Compressors in the Transmission and Storage Segment

EPA should exclude reciprocating compressors in the transmission and storage sector, located after the point of custody transfer, due to the low VOC content of natural gas in that sector. A more detailed discussion can be found in Sections 3 and 5.1.

Suggested Rule Text:

§60.5365

* * * * *

(c) A reciprocating compressor affected facility, which is defined as a single reciprocating compressor in VOC service, located between the wellhead and the point of custody transfer city gate (as defined in §60.5430), except that a reciprocating compressor located at a well site (as defined in §60.5430) is not an affected facility under this subpart. ~~For the purposes of this subpart, your reciprocating compressor is considered to have commenced construction on the date the compressor is installed at the facility.~~

18.5. Reciprocating Compressor Definition

The definition should be changed to a more accurate description. API recommends the following definition:

Suggested Rule Text:

§60.5430

Reciprocating compressor means a [positive-displacement machine in which the compressing and displacing element is a piston having a reciprocating motion within a cylinder. The pressure increase is achieved by reducing the volume of a fixed amount of natural gas or field gas](#) ~~piece of equipment that increases the pressure of a process gas by positive displacement, employing linear movement of the driveshaft.~~

18.6. Typographical Error

It appears there is a typographical error in §60.5420(b)(4)(ii). This paragraph references documentation for the reciprocating rod packing being replaced before reaching 24,000 hours. However, the proposed standard in §60.5385 requires replacement of the rod packing every 26,000 hours.

CENTRIFUGAL COMPRESSORS

18.7. Exclude Centrifugal Compressors in Gathering and Boosting and Transmission Segments

In Chapter 6 of the Technical Support Document (TSD), the evaluation for centrifugal compressors is limited to only centrifugal compressors in processing, transmission, and storage. The cost-benefit analysis does not include centrifugal compressors located in production or gathering and boosting. EPA accurately exempted centrifugal compressors located at a wellsite as an affected facility. However, a centrifugal compressor located in the gathering and boosting segment was considered an affected facility without the necessary cost-benefit analysis to support this decision. EPA should revise the affected facility description to accurately reflect the TSD and basis for determining an affected facility for centrifugal compressors.

Because of the low VOC content, EPA should also exclude centrifugal compressors in the transmission and storage segment, located after the point of custody transfer. A more detailed discussion can be found in Sections 3 and 5.1.

Suggested Rule Text:

§60.5365

- (b) A centrifugal compressor affected facility, which is defined as a single centrifugal compressor [in VOC service](#) located between the wellhead and the [point of custody transfer](#) ~~city gate~~ (as defined in §60.5430), except that a centrifugal compressor located at a well site (as defined in §60.5430) [and prior to the natural gas processing plant](#) is not an affected

facility under this subpart. ~~For the purposes of this subpart, your centrifugal compressor is considered to have commenced construction on the date the compressor is installed at the facility.~~

18.8. Allow for a Wet Seal Option for Centrifugal Compressors

Although EPA indicates controls for wet seals are not cost-effective, recent information indicates this is not correct and EPA should not preclude the use of a wet seal equipped centrifugal compressor with controls capable of meeting a 95% VOC control efficiency or routing captured seal-oil gas to a fuel gas system, recycle, or another processing system.^{MM} Centrifugal compressors located at natural gas processing plants may have wet seal compressors with a seal-oil degassing recovery system that separates gas from the seal-oil and routes the separated gas back to compression suction, fuel system, or flare system. For example, many Solar® compressors packages will have a seal oil system. But, the system does not vent the seal gas to atmosphere. The oil and gas mixture that drains from the seals is routed through a seal oil trap that separates the oil and gas. The oil is returned to the package oil tank. The gas is returned to the compressor suction. In the case of existing wet seal centrifugal compressors which may become subject to NSPS OOOO due to modification or reconstruction utilizing an existing gas capture system or retrofitting the centrifugal compressor with a seal oil vapor separation and control system is far more cost-effective than installing a dry gas seal compressor. Conversion of a wet seal centrifugal compressor to dry seals costs from \$250,000 to \$1,000,000 per machine while retrofit with a seal oil gas separator is estimated to cost in the range of \$22,000¹. This option would also provide flexibility for cases where the owner/operator believes a dry gas seal system is not technically feasible (e.g., “dirty” gas) or believe the wet seal system is more economic for the specific location and service. This will also allow compressors with wet seals installed between the date for an affected facility and the final rule to be able to install necessary controls or process modifications rather than retrofit a dry gas seal system.

The preliminary results from a joint EPA (Natural Gas STAR) and BP study of these types of seal-oil gas recovery systems in place on wet seal centrifugal compressors at BP's Alaska North Slope operations were co-presented by BP and ICF (as EPA's contractor) at the Global Methane Initiative (GMI) meeting in Krakow, Poland on October 14, 2011. As the preliminary results illustrate, seal-oil gas separation systems have atmospheric vent volumetric rates broadly similar to dry seal leak rates and may perform incrementally better in some instances. Although EPA and BP have additional work prior to publishing detailed results of the study the preliminary results are quite compelling and should be adequate basis for allowance of this option. A full copy of the presentation in Krakow can be downloaded at the GMI website.^{NN}

^{MM} Routing Centrifugal Compressor Seal Oil De-gassing Emissions to Fuel Gas as an Alternative to Installing Dry Seals”; Global Methane Initiative All-Partnership Meeting; Oil and Gas Subcommittee – Technical and Policy Sessions; October 14, 2011 Krakow, Poland; Reid Smith-BP & Don Robinson-ICF

^{NN} http://www.globalmethane.org/documents/events_oilgas_101411_tech_smith2.pdf

Suggested rule text to accommodate the option of using a wet seal gas system:

§60.5380

You must comply with the standards in paragraphs (a) through (d) of this section, as applicable for each centrifugal compressor affected facility.

- (a) You must control VOC emissions from centrifugal compressors using one the methods described in paragraph (a)(1),(a)(2), or (a)(3). ~~equip each rotating compressor shaft with a dry seal system upon initial startup.~~

(1) Equip the rotating compressor shaft with a dry seal system upon initial startup.

(2) Equip the rotating compressor shaft with a wet seal-oil degassing system and route the separated gas to one of the following:

(i) a flare designed and operated in accordance with the requirements of §60.18(b), or

(ii) a flare designed and operated in accordance with the requirements of §60.18(b), except §60.18(c)(2) and (f)(2). An electronic flare ignition device shall be used to satisfy the requirement for an ignition system when a VOC stream is sent to the flare.

(iii) a combustion device designed to reduce VOC emissions by 95%, or

(iv) a fuel system, or

(v) recycle (compression suction), or

(vi) a combination of (2)(i) through (2)(v)

(3) Equip the rotating compressor shaft with a wet seal. You must route the seal oil degassing tank vapors through a closed vent system to one of the following:

(i) a flare designed and operated in accordance with the requirements of §60.18(b), or

(ii) a flare designed and operated in accordance with the requirements of §60.18(b), except §60.18(c)(2) and (f)(2). An electronic flare ignition device shall be used to satisfy the requirement for an ignition system when a VOC stream is sent to the flare.

(iii) a combustion device designed to reduce VOC emissions by 95%, or

(iv) a vapor recovery device routed to a combustion device designed to reduce VOC emissions by 95%; a fuel system, or recycle (compression suction/process), or

(v) a combination of (3)(i) through (3)(iv).

§60.5410

* * * * *

- (b) You have achieved initial compliance with standards for your centrifugal compressor affected facility if the centrifugal compressor is fitted ~~with a dry seal system~~ upon initial startup as required by §60.5380.

§60.5415

* * * * *

- (b) For each centrifugal compressor affected facility, continuous compliance is demonstrated if the rotating compressor shaft is equipped ~~with a dry seal~~ as specified in §60.5380(a).

§60.5420

* * * * *

- (b)(3) For each centrifugal compressor affected facility installed during the reporting period, documentation ~~that if~~ the centrifugal compressor ~~is was not~~ equipped ~~with dry seals~~ as specified in §60.5380(a).

18.9. Centrifugal Compressor Definition

Centrifugal compressors associated with vapor recovery should be excluded from the definition because shutdowns to replace seals would increase emissions as compared to waiting for the next scheduled process unit shutdown. Certain centrifugal compressors are designed to capture and route vapors back into the process to prevent or reduce emissions. The design necessary to efficiently capture and control emissions should be left to the manufacture and not EPA. EPA should make it clear that the definition of centrifugal compressor does not include compressors associated with vapor recovery.

The definition should be changed to more accurately describe affected facility. API recommends the following definition:

Suggested Rule Text:

§60.5430

Centrifugal compressor means a dynamic machine in which one or more rotating impellers, usually shrouded on the sides, accelerate the flow of natural gas or field gas. The main gas flow is radial. The pressure increase is achieved by converting kinetic energy to static energy. Centrifugal compressor does not include compressors associated with vapor recovery or any other pollution control device ~~piece of equipment that compresses a process gas by means of mechanical rotating vanes or impellers.~~

19. EQUIPMENT LEAKS

API fully supports EPA's determination not to propose NSPS for addressing VOC emissions from equipment leaks at exploration and production field facilities. However, API has a number of concerns and issues with

regard to EPA's proposed revisions to NSPS and NESHAP addressing VOC/HAP emissions from equipment leaks at natural gas processing plants.

19.1. Subpart OOOO – Stringency of Subpart VVa Requirements

EPA states that their technology review has led them to propose that the requirements at 40 CFR Part 60, Subpart KKK for controlling VOC emissions from equipment leaks at natural gas processing plants be updated to reflect the requirements in 40 CFR Part 60, Subpart VVa. EPA indicates that it has evaluated four options for updated control requirements and is proposing a program that is largely based on the equipment leaks standards promulgated under 40 CFR 60 Subpart VVa. The leak detection and repair (LDAR) program prescribed in Subpart VVa requires the monitoring of pumps, pressure relief devices, valves, and connectors. These components are monitored with an Organic Vapor Analyzer (OVA) or Toxic Vapor Analyzer (TVA) to determine if a component is leaking by measuring the concentration of the mixture of organic compounds at the potential leaking interface. Connectors, valves, and pressure relief devices are defined as leaking if the concentration is equal to or greater than a threshold of 500 parts per million by volume (ppmv); pumps are defined as leaking if the concentration around the seals equals or exceeds 2,000 parts per million. Valves and pumps are monitored monthly, connectors are monitored annually, and atmospheric pressure relief valves are monitored after a pressure release event. Open-ended lines must be capped or plugged when not in use or must be equipped with a second valve.

19.1.1. Proposed LDAR Program for Valves

EPA overestimated valve control-effectiveness for its model plant.

The natural gas processing plant model used by the agency in its technical support document (TSD) to analyze the impact of these new leak definitions for the LDAR program is flawed. EPA correctly states that New Source Performance Standards (NSPS) have already been promulgated for equipment leaks at new natural gas processing plants (40 CFR Part 60, Subpart KKK), and were assumed to be the baseline emissions for this analysis. However, the calculations of baseline emissions for the model plant - as presented in the TSD - significantly overestimate these emissions since the method used relies on component counts and average emission factors by component type, which are, *at best, representative of uncontrolled facilities*. Since Subpart KKK was promulgated in 1985, a significant proportion of the existing natural gas plants that would become subject to Subpart OOOO through modification will already be complying with Subpart KKK, and all new natural gas plants would have to comply with Subpart KKK if Subpart OOOO was not in place. Thus, the basis for evaluating Subpart OOOO impacts must be compliance with Subpart KKK, not an uncontrolled emissions scenario as was used in EPA's TSD analysis that supports the proposed rule.

Table 8-12 of the TSD provides a listing of estimated control effectiveness (CE) for select LDAR programs at a Chemical Process Unit and a Petroleum Refinery. The CE for a quarterly LDAR program with a 10,000 ppm leak definition is assumed to be in the range of 60% to 70%, which is assumed to be applicable also for natural gas processing plants that are subject to 40 CFR 60 Subpart KKK. In the TSD, EPA used baseline VOC emissions of 14.3 tons /yr for its model natural gas processing plant facility. This baseline is in error

because it represents emissions from an uncontrolled facility. A more realistic value, based on applying the CE stated above to EPA’s uncontrolled emissions estimate, would be in the range of 4.3 to 5.7 tons/yr, per facility. This range of values accounts for the CE of Subpart KKK controls, and should be used as the baseline from which it is appropriate to calculate the incremental impact of the proposed regulations.

The TSD model calculates uncontrolled emissions using average emission factors that typically overestimate emissions when compared to calculation methods that are based on Leak/No-Leak factors, or the correlation equation approach when the screening value details are available. This overestimate occurs, among other reasons, because the average emission factors assume a much higher percentage of leaking components than those that are typically found at facilities where monitoring programs, such as the ones imposed by Subpart KKK, are in place. The table below provides a comparison of VOC emissions calculations for valves from several natural gas processing plants. The results in the table are based on using the Average Emission Factor vs. the Leak/No Leak methods for the same facilities. The data are based on examples provided by API members for process units that are currently subject to Subpart KKK. The computed percent difference is an indication of the overestimate of valves emissions due to using an average emission factor.

Table 19-1 Comparison of VOC Emissions Calculations For Valves From Natural Gas Processing Plants

| Facility | VOC Emissions from Valves (tons/year) | | % Difference |
|----------|---------------------------------------|----------------------------|--------------|
| | Average Emission Factor | Subpart KKK (Leak/No Leak) | |
| A | 5.7 | 1.36 | 76% |
| B | 8.2 | 1.54 | 81% |
| C | 0.98 | 0.0055 | 99% |
| D | 6.73 | 0.20 | 97% |
| E | 4.0 | 0.19 | 95% |
| F | 19.4 | 17.00 | 12.4% |

By overestimating the baseline emissions for the model plants, as well as the emission reduction associated with applying the VVa program to facilities that are otherwise subject to a Subpart KKK program, the TSD derives an estimated VOC emission control effectiveness for this proposal of 94%; which is not realistic nor is it representative of the incremental control that might be attained from a Subpart KKK baseline.

API’s data demonstrated EPA’s overestimation.

Based on data provided by API member companies for several natural gas processing plants that are currently subject to 40CFR60 Subpart KKK, the percent of valves that leak above 10,000 ppm ranges between 0.1 - 4.0%; however, these leaking valves contribute 82 - 99% of the total mass emissions from facility valves when using the Leak/No-Leak method from EPA’s 1995 protocol for estimating emissions. This is consistent with an earlier API study (API # 310, November 1997) of petroleum refineries equipment leaks that showed that 92% of reducible emissions are due to only ~ 0.13% of components.

API obtained more detailed data for three different natural gas processing units where the actual parts per million concentration values monitored are recorded. This enables the use of the correlation equation method to calculate total emissions from valves and to estimate the contribution of valves that are leaking in various screening value ranges. The table below summarizes the available data. The data indicate that the existing Subpart KKK is contributing to controlling valve leakage above 10,000 ppm. About 80% or more of the valves monitored screen below 500 ppm, and the fraction that screens between 500 and 10,000 ppm ranges between 2-15%. The fraction of the valves that screens between 500 – 10,000 ppm is shown to contribute less than 30% to overall emissions from facility valves.

Table 19-2. Detailed Data for Valves from Three Natural Gas Processing Units

| Process Unit | Screening Value Range | VOC Emissions (tons/yr) | % of Emission | Valve Count | % of Components |
|--------------|--------------------------------------|-------------------------|---------------|-------------|-----------------|
| A | Less than 500 ppm | 0.030 | 68.7% | 677 | 97.8% |
| | Between 500 and 10,000 ppm | 0.014 | 31.3% | 15 | 2.2% |
| | TOTAL | 0.044 | 100.0% | 692 | 100.0% |
| B | Less than 500 ppm | 0.301 | 15.9% | 3759 | 87.0% |
| | Between 500 and 10,000 ppm | 0.543 | 28.7% | 527 | 12.2% |
| | over 10,000 ppm | 1.049 | 55.4% | 36 | 0.8% |
| | TOTAL | 1.893 | 100.0% | 4322 | 100.0% |
| C | Less than 500 ppm | 0.182 | 1.6% | 2058 | 80.9% |
| | Between 500 and 10,000 ppm | 0.417 | 3.7% | 385 | 15.1% |
| | Between 10,000 and pegged at 100,000 | 2.575 | 23.1% | 73 | 2.9% |
| | Pegged 100,000 | 7.98 | 71.5% | 29 | 1.1% |
| | TOTAL | 11.154 | 100.0% | 2545 | 100.0% |

Hence, the proposed changes to the LDAR program for natural gas processing plants that will redefine leaking valves as those leaking above 500 ppm will not lead to any substantial VOC emissions reductions. Per the examples shown in the table above, for a facility that is either currently subject to Subpart KKK or, if new, would become subject to Subpart KKK, the overall VOC emissions from its valves are about 2 tons/year. Lowering the leak definition to 500 ppm might reduce VOC emissions by less than 0.6 tons/year. This is much lower than the 10.9 tons/yr postulated by EPA for the TSD model plant. Therefore, the proposed revised LDAR program for valves will be burdensome without achieving the VOC control claimed and, considering its poor cost effectiveness, does not represent the Best System of Emission Reduction (BSER) for natural gas plant equipment leaks, as required by the Clean Air Act (CAA) for New Source Performance Standards (NSPS).

19.1.2. Proposed LDAR Program for Connectors

EPA overestimated emission reductions.

The changes to the proposed LDAR program for natural gas processing plants includes introduction of a connector program with a leak definition of 500 ppm, which is based on similar programs for chemical and refinery units. Current Subpart KKK LDAR programs impose only auditory, visual and olfactory (AVO) inspection requirements for connectors. Based on the TSD model plant, EPA expects a VOC reduction of 1.57 tons/year for the model facility with the assumption of a CE of 95.9%. This amounts to about a 20% overestimate of the emission reduction potential when compared to the TSD citations of a 93% CE for a chemical plant, and an 81% CE for a refinery, both with a 500 ppm connector program (TSD Table 8-12).

Moreover, API has collected limited data from three natural gas processing facilities that voluntarily monitor and record screening values for connectors. The table below summarizes the data and it demonstrates - as expected - that connectors do not exhibit significant VOC emissions, and do not typically register concentrations over 10,000 ppm when monitored with VOC sniffers. For the process units analyzed, the number of connectors range from 1,463 to 11,272, and the corresponding emissions range from 0.076 to 1.77 tons per year of VOCs. For those process units 27 - 57% of the connectors are found to be in the screening value range of 500 and 10,000 ppm. When these data are normalized for a facility with an equivalent number of connectors as in the model plant, potentially reducible emissions from connectors are 0.87 tons VOC/year.

Table 19-3. Detailed Data for Connectors from Three Natural Gas Process Facilities

| Process Unit | Screening Value Range | VOC tons/year | % Emissions | Connectors Count | % connectors |
|--------------|----------------------------|---------------|-------------|------------------|--------------|
| A | Less than 500 ppm | 0.0087 | 11.4% | 1069 | 73.1% |
| | Between 500 and 10,000 ppm | 0.0672 | 88.6% | 394 | 26.9% |
| | TOTAL | 0.0759 | | 1463 | |
| B | Less than 500 ppm | 1.5980 | 100.0% | 11272 | 100.0% |
| | TOTAL | 1.5980 | | 11272 | |
| C | Less than 500 ppm | 0.4192 | 23.7% | 2922 | 42.8% |
| | Between 500 and 10,000 ppm | 1.3508 | 76.3% | 3899 | 57.2% |
| | TOTAL | 1.7700 | | 6821 | |

Therefore, a value of 0.87 tons/yr of VOC emission reduction is a more realistic value than EPA's 1.57 ton/yr estimate to judge the effectiveness of the proposed connector program. This value and a more realistic CE than the 95.9% EPA assumed should be used to calculate the cost effectiveness of the proposed connectors program.

EPA underestimated the cost and overestimated cost-effectiveness.

EPA is proposing a connectors control program that is not cost-effective and thus not BSER. In fact, it is evident from the data presented and from a previous study of American Chemistry Council (ACC) member facilities⁰⁰ that there is no statistically significant difference in average connector emissions between the initial Method 21 inspections for connectors and the subsequent inspections. Thus, an LDAR program for connectors is ineffective in leading to significant emission reductions.

EPA is oversimplifying the cost assumptions by basing its entire cost effectiveness analysis on data it has previously developed for promulgating Subpart VVa in 2006. The TSD is based on the assumption that the same cost spreadsheets model used for chemical plants and refineries is also applicable for estimating the costs associated with monitoring at natural gas processing plants. This assumption is erroneous and does not take into account many additional factors that should be considered when assessing the cost impacts of a connectors monitoring program at gas plants. Factors that should be considered include:

- (a) Due to the high turnover associated with LDAR personnel and the annual monitoring interval for connectors, it is likely that each time connectors are monitored training will be required to acquaint the monitoring personnel with the process detail, adding to program costs.
- (b) Many natural gas plants are located in remote locations and monitoring personnel, maintenance personnel and even operators will have to travel significant distances to reach the site, incurring significant additional costs to those typical of chemical and refining operations.
- (c) From a recordkeeping perspective, connectors result in a much greater administrative burden than is incurred for other component types. Unlike pumps and valves, connectors are not typically shown on Process & Instrumentation diagrams. Valve end connectors may be identified in an LDAR database via the valve LDAR identification number, such that the connectors are not individually tagged. Both of these conditions make it much more difficult and costly to track additions or deletions of connectors and to maintain accurate component records.

If we review EPA's cost estimates of \$17.70 for the **initial monitoring and setup costs** for valves, and a mere incremental cost of \$1.13 per connector, it is immediately evident that these figures are grossly underestimated. Adding connectors to an existing monitoring system is costly. It will require expanding data collection and tagging systems to identify the connectors being added, and additional time for the associated logistical and planning aspects of an expanded program. Based on data provided by an API member, the costs for setting up a monitoring system for valves is over \$26 per valve (for a model plant consisting of 1500 valves). For the same such plant, the incremental cost for adding a connectors program would be in the range of \$3 - \$9.50 or more per connector (for a model consisting of 4400 connectors) depending on the exact nature of the existing LDAR program, the

⁰⁰ Exhibit 1 – CMA (ACC) Analysis of Connector Monitoring Data from Hazardous Organic NESHAP (HON) and Miscellaneous Organic NESHAP (MON) Units. Pages 15 through 37 of ACC's comments on proposed NSPS Subpart VV, Docket Number EPA-HQ-OAR-2006-0699, February 8, 2006.

adequacy of the existing data collection and archiving system and the amount of time that needs to be spent on site at remote locations.

Similarly, the assumed equivalency of cost (\$1.50 per monitoring event) for both valves and connectors does not reflect the true cost of monitoring connectors. For the reasons stated above connectors would cost more to monitor per component than valves. None of these costs are reflected in EPA's \$1.50 per component cost estimate. Based on data available from API members a more realistic estimate would be a cost of \$ 2.70 - \$ 3.00, or more, per connector monitoring event, depending on individual facility circumstances and location.

The calculation presented in the TSD lists the cost effectiveness for connectors in the range of \$4,800/ton-VOC. However, for the reasons discussed above, the proposed connector LDAR program is not expected to lead to the emission control estimated by EPA and thus, even if we accept the assumed costs used by EPA to add an incremental connectors program, the cost effectiveness figure would be much higher, something in the range of over \$7800/ton-VOC when the initial capital costs are amortized over 10 years. If more realistic setup and monitoring costs are considered as discussed above, the cost effectiveness for connectors would be on the order of \$14,100/ton-VOC based on average costs reported by a few API members. Moreover, under special circumstances such as very remote locations, and connectors that are hard to access (though would not be considered 'difficult to monitor') the costs might double or triple.

Cost effectiveness is even further diminished if a lower amortization period is used. The capital equipment investment needed for implementing an Equipment Leaks program consists primarily of monitoring equipment and data systems for data collection and analysis in addition to physical tags for the components. The required field equipment would probably have only a 5-year lifetime, due to on-going improvements in both monitoring instrumentation and hand-held devices. Using the 5-year lifetime for capital equipment amortization would lead to a revised cost effectiveness estimate that is over \$8,400/ton-VOC. If we are to apply the API data discussed above assuming a 5-year lifetime for the capital equipment purchased, the cost effectiveness increases to over \$17,000/ton-VOC.

API contends that the low emission reductions that could be attained by a connectors program would entail high incremental costs, rendering a connectors program not cost-effective.

19.1.3. Additional Cost to Repair Valves and Connectors

EPA did not account for the additional cost to repair valves and connectors at natural gas processing plant if a leak is defined as 500 ppm. In contrast with chemical plants and refineries, natural gas processing plants do not have all required maintenance personnel onsite. In order to perform the initial attempt at repair, they have to rely on contractor personnel and in many cases it would be a different 'trades' crew that is dispatched to perform the repairs as compared to the ones that conducted the monitoring and initial data collection. The additional annual costs for repairing valves and connectors to a more stringent leak definition of less than 500 ppm are significant. For a natural gas processing plant, similar to the model plant in the TSD, API estimates the incremental repair costs to

range from \$60,500 to \$121,000 with an average of \$90,750. These costs must also be accounted for in the Agency's BSER analysis prior to promulgating the new LDAR requirements.

API further affirms that the incremental cost of repair of valves and connectors, if the leak definition were to be reduced to less than 500 ppm, is an additional burden which is not justified in terms of its potential for VOC emission reductions.

19.1.4. Proposed LDAR Program for Pumps – BSER Not Demonstrated

EPA is proposing to lower the leak definition for all pumps from 10,000 ppm to 2,000 ppm. Such a requirement could be very costly, but EPA does not address these potential costs nor does it outline the potential for emission reductions due to such an amended program. As a matter of fact, EPA did not include pumps in its model plants for natural gas processing facilities and thus it is not justifying the extra burden and not demonstrating any environmental benefit.

The proposed leak definition for pumps would likely require different seal material. EPA must demonstrate the need for such a LDAR program for pumps and that these requirements are BSER. That demonstration has not been made and thus these requirements cannot be finalized. If the Agency intends to proceed with lower leak thresholds for pumps, the required BSER and other analyses must be published for notice and comment.

19.1.5. Reciprocating Pumps

Reciprocating pumps are much more common in oil and gas operations than in refining and chemical operations. A 2000 ppm or even a 5000 ppm leak definition will be difficult to meet for reciprocating pumps in general and will be impossible to meet for some reciprocating pumps, without recasting the distance piece or pump replacement. Replacement of such pumps or the pump distance piece was not considered in proposal development and does not reflect BSER.

§60.482-3a(j) of Subpart VVa deals with this issue for reciprocating compressors. That paragraph exempts existing reciprocating compressors from VVa requirements if the owner or operator can demonstrate that recasting the distance piece or replacing the compressor are the only options available to bring the compressor into compliance. The term "distance piece" is defined in Subpart VVa for compressors.

Similar provision and definition can be added to Subpart OOOO for reciprocating pumps.

Thus, API requests the final Subpart OOOO includes a provision similar to §60.482-3a(j) of Subpart VVa and a definition of "distance piece" relative to reciprocating pumps.

Suggested Rule Text**§60.5401**

* * * * *

(i) Any existing reciprocating pump in a process unit which becomes an affected facility under the provisions of §60.14 or §60.15 is exempt from §60.482-2a of this part, provided the owner or operator demonstrates that recasting the distance piece or replacing the pump are the only options available to bring the pump into compliance with the provisions of §60.482-2a of this part.

§60.5430

Distance piece means an open or enclosed casing through which the piston rod travels, separating the compressor or pump cylinder from the crankcase.

19.1.6. API Request: Stringency of Leak Definition in Subpart OOOO

Due to all the issues raised above, API is requesting that EPA reconsider its proposed alteration of the equipment leaks program for natural gas processing plants. If EPA demonstrates that tighter VOC emission control is justified, we offer the below elements as an alternative program. We believe that the alternate program provides for real emissions reductions in a cost-effective manner.

- a) Set up an LDAR program that requires on-going quarterly monitoring for valves (no skip periods allowed), in lieu of going down to a 500 ppm leak definition for valves. This approach retains the current Subpart KKK leak definition of 10,000 ppm, with its associated repair intervals.
- b) For initial compliance purposes, valve monitoring would be undertaken monthly during the first quarter of becoming subject to this program. Following that, monitoring would continue on a quarterly basis. New and repaired components would be monitored on the quarterly basis rather than having to be monitored monthly.
- c) Facilities would be required to establish internal programs to identify valves that are 'chronic leakers' (valves that leak above 10,000 ppm during three of the four quarters in a year). These valves would be placed on a 'chronic leakers' list and would be designated for refurbishment and/or replacement during the next process unit shutdown.
- d) No new LDAR program for connectors would be imposed, as such a program is not cost effective. API recommends that connectors in gas/vapor service and in light liquid service be subject to the monitoring and leak definition provisions in §60.482-8a.
- e) Retain the 10,000 ppm leak definition for pumps because EPA has not demonstrated the proposed 2000 ppm leak definition as BSER. API recommends that if EPA wishes to evaluate lowering the pump leak definition it might consider the possibility of establishing a 5000 ppm leak definition, after notice and comment rulemaking, if the proposed leak definition is justified as BSER.

- f) Incorporate into the final Subpart OOOO a provision similar to §60.482-3a(j) of Subpart VVa relative to reciprocating pumps. A definition of “distance piece” that is similar to the one in Subpart VVa needs to be added in the final Subpart OOOO, §60.5430. The proposed regulatory language is shown in Section 19.1.5 above.

19.2. Subpart OOOO – Alternative Work Practice

EPA has evaluated several options for an LDAR program for gas processing plants using optical gas imaging (OGI). The options evaluated included: (a) OGI monitoring with an annual EPA Method 21 check (i.e., the alternative work practice for monitoring equipment for leaks at §60.18(g)); (b) monthly OGI without an annual Method 21 check; and (c) Similar to (b) only annual rather than monthly OGI.

19.2.1. Response to EPA's Request for Comments

On page 52755 of the preamble EPA states, “We request comment on the applicability of a leak detection and repair program based solely on the use of optical imaging or other technologies.” EPA recognizes that analysis they have conducted previously have determined that the VOC reduction achieved by bi-monthly OGI monitoring provides an equivalent, or better, VOC emissions reduction when compared to a quarterly M21 based program with a leak definition of 500 ppm. The key to the OGI based monitoring is the ability to conduct more frequent monitoring, with identification and repair of leaking components that contribute a high percentage of the total mass emissions.

The AWP at §60.18(g) specifies the required monitoring frequency and sensitivity threshold for OGI instruments that would ensure the equivalency of emissions control. The analysis that supported the promulgation of §60.18(g) confirmed the specified OGI program would provide equivalent emissions control to a VVa type program without any associated M21 screening. None-the-less the promulgated AWP includes a requirement for annual M21 monitoring.

Requiring an annual leak survey using M21 makes this AWP impractical, burdensome, and ineffective. It actually negates the flexibility that would otherwise be afforded by allowing an OGI only AWP for Subpart OOOO compliance.

Implementing an OGI only AWP is consistent with the monitoring requirements for the mandatory GHG reporting under 40 CFR Part 98 Subpart W. Hence using such an approach to satisfy both LDAR and GHG monitoring would improve its effectiveness and reduce duplicative and redundant requirements for facilities.

19.2.2. API's Previous Recommendations on AWP

API staff and member companies met with Office of Air Quality, Planning and Standards (OAQPS) staff on August 18, 2011 to address the issues and barriers to the implementation of the AWP as noted in Section 19.2.1 above. In response to EPA's request for comment on the potential applicability of an LDAR program that is based solely on OGI monitoring, we

would like to recap here API's major recommendations from the August 2011 meeting with OAQPS:

- a) API urged OAQPS to return to an OGI AWP without requiring an annual M21 survey, as analytical and field studies have been completed and all of them demonstrate AWP equivalency. Additional data will become available as to the effectiveness of the OGI AWP if the M21 requirement is removed and facilities then will start using it.
- b) API urged EPA to restore the 10% AWP Sensitivity Test Option. This option demonstrates high instrument sensitivity and eliminates the need for the burdensome "least-detectable-fraction" stream analyses.
- c) API requested that EPA clarify and modify the video recording requirements by amending rule language to clarify that video records will identify regulated equipment via a defined area grouping, not by a recording of each equipment component. EPA should also evaluate how the video data will be used and whether a complete video recording is really needed.
- d) API believes that OGI has the potential to be useful for difficult or unsafe to monitor components. However in order to make it work in the field, an extended or conditional repair schedule (first attempt at repair) is needed for difficult to access and unsafe to access components, with the final repair falling under the delay-of-repair provisions.
- e) API also urged EPA to work with stakeholders to develop an OGI Application Protocol for the AWP that is based on OGI techniques for LDAR programs. Guidance could include information on instrument sensitivity checks, techniques for process area monitoring, and emissions estimating from the optical imaging monitoring data.

19.2.3. API Requests

API requests that EPA make it possible to use an OGI only approach for LDAR by taking the following steps:

- a) Explicitly allow the use of OGI techniques without requiring an annual M21 survey.
- b) Implement the recommendations provided during the August 18, 2011 meeting with OAQPS, which are summarized in Section 19.2.2 above, to amend §60.18 and make it a real alternative work practice that could be widely implemented.
- c) As a fall back option, evaluate the use of a one-time, side-by-side survey using OGI and M21 as part of initial compliance for Subpart OOOO, with no further requirements for M21 annual surveys.

19.3. Subpart OOOO – Compressors at Natural Gas Processing Plants

As currently proposed, at natural gas processing plants, compressors are affected facilities under §60.5365(b) [centrifugal compressor affected facility] and §60.5365(c) [reciprocating affected facility], as well as §60.5365(f)(1) [compressor in VOC or wet gas service at onshore natural gas

processing plant]. Sections §60.5380 and §60.5385 outline the proposed dry seal and rod packing change-out requirements for centrifugal and reciprocating compressors, respectively. Even though the introductory language for VOC standards at natural gas processing plants in §60.5400 refers to compressors by stating, “(t)his section applies to each compressor in VOC service or in wet gas service...,” compressor control standards in Subpart VVa (§60.482-3a) was not referenced in §60.5400. Additionally, §60.5422, which addresses additional reporting requirements for gas processing plants, contains no VVa references for compressors. Thus, while compressors at natural gas processing plants are affected facilities under §60.5365(f)(1), there are no substantive control or reporting requirements that address VOC equipment leaks from such compressors.

To avoid compliance confusion, EPA should remove the reference to compressors at onshore natural gas processing plants from the VOC equipment leak provisions in the proposed rule, specifically, §§60.5365(f)(1) and 60.5400, and the definition of equipment in §60.5430.

Suggested Rule Text

§60.5365

(f) ~~Compressors and e~~Equipment (as defined in §60.5430) located at onshore natural gas processing plants.

~~(1) Each compressor in VOC service or in wet gas service is an affected facility.~~

~~(1)(2)~~ The group of all equipment, ~~except compressors~~, within a process unit is an affected facility.

~~(2)(3)~~ Addition or replacement of equipment, as defined in §60.5430, for the purpose of process improvement that is accomplished without a capital expenditure shall not by itself be considered a modification under this subpart.

~~(3)(4)~~ Equipment (as defined in §60.5430) associated with a compressor station, dehydration unit, sweetening unit, underground storage tank, field gas gathering system, or liquefied natural gas unit is covered by §§60.5400, 60.5401, 60.5402, 60.5421 and 60.5422 of this subpart if it is located at an onshore natural gas processing plant. Equipment (as defined in §60.5430) not located at the onshore natural gas processing plant site is exempt from the provisions of §§60.5400, 60.5401, 60.5402, 60.5421 and 60.5422 of this subpart.

~~(4)(5)~~ Affected facilities located at onshore natural gas processing plants and described in paragraphs (f)(1) ~~and (f)(2)~~ of this section are exempt from this subpart if they are subject to and controlled according to subparts VVa, GGG or GGGa of this part.

§60.5400

This section applies to ~~each compressor in VOC service or in wet gas service and~~ the group of all equipment (as defined in §60.5430), ~~except compressors~~, within a process unit.

19.4. Subpart OOOO – Applicability

API has concerns with several issues in the proposed rule that will determine whether and/or how the LDAR provisions would apply to certain natural gas processing plants, process units, equipment, or process streams. These issues are described below along with API's recommendations.

19.4.1. Definition of Natural Gas Processing Plant

Under the current definition in the proposed §60.5430, many very small remote sites without stable power supply would be defined as a natural gas processing plant, and thus subject to the LDAR requirements of the proposed rule. One example is the small sites in the production field that operate a single small JT unit. It is both technically and economically infeasible for such sites to comply with any LDAR requirements, especially the very stringent Subpart VVa requirements.

API requests that EPA address this issue by the following:

- (a) Modify the definition of natural gas processing plant by inserting the word "forced" before "extraction of natural gas liquids..."; and
- (b) Add a new definition of "forced extraction of natural gas liquids" that is essentially adopted from the Greenhouse Gas Mandatory Reporting Rule, 40CFR98, Subpart W (see 76 FR 56050).

Suggested Rule Text – one revised definition, one new definition:

§60.5430

Natural gas processing plant (gas plant) means any processing site engaged in the [forced](#) extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both.

[Forced extraction of natural gas liquids means removal of ethane or higher carbon number hydrocarbons existing in the vapor phase in natural gas, by removing ethane or heavier hydrocarbons derived from natural gas into natural gas liquids by means of a forced extraction process. Forced extraction processes include but are not limited to refrigeration, absorption \(lean oil\), cryogenic expander, and combinations of these processes. Forced extraction does not include in and of itself; natural gas dehydration, or the collection or gravity separation of water or hydrocarbon liquids from natural gas at ambient temperature or heated above ambient temperatures, or the condensation of water or hydrocarbon liquids through passive reduction in pressure or temperature, or portable dewpoint suppression skids or fuel treatment skids.](#)

19.4.2. Definition of in Wet Gas Service

Proposed §60.5430 defines "in wet gas service" based on whether a component is handling material that has not been through the extraction step in a gas plant. As a result, the proposed *equipment leak provisions would apply to all such components regardless of the quantity of VOC present*. In VOC service, on the other hand, while not defined in the proposal is indicated in §60.5400(f) to be based on the VOC content of the material handled

(i.e., ≥ 10 wt% VOC). Under the proposed language, then, the equipment leak requirements would apply to components in wet gas service regardless of the VOC content of that material. This follows the example set in Part 60 Subpart KKK. In the BID for Subpart KKK^{PP}, EPA explained the reason for applying the equipment leak requirements to all components in wet gas service is that it is cost effective since, unlike in refineries and chemical plants, there are a relatively large number of wet gas components **containing between 1 and 10% VOC**.

On pages 5-5 and 5-6 of the NSPS KKK BID EPA states:

Response: In setting the VOC concentration limit, EPA took into consideration the VOC content below which equipment leak controls may not be cost effective. In the case of synthetic organic chemical plants and petroleum refineries, the costs of controlling the small number of streams containing less than 10 weight percent VOC appeared to be unreasonable in light of the emission reduction potential. Therefore [*sic*], EPA considered 10 weight percent VOC appeared to be an appropriate VOC concentration limit for those standards. In contrast, gas processing plants can have a large number of components in streams containing between 1 weight percent and 10 weight percent VOC, and the cost effectiveness of controlling emissions from these components is reasonable. Thus, the lower VOC concentration limit appeared to be warranted as a way to cover these streams.

However, this argument is invalid since cost effectiveness is not a function of the number of components in the 1-10% VOC range. The same overall emission factor and cost is used (and incurred) for every component subject to monitoring. It is the potential VOC emission reduction that changes with the VOC concentration. Thus, the potential VOC emission reduction per dollar of cost from monitoring a component containing 10 percent VOC is one tenth the potential VOC reduction per dollar of cost from monitoring components containing 100% VOC.

EPA has concluded in establishing the criteria for a component in VOC service that it is not cost effective to monitor components containing <10% VOC. That conclusion is consistent with the conclusions reached in NSPS VV, VVa and other VOC regulations. Exactly the same logic applies to components handling wet gas that contains <10% VOC. In the Technical Support Document for this proposal EPA assumed 20% of the TOC found to be leaking is VOC and based its cost effectiveness analyses on this assumption. For wet gas components in the 1-10% VOC concentration range, the cost effectiveness is therefore between 20 and 2 times EPA's estimates, depending on the VOC concentration of each particular stream. Thus, as for components in VOC service, it is not cost effective (and not BSER) to apply the proposed equipment leak requirements to such components and the definition of "in wet gas service" should be deleted and the "in VOC service" criterion should be applied to all components in the source category.

However, if EPA intends to continue regulation of lower VOC content streams at natural gas processing plants, API recommends that the definition of "in wet gas service" be revised as

^{PP} EPA-450/3-82-024b, section 5.1.7

discussed in Sections 5.1.2 and 6.1.2 of the General Comments. As outlined in Section 5.1.2, "in wet gas service" would be defined to include field gas before extraction step that contain more than X% VOC by weight (API recommends X be equal to or greater than 5). While a revised definition of "in wet gas service" will still result in mandate of controls that are not cost-effective, the impact would be lessened because inert gas streams from enhanced recovery systems, coal-bed methane, and dry shale gas streams that contain little to no VOC would no longer require monitoring.

19.4.3. Definition of Equipment

As currently defined in §60.5430, "*Equipment* means each pump, pressure relief device, open-ended valve or line, valve, *compressor*, and flange or other connector that is in VOC *or wet gas service, and any device or system required by this subpart.*"

EPA should modify the definition as follows:

- (a) Remove the reference to compressor as compressors are affected facilities but have no associated requirements under the equipment leak provisions of Subpart OOOO. See the discussion in Section 19.3 above.
- (b) Delete applicability to components in wet gas service. If EPA insists on regulating low VOC content streams at gas processing plants, define "wet gas" such that the equipment leak provisions of this rule apply to only those field gas streams that contain 5% or more by weight of VOC. See the discussion in Section 19.4.2 above, as well as Sections 5.1.2 and 6.1.2 in the General Comments.
- (c) Clarify that the regulated components include *any device or system* required by *the equipment leak provisions* of this subpart. The proposed definition is taken from Part 60 Subpart KKK, because it only addresses VOC equipment leaks. Thus, "Any device or system required by [Subpart KKK]" is associated with controlling equipment leaks. Contrary to Subpart KKK, Subpart OOOO includes requirements for many types of affected facilities in addition to VOC equipment leaks. EPA should modify the definition of "equipment" to clarify that "any device or system required" is limited to "any device or system required by *the equipment leak provisions* of this subpart."

Suggested Rule Text:

§60.5430

Preferred Option:

Equipment means each pump, pressure relief device, open-ended valve or line, valve, ~~compressor~~, and flange or other connector that is in VOC service ~~or in wet gas service~~, and any device or system required by [the equipment leak provisions of](#) this subpart.

Alternative Option:

Equipment means each pump, pressure relief device, open-ended valve or line, valve, ~~compressor~~, and flange or other connector that is in VOC service or in wet gas service, and any device or system required by [the equipment leak provisions of](#) this subpart.

19.4.4. Definition of Modification and Capital Expenditure

EPA should clarify the definition of *modification* as it pertains to applicable *equipment* in order to prevent minor additions/repairs from triggering Subpart OOOO requirements for existing KKK facilities, for consistency with Subpart KKK, and for clear expression of the indicated intent of this proposal.

Under the provisions of §60.14(e)(2), a change made to increase production is not a modification if the change does not require a capital expenditure. Capital expenditure is defined in §60.2 as “an expenditure for a physical or operational change to an existing facility which exceeds the product of the applicable ‘annual asset guideline repair allowance percentage’ specified in the latest edition of Internal Revenue Service (IRS) Publication 534 and the existing facility's basis, as defined by section 1012 of the Internal Revenue Code. However, the total expenditure for a physical or operational change to an existing facility must not be reduced by any “excluded additions” as defined in IRS Publication 534, as would be done for tax purposes.” The Part 60 equipment leak rules, including Part 60 Subpart KKK and this proposal (at §60.5365(f)(3)), further exclude process improvements made without a capital expenditure.

Part 60 Subpart VVa, whose requirements are applied under this proposal, extends the definition of capital expenditure as follows:

Capital expenditure means, in addition to the definition in §60.2, an expenditure for a physical or operational change to an existing facility that:

(a) Exceeds P, the product of the facility's replacement cost, R, and an adjusted annual asset guideline repair allowance, A, as reflected by the following equation:

$$P = R \times A, \text{ where:}$$

(1) The adjusted annual asset guideline repair allowance, A, is the product of the percent of the replacement cost, Y, and the applicable basic annual asset guideline repair allowance, B, divided by 100 as reflected by the following equation:

$$A = Y \times (B \div 100);$$

(2) The percent Y is determined from the following equation:

$$Y = 1.0 - 0.575 \log X, \text{ where } X \text{ is } 2006 \text{ minus the year of construction; and}$$

(3) The applicable basic annual asset guideline repair allowance, B, is selected from the following table consistent with the applicable subpart:

Table for Determining Applicable Value for B

| Subpart applicable to facility | Value of B to be used in equation |
|--------------------------------|-----------------------------------|
| VVa | 12.5 |
| GGGa | 7.0 |

Because capital expenditure is not defined in the proposal, the applicability provisions of Part 60 Subpart VVa are not referenced, and the applicable basic annual asset guideline repair allowance is not clearly indicated in the proposal or any of the referenced material, it is unclear how to determine if a modification associated with a production rate increase or process improvement has occurred.

API recommends that EPA add a definition of capital expenditure to Subpart OOOO §60.5430 that copies the definition from Subpart VVa, with modifications that are appropriate for natural gas processing plants and this rulemaking. Specifically, the modifications include: a) the year used in paragraph (2) above is, consistent with the Section 111 of the CAA, the year of the proposed Subpart OOOO, namely, 2011; and b) the value of B, as documented in §60.481 of Subpart VV for these facilities (identified as Subpart KKK facilities), is 4.5, if EPA incorporates in the final rule API's recommendations listed in Section 19.1.6 with regard to leak definition and the connector program. If EPA does not adopt those recommendations, then the value of B should be 12.5, the same as that for Subpart VVa.

Suggested Rule Text – new definition:

§60.5430

Preferred Option (if the leak definition remains at 10,000 ppm, and only AVO is required for connectors):

Capital expenditure means, in addition to the definition in 40 CFR 60.2, an expenditure for a physical or operational change to an existing facility that:

(a) Exceeds P, the product of the facility's replacement cost, R, and an adjusted annual asset guideline repair allowance, A, as reflected by the following equation:

$P = R \times A$, where:

(1) The adjusted annual asset guideline repair allowance, A, is the product of the percent of the replacement cost, Y, and the applicable basic annual asset guideline repair allowance, B, divided by 100 as reflected by the following equation:

$A = Y \times (B \div 100)$;

(2) The percent Y is determined from the following equation:

$Y = 1.0 - 0.575 \log X$, where X is 2011 minus the year of construction; and

(3) The applicable basic annual asset guideline repair allowance, B, is 4.5.

Alternative Option (if the leak definition is 500 ppm, or there is a connector monitoring program required) The definition would be the same as above, except:

(3) The applicable basic annual asset guideline repair allowance, B, is 12.5.

19.5. Subpart OOOO – New Delay of Repair Option for On-line Equipment Repair Using Specialized Methods

There are multiple technical and logistical issues that impact the feasibility of online repair using specialized methods, such as repair of a valve by injecting packing via drill and tap.

According to §60.482–9(a) of subpart VV, delay of repair is allowed if repair is technically infeasible without a process unit shutdown, and §60.482–9(c) of subpart VV allows delay of repair of valves if emissions associated with immediate repair would exceed continued emissions from the leak.

EPA has not demonstrated that use of specialized on-line repair methods is cost effective, particularly at the proposed leak definitions of 500 ppm for valves and connectors, and that the emissions associated with such repair attempts would be lower than if repair was delayed. Unlike refineries and chemical plants that have ready access to specialized maintenance contractors, many natural gas processing plants have to mobilize specialized contractors from long distances in order to attempt on-line repairs. This results both in increased costs and additional emissions from transportation and other logistical activities. The additional emissions may be more than would result from continued leaking at a low concentration range between 500 – 10,000 ppm.

API recommends that EPA add an additional delay of repair provision for on-line repairs utilizing specialized methods. Such repairs may be technically feasible, but are not logistically or economically feasible to be performed repeatedly to below 500 ppm within very narrow time windows. Facilities should be allowed a maximum of 90 days to complete these specialized repair attempts. Allowing more time reduces the cost burden and minimizes travel-associated emissions by enabling the repair of multiple components during fewer contractor site visits.

Suggested Rule Text:

§60.5401

* * * * *

(h) In addition to the provisions of §60.482-9a, delay of repair for valves and connectors will be allowed if:

(1) Initial (within 5 days of the leak being detected) and follow-up (within 15 days of the leak being detected) repair attempts using routine methods have been completed and were unsuccessful and

(2) Further on-line repair attempts require the use of a specialized repair contractor, and

(3) Further specialized repair attempts are completed as soon as practicable, but not later than 90 days after the leak was detected. If a repair attempt using a specialized

[technique is unsuccessful, repair shall occur before the end of the next process unit shutdown or as otherwise allowed by §60.482-9a\(e\).](#)

[A specialized repair contractor provides repair services not available from the facility or contractor maintenance personnel who perform routine repairs of most facility equipment leaks. An example of a specialized repair contractor is a contractor who provides valve gland drill and tap services.](#)

19.6. Subpart OOOO – Work Practice Implementation

The date by which LDAR work practices must begin is unclear in NSPS rules. At least a one year compliance period is needed for modified facilities to allow time to identify all covered components, tag them, gather and input all required information about each component into an LDAR database, develop testing routes, contract for the service, develop and arrange for required, timely leak repair and institute all of the procedures and recordkeeping associated with these programs. At new or reconstructed facilities, some of this work can be done prior to start-up, but not all of it. Furthermore, the compliance date for new and reconstructed facilities is unclear. For such facilities, we request the Agency clearly provide up to 180 days for sources to complete the initial round of monitoring.

In sum, **API requests** EPA allow at least a year for modified facilities, and 180 days for new or reconstructed facilities to implement work practice requirements.

19.7. Subpart OOOO – Equipment Upgrade Implementation

In some cases, facility upgrades will be needed at sources that become subject through modification. In particular, pump seals may require replacement or PSVs may need to be upgraded. Design, procurement and installation of such equipment takes considerable time and sources that come under these requirements through modification should be allowed up to three years to install such equipment upgrades.

API requests EPA allow three years for modified facilities to implement equipment upgrades as required.

19.8. Subpart OOOO – Exceptions in §60.5401 (d) and (e).

These two paragraphs exempt small gas processing plants and plants located in the Alaskan North Slope from routine monitoring requirements. However, there are several issues in these paragraphs that need to be addressed.

19.8.1. Typo in §60.5401(d)

There is an apparent typographical error in §60.5401(d), which reverses the small non-fractionating plant exemption in Subpart KKK. Subpart KKKK exempts any non-fractionating plant that does not have the design capacity to process 10 million scf/day or more of field gas.

19.8.2. Exemption from Reporting

Paragraph §60.5401(d) exempts certain components at small non-fractionating gas plants from the routine monitoring requirements of §§60.482-2a(a)(1), 60.482-7a(a), and 60.5401(b)(1). Paragraph §60.5401(e) exempts the same group of components located in the Alaskan North Slope from the same monitoring requirements. API recommends that these components also be exempt from the reporting requirements by adding the following words at the end of these paragraphs: “*and the reporting requirements found in §§60.5420 and 60.5422.*”

19.8.3. Exemption for Connectors

As stated above, paragraphs (d) and (e) exempt the small non-fractionating plants and Alaskan North Slope plants from routine monitoring of pumps, valves and pressure relief devices (PRDs). Since Subpart KKK does not require routine monitoring of connectors, an exception for connector routine monitoring is not necessary in Subpart KKK. As discussed in Sections 19.1.2 and 19.1.6, API recommends that EPA only require auditory, visual and olfactory (AVO) inspections on connectors in the final rule. If EPA adopts API's recommendation, then no additional revision of §60.5401(d) and (e) is necessary. However, if EPA decides to adopt the Subpart VVa connector program requirements in the final rule, then API recommends that these two paragraphs be revised such that connectors at small non-fractionating plants and Alaskan North Slope plants are also exempt from routine monitoring, as pumps, valves and PRDs are.

19.9. Subpart OOOO – Clarifications Sought.

A couple of parts of the proposed rule language seem to either have typographical errors or statements that require clarification by EPA:

19.9.1. Pressure Relief Devices

It is unclear whether the stated alternate leak definition for PRDs in §60.5401(b)(2) is a typographical error. It states, “If an instrument reading of 5000 ppm or greater is measured, a leak is detected.” This seems to be in contrast with §60.5421(b)(2)(iv), where the language suggests a leak definition of 500 ppm.

19.9.2. Sampling Connection Systems

§60.5400(a) lists all the provisions in Subpart VVa with which an affected facility must comply, including the sampling connection systems requirements in §60.482-5a. However, §60.5401(c) exempts the affected sampling connection systems from the requirements in §60.482-5a. API requests that §60.482-5a be deleted from the list in §60.5400(a).

19.10. Subpart HH – Alternative Work Practice.

Concerns and recommendations described in Section 19.2 also apply to Subpart HH.

19.11. Subpart HH – Applicability.

19.11.1. Definition of Natural Gas Processing Plant

Concerns and recommendations described in Section 19.4.1 also apply to Subpart HH.

19.11.2. Definition of In Wet Gas Service

Concerns and recommendations described in Section 19.4.2 also apply to Subpart HH.

19.12. Subpart HH – Lower Leak Definition for Valves

§63.769 (c) states that,

“For each piece of ancillary equipment and each compressor subject to this section located at an existing or new source, the owner or operator shall meet the requirements specified in 40 CFR Part 61, Subpart V, §§61.241 through 61.247, except as specified in paragraphs (c)(1) through (8) of this section, except for valves subject to §61.247–2(b) a leak is detected if an instrument reading of 500 ppm or greater is measured.”

This section of the rule may apply not only to large natural gas processing plants that are subject to Subpart KKK but also to smaller natural gas processing plant units where certain streams might be in VHAP service, which are currently not subject to Subpart KKK per the intent expressed in §63.769(b). Therefore, as documented in the discussion above (see Section 19.1), EPA's analysis overestimates the potential for emission reductions by lowering the leak definition for valves to 500 ppm. Therefore, the imposition of such a lower leak definition for valves at both new and existing natural gas processing plants is not warranted in terms of exposure reduction from plant operations. The risk benefit from the lower leak definition has not been demonstrated by EPA especially for smaller natural gas processing units.

API recommends that EPA retain the leak definitions for equipment leaks as currently promulgated in Subpart HH. This will prevent added compliance confusion and high costs to industry without demonstrated significant risk reductions.

19.13. Subpart HH – Extending Compliance Time

40 CFR 63 Subpart HH applies to both new and existing facilities. It is not feasible to expect existing facilities to be able to be in compliance instantaneously upon promulgation. For example, the leak definition for valves would be lowered from 10,000 ppm to 500 ppm. Upon promulgation of the final rule, it is expected that at an existing facility, a great number of valves which were previously not a leaker would suddenly become a leaker. Adequate supply of maintenance personnel and valve parts necessary to repair that many leakers within the time frame allowed in the rule is very questionable. In certain cases, the needed personnel and/or parts would simply not be available. If the rule provides a reasonable compliance time, the owner/operator of the facility would be able to plan and execute the leaker repair maintenance activities in a much more orderly fashion, and more importantly, in compliance with the rule. Our preference is to keep the 10,000 ppm leak definition. However, if the leak definition is to drop down to 500 ppm, then additional time to comply should be allowed as we recommended above for Subpart OOOO, namely, at least a year for existing facilities, and 180 days for new facilities to implement work practice requirements.

19.14. Subpart HH – Overlap with Subpart OOOO

Proposed §63.769(b) exempts ancillary equipment and compressors subject to Part 63 Subpart H and Part 60 Subpart KKK from the proposed §63.769(c) equipment leak requirements. This exemption should also apply to equipment and compressors that are subject to the new Part 60 Subpart OOOO, since otherwise duplicative and sometimes conflicting requirements would apply.

Suggested Rule Text

§63.769

* * * * *

(b) This section does not apply to ancillary equipment and compressors for which the owner or operator is subject to and controlled under the requirements specified in subpart H of this part; or the requirements specified in 40 CFR part 60, subparts KKK or OOOO.

20. GLYCOL DEHYDRATORS [NESHAP HH & HHH]

In both the Oil and Gas Production MACT (subpart HH) and the Natural Gas Production and Storage MACT (subpart HHH), EPA separated glycol dehydrators into two groups, or “subcategories.” While the “small dehydrator” and “large dehydrator” terminology is new in the proposed regulations, the concept and criteria defining these groups is present in the existing subparts HH and HHH. Table 20-1 shows the characteristics of each of these groups, as well as the current and proposed standards for each.

Table 20-1. Summary of Glycol Dehydrator Group Criteria and Emission Limitations

| Subpart | Dehydrator Group | Characteristics of Group | Requirements | |
|---------|------------------|--|---|--|
| | | | Current | Proposed |
| HH | Large | Flow rate ≥ 85,000 m ³ /day (3 million ft ³ /day) AND benzene emissions ≥ 0.9 Mg/yr (1 ton/yr) | Reduce HAP by 95% or reduce benzene emissions < 0.9 Mg/yr (1 tpy) | Reduce HAP by 95% |
| | Small | Flow rate < 85,000 m ³ /day (3 million ft ³ /day) OR benzene emissions < 0.9 Mg/yr (1 ton/yr) | NONE | Reduce BTEX emissions to a unit-specific emission limit calculated based on the dehydrator throughput and BTEX concentration at the inlet to the glycol dehydration unit |
| HHH | Large | Flow rate ≥ 283,000 m ³ /day (10 million ft ³ /day) AND benzene emissions ≥ 0.9 Mg/yr (1 ton/yr) | Reduce HAP by 95% or reduce benzene emissions < 0.9 Mg/yr (1 tpy) | Reduce HAP by 95% |
| | Small | Flow rate < 283,000 m ³ /day (10 million ft ³ /day) OR benzene emissions < 0.9 Mg/yr (1 ton/yr) | NONE | Reduce BTEX emissions to a unit-specific emission limit calculated based on the dehydrator throughput and BTEX concentration at the inlet to the glycol dehydration unit |

As can be seen in Table 20-1, EPA proposed two significant changes to the glycol dehydrator provisions:

- (1) eliminate the alternative 0.9 Mg/yr benzene emission limitation for large dehydrators, and
- (2) propose standards for small dehydrators.

API disagrees with both these decisions and does not believe that EPA has adequately justified them.

20.1. Large Dehydrators – The 0.9 Mg/yr Benzene Alternative Emission Limitation Must Be Retained in both Subpart HH and Subpart HHH

As discussed above, the Oil and Gas Production MACT (Subpart HH) currently includes two compliance options for glycol dehydrators with an actual annual average natural gas flow rate greater than or equal to 85,000 m³/day and actual average benzene emissions greater than or equal to 0.9 Mg/yr (i.e., “large” dehydrators). These options are to reduce organic HAP emissions by 95% or to reduce benzene emissions to less than 0.9 Mg/yr. Similarly, the Natural Gas Transmission and Storage MACT (subpart HHH) requires glycol dehydrators with an actual annual average natural gas flow rate greater than or equal to 283,000 m³/day and actual average benzene emissions greater than or equal to 0.9 Mg/yr to reduce HAP emissions by 95% or benzene emissions to less than 0.9 Mg/yr. EPA is proposing to eliminate the 0.9 Mg/yr benzene emissions compliance alternative for large dehydrators for both source categories.

Note that EPA decisions related to the 0.9 Mg/yr benzene alternative for large dehydrators in both MACT standards are unrelated to the 0.9 Mg/yr benzene emission threshold used to differentiate between small and large dehydrators. API has comments on the emission limits proposed for small dehydrators, which are provided in Section 20.3. However, as will be evident in API's comments below, EPA must restore the 0.9 Mg/yr benzene emissions for large dehydrators independent of any decisions related to small dehydrators.

For both MACT standards, these decisions were proposed under the authority of CAA section 112(f)(2). Thus, these are “risk-based” decisions. As discussed in Section 12, we have numerous basic concerns with EPA's decision to make significant and substantive changes unilaterally to the residual risk procedure that has been established in accordance with CAA mandates, vetted with Congress, and ratified by precedent. Some of the primary areas of concern include consideration of risk from the total facility, consideration of risk across selected social, demographic, and economic groups within the population living near the facility, and consideration of the hypothetical risk associated with the level of emissions allowed by the MACT standard. In addition, API believes that several factors, including the following, result in overestimates of risk that are between 100 and 1000-fold higher than estimates using more central factors:

- Assuming that all members of the population are continuously exposed for their lifetimes,
- Failing to consider time-activity patterns,
- Using only high end URE for decision-making, and
- Using only ultra conservative URE from CalEPA in the absence of IRIS values.

More detail on API's concerns with these aspects is provided in Attachment N, which is incorporated in these comments by reference.

While API has the overarching concerns with EPA's risk assessment and methodologies mentioned above, the risk-related decisions for large glycol dehydrators are based on flawed analysis. The evidence provided by EPA to support these conclusions is incorrect, and the outcome is that EPA has no basis for removing the 0.9 Mg/yr benzene alternative for either subpart HH or subpart HHH. Further details are provided in Attachment O, which is incorporated in these comments by reference.

20.1.1. Oil and Gas Production MACT – Subpart HH

In EPA's analysis for subpart HH,^{QQ} there are two facilities with a cancer MIR greater than 100-in-1 million based on MACT allowable emissions. These facilities are the Hawkins Gas Plant in Hawkins, Texas and the Kathleen Tharp 2 facility in Huffman, Texas. Since EPA determined that these facilities had a cancer maximum individual risk (MIR) greater than 100-in-1 million based on MACT allowable emissions, EPA determined that the risks are unacceptable for the oil and gas production MACT category and additional regulation is needed. However, as will be shown below, the results are entirely incorrect due to fundamental errors in EPA's calculations of MACT allowable risk for these two facilities. In addition, even if the analysis had been correct, there are significant issues associated with the data for both of these facilities that are sufficient to invalidate the results and EPA's conclusion that risks from the Oil and Natural Gas Production source category are unacceptable.

Fundamental Errors in EPA's Analysis. As noted above, EPA identified two facilities with cancer MIRs greater than 100-in-1 million based on MACT allowable emission levels. However, examination of EPA's analysis shows that the results are entirely incorrect due to fundamental errors in EPA's calculations of MACT allowable risk. This caused the calculation of MACT allowable risk estimates that are orders of magnitude too high. Following are details of this error.

In the analysis of risk based on the MACT allowable emissions level, EPA assumes that glycol dehydrators which control benzene emissions to levels less than 0.9 Mg/yr could increase benzene emissions to 0.9 Mg/yr. The analysis assumes a linear relationship between benzene emissions and risk, so the risk due to the actual benzene emissions level was multiplied by the ratio of 0.9 Mg/yr divided by the actual emission level. For example, if the cancer MIR based on 0.45 Mg/yr of actual benzene emissions was 40-in-1 million, the cancer MIR based on the 0.9 Mg/yr benzene MACT allowable emissions level would be 80-in-1 million.

In their MACT allowable analysis, EPA used the incorrect actual emissions level to adjust the risk to a 0.9 Mg/yr basis. Specifically, for dehydrator DN0005 at the Hawkins Gas Plant, EPA used a benzene emission rate of 0.00004 tons/yr instead of the correct value of 0.01290

^{QQ} Memorandum. From Heather Brown, P.E., EC/R Incorporated and Lesley Stobert, EC/R Incorporated, to Bruce Moore, EPA/OAQPS/SPPD/FIG. "Oil and Natural Gas Production MACT and Natural Gas Transmission and Storage MACT – MACT Allowable Emissions and Risks." July 28, 2011. (Docket Item EPA-HQ-OAR-2010-0505-0055)

tons/yr. This resulted in a multiplier of over 23,000 ($1 / 0.00004$) and a MIR of 400-in-1 million. The benzene emission rate for this point, as shown in the Appendix to EPA's Risk Assessment Document,^{RR} is 0.01290 tons/yr. This emission rate results in a MACT allowable multiplier over 300 times lower than the value used by EPA. Inserting the correct actual emissions number in EPA's analysis results in a MACT Allowable MIR of 3-in-1 million for the Hawkins Gas Plant.

A similar error occurs for the Kathleen Tharp2 facility. For dehydrator DN0001, the correct actual benzene emissions rate is 0.1140 tons/yr. However, EPA used an incorrect emission rate of 0.0001 tons/yr. Inserting the correct benzene rate in the analysis results in a MACT allowable MIR of 0.2-in-1 million for this facility. Details of the errors and API's corrections are provided in Attachment O, which is incorporated in these comments by reference.

After the MACT allowable MIRs are corrected for these two facilities, the highest MACT allowable MIR is 50-in-1 million for the Seneca Resources Corporation facility in Ojai, CA. This is clearly at a level that EPA has never considered as unacceptable.

Major Issues in EPA's Data Set for Facilities Driving the Risk. The issues associated with the data for the two facilities with cancer MIRs greater than 100-in-1 million based on MACT allowable emissions are sufficient to invalidate the results and EPA's conclusion that risks from the Oil and Natural Gas Production source category are unacceptable. The highest risk facility, with a cancer MIR of 400-in-1 million based on MACT allowable emissions, is the Hawkins Gas Plant in Hawkins, Texas. A review of the background data in EPA's dataset for this facility has found significant errors. For example, the EPA data set includes data for eight dehydrators when in fact there are only three dehydrators at the plant. The Hawkins Gas Plant operates three glycol dehydrators, with a fourth dehydrator on site but has been shut down for more than 10 years. In addition, one of these dehydrators (DehyRod) falls into EPA's definition of "small dehydrator" and should not have been considered in the large dehydrator analysis, as its throughput is less than 60,000 m³/day. For the past 10 or more years, only emissions data for the three operating glycol dehydrators has been submitted to the TCEQ for the annual emissions inventory.

There are no emissions during normal operation of these three dehydrators as the still vent vapors are routed through a vapor recovery compressor (VRC) and back into the process. There is no emissions point. However, as a backup for times when the vapor recovery compressor is down, dehydrator still vent emissions are routed first through a BTEX condenser, then to the low pressure flare. Emissions only occur during VRC downtime which is reported to the TCEQ each year in the emissions inventory. The table below lists the annual emissions reported to the TCEQ for the emissions inventory for 2005-2009.

^{RR} "Draft Residual Risk Assessment for the Oil and Gas Production and Natural Gas Transmission and Storage Source Categories." EPA, Office of Air Quality Planning and Standards, Office of Air and Radiation. July 2011. (Docket Item EPA-HQ-OAR-2010-0505-0032)

Table 20-2. Hawkins Plant Dehydrator Emissions

| Hawkins Plant Dehy | Annual Emissions (tons/yr) | | | | | | | | | |
|--------------------------|----------------------------|-------|-------|------|-------|------|-------|------|-------|------|
| | 2005 | | 2006 | | 2007 | | 2008 | | 2009 | |
| | VOC | BTEX | VOC | BTEX | VOC | BTEX | VOC | BTEX | VOC | BTEX |
| DehyHP | 0.05 | 0.009 | 0.15 | NA | 0.024 | NA | 0.01 | NA | 0.004 | NA |
| Dehy80 | 0.86 | 0.03 | 0.027 | NA | 0.21 | NA | 0.045 | NA | 0.023 | NA |
| DehyRod | 0.005 | 0.005 | 0.33 | NA | 0.057 | NA | 0.003 | NA | 0.004 | NA |

The facility with the second highest MACT Allowable risk (200-in-1 million) is the Kathleen Tharp 2 facility in Huffman, Texas. API has confirmed with the Texas Commission on Environmental Quality (TCEQ) that this facility does not have a Title V permit and is not a major source of HAP.^{SS} API has also obtained documentation that a Form PI-8 has been filed for this facility. A Form PI-8 certifies emissions below the minor source limit of 25 tons/yr VOC, and makes the certified emissions enforceable. Therefore, it should not be considered in this analysis.

Conclusion for Oil and Gas Production MACT. EPA must reverse its proposed decision to eliminate the 0.9 Mg/yr benzene compliance alternative in subpart HH for glycol dehydrators with actual annual average natural gas flow rates greater than or equal to 85,000 m³/day and actual average benzene emissions greater than or equal to 0.9 Mg/yr. The analysis that resulted in risks determined by EPA to be unacceptable, and the data used in the analysis, both have significant errors. Correction of these errors leads to risk estimates well within the ranges that EPA determines to be acceptable.

In the absence of an unacceptability risk determination, EPA cannot legitimately argue that removal of the 0.9 Mg/yr is a cost effective measure under the ample margin of safety decision. In the technical documentation estimating the impacts of RTR control options,^{TT} EPA estimated the cost effectiveness of removing the 0.9 Mg/yr benzene alternative was \$14,000/Mg HAP. This cost effectiveness, which is EPA's estimate, is at the high range of most past EPA MACT decisions. However, this EPA estimate is lacking and actually significantly underestimates the cost effectiveness. EPA's estimate takes full credit for a 95% reduction in HAP emissions. However, any large dehydrator that is currently complying with the 0.9 Mg/yr benzene limit utilizes some type of control device designed to reduce benzene emissions 0.9 Mg/yr. The benzene emission reduction needed to achieve 0.9 Mg/yr could be less than 95%. In such cases, it would only be appropriate to consider the incremental emission reduction obtained when additional control is installed.

^{SS} Personal Communication. Norwood, P., ERM, and Moore, S., TCEQ Houston Regional Office. October 13, 2011.

^{TT} Memorandum. From Heather Brown, P.E., and Lesley Stobert, EC/R Inc. to Bruce Moore, EPA/OAQPS/SPPD/FIG. "Impacts for Control Options for the Oil and Natural Gas Production and the Natural Gas Transmission and Storage Categories as a Result of the Residual Risk and Technology Review." August 19, 2011. (Docket Item EPA-HQ-OAR-2010-0505-0077)

For example, consider a large dehydrator with uncontrolled benzene emissions of 3 Mg/yr. In order to comply with the 0.9 Mg/yr benzene limitation, a condenser or other control device could be installed that achieves approximately 70% reduction. If the 0.9 Mg/yr benzene emission limitation is removed, the facility would need to install an additional control device to meet the 95% requirement (which would require that emissions be reduced to 0.15 Mg/yr). However, EPA must claim only the incremental reduction (0.75 Mg/yr) and not the total 95% reduction (2.85 Mg/yr). This would increase the calculated cost per ton 4 fold.

In fact, EPA has already estimated the cost effectiveness for this incremental control. The cost effectiveness that is more appropriate for this option is \$167,200/Mg HAP, which is the cost effectiveness estimated by EPA for the addition of a second control device (76 FR 52768). Without a doubt, this cost effectiveness is not reasonable.

In view of these clear facts, EPA must repeal its proposed conclusion under section 112(f)(2) of the CAA to remove the 0.9 Mg/yr benzene compliance alternative for subpart HH. The corrected analysis does not result in an unacceptable risk and the available information cannot support a conclusion that this action is necessary to achieve an ample margin of safety.

Further, EPA has no basis under any other CAA authority to remove the 0.9 Mg/yr benzene alternative for large dehydrators at oil and gas production facilities. Under 112(d)(6), EPA did not identify any developments in practices, processes, or control technologies to further reduce emissions from large dehydrators. EPA already established MACT floors for glycol dehydrators and promulgated these decisions on June 17, 1999 (64 FR 32610), and the rule was not challenged within the statutory period (90 days). Therefore, EPA does not have authority to revisit the floor at this time. Further, since large dehydrators are subject to standards under the existing subpart HH, they do not represent an "unregulated" emission sources that EPA can address under section 112(d)(2) and (3). Finally, as noted above, EPA estimated that the cost effectiveness of additional controls to be \$167,200/Mg HAP, which cannot be justified as reasonable under any circumstance.

20.1.2. Natural Gas Transmission and Storage MACT – Subpart HHH

For the Natural Gas Transmission and Storage source category, EPA found that risks from sources subpart to subpart HHH were acceptable (even when considering MACT allowable emissions). In the second step of the risk decision, EPA then proposed to eliminate the 0.9 Mg/yr benzene compliance alternative as part of their ample margin of safety determination.

While an ample margin of safety decision can consider numerous factors, EPA bases the decision to eliminate the 0.9 Mg/yr benzene emission limitation for subpart HHH on two basic factors: (1) it would reduce the cancer MIR from 90-in-1 million to 20-in-1 million, and (2) the cost effectiveness to comply with this option is reasonable. As will be demonstrated below, both of these conclusions are erroneous.

Removal of 0.9 Mg/yr Benzene Alternative Does Not Reduce Risk. EPA indicates that removal of the 0.9 Mg/yr benzene compliance alternative for glycol dehydrators with actual

annual average natural gas flow rates greater than or equal to 283,000 m³/day and actual average benzene emissions greater than or equal to 0.9 Mg/yr would reduce the cancer MIR for the source category from 90-in-1 million to 20-in-1 million. However, this assertion is entirely incorrect as EPA's own technical analysis indicates that removal of the 0.9 Mg/yr benzene alternative would have NO effect on the MIR.

To summarize, EPA separates dehydrators into two groups, or subcategories for the natural gas transmission and storage source category:

- 1) Dehydrators with an actual annual average natural gas flow rate greater than or equal to 283,000 m³/day and actual average benzene emissions greater than or equal to 0.9 Mg/yr (i.e., "large" dehydrators), and
- 2) Dehydrators with an actual annual average natural gas flow rate greater less than 283,000 m³/day or actual average benzene emissions less than 0.9 Mg/yr (i.e., "small" dehydrators).

Large dehydrators in the first group are subject to the current standards, which require that organic reduce HAP emissions be reduced by 95% or benzene emissions reduced to less than 0.9 Mg/yr. Small dehydrators in the second group are not subject to standards in the current rule.

EPA's analysis shows that the dehydrators causing the 90-in-1 million MIR are in the second small dehydrator category, which means they are not even subject to the 0.9 Mg/yr benzene alternative. Therefore, removing it will have **NO** impact on these highest MIRs. This is clearly stated in a technical memorandum prepared by EPA's contractor which shows the MIR for the source category unchanged (90-in-1 million) without the 0.9 Mg/yr benzene alternative.^{UU}

EPA's Cost Analysis is Severely Flawed. Second, EPA concludes that the cost effectiveness of the proposed removal of the 0.9 Mg/yr benzene compliance alternative for natural gas transmission and storage facilities is reasonable. However, the costs estimates used by EPA in the ample margin of safety determination are inadequate. EPA did conduct any analysis using actual data. Rather, EPA used costs estimated for small dehydrators and rashly made general assumptions to estimate an upper-end cost effectiveness for removing the 0.9 Mg/yr benzene alternative limit for large dehydrators at natural gas transmission and storage facilities.

Specifically, EPA based their cost "analysis" on the following points.

"Although control methodologies are similar for large and small dehydrators, we expect that the costs for controls on large units could be as much as twice as high as for small units because of the large gas flow being processed." (76 FR 52783).

^{UU} Memorandum. From Heather Brown, P.E., and Lesley Stobert, EC/R Inc. to Bruce Moore, EPA/OAQPS/SPPD/FIG. "Impacts for Control Options for the Oil and Natural Gas Production and the Natural Gas Transmission and Storage Categories as a Result of the Residual Risk and Technology Review." August 19, 2011. (Docket Item EPA-HQ-OAR-2010-0505-0077)

API agrees that flow rates for the large dehydrators would, in general, be higher than those for small dehydrators. API also agrees that the costs for these controllers would be higher, although EPA has provided no support for the argument that the upper range of this cost would be twice that of controls for small dehydrators.

“However, we also expect that the amount of HAP emission reduction for the large dehydrators, in general, to be as much as, or more than, the amount achieved by small dehydrators.” (76 FR 52783).

EPA provides no data to support this claim. API disagrees with this statement, and believes that in general, the emission reductions for dehydrators forced to switch from the 0.9 Mg/yr benzene alternative to 95% control would be considerably less than those achieved by small dehydrators. The cost effectiveness calculated for small dehydrators is based on a 95% reduction from an uncontrolled baseline level. If a large dehydrator has installed controls to meet the 0.9 Mg/yr alternative benzene limitation, the cost effectiveness must be based on the incremental reduction between the existing controls and 95%. EPA has provided no evidence that these incremental reductions would be greater than or equal to the 95% reductions that would be achieved for smaller dehydrators.

This does not even approach a credible analysis that should be considered for any EPA decision, much less a major decision to eliminate the 0.9 Mg/yr benzene alternative emission limitation.

Conclusion for Natural Gas Transmission and Storage MACT. The rationale used by EPA in the preamble to support the removal of the 0.9 Mg/yr compliance alternative for dehydrators at natural gas transmission and storage facilities under 112(f)(2) of the CAA is not supported by any of the background technical documentation and analyses. The high risks that EPA claims will be reduced by removal of the 0.9 Mg/yr benzene alternative are, by EPA's own estimation, dehydrators that are not even subject to the current 0.9 Mg/yr benzene alternative in the regulation. Further, the cost analysis relied upon by EPA to conclude that controls for this option are cost effective does not even pass a “straight-face” test. Therefore, EPA has demonstrated no valid rationale for removing this 0.9 Mg/yr benzene alternative at natural gas transmission and storage facilities. Since there is no justification for removing the 0.9 Mg/yr benzene alternative, EPA must maintain it in subpart HHH.

Further, EPA has no basis under any other CAA authority to remove the 0.9 Mg/yr benzene alternative for large dehydrators at natural gas transmission and storage facilities. Under 112(d)(6), EPA did not identify any developments in practices, processes, or control technologies to further reduce emissions from large dehydrators. EPA already established MACT floors for glycol dehydrators and promulgated these decisions on June 17, 1999 (64 FR 32610), and the rule was not challenged within the statutory period (90 days). Therefore, EPA does not have authority to revisit the floor at this time. Further, since large dehydrators are subject to standards under the existing subpart HHH, they do not represent an “unregulated” emission sources that EPA can address under section 112(d)(2) and (3).

20.2. 90 Day Compliance Time For Large Dehydrators Is Insufficient If The 0.9 Mg/Yr Benzene Compliance Option Is Removed

The proposed regulation only allows a 90 day compliance period for large dehydrators that are currently complying with the 0.9 Mg/yr benzene alternative emission limitation. As discussed above in Section 20.1, EPA's rationale for eliminating the 0.9 Mg/yr benzene limitation is severely flawed. We expect that EPA will restore the 0.9 Mg/yr benzene limitation after consideration of these comments. However, in the unlikely case that EPA does not restore this alternative limitations, EPA must extend the compliance date to the same three year period proposed for newly regulated small dehydrators and storage vessels without the potential for flash emissions.

In the preamble, EPA states the following:

“Without the compliance alternative, affected glycol dehydrators (i.e., those units with annual average benzene emissions of 0.9 Mg/yr or greater and an annual average natural gas throughput of 283,000 scmd or greater) must demonstrate compliance with the 95-percent control requirement, which we believe can be shown with their existing control devices in most cases, although, in some instances, installation of a different or an additional control may be necessary.” (76 FR 52783)

EPA's assertion that existing controls used to comply with the 0.9 Mg/yr benzene alternative emission limitation could achieve compliance with the 95% requirement “in most cases” does not appear to be supported by information or analysis. This clearly was a factor in EPA's decision to only allow 90 days for compliance. However, basic logic would not lead to a conclusion that existing control devices installed to meet the 0.9 Mg/yr benzene limit could also achieve 95% BTEX control. It is logical to assume that owners and operators complying with the 0.9 Mg/yr benzene limitation selected this alternative because it was less costly and less burdensome than complying with the 95% HAP reduction standard. As EPA is aware, the composition of natural gas processed in dehydrators across the county varies considerably. For situations with lower benzene content, the 0.9 Mg/yr emission limitation could be met using controls that achieve less than 95% reduction. While these units are in full compliance with the 0.9 Mg/yr limit, additional controls would need to be added to comply with the 95% standard. The process for evaluating, identifying, selecting, and installing these controls would be the same for these situations as for a small dehydrator previously not subject to any standards. Therefore, the time frame for compliance should also be the same – 3 years.

20.3. Small Dehydrators – The BTEX Emission Limit Is Not Necessary And Should Be Removed

In the preamble for the proposed rule (76 FR 52746), EPA identifies small dehydrators as an unregulated emission source. Therefore, under the authority of section 112(d)(2) and (3), EPA proposed to establish emission standards for small dehydrators in both subpart HH and subpart HHH.

EPA already established MACT floors for glycol dehydrators and promulgated regulatory decisions on June 17, 1999 (64 FR 32610), and the rule was not challenged within the statutory period (90 days). Therefore, EPA does not have authority to revisit the floor at this time and should not promulgate any standards for small dehydrators.

Further, as will be demonstrated below, small dehydrators are already subject to emission standards under the current regulations and therefore, cannot be classified as unregulated emission sources. Given the fact that the 0.9 Mg/yr benzene level serves as both an emission limitation and a threshold separating the two groups of dehydrators, the reality that small dehydrators are subject to standards is not readily apparent. API will demonstrate that this is, in fact, consistent with the original regulatory determinations in 1998/1999.

It is very clear from the language of subparts HH and HHH that dehydrators of any size are subject to the rules:

Subpart HH: §63.760

* * * * *

(b)(1) For major sources, the affected source shall comprise each emission point located at a facility that meets the criteria specified in paragraph (a) of this section and listed in paragraphs (b)(1)(i) through (b)(1)(iv) of this section.

- (i) Each glycol dehydration unit;

Subpart HHH: §63.1270

* * * * *

(b) The affected source is each glycol dehydration unit.

Small dehydrators are clearly subject to rules of general applicability, such as reporting and recordkeeping. They are subject to the general duty in §63.6(e) (as it was in effect at the time the rule was published) relating to good operation and maintenance requirements, effectively imposing a work practice standard on these units, even if no emissions standard actually applies. Section 63.762 also imposes similar work practice requirements on all affected facilities. But, in effect, subparts HH and HHH do impose emissions limitations on all dehydrators.

As shown in Table 20-1, the 0.9 Mg/yr benzene level appears both as a criterion distinguishing small and large dehydrators and as an emission limit for large dehydrators. The effect is that the current regulation actually imposes emission limitations on all dehydrators. This is particularly clear from the fact that small dehydrators must document that the control requirements do not apply to a dehydrator by, in effect, performing an emissions analysis.

This fact was extremely obvious in the original proposal, where EPA stated the following:

“An owner or operator must be able to demonstrate that exemption from control criteria are met when controls are not applied. For example, owners or operators of glycol dehydration units that do not install air emission controls because the benzene emission rate from the unit is less than 0.9 Mg/yr (1 tpy) must be able to demonstrate that the benzene emission rate from the unit is less than 0.9 Mg/yr (1 tpy).” (63 FR 6295, February 6, 1998)

In response to both subparts HH and HHH, many owners and operators installed controls or made process improvements to reduce benzene emissions to less than 0.9 Mg/yr benzene. In some of these situations, the dehydrators are subject to the control device, testing, and monitoring provisions in

subpart HH or HHH, while in other situations owners and operators obtained permit conditions to limit their benzene emissions below 0.9 Mg/yr. In all these cases, the benzene emissions were reduced to achieve a level below 0.9 Mg/yr. For example, an API member company operates a glycol dehydrator at a major source production facility in Texas with an actual average annual natural gas flow rate of 570,000 SCMD (20 MMSCFD). Emissions are reduced by a condenser, followed by a flare. The facility complies with the provisions in §63.765(b)(1)(ii) to reduce benzene emissions to less than 0.9 Mg/yr. The facility has a state federally enforceable permit condition limiting the benzene emissions less than 0.9 Mg/yr. The facility also complies with the associated testing, monitoring, recordkeeping, and reporting requirements under subpart HH. Another example is an API member company glycol dehydrator at a production facility in Colorado. Emissions are reduced by a condenser, followed by a flare. The facility complies with the provisions in §63.765(b)(1)(ii) to reduce benzene emissions to less than 0.9 Mg/yr. The facility has a state federally enforceable permit condition limiting the benzene emissions less than 0.9 Mg/yr. The facility also complies with the associated testing, monitoring, recordkeeping, and reporting requirements under subpart HH.

In many situations, the benzene emissions without any controls may be less than 0.9 Mg/yr. For example, an API member facility in the Barnett Shale contains several dehydrators that treat a very dry east Barnett Shale gas with a VOC content of around 0.25 mole% (0.63 weight %) and a benzene content of around 10 ppm. The uncontrolled emissions from each of these units, which process over 500,000 SCMD (18 MMSCF), are only around 0.13 tpy benzene and 0.36 tpy total BTEX. As described above in the excerpt from the 1998 preamble, in such situations owners and operators would be required to “*demonstrate that the benzene emission rate from the unit is less than 0.9 Mg/yr (1 tpy).*”

Therefore, in reality, the 0.9 Mg/yr represents an emission limit to which every facility is subject, thus meaning there are no “unregulated” dehydrators.

In the original proposal and promulgation of subparts HH and HHH (February 5, 1998 and June 17, 1999, respectively), EPA was not consistent in the discussion of subcategorization and MACT floors for glycol dehydrator vents. In the preamble for the promulgated rule (June 17, 1999), EPA states the following:

To determine the MACT floor, the EPA divided glycol dehydration units into two sizes: (1) small glycol dehydration units with actual annual average natural gas throughputs less than 85 thousand m³/day or with actual average benzene emissions less than 0.90 Mg/yr, and (2) large glycol dehydration units with actual annual average natural gas throughputs equal to or greater than 85 thousand m³/day or with actual average benzene emissions equal to or greater than 0.90 Mg/yr. For small glycol dehydration units, the EPA determined that the MACT floor was no control and that it was not cost effective to select a regulatory alternative beyond the floor. For large glycol dehydration units, the EPA reviewed the information that was available to develop a MACT floor (a detailed discussion of the development of the MACT floor can be found in the docket, Air Docket A-94-04). (64 FR 32613)

However, examination of the MACT floor technical memorandum^{vv} does not indicate that there was any consideration given to different sizes of dehydration units. In fact, the memorandum states the following:

Therefore, the determination of the MACT floor level of control for glycol dehydration units in this analysis is based on the data reported for all glycol dehydration units from the company responses to the four Air Emission Survey Questionnaires.” (p. 6).

Similarly, the proposed preamble made it clear that the MACT floor determination was not limited to large dehydrators –

The MACT floor for all process vents at glycol dehydration units . . . (63 FR 6304, underline added).

Further, while EPA's terminology was inconsistent, EPA recognized that the proposed and promulgated standards did subject all glycol dehydrators to standards. The 0.9 Mg/yr threshold/emission limit recognized and rewarded compliance via more environmentally friendly and cost effective process modifications and pollution prevention measures. However, it was clear that EPA was not totally exempting dehydrators below 0.9 Mg/yr benzene from the responsibility to maintain emissions below this level and demonstrate compliance with this alternative.

“For example, owners or operators of glycol dehydration units that do not install air emission controls because the benzene emission rate from the unit is less than 0.9 Mg/yr (1 tpy) must be able to demonstrate that the benzene emission rate from the unit is less than 0.9 Mg/yr (1 tpy). In general, the selected exemption criteria minimize the demonstration burden on owners and operators.” (63 FR 6295)

Therefore, EPA must consider the proposed limit for small glycol dehydrators as an adjustment to the existing limit under the authority of § 112(d)(6). As such, if EPA intends to promulgate these provisions, the Agency must first re-propose these provisions and justify the proposal as “necessary (taking into account developments in practices, processes, and control technologies).” This must include consideration of the naturally occurring variability in gas compositions, the variable throughput of dehydrators in this sector, and the resulting variation in dehydrator emissions and cost effectiveness of control.

EPA estimated the cost effectiveness of the proposed small dehydrator standards to be \$8,360/Mg HAP (76 FR 52768). While this EPA cost effectiveness is high, API maintains that this cost effectiveness analysis significantly underestimates the cost effectiveness of many dehydrators. This is primarily due to the fact that EPA did not account for the naturally occurring variability in HAP content in natural gas streams that would be covered by the proposed small dehydrator standards. Table 20-3 was generated from GRI-GLYCalc runs using a range of dehydrator operating throughputs and actual gas compositions (furnished by API member companies); and EPA's

^{vv} Memorandum. From Graham Fitzsimons and George Viconovic, EC/R Inc. to Martha Smith, EPA/WCPG. “Recommendation of MACT Floor Levels for HAP Emission Points at Major Sources in the Oil and Natural Gas Production Source Category.” September 23, 1997. (Docket A-94-04, Item Number II-A-7)

annualized cost of control for dehydrators from Table 3-7 of the proposal RIA.^{ww} Unless noted, these examples reflect actual dehydrators in operation with their actual throughputs and gas compositions. More detail on these calculations is provided in Attachment P, which is incorporated in these comments by reference.

Table 20-3. Cost Effectiveness for Compliance with Proposed Small Dehydrator Emission Limitation at Oil and Gas Production Facilities

¹Annualized Cost from page 3-26; Table 3-7 of RIA; with control % above ~20% the only viable option is to use a combustion device which is the basis for the Table 3-7 cost. Hence, the control cost does not go down with incrementally lower control %.

²For sites with no BTEX and undefined BTEX control % the control cost uses total emissions for species present.

As can be seen in Table 20-3, the cost effectiveness at the small dehydrator threshold ranges from \$152,000,000/ton-HAP to \$6,638/ton-HAP with most of the costs evaluated being substantially

^{ww} Regulatory Impact Analysis. Proposed New Source Performance Standards and Amendments to the National Emissions Standards for Hazardous Air Pollutants for the Oil and Natural Gas Industry – U.S. Environmental Protection Agency, Office of Air and Radiation, Office of Air Quality Planning and Standards Research Triangle Park, NC 27711. July 2011. (Docket Item EPA-HQ-OAR-2010-0505-0075)

greater than EPA's estimate. These unreasonable costs occur for low BTEX content (San Juan Basin Coal Bed Methane) gasses regardless of throughput; moderate BTEX content (Haynesville shale) gasses with relatively high throughputs; and high BTEX content (Green River Basin Tight Sand) gasses with low throughputs (which are common in the Green River Basin). Obviously most of the illustrated control costs far exceed any reasonableness test and EPA cannot possibly justify the proposed requirements as a beyond the floor option with knowledge of these values. The situation for dehydrators in service for gas streams without any BTEX content (at a detection limit of 1 ppmv) becomes even more untenable and unreasonable. As defined in the proposed rule, these dehydrators would be classified as "small" and subject to application of "Equation 1" to determine allowable emissions. Application of "Equation 1" results in zero allowable emissions of BTEX. With the likely prospect of BTEX at some concentration lower than normal gas analysis detection limits this outcome essentially imposes 100% control requirements on dehydrators with almost zero potential for HAP emissions and almost infinite control costs. Obviously this is an unreasonable and likely technically unachievable requirement and must be corrected.

In conclusion, both subpart HH and subpart HHH, as currently promulgated, impose emission limitations on all glycol dehydrators. Therefore, these small dehydrators cannot be considered unregulated sources and EPA does not need to develop emission standards for the small dehydrators under CAA section 112(d)(2) and (3). In fact, since EPA already established MACT floors for all glycol dehydrators and promulgated these decisions on June 17, 1999 (64 FR 32610), and the rule was not challenged within the statutory period (90 days), EPA does not have authority to revisit the floor determinations at this time. EPA's proposed scheme for regulation of "small" dehydrators requires control on all dehydrators regardless of emissions or potential for emissions and results in completely unreasonable control costs for a wide range of gas compositions and throughputs. Further, as shown above, if EPA elects to move forward to propose separate standards for small dehydrators, such standards must be shown to be "necessary" in light of the factors specified in § 112(d)(6).

20.4. If EPA Moves Forward With Standards for Small Dehydrators, They Must Account for Fundamental Differences in Naturally Occurring Inlet Gas Concentrations and Dehydrator Design

As noted above, API does not believe that a separate standard is justified for small dehydrators. However, if EPA decides to move forward with standards for small dehydrators, they must not promulgate the proposed standards, as they are not technically and legally sound.

Subpart HH Proposed Equation 1 Would Require Over 90% Of The "Best Performing" Dehydrators To Install Additional Control. The severe flaws in EPA's small dehydrator floor analysis, derived equation 1, and control approach to calculate dehydrator-specific BTEX emission limitations are clearly illustrated by the application of Equation 1 to the 11 dehydrator units used by EPA for the MACT floor analysis for subpart HH. Table 20-4 illustrates the flawed construct by applying the proposed equation for subpart HH to the specific dehydrators making up the "top 12%" in EPA's MACT floor dataset.

Table 20-4. Application of Subpart HH Proposed Equation 1 for Small Dehydrators to MACT Floor Oil and Natural Gas Production Small Dehydrators

| Unit ID No. | Legacy Docket A-94-04, Docket ID No. | No of Units | Control at Baseline? | BTEX Inlet Conc (ppmv) | Throughput (SCMD) Per Dehy Unit | BTEX Emissions at Baseline (Mg/yr) | Equation 1 Allowable BTEX Emission (Mg/yr) | Control % to meet proposed equation |
|-------------|--------------------------------------|-------------|----------------------|------------------------|---------------------------------|------------------------------------|--|-------------------------------------|
| A | II-D-10, pg 55 | 1 | Y | 116 | 17,556 | 0.0036 | 0.0477 | n/a |
| B | II-D-09, pg 182 | 1 | N | 69 | 566,338 | 0.9979 | 0.9157 | 8.2% |
| C | II-D-19, pg 73 | 5 | Y | 60 | 45,307 | 0.0762 | 0.0637 | 16.4% |
| D | II-D-19, pg 21 | 1 | N | 140 | 99,109 | 0.5443 | 0.3251 | 40.3% |
| E | II-D-10, pg 115 | 1 | N | 39 | 42,475 | 0.0907 | 0.0388 | 57.2% |
| F | II-D-19, pg 41 | 1 | N | 308 | 29,450 | 0.8165 | 0.2125 | 74.0% |
| G | II-D-19, pg 39 | 1 | N | 5 | 45,307 | 0.0181 | 0.0053 | 70.7% |

As can be seen in Table 20-4, only one of the 11 dehydrators that were used to calculate the MACT floor for small dehydrators in the oil and natural gas production source category can meet the proposed standard without the installation of additional controls. This would mean that the equation represents the average emission limitation achieved by best performing 1% of the dehydrators, not the best performing 12%. This obviously does not represent a legitimate MACT floor. Rather, the equations represent a beyond-the-floor level of control that EPA has not contemplated nor justified.

Proposed Small Dehydrator Equations Are Only Sensitive to BTEX Inlet Concentration. API believes the absurd results from application of the proposed Equation 1 to small dehydrators are an outcome of the floor analysis EPA conducted and erroneous conclusions reached that led to the Equation 1 construct. This construct is inherently flawed. Despite EPA’s inclusion of a throughput variable in the equations, the net effect is that the equations are only sensitive to the BTEX concentration (ppmv) in the inlet gas stream. Therefore, throughput or potential emissions have no effect on the control efficiencies required to meet the calculation emission limitation. This artifact is illustrated by the analysis summarized in Table 20-5, which clearly shows the Equation 1 outcome to be sensitive only to BTEX inlet concentration from the perspective of required control percentage. More details on this analysis are provided in Attachment Q.

Table 20-5. Illustration of Sensitivity of the Proposed Subpart HH Proposed Equation 1 for Small Dehydrators to Throughput Rates

| Facility Name/Throughput (in MMSCFD) | Inlet BTEX Content ppmv (Ci, BTEX) | Throughput SCMD | Uncontrolled BTEX (tpy) | BTEX Emissions Allowed by Equation (tpy) | Control % to meet proposed equation (BTEX) | HAPS \$ ¹ /Ton | BTEX \$ ¹ /Ton |

¹Annualized Cost of \$30,409 from page 3-26; Table 3-7 of RIA.

²100 MMSCFD is about the maximum throughput limit for a dehydration system.

The Proposed Requirements Do Not Account For The Naturally Occurring Differences In HAP/BTEX In The Gas Being Treated In The Dehydrators. As shown above, the proposed small dehydrator equations are only sensitive to BTEX concentration. In addition, another fundamental problem with the proposed equations is the failure to account for situations where the very gas being treated contains very low levels of BTEX. Unlike processes where owners and operators have some ability to adjust raw materials to impact emissions, operators of dehydrators at oil and gas production and natural gas transmission and storage sites must deal with the naturally occurring composition of the natural gas. The proposed requirements would cover ALL dehydrators without regard to the inlet gas composition, throughput, or potential emissions. In other words, the propose approach for small dehydrators require controls in situations where the emissions rate is not a result of some kind of controllable circumstance, like emissions controls or affirmative choices as to raw materials.

Table 20-3 illustrated how this coverage of all dehydrators at oil and gas production sites results in unreasonable control scenarios. Further, Table 20-5 shows that the proposed subpart HH equation results in higher required control efficiencies for lower BTEX concentration streams. For example, the proposed rule would require a 94% reduction in BTEX emissions for a 10 MMSCFD dehydrator in the North San Juan Basin with inlet BTEX concentration of 0.9 ppmv and uncontrolled BTEX

emissions of 0.011 tpy. A similarly sized dehydrator in the Haynesville Shale with an inlet BTEX concentration over 85 times higher, and uncontrolled BTEX emissions over 4 times higher, would only be required to reduce BTEX emissions by 76.5%.

If EPA elects to pursue the development of standards for small dehydrators, API offers the following two suggestions for moving forward with standards that are both technically sound and legally defensible: (1) subcategorize small dehydrators appropriately and develop MACT floors for each subcategory and (2) identify de minimis emission levels for dehydrators with insignificant emission levels.

20.4.1. EPA Must Properly Subcategorize Small Dehydrators and Establish Legal and Technically Feasible Standards

The analyses discussed above demonstrate that EPA has not properly subcategorized or otherwise appropriately accounted for fundamental differences among small dehydrators in determining the “classes, types, and sizes” of sources to be regulated. The record clearly shows that the cost of controlling HAP emissions from small dehydrators varies considerably, depending on such factors as concentration of HAP/BTEX in the inlet gas, throughput, and the type and efficiency of control measures. While EPA has attempted to account for some of these factors in the form of the equation-based standard, the cost data described above in Tables 20-3 and 20-5 (which show that the cost of compliance for certain classes of small dehydrators will be inordinate) prove that the form of the standard fails to properly accommodate certain classes of small dehydrators. EPA has ample authority to further subdivide the population of small dehydrators to make sure the standard reasonably fits each affected dehydrator. *See Sierra Club v. EPA*, 479 F.3d 875, 885 (D.C. Cir. 2007) (Williams concurring) (“[O]ne legitimate basis for creating additional subcategories must be the interest in keeping the relation between “achieved” and “achievable” in accord with common sense and the reasonable meaning of the statute.”). In the face of the cost data showing inordinate impacts on certain small dehydrators, the Agency’s failure to consider alternative groupings of small dehydrators is arbitrary and capricious.

EPA recognized differences in emission potential based on factors such as inlet BTEX concentration and throughput, as evidenced by the attempt to develop an equation to adjust the emission limitation based on these factors. However, as proven above, this approach was entirely insufficient. The proposed subcategorization scheme and resulting equations would require controls on every dehydrator, no matter how low the natural BTEX level or the potential dehydrator emissions. That is not the CAA’s intent of an emission “floor.”

API examined EPA’s small dehydrator dataset^{xx} to evaluate potential subcategorization and MACT floor options. Table 20-6 illustrates EPA’s small dehydrator dataset sorted by uncontrolled BTEX emissions.

^{xx} Memorandum. ¹ Emissions from these dehydrators were identified as controlled. A control efficiency of 98% was assumed to calculate the uncontrolled emissions.

If the outliers created by applying an assumed 98% control efficiency to the controlled streams are not considered (this assumption resulted in uncontrolled BTEX emissions of 125 tpy, 375 tpy, and 2,965 tpy), the data do show some expected outcomes. For example:

- The average emissions for the 25% lowest inlet BTEX concentrations are 2.5 tpy BTEX and 0.2 tpy benzene, while the remaining 75% have average emissions of just over 5 tpy BTEX and 1.2 tpy benzene.
- The BTEX emissions for the lowest 25% of the throughputs average 3 tpy, while the BTEX emissions for the remaining 75% of the data set with higher throughputs average over 5 tpy.

However, the average benzene emissions from the lowest 25% throughput dehydrators (1.3 tpy) are actually higher than the average benzene emissions for the higher throughput dehydrators (0.8 tpy).

Evaluation of all the data show a slight correlation between BTEX emissions and inlet BTEX concentration ($R^2 = 0.2$), but the data show a decrease in BTEX emissions with increasing throughput.

In conclusion, this cursory analysis of EPA's dataset (see Attachment R) indicates that neither inlet BTEX concentration or dehydrator throughput have a sufficient correlation with emissions to further break small dehydrators into technically and legally sound subcategories based only on these characteristics.

Therefore, API recommends that an uncontrolled emissions threshold be established to subcategorize small dehydrators. Given the large number of variables that impact emissions from dehydrators, emissions are the most relevant and comprehensive indicator of differences in dehydrator class, type, and size.

Further, EPA has already established the appropriate threshold for this subcategorization – 0.9 Mg/yr (1 tpy) benzene. During the original development of subparts HH and HHH, EPA established this 0.9 Mg/yr level “for owners or operators of facilities with low BTEX concentrations in the natural gas”^{YY}. Therefore, API recommends that the small dehydrator subcategory for oil and natural gas production (subpart HH) be separated into (1) those dehydrators with uncontrolled average benzene emissions less than 0.9 Mg/yr and (2) those dehydrators with uncontrolled average benzene emissions of 0.9 Mg/yr or greater and actual annual average flow rates less than 85,000 SCMD. For natural gas transmission and storage, these subcategories are (1) those dehydrators with uncontrolled average benzene emissions less than 0.9 Mg/yr and (2) those dehydrators with uncontrolled average benzene emissions of 0.9 Mg/yr or greater and actual annual average flow rates less than 283,000 SCMD.

Once the subcategories are established, EPA must then determine MACT floors for each subcategory. EPA's dataset available in the docket does not include sufficient levels of detail to fully evaluate process variations or other factors that influence emissions. More importantly, there is no way that EPA can determine whether any simple “floor” level calculated from these data can be achievable by all dehydrators in the subcategory. This is especially germane in this situation where many aspects that impact emissions are not under

^{YY} National Emission Standards For Hazardous Air Pollutants For Source Categories : Oil And Natural Gas Production And Natural Gas Transmission And Storage - Background Information For Final Standards: Summary Of Public Comments And Responses. EPA-453/R-99-004b. May 1999.

the control of the owner or operator. However, the owner or operator can ensure that the dehydrator is operated in a manner to reduce emissions to the maximum extent possible without add-on controls by optimizing the glycol circulate rate. This practice is already recognized as an effective method by EPA and is required by §63,764(d)(2) for area source dehydrators not located within an urbanized area (UA) plus offset and urban cluster (UC) boundary, as defined in §63.761 of subpart HH.

This is a clear example of the type of “design, equipment, work practice, or operational standard, or combination thereof,” standard allowed under section 112(h) of the CAA. To establish standards under the authority of 112(h), the CAA requires EPA to establish that:

- (A) a hazardous air pollutant or pollutants cannot be emitted through a conveyance designed and constructed to emit or capture such pollutant, or that any requirement for, or use of, such a conveyance would be inconsistent with any Federal, State or local law, or
- (B) the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.

In many situations, the emissions from these low-emitting dehydrators are below the detection limit of prescribed test methods. This clearly meets the criteria in paragraph (B) above, justifying the establishment of standards that require the optimization of glycol circulation rate to reduce emissions.

As dehydrator emissions increase (i.e., are above 0.9 Mg/yr), the ability to effectively control increases and differences in inlet BTEX concentration, throughput, and other variables are less critical. Therefore, API believes it is technically valid and legally defensible to determine the MACT floor for those small dehydrators with uncontrolled benzene emissions of 0.9 Mg/yr or greater.

For oil and natural gas production, the average of the lowest 5 emitting dehydrators (since there are less than 30 dehydrators in the data set for the subcategory) is 4 tpy BTEX. For natural gas transmission and storage, there is only one dehydrator in the dataset with benzene emissions of 1 tpy or greater, and the BTEX emissions for this dehydrator are 5.5 tpy.

In summary, API offers the recommendations shown in Table 20-7.

Table 20-7. Recommended Subcategories and Standards for Small Dehydrators

| Recommended Dehydrator Subcategory | Recommended MACT Floor/Standard |
|---|---|
| Oil and Natural Gas Production | |
| Dehydrators with uncontrolled benzene emissions less than 0.9 Mg/yr | Optimize glycol circulation rate in accordance with §63,764(d)(2) |
| Dehydrators with uncontrolled benzene emissions of 0.9 Mg/yr or greater and actual annual average flow rates of less than 85,000 SCMD | BTEX Emissions < 3.6 Mg/yr or 95% reduction ¹ |
| Natural Gas Transmission and Storage | |
| Dehydrators with uncontrolled benzene emissions | Optimize glycol circulation rate in accordance |

| | |
|--|--|
| less than 0.9 Mg/yr | with §63.764(d)(2) |
| Dehydrators with uncontrolled benzene emissions of 0.9 Mg/yr or greater and actual annual average flow rates of less than 283,000 SCMD | BTEX Emissions < 5.0 Mg/yr or 95% reduction ¹ |

¹ A mass emissions limit imposes complicated and costly compliance and recordkeeping obligations when contrasted with a control efficiency standard. Therefore, API recommends that small dehydrators have the option to comply with 95% control requirements for large dehydrations in §63.765(b) as an alternative to complying the mass emission limitations determined by the equation. API believes that EPA should welcome this option, which would result in greater emission reduction for a lower burden.

If EPA does not decide to adopt API’s recommendations noted above, they must, at a minimum, revisit the proposed subcategorization and MACT floor decisions, which as was clearly shown above, do not meet their statutory-mandated requirements. EPA must then re-propose their updated evaluations and standards.

20.4.2. Dehydrators With No/Low Emission Potential Should Be Considered De Minimis

In MACT standards, EPA has routinely identified equipment with such low HAP emission potential that they should not be regulated.

As was shown in the real-world examples provided in Tables 20-3, 20-4, and 20-5, there are situations across the country where the natural gas being treated in dehydrators has such low benzene, BTEX, and HAP that the emissions will be trivial. API recommends that EPA establish de-minimis levels of HAP emissions that would exempt small dehydrators from all requirements under subparts HH and HHH.

In Alabama Power, the District of Columbia Circuit held that EPA could exempt de minimis sources of air pollution from the requirements of the Clean Air Act (See Alabama Power Co. v. Costle, 636 F.2d 323, 360 (D.C.Cir.1979)).

Glycol dehydrators are a clear example of where the establishment of a de minimis threshold is warranted. API insists there is a strong justification for such a threshold in the oil and natural gas production and natural gas transmission and storage source categories due to the naturally occurring differences in gas composition across the United States and thus, varying differences in dehydrator input stream HAP concentrations, throughputs, and in emissions.

API is recommending that EPA adopt a lower bound threshold below which dehydrators would not be subject to standards. As discussed above, the inlet composition of gas entering the dehydrator is not a stand-alone determiner of HAP emissions. However, situations where the inlet stream contains no BTEX should be exempt from regulation. In addition, API recommends that EPA establish a de minimis emission level. Owners and operators can document their emission level by using GRI-GLYCalc™ or another acceptable emission estimation method. Further, API recommends that this de minimis level be 0.5 Mg/yr total uncontrolled BTEX emissions.

20.5. EPA’s Proposed Equation Does Not Reflect the MACT Floor Determined

As discussed above, API does not believe that any new standards are required for small dehydrators. Further, as also discussed above, if EPA does elect to pursue standards for small dehydrators they must (1) establish reasonable and legal subcategories and promulgate standards reflecting the MACT floor for each subcategory and (2) establish de minimis thresholds to exempt dehydrators with insignificant emissions.

In the event that EPA chooses to continue with the proposed subcategorization approach (which, as clearly demonstrated above, is unlawful and technically unjustified), EPA must make changes to the proposed equations. In short, the BTEX emission limit equation for small dehydrators should not go to zero. For small dehydrators in the oil and natural gas production source category (subpart HH), EPA determined a MACT Floor of 0.286 tpy BTEX. For small dehydrators in the natural gas and production source category (subpart HHH), EPA determined a MACT floor of 1.45 tpy BTEX. However, the equations proposed in the rules approach a mass limit of zero.

This was undoubtedly an inadvertent error by EPA in the proposed equation, as it does not represent the MACT floor calculated. The equation would give the intended result if the product of Throughput and Concentration ($C_{i,BTEX}$) were assigned a lower bound, as shown below. This correction to the equation would result in a minimum emission limit of 0.286 tpy BTEX for oil and natural gas production and 1.45 tpy BTEX for natural gas transmission and storage (i.e., the MACT floors), rather than 0.

For Equation 1 in subpart HH:

$$EL_{BTEX} = (1.10 \times 10^{-4})(\text{Throughput})(C_{i,BTEX})(365 \text{ day/yr})(1 \text{ Mg}/10^6 \text{ g})$$

where:

$$EL_{BTEX} = \text{Unit-specific BTEX emission limit (Mg/yr)}$$

$$1.10 \times 10^{-4} = \text{BTEX emission limit (g BTEX}/(\text{standard m}^3 - \text{ppmv}))$$

$$\text{Throughput} = \text{annual average daily natural gas throughput (standard m}^3/\text{day)}$$

$$C_{i,BTEX} = \text{BTEX concentration of the natural gas at the inlet to the glycol dehydrator unit (ppmv)}$$

If:

$$\underline{(\text{Throughput})(C_{i,BTEX}) < 6.46 \times 10^6 (\text{standard m}^3 - \text{ppmv})/\text{day},}$$

then set:

$$\underline{(\text{Throughput})(C_{i,BTEX}) = 6.46 \times 10^6 (\text{standard m}^3 - \text{ppmv})/\text{day}.}$$

For Equation 1 in subpart HHH:

$$EL_{BTEX} = (6.42 \times 10^{-5})(\text{Throughput})(C_{i,BTEX})(365 \text{ day/yr})(1 \text{ Mg}/10^6 \text{ g})$$

where:

EL_{BTEX} = Unit-specific BTEX emission limit (Mg/yr)

6.42×10^{-5} = BTEX emission limit (g BTEX/(standard m^3 – ppmv))

Throughput = annual average daily natural gas throughput (standard m^3 /day)

$C_{i,BTEX}$ = BTEX concentration of the natural gas at the inlet to the glycol dehydrator unit (ppmv)

If:

$$(\text{Throughput})(C_{i,BTEX}) < 5.61 \times 10^7 \text{ (standard } \text{m}^3 \text{ – ppmv)/day,}$$

then set:

$$(\text{Throughput})(C_{i,BTEX}) = 5.61 \times 10^7 \text{ (standard } \text{m}^3 \text{ – ppmv)/day.}$$

A mass emissions limit imposes complicated and costly compliance and recordkeeping obligations when contrasted with a control efficiency standard. Therefore, API recommends that small dehydrators have the option to comply with 95% control requirements for large dehydrations in §63.765(b) as an alternative to complying the mass emission limitations determined by the equation. API believes that EPA should welcome this option, which would result in greater emission reduction for a lower burden.

If EPA's proposed equation were to be promulgated, it represents a level of control beyond the MACT floor. This is clearly demonstrated above in Table 20-4, as the proposed equation for subpart HH would result in every dehydrator in the top 12% of the dataset, save one, to install controls. EPA estimates that the incremental cost effectiveness of beyond the floor controls to be \$167,200/Mg for oil and gas production small dehydrators (40 FR 52768) and \$33,000/Mg for natural gas transmission and storage small dehydrators (40 CFR 52769). In both cases, EPA clearly stated that they did not believe these cost effectiveness values were reasonable. If EPA does not adjust the equations in accordance with the above suggestions, then they are in effect accepting these unreasonable cost effectiveness values. API does not believe this is justified and maintains that EPA must not promulgate the equations as proposed.

20.6. Clarification of Terminology

API maintains that the following changes are needed to clarify terminology related to glycol dehydrators.

20.6.1. Boiler Definition

In the NESHAP boiler definition, the rule must clarify that glycol reboilers are not boilers.

§63.761

Boiler means an enclosed device using controlled flame combustion and having the primary purpose of recovering and exporting thermal energy in the form of steam or hot water. Boiler also means any industrial furnace as defined in 40 CFR 260.10. [This definition excludes line heaters and glycol reboilers.](#)

20.6.2. Glycol System Condensers are not Control Devices

EPA uses the term “condenser” multiple times in the rule when describing control devices and requirements. It is not uncommon for a condenser on a dehydrator vent stream to precede a flare or other combustion device. A key purpose of this condenser is to remove water vapor. Since the 95% HAP emission reduction is met by the flare or combustion device, it is not reasonable to consider the condenser as a control device in this situation and require all the associated monitoring, recordkeeping, and reporting requirements. We therefore, request that only condensers that are the final control device, or condensers used to help achieve the 95% control efficiency, be classified as control devices. We ask that EPA clarify that condensers which are part of a glycol system prior to a control device should not be considered control devices.

21. PRODUCED WATER EVAPORATION PONDS

EPA solicited comments on several questions regarding produced water evaporation ponds in the Preamble. EPA stated, “*We believe that produced water ponds are also a potentially significant source of emissions, but we have only limited information. We, therefore, solicit comments on produced water ponds...*”

It is wrong for EPA to conclude that produced water ponds are “a potentially significant source of emissions,” especially based on their statement that “limited information” is available. In fact, there is no information to date indicating that produced water ponds are significant emission sources. The appropriate method for determining potential impacts is to rely on a valid scientific approach to addressing the concern. Preferably that would include determining what information is available, evaluating available data to determine data gaps, developing a plan to fill data gaps, and evaluating the updated data set. With that in mind, industry is open to cooperating with EPA in an appropriate manner to address their concerns.

Here are the questions that EPA included and our responses.

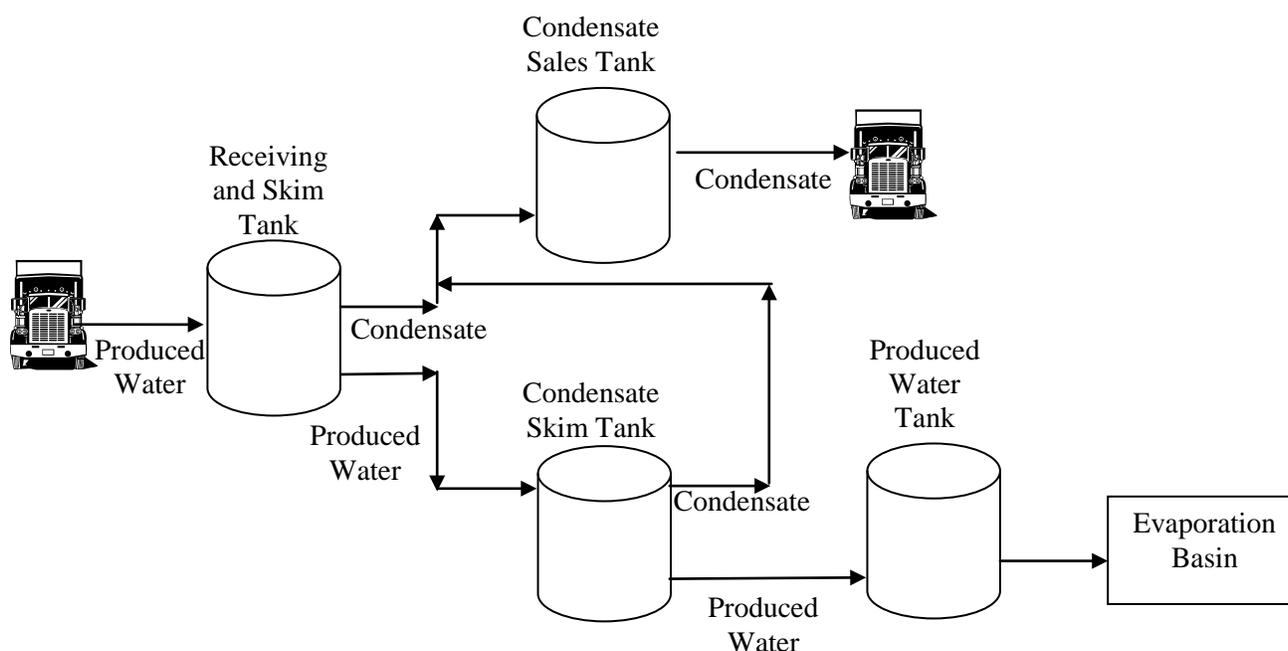

(a) We are requesting comments pertaining to methods for calculating emissions. The State of Colorado currently uses a mass balance that assumes 100 percent of the VOC content is emitted to the atmosphere. Water9, an air emissions model, is another option that has some limitations, including poor methanol estimation.

Any model used for calculating emissions will depend upon valid input data. All inputs must be confirmed, subjected to quality analysis, sensitivity tested, and validated. Initial input VOC concentrations to ponds, local climatic conditions, biodegradation potential, sorption to solids and other parameters must be properly determined through process examination or measurement.

The Endangered Species Act strictly limits the amount of hydrocarbons that can be on an unnetted pond. Consequently, evaporation pond operators are very sensitive to the existence of hydrocarbons on/in a pond

and they take extensive steps to prevent them. Typically, oil /condensate and water are separated initially at the wellhead with a three phase separator. Then the produced water enters a tank. Any oil or condensate entrained in the produced water then separates out in the produced water tank. Trucks are used to vacuum the oil or condensate from the top of the tank. The produced water is then trucked to the evaporation pond facility. There additional separation is done using a series of skim oil tanks as shown below. The produced water then enters the evaporation pond. Hydrocarbon emissions from the evaporation ponds are minimized since almost no separate phase hydrocarbon remains in the produced water placed into the evaporation ponds.

Figure 20-1. Process Flow for Produced Water To Evaporation Basins

As far as estimating emissions, WATER9 is the only EPA approved method for calculating emissions from evaporation basins. The assumptions in this model are quite conservative and tend to overestimate emissions, not underestimate emissions. Assuming 100% of VOCs in the water enter the atmosphere is a completely false assumption that ignores the fate and transport of various chemicals. Many chemicals, like methanol, have a very high affinity for water and do not evaporate. Also, many chemicals, like methanol, can only be removed from water using biodegradation. EPA's "Measurement of Emissions from Produced Water Ponds: Upstream Oil and Gas Study #1"^{ZZ} found minimal emissions from the evaporation ponds.

The Office of Pollution Prevention and Toxics of the U.S. Environmental Protection Agency (EPA) acknowledges that "most methanol is removed from water by biodegradation"^{AAA}. The Hazardous Substances Data Bank of the National Library of Medicine says that aquatic hydrolysis, oxidation, and

^{ZZ} <http://www.epa.gov/nrmrl/pubs/600r09132/600r09132.pdf>

^{AAA} United States Environmental Protection Agency, Office of Pollution and Toxics. *Chemical Summary for Methanol, Report No. EPA749-F-94-013a*. United States Environmental Protection Agency, August 1994.

photolysis are not significant fate processes for methanol^{BBB}. Additionally, in 1999, Malcolm Pirnie conducted a study for the American Methanol Institute called "Evaluation of the Fate and Transport of Methanol in the Environment"; part of this study included reviewing the losses of methanol in water. Malcolm Pirnie found that the dominant loss mechanism was biodegradation^{CCC}. According to a 1991 study "The reported half-life of methanol in surface waters under aerobic conditions is short and has been reported to be as low as 24 hours^{DDD}". In fact, the half-life of methanol even in anaerobic conditions is from 1 to 5 days^{EEE}.

Since methanol is very polar and stable in water, hydrolysis does not contribute significantly to methanol removal from bodies of water. Photolysis is not a significant contributor to methanol degradation either since methanol does not absorb light in the visible spectrum and long wavelength UV. Methanol does, however, absorb very short wavelength ultra violet (UV), which is present in negligible amounts in solar radiation. "In addition, methanol can be naturally oxidized by hydroxyl radicals formed in the water by the photolysis of nitrate, nitrite, and hydrogen peroxide resulting from reactions with excited humic material or from the reaction with H₂O₂ with Fe(II)"^{FFF}.

Bioaccumulation in aquatic organisms is expressed in bioconcentration factors (BCF). The bioaccumulation in solids and organic materials is expressed as the octanol-water coefficient. The BCF and octanol-water partition coefficient for methanol, as represented in the Malcolm Pirnie study, was less than ethanol and significantly less than for benzene. Thus the bioaccumulation of methanol is fairly low. Further, since methanol has a low partition air/water coefficient and a rate of biodegradation that exceeds the rate of volatilization, volatilization is not a primary source of methanol losses either. The half-life of methanol from volatilization is 60 days in comparison to 24 hours for biodegradation^{GGG}. This comparison leads to the conclusion that the most of the methanol losses in water are from biodegradation.

The EPA WATER9 model considers biodegradation, bioaccumulation of solids and organic materials, and volatilization of chemicals in water. Since photolysis is not a significant contributor to methanol losses, WATER9 is an acceptable tool to use to estimate methanol emissions to air from wastewater. WATER9 predicts that the emissions of methanol decrease as temperatures increase. The phenomenon occurs because biodegradation increases with temperature, leaving less material to volatilize. Additionally, volatilization is much slower than biodegradation for methanol. Enviromega determined that WATER8 (the predecessor to WATER9) predicted methanol emissions at a relatively high rate because the biorate coefficient was

erroneously assumed low relative to the stripping coefficient^{HHH}. Later, Enviromega was retained by a large manufacturing association to estimate the biodegradation rate coefficient for methanol using a version of 40 CFR 63, Appendix C, Method 304. First order biodegradation rate coefficients were estimated by Enviromega. The biorate coefficients for methanol determined by this study were two orders of magnitude higher than in the WATER8 model. The Monod first order biodegradation rate from their study was -32.6 L/g-h at 22°C and in WATER8 it is only -0.2 L/g-h^{III}. The table below summarizes the findings from Enviromega's study.

Comparison of Methanol First Order Biodegradation Rate Coefficients

| Compound | Initial MeOH Con. (mg/L) | No. of Data Points | K ₀ (mg/L-min.) | r ² | Monod Parameters | | | |
|----------|--------------------------|--------------------|----------------------------|----------------|-------------------------------|-----------------------|-------------------------------|-----------------------|
| | | | | | Montheith Study | | WATER8 | |
| | | | | | K _{max} (mg/g VSS-h) | K _s (mg/L) | K _{max} (mg/g VSS-h) | K _s (mg/L) |
| Methanol | 20 | 6 | -0.185 | 0.988 | -11.08 | 0.34 | -18 | 90 |
| | 15 | 5 | -0.365 | 0.909 | | | | |
| | 10 | 5 | -0.246 | 0.870 | | | | |
| | 5 | 4 | -0.236 | 0.694 | | | | |
| Ethanol | 20 | 5 | -0.117 | 0.974 | -6.14 | 0.36 | -8.8 | 9.8 |
| | 15 | 5 | -0.168 | 0.944 | | | | |
| | 10 | 4 | -0.137 | 0.940 | | | | |
| | 5 | 4 | -0.121 | 0.762 | | | | |

Enviromega found that the emissions from various units using the biorate coefficient from their study were lower than the emissions using the biorate coefficient from WATER8. The largest difference was in the activated sludge unit, which had 0.03 g/d of methanol emissions using biorate coefficient from their study compared to 0.8 g/d of methanol using the biorate coefficient from WATER8. Based on this information, the methanol emissions estimated by the EPA models WATER8 and WATER9 are significantly conservatively high.

(b) We are requesting additional information on typical VOC content in produced water and any available chemical analyses, including data that could help clarify seasonal variations or differences among gas fields. Additionally, we request data that increase our understanding of how changing process variables or age of wells affect produced water output and VOC content.

Evaporation pond operators use pre-treatment facilities to ensure that free hydrocarbons do not enter the ponds as discussed above. The limited comment period has not allowed for time to gather comprehensive data on the concentrations of VOCs in produced water evaporation ponds but they are believed to be very insignificant. While the water cut of some wells may increase with age, there is an insufficient database of information on the VOC content of such waters over time to come to any reasonable conclusion as to increases or decreases in VOC content that may occur over the life of a well. In the case of wells completed

^{HHH} Enviromega. *Estimation of Methanol Biodegradation Rate Coefficient Using EPA's Method 304*. Wastewater Toxics, <http://www.enviromega.com/methbio.htm>.

^{III} Montheith, H. D. and Tischler, L. F. *Testing EPA's Method 304: Biodegradation Rates for Methanol and Other Oxygenated Solvents in a Pharmaceutical Wastewater*. Flamborough, ON, Canada: Enviromega Ltd., 1996.

in shale formations, the water flow from such diminishes rapidly following completion and usually has a minimal flow rate over time.

(c) We solicit information on the size and throughput capacity of typical evaporation pond facilities and request suggestions on parameters that could be used to define affected facilities or affected sources. We also seek information on impacts of smaller evaporation pits that are co-located with drilling operations, whether those warrant control and, if so, how controls should be developed.

There is no such thing as a "typical" evaporation facility. The limited comment period has not allowed for time to gather comprehensive data for determining a statistically valid set of data for pond size and throughput. Throughput may range from a few barrels a day to several thousand. There are facilities with a simple gun barrel separator and a small pond to facilities with multiple stages of inlet separation and multiple ponds. Evaporation ponds are the least likely facilities in upstream oil and gas to provide cost effective reductions in VOC or HAP.

(d) An important factor is cost of emission reduction technologies, including recovery credits or cost savings realized from recovered salable product. We are seeking information on these considerations as well.

Salable hydrocarbons are captured prior to entering the pond as described above, using existing recovery technologies. As EPA's intent of this question is likely to determine just that, API suggests that EPA conduct a valid study. The complexity of the study might range from well planned mass balance calculations to more detailed data collection and analysis. Industry welcomes the opportunity to cooperate with EPA on any necessary study performed with sufficient time allotted.

(e) We are also seeking information on any limitations for emission reduction technologies such as availability of electricity, waste generation and disposal and throughput and concentration constraints.

Typically, evaporation ponds are placed in locations with access to 3-phase power to operate pumps, aerators, and lighting. The main limitation is that the VOC concentrations in the produced water are already extremely low. Further treatment to remove VOCs would be quite difficult and expensive and would bear little environmental benefit.

(f) Finally, we solicit information on separator technologies that are able to improve the oil-water separation efficiency.

Traditional gravity separation as described above is very effective. More sophisticated technology has been much less effective. Industry may be able to respond further if provided the information that led EPA to conclude that existing separation technologies are not effective, and with sufficient time to respond.

Then there is the collection, compression, treating, and processing

- **Conventional O&G Reservoirs**
 - High Permeability
- **Unconventional Gas**
 - Deep Reservoirs – Typically Dry/High Pressure Gas
 - Low Permeability
 - Coal Bed Methane – No Petrol. Liq.; Often Lower Pressure; Shallower Depth; Higher Water Production
 - Tight Sands Gas
 - Shale
- **Field Pressure Decreases as Field is Produced.**

Wild Cat Wells

- Prospect Identification
 - Basin Evaluation, Seismic and Other Geotechnical Evaluation, Offset Area Evaluation, Land Evaluation
- Obtain a Land/Lease (mineral and surface) Position
- Drill, Complete and Test Exploratory Well(s)

Initial Field Development

- Evaluate Reserves, Costs, and Initial Full Cycle Economics
- Drill, Complete and Test Initial Development Wells;
- Install Infrastructure
- Begin Production Operations
- Competing Operators Start Developing the Field.

Life Cycle of a Field

Mature Field Development

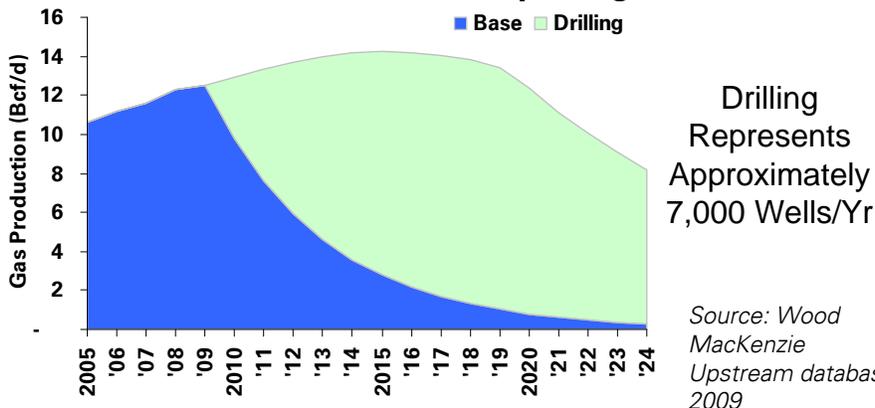

- On-going Economic Evaluations/Optimization on a Well-by-Well Basis
- Buy/Sell/Trade Assets
- Reservoir Drainage Evaluation
- Step-Out Delineation (i.e. reservoir boundaries)
- Explore Alternate Reservoir Potential (i.e. deeper prod. zones)

Infield Development

- Optimize Production Systems as Decline Progresses
- Reduced Well Spacing to Increase Recovery of Reserves
- Abandon Field at End of Economic Life

Drill to Maintain Production

Projected gas production from Colorado, New Mexico and Wyoming

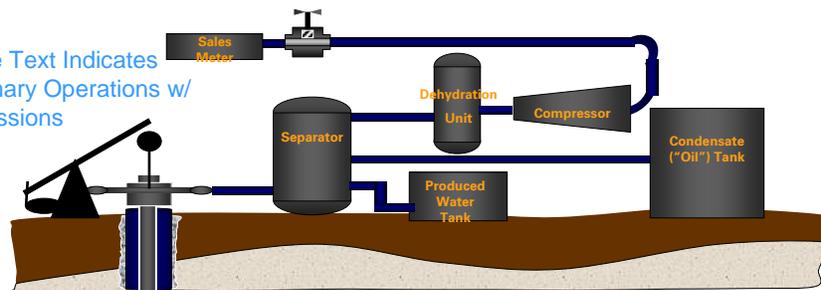

Ongoing drilling, well work, and infrastructure investment are required to maintain a steady state of U.S. natural gas production.

- **One Operator Fields**
 - Typically Only Young Fields
 - Even These Have Partners
 - Other Operators Drill Wells
- **More Operators as Field Mature**
 - Increasingly Complex as Multiple Companies Install Infrastructure
 - Services (i.e. comp., dehyd., gas proc., etc.) are contracted within negotiated limits.
 - Assets Bought/Sold/Traded/Change Operators Often
- **Contracts and Ownership Issues Get Very Complex with Infinite Variations**

- Gas/Oil/Water Separation
- Oil/Water Storage
- Gas Measurement
- Dehydration
- Gas Gathering
- Compression
- Gas Sweetening
- Gas Processing Plant

Blue Text Indicates Primary Operations w/ Emissions

Typical Traits of O&G Well and Most Compressor Station Sites

- Disperse – often miles apart
- Remote – closest receptor often mile +
- Unmanned – checked only periodically
- No Utilities – generator, water and air compressor must be brought with operator if it is needed.

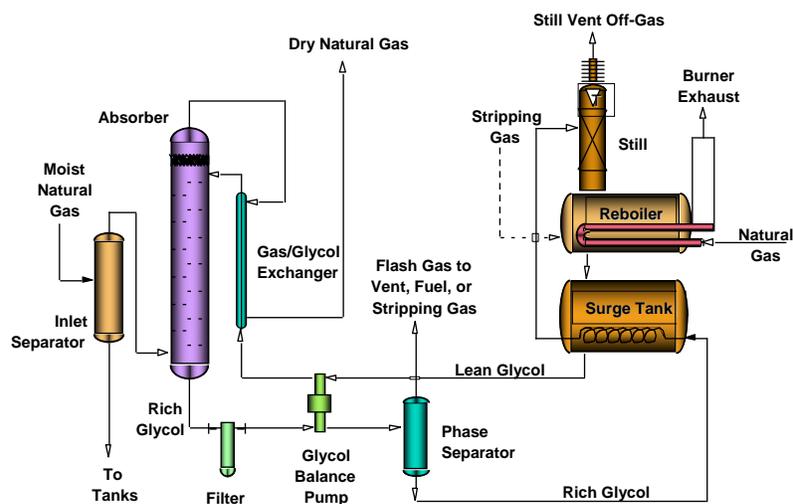

Liquid Storage Location

- Most often at well head
- During in-field development – central tank batteries may be considered.
 - Requires same well operator and
 - Wells close together.

Dehydrator Location

- Wet/high pressure gas causes hydrate formation (hydrocarbon/ice mixture) at warm temperatures.
- Water limitations in gathering/transmission lines for corrosion protection.
- High pressure fields may require dehydration at well head.
- Med. pressure fields may be dehydrated at compressor station.
- Low pressure fields may be dehydrated at gas processing plant.
- Dry gas (low NGL content) has lower hydrate formation concerns

Process Flow Diagram for Glycol Dehydration Field Unit

Glycol Dehydrator

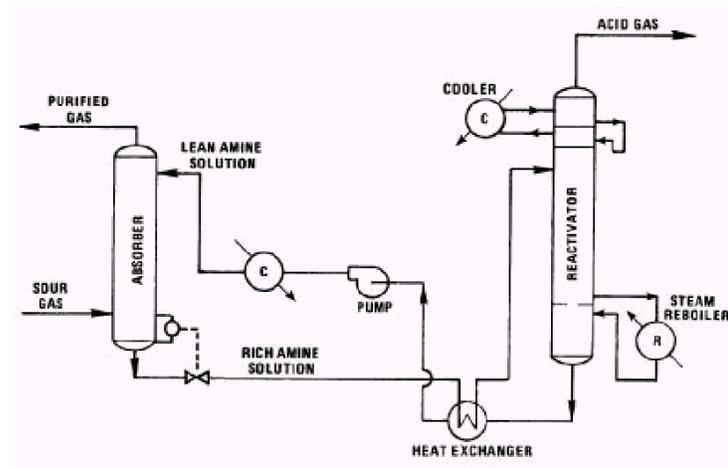

- Absorber (Contactor)
 - Countercurrent contacting of incoming wet gas and lean TEG to reduce water content
 - Avoid corrosion & hydrate formation
 - In EG system, glycol is injected directly into natural gas stream, thus absorber is not used
 - Glycol also absorbs some organics (including HAPs) from gas stream
- Key design parameters:
 - Gas flow rate & specific gravity
 - Gas temperature & Pressure
 - Outlet dewpoint required

- Still/Stripper Column
 - Used with reboiler to regenerate glycol
 - Often placed vertically on top of reboiler
 - Reboiler supplies heat to regenerate glycol via simple distillation

- Well head compression most often used in older, low pressure fields with multiple production operators in gathering system.
- Compressor stations used for better utilization of existing pipe.
- Most gas processing plants have pre- and or post compression.
- Reciprocating natural gas fired engines typically the only choice.

- Typically at gas processing plant.
- Removes H₂S (safety) & CO₂ (heat content and dry ice formation in cryogenic gas plants)
- Gas must be dehydrated after amine treater.
- Acid gas may be:
 - Processed in Sulfur Recovery Unit (SRU)
 - Flared, etc.
 - Vented (CO₂, methane, typically few hydrocarbons).

- Removes NGL (natural gas liquids) and lowers hydrocarbon dew point.
 - Liquids in gathering/transmission lines causes operational problems.
 - Heavy hydrocarbons cause consumer problems
 - NGLs used as feed stock and gasoline blending stocks.
- Gas processing also includes fractionation of NGLs into individual components (ethane, propane, iso-butane, n-butane, natural gasoline).

- Oil & Gas Operations Vary Widely Between
 - Reservoir Type/Basin
 - Maturity of Field
 - Type, Size, Age and Location of Equipment
 - Business Arrangements
 - Geography (Arctic, Mountainous, Offshore, etc.)
- One Control Scheme Doesn't Fit All

Oil & Gas Emission Inventories

EPA Meeting On O&G
NSPS/NESHAP Review
March 23, 2010

Sources of Oil & Gas Emissions Data

- State Inventories
 - Triennial reports to EPA
- Regional Partnership Inventories
 - Western Regional Air Partnership (WRAP)
 - <http://www.wrapair.org>
 - Central Regional Air Planning Association (CENRAP)
 - <http://www.cenrap.org>

State Agency Prepared Inventories

- Often have little or no Operator input
- Are frequently based upon Permitted rather than Actual Emissions
 - Tends to overestimate emissions for permitted source categories
- May use broad assumptions not applicable to all basins or types of operations within a State or jurisdiction
 - For example, emission factors applicable to oil operations may be applied to gas wells, or vice versa

State Agency Prepared Inventories

- May omit equipment or activities with permit exempt emissions that are prevalent and due to the large number of sources emit significant emissions.
 - Pneumatic controllers
 - Pneumatic pumps
 - Natural gas fueled burners less than 5 MMBTU/hr used in separators, heater treaters, dehydrators, storage tanks, etc.

Western Regional Air Partnership Oil & Gas Emission Inventories

- Phase I and Phase II Inventories are available at:
 - http://www.wrapair.org/forums/ogwg/Phases_I_and_II_Inventories.html
- Developed initially as a tool for regional haze evaluations
 - Phase I report completed in late 2005 developed baseline emissions for year 2002
 - Phase II report completed in Fall of 2007 improved upon the 2002 inventory methods and developed emissions for year 2005
- Provided a foundation for regional Oil & Gas Industry Emissions
- Phase II did not meet all the needs of the regulated community
 - Need for regional inventories suitable for use in photochemical models for ozone analyses

Western Regional Air Partnership Oil & Gas Emission Inventories

- Recognized limitations of the WRAP Phase II Inventory
 - As a result of the initial focus on Regional Haze planning, many sources of VOC emissions were omitted
 - Limited Operator participation
 - Broad assumptions concerning emission factors were applied across vastly different basins and types of operations
- To address these limitations, member companies of the Independent Petroleum Association of Mountain States (IPAMS) volunteered to fund a WRAP Phase III Oil and Gas inventory initiative.

energy API WRAP Phase III Oil & Gas Inventory

Phase III inventories are completed for the following basins:

- Denver-Julesburg (D-J)
- Piceance
- Uinta
- North and South San Juan

• *Wind River inventory to be available shortly*

The inventories are publically available:
http://www.wrapair.org/forums/ogwg/Phase III_Inventory.html

energy API WRAP Phase III Oil & Gas Inventory

- Evaluated a comprehensive spectrum of emission sources, many of which were not previously considered
- Included all phases of the well life-cycle (Drilling, Completion, Production, Decline).
- Types of production operations (oil, gas, coal-bed methane (CBM)) were differentiated within each source category
 - Lateral/wellhead compressor engines
 - Drilling rigs
 - Workover rigs/frac rigs
 - CBM well pump engines
 - Salt-water disposal pump engines
 - Artificial lift engines (pumpjacks)
 - Vapor recovery unit (VRU) compressor engines
 - Miscellaneous gas-fired engines
 - Wellsite heaters
 - Miscellaneous gas-fired heaters or boilers
 - Flaring
 - Pneumatic devices
 - Stock tanks- working, breathing, storage, losses, flashing emissions
 - Fugitive emissions
 - Completions (well flowback)
 - Venting events
 - Periodic well blowdowns
 - Glycol Dehydrators
 - Amine units
 - Truck loading operations
 - Pipeline/compressor station emissions
 - Water treatment/water injection facilities

WRAP Inventory Comparison

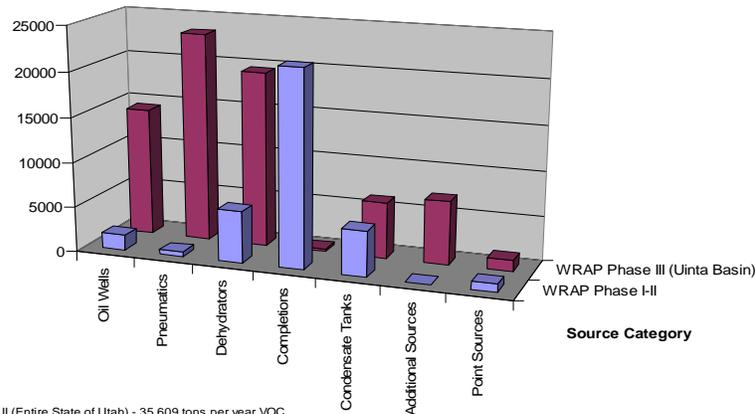

| WRAP Phases I and II | Issue Identified | Example | WRAP Phase III |
|--|---|--|---|
| Very limited industry participation | Inventory didn't reflect the dynamic regulatory changes since 2002 and the emission reduction strategies industry has implemented on non-regulated source groups. | Green completions, low-bleed pneumatics, EPA tiered diesel emission standards | Better than 70% operator participation in most basins |
| Did not reflect basin specific emissions | Due to limited information, final inventory reflected the most conservative emission rate from collected data. | Completion emissions for conventional wells in Southwest Wyoming were incorrectly applied to other basins. | All emission factors were basin specific |
| Inventoried NOx emission from 4 source groups | Many smaller sources not adequately addressed | Unpermitted pump engines excluded from the inventory | Inventory considered 23 separate source categories |
| Inventoried VOC emissions from 5 source groups | Many significant sources of VOC not addressed | Truck loading, pneumatic pumps, fugitive emissions were never considered. Standard WY estimates used for pneumatic controllers, dehydrators, and condensate tanks. | |

WRAP Inventory Comparison

| WRAP Phases I and II | Issue identified | Example | Uinta WRAP Phase III |
|---|---|---|--|
| Projections - basin wide emissions were divided by the number of operating wells to determine a well based emission factor. | Did not allow projections to incorporate production decline or new emission control technology. | Emission projections for NEPA projects were based on a single dimensional growth and significantly over estimated potential emissions for individual sources. | Multi dimensional growth projection methodology based on number of spuds, total well count, annual gas production, and annual liquid hydrocarbon production. Inventory reflects dynamic changes in product composition, production rates (production decline and new production) and operating conditions between the basins. This multi dimensional approach allows potential emissions to be more accurately characterized as the basin matures and the number of spuds continues to grow but regional gas production stabilizes or declines. |
| Focused as a NO _x and SO ₂ inventory | VOC inventories used for photo-chemical modeling showed poor alignment with monitored data. | Photo-chemical modeling assigns source specific chemistry to each source category. | Significant changes to the VOC emission profile in each basin. This update allows better source specific chemistry to be implemented for each source category. |
| Snap-shot in time | Was not possible to efficiently update the baseline year/2018 projections. | | Provides for a planned methodology to periodically update information to reflect actual growth rates in spuds, well counts, gas and hydrocarbon production. |

VOC Emissions (TPY)

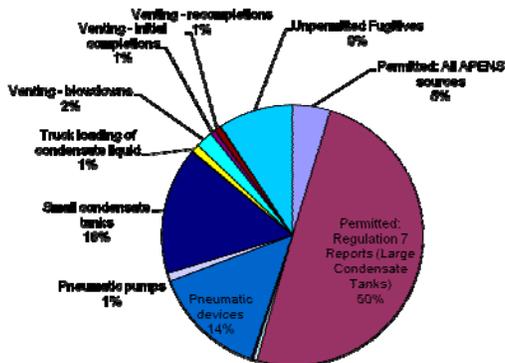

Phase II (Entire State of Utah) - 35,609 tons per year VOC
 Phase III (Uinta Basin) - 70,663 tons per year VOC

1. IPAMS conducted outreach meetings with State permitting authorities
 - a. Provided and overview of the Phase III initiative
 - b. Gathered State input on source categories of concern
 - c. Obtained State inventories for permitted sources
2. Operators were selected for participation within each basin
 - a. State Oil and Gas Commission records used to identify top producing companies
 - b. Selection reviewed to ensure adequate representation for oil, gas and CBM operations
3. A detailed emission source survey was prepared and provided to participating Operators
 - a. An example survey form is available on the WRAP website
4. Survey responses were reviewed for technical accuracy
 - a. Outlier data were verified with the Operator and corrected when necessary

5. Survey responses were processed to develop representative emission factors for each source category
 - a. Weighted averages were applied to develop the emission factors
 - b. Individual operator survey responses are held confidential
6. Emissions were extrapolated to include 100% of Oil and Gas Industry Operations
 - a. Extrapolations were based upon 4 factors
 - i. Number of Spuds (newly drilled wells)
 - ii. Total number of wells within the basin
 - iii. Total natural gas production (conventional and CBM)
 - iv. Total oil and condensate production
 - b. Extrapolation factors were obtained from public Oil and Gas Commission record
7. Inventories were reviewed by basin Operators prior to posting on the WRAP website.

In the D-J Basin (Eastern Colorado) VOC emissions are predominately generated from Condensate Storage Tanks (large and small throughputs)

D-J Basin VOC Emissions by Source Category

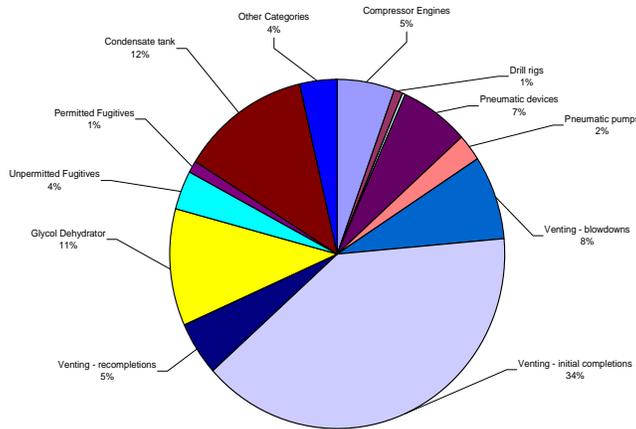

WRAP Phase III Inventory Results

In the Piceance Basin (Western Colorado), well completion flowback and periodic blowdowns are the predominate VOC emission sources

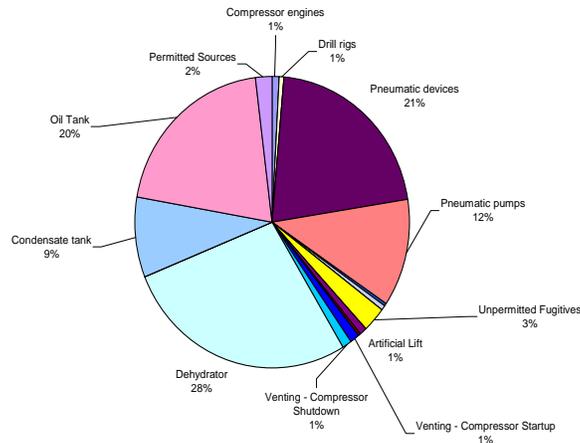

Piceance Basin VOC Emissions by Source Category

WRAP Phase III Inventory Results

In the Uinta Basin (Eastern Utah) glycol dehydrator still vents and pneumatic controls predominate VOC emission sources.

Uinta Basin VOC Emissions by Source Category

WRAP Inventory Conclusions

- Represents a significant improvement over previous Oil & Gas emission inventories
- Includes unpermitted sources and activities which may be significant in some basins
- Documents the diversity of the industry between basins and types of operations (oil, gas, CBM) within basins

Other Sources of Oil & Gas Emission Inventory Data

- Central Regional Air Planning Association (CENRAP)
<http://www.cenrap.org>
 - Includes Texas, Oklahoma, Louisiana, Kansas
 - Emissions are not available from CENRAP
 - State have developed independent inventories
 - There has been limited Operator involvement
 - Roughly similar to the WRAP Phase II effort, likely with similar limitations
- Wyoming 2008 Statewide Emission Inventory
 - Extensive surveys completed by Operators across the state
 - Data currently undergoing QA
 - Contact Brian Bohlmann at WDEQ for more information
 - BBohlm@wyo.gov, (307) 777-6993

Stock Tank Flashing Emissions

- Industry standard practice is to estimate emissions utilizing E&P Tank simulation software
 - Program inputs include a pressurized oil sample fractional analysis
- A 2009 study* completed for the Texas Commission on Environmental Quality (TCEQ) found that the E&P Tank methodology overestimates emissions by a factor of 2.8 when compared to actual emission measurements.
- WRAP III and other inventories probably over estimate tank flashing emissions.

• Upstream Oil and Gas Storage Tank Project Flash Emission Models Evaluation – Final Report.
July 16, 2009

Conclusions

- Oil and Gas is a diverse industry with emissions that vary greatly between basins and types of operations – One size does not fit all
- The WRAP III Oil and Gas emission inventory provides a comprehensive study of emissions across multiple basins within the Rocky Mountain West.
- Stock tank flashing emissions are most probably over estimated in the WRAP III and other inventories

Questions or Comments

Doug Henderer, *VP of Regulatory Affairs & Engineering*

dhenderer@buysandassociates.com

www.buysandassociates.com

Oil & Gas¹ VOC Emission Control Options

| Emission Control Technology | Applicable Emission Sources | Description of Control | Limitations of Control Technology ³ | Implementation Concerns and Limitations | Variables Impacting Control Cost | Current Use | Cost Effectiveness Factors |
|--|---|---|--|--|--|---|--|
| Flare | VOC emissions from emergency operations, equipment blow downs, tank vapors, dehydration units, etc. | Naturally aspirated pipe flare with auto ignition (spark ignited) pilot | Low flow can lead to inefficient combustion for flare designed for high flows. Low BTU gases (i.e. amine overhead) may have low combustion efficiencies and require use of “assist gas” (also referred to as make-up or power gas) to boost BTU. | Remote, unmanned operations may lead to safety and pilot monitoring concerns for continuous operation. When tying in tanks or other sources that may contain air, proper flame arrestor design must be included to mitigate explosion potential. | Maximum expected flow for flare size, minimum BTU content for operational cost of enrichment gas. | Mainly at gas plants and larger compressor stations and sour gas treating facilities. May also be used at tank batteries. Portable flares may be used for temporary maintenance and gathering system blow down. Spark ignition system often used in lieu of continuous flame pilots to overcome safety concerns of remote operations. | Cost effective for routine operations blow downs or upset/emergency use. |
| Smokeless Combustion Chambers (vapor flares) | VOC emissions from tank flash, dehydration units, pneumatic pumps, etc. | An enclosed combustor with air intake flame arrestor | Heat input capacity per stack height and diameter per manufacturer's information. | Remote, unmanned operations lead to safety and pilot monitoring concerns for continuous operation | Maximum hourly heat input | Controlling tank flash, dehydration units, and pneumatic pumps in Wyoming. | |
| Vapor Recovery Unit | VOC emissions from tank flash and vapors, dehydration still vents, treater vents, etc. | Compressor or venturi used to pressurize gas vapor and inject into the process stream. VRU is considered a part of the process and not an emission control. | Need relatively constant flow to prevent frequent cycling of compressor, | Availability and stability of electricity or gas supply to drive VRU. Frequently cycling of VRU may cause increased downtime of gas fired engines particularly at unmanned operations. Venturi type VRUs require high pressure motive gas. Low pressure gas system needed for discharge. | Wide variation in gas flow, suction pressure and discharge pressure can make designing a properly sized VRU difficult. | Mainly at gas plants and compressor stations, and some tank batteries | Availability of electricity at site as well as sufficient vapors to meet minimum design volume requirements. |

¹ Characterized by dispersed²/remote operations.

² Dispersed – typically small facilities spread out over large areas.

³ Space and weight limitations limit the retrofitting of existing offshore platforms

Oil & Gas¹ VOC Emission Control Options

| Emission Control Technology | Applicable Emission Sources | Description of Control | Limitations of Control Technology ³ | Implementation Concerns and Limitations | Variables Impacting Control Cost | Current Use | Cost Effectiveness Factors |
|---|---------------------------------|---|--|--|--|--|--|
| LDAR - AVO (Auditory, Visual, Olfactory) Inspection | Fugitive components | Audio/Visual/Olfactory inspection of fugitive components for leaks | Small leaks can be missed. | | Low to no cost, depending on recordkeeping requirements. | Common operator inspection at dispersed and remote oil and gas production facilities. Typically documented by exception only (i.e. work order completed when maintenance is required). Required for NSPS, Subpart KKK regulated gas plants for heavy liquid streams. | |
| LDAR - Method 21 | Fugitive components | Inspection of fugitive components for leaks utilizing an organic vapor analyzer under Method 21 | May be difficult at times to determine the exact source of the leak. | Difficult and costly for dispersed oil and gas facilities. Cost and availability of third party contractors (monitoring and valve repair) are an issue in some remote areas (i.e. Alaska and Wyoming). | Number of components, number of facilities, dispersed location travel, hot work permits, etc. | Gas plants subject to NSPS KKK or HAP Major subject to NESHAP, Subpart HH | Increased operating expense for all upstream facilities. potential for little emission reduction |
| LDAR - Infrared Camera | Fugitive components | Inspection of fugitive components for leaks utilizing an infrared camera. | Requires viewing the component from different angles and good weather conditions. No quantification of flow. | Must be trained in proper use of the camera and able to distinguish between water vapor and emissions. | Number of cameras and operators needed to scan dispersed oil and gas facilities. May be reasonable alternative to Method 21 if recordkeeping burden is manageable. | Mainly for equipment integrity purposes. | Costly equipment and operator training required |
| Collection of low pressure gases into fuel supply. | Pneumatic pumps and controllers | Routing of emissions from pneumatic pumps and controllers that use natural gas to a collection line for fuel supply. Process, not emission control. | | Sufficient pressure must be available to enter the closed loop system. If routing to a fuel system, may have more emissions than needed for fuel. | | Dispersed oil and gas production facilities with pneumatic pumps and controllers | |

¹ Characterized by dispersed²/remote operations.

² Dispersed – typically small facilities spread out over large areas.

³ Space and weight limitations limit the retrofitting of existing offshore platforms

Oil & Gas¹ VOC Emission Control Options

| Emission Control Technology | Applicable Emission Sources | Description of Control | Limitations of Control Technology ³ | Implementation Concerns and Limitations | Variables Impacting Control Cost | Current Use | Cost Effectiveness Factors |
|--|---|--|--|--|---|---|----------------------------|
| Solar Pumps | Replace small pneumatic pumps (<100 gallons/day) | Using solar pumps in place of pneumatic pumps that use natural gas | Only available for pumps that circulate <100 gallons/day. Sold as a package. | Solar panels are often stolen. | | Chemical and methanol pumps at dispersed oil and gas production facilities. | |
| Installation of air compression to replace natural gas driven (i.e. pressure drop) equipment | Instruments, controls, starting air and pneumatic pump services | Provide compressed air to drive pressure drop driven equipment to replace natural gas that is vented to atmosphere | Requires availability of electricity to be reliable and affordable. | | Certain weather conditions may require air dehydrators for instrument systems to prevent condensate blocking the signal. High cost of manpower for frequent inspection. | Gas plants and some central tank batteries and compressor stations. | |
| Low Bleed/No Bleed Controllers | controllers | Install, replace, or retrofit low bleed/no bleed controllers in place of high bleed controllers | | Some old high bleed controllers can not be retrofitted and would have to be replaced | | Controllers at dispersed oil and gas production facilities and gas plants | |
| Minimize manual blow down/venting to atmosphere during maintenance/operational events. | Depressurizing equipment for maintenance. Response to vapor locked equipment (i.e. pumps or de-liquefying well bore), | Have personnel on site during the blow down/venting, operator training, etc. to ensure that minimal gas venting occurs | | Over restrictive procedures may cause reoccurrence (vapor locked equipment) or safety concerns (depressurizing equipment). | Distance between facilities. | | |

¹ Characterized by dispersed²/remote operations.

² Dispersed – typically small facilities spread out over large areas.

³ Space and weight limitations limit the retrofitting of existing offshore platforms

Oil & Gas¹ VOC Emission Control Options

| Emission Control Technology | Applicable Emission Sources | Description of Control | Limitations of Control Technology ³ | Implementation Concerns and Limitations | Variables Impacting Control Cost | Current Use | Cost Effectiveness Factors |
|---|---|---|---|--|--|--|----------------------------|
| Minimize upset or emergency blow down/venting to atmosphere. Upsets include loss of electricity, loss of distribution point without ability to shut off source, or process event. | Natural gas released to atmosphere due to emergency event or upset (typically a third party event out of the operators control). | Prior contingency planning for predictable events. Communication with third parties to determine duration, thus select option to minimize emissions. | Operator does not have control of the event causing the blow down/venting. Cooperation of third parties required. May have contractual limitations. | Source of natural gas is typically a gathering system with dispersed well locations. Significant time is required to shut each well in. Stopping the flow in many wells may require atmospheric venting to de-liquefy the well to start flow (resolve vapor lock). | | Venting or blow downs during an emergency or upset situation is a common occurrence in upstream oil and gas operations, venting is usually through a vent stack or relief valve system | |
| Glycol Dehydrator Rich Glycol Flash Separator | Water saturated glycol in dehy. must drop the pressure from contactor pres. to near atmospheric pressure before the water can be cooked off in the still. | A flash tank can separate the gas from the glycol for use as fuel or to be returned to the process. | Requires a low pressure gas collection system or use, such as fuel system, low pressure gathering system, vapor recovery compressor, flare, etc. | If use or system is insufficient for gas volume generated, then gas must be vented | | | |
| Secondary Separator for liquid stream | High pressure production separators where a low pressure gas handling system is available. | Condensate/crude oil from a high pressure prod. separator is flashed at a lower pressure, so flash gas can be collected for use or return to the process. | Requires a low pressure gas collection system or use, such as fuel system, low pressure gathering system, vapor recovery compressor, flare, etc. | If use or system is insufficient for gas volume generated, then gas must be vented | Process system and stability of gas volume | Primarily fuel systems and vapor recovery compressors. | |

¹ Characterized by dispersed²/remote operations.

² Dispersed – typically small facilities spread out over large areas.

³ Space and weight limitations limit the retrofitting of existing offshore platforms

Oil & Gas¹ VOC Emission Control Options

| Emission Control Technology | Applicable Emission Sources | Description of Control | Limitations of Control Technology ³ | Implementation Concerns and Limitations | Variables Impacting Control Cost | Current Use | Cost Effectiveness Factors |
|--|---|---|--|---|--|---------------------------|----------------------------|
| Green Completions (i.e. reduction of natural gas vented to the atmosphere during well completion operations) | Venting and flaring during completions (flow back of hydraulic fracturing fluids) | After hydraulic fracturing the much of the injected fluids must “flow back” out of the well. Historic operations produce flow back fluids into an open pit until the gas/oil is sellable. Green completions use specially designed sand traps and 3-phase separators to capture the natural gas for sale quicker than normal production equipment allows. | Sand traps and separators must be designed to handle the highly erosive conditions associated with producing high volume, high pressure completion fluids. Produced gas must meet the gathering system specifications before natural gas can be delivered into the pipeline. Certain well completion activities (i.e. drilling out frac. plugs and running production tubing) must be completed before space is available for the equipment required for “green completions”, requiring well fluids to be routed to the pit during these operations. | Gathering system piping must be run to the well before the well test is complete and production volumes are known. Gas pressure is typically below pipeline pressure during initial flow back operations. Pipeline pressure may limit how soon natural gas can be delivered to the pipeline. Hydrate formation – Hydrates are a solid ice/hydrocarbon mixture that forms because of high pressure and/or low temperature. Hydrates can form for many reasons including cold weather, pressure reduction from high pressure reservoirs, and excessive moisture due to dehydration equipment not being available. | Location of well – Green completions are most economical during infield drilling projects (drilling wells to reduce “well spacing” to allow remaining reserves to be produced in an older reservoir), due to gather system availability. Gathering system will not be available before well testing on wild cat wells or reservoir boundary exploration wells. | See attached issue paper. | See attached issue paper. |

¹ Characterized by dispersed²/remote operations.

² Dispersed – typically small facilities spread out over large areas.

³ Space and weight limitations limit the retrofitting of existing offshore platforms

“Green Completions” for Natural Gas Issue Paper

Use of Green Completion techniques can recover and preserve valuable energy resources while protecting the environment. Depending on the field/well characteristics, it may also be economically positive for the operator to use these techniques. However, application of Green Completion techniques are limited due to technical barriers in many instances and must be well planned and designed where used.

Process Description:

Flaring or venting wells, against atmospheric pressure, for clean-up following completion and fracture stimulation is the traditional practice/methodology. This approach results in the least back-pressure on the well, the highest flow rates and velocity up the well-bore, and promotes better flow back of the fracture fluids and clean-up of the formation near the well-bore. Adequate clean-up of the near well formation is critical to prevent formation damage and allow optimum long-term production from the well.

Green Completions is a departure from this traditional practice where the well clean-up is done through specialty surface separation equipment and part of the gas and condensate, which would have been flared (or gas vented), is recovered for sales. Gas recovered during Green Completions operations is routed to a sales gas or gathering line which increases the back pressure on the well by whatever pressure the line is operating at along with the additional pressure drop caused by the surface equipment. This results in more back-pressure on the well, lowers the flow rates and velocity up the well-bore, and may not allow adequate clean-up of the formation near the well-bore. Due to this affect, the applicability of Green Completions techniques to a particular area/field needs to be carefully considered and adequate clean-up with no damage to the formation or long term well productivity demonstrated.

Technical and Operational Limitations – There are many situations that limit the ability to utilize green completions for reducing emissions in natural gas production. Some of them include:

- Sand traps and three phase separators must be designed and manufactured to endure the highly erosive conditions associated with producing high volume, high pressure fluids containing sand. A one-size-fits all or off-the-shelf design philosophy can lead to operational problems/delays, short equipment life, and/or safety concerns like the erosion created washout pictured below.

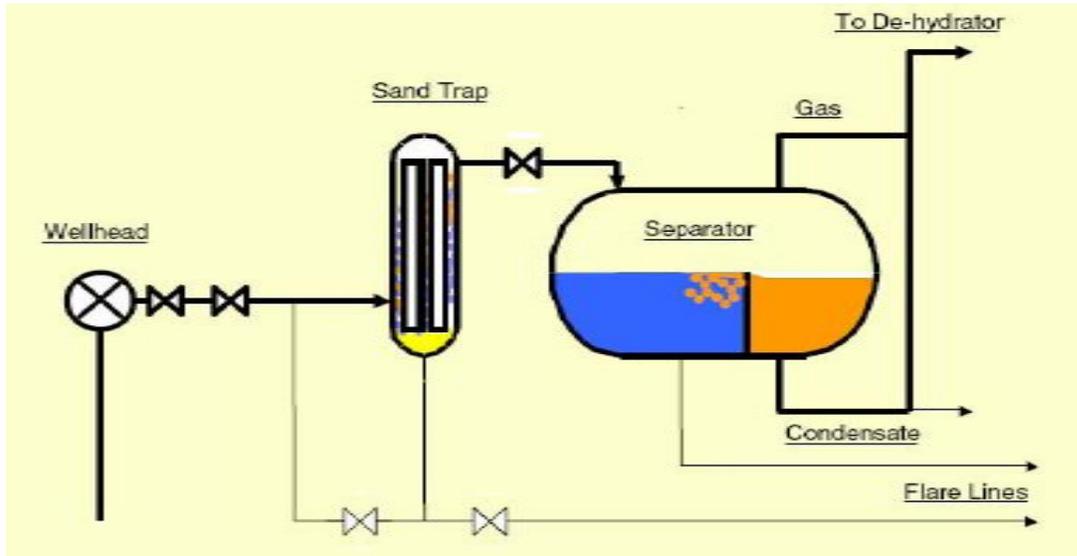

EPA Natural Gas Star Website

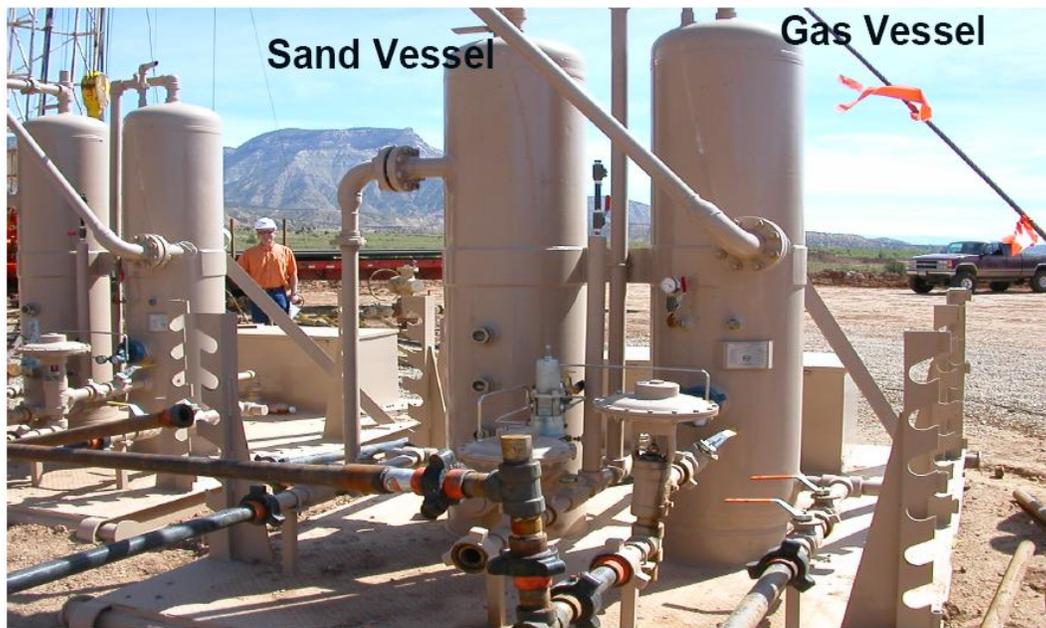

- In order to deliver gas to the sales pipeline or gathering system, gas must meet quality specifications. Many well stimulations are energized with nitrogen or carbon dioxide to assist the flow back and cleanup. Since these gases come back with the well production, gas cannot be routed to the pipeline.
- A pipeline must be laid to the well in advance of the completion, which results in a capital outlay risk for the pipeline company since the results of the well are not fully understood until the completion is performed. It is difficult for a pipeline company to size the pipeline and spend capital in advance without fully understanding the production potential of the well.
- Gas gathering pipelines are not in close proximity to all drilling locations. Wild cat wells are drilled in areas where O&G reserves have not been proven or developed. Gas gathering lines must be run many miles to the nearest gas transmission line or consumer, which will not be done until sufficient gas reserves are proven to make the pipeline economical. Reservoir boundary exploration wells seek to extend the production area outside the area of existing gathering system infrastructure. Again, the well must be completed and tested to have reasonable confidence that running a pipeline to the well will be economical. Typically, only infield drilling projects (inside known production areas, often to reduce well spacing to completely produce remaining reserves) have sufficient certainty of production volumes and close availability of gathering system to make green completions viable.
- When each stage of a stimulation program is initially completed, the pressure of the gas may not be high enough to overcome pipeline pressure. Any time this occurs, the well will be flared or vented until enough pressure is available to send gas to the pipeline. This allows clean up of the wellbore and is critical to minimize the potential for formation damage. Once a fracture stimulation is pumped, flowback and clean-up must proceed regardless of sufficient pressure to enter pipeline system.

Therefore, green completions should be encouraged where possible, but understood that they are only feasible in certain situations.

Thief Hatch Work Practices

Research indicates there are no API or ASTM standards that address specific inspection and maintenance practices for thief hatches. However, API RP 12R may come the closest to being a technical reference for thief hatch work and maintenance practices.

From what has been found in engineering and vendor literature, four general work practices for thief hatches on tanks controlled for emissions can be listed as the following:

- Operator needs to select the appropriate gasket material based on fluid composition of the storage tank and weather conditions.
- Inspect in a regularly scheduled preventive maintenance (PM) program. Annual inspection of thief hatch seal is the most common suggestion although some sites inspect on a more or less frequent basis. When applicable, inspection should occur in conjunction with thieving or gauging tank to minimize additional periods of an open hatch.
- Replace gasket within 30 days if inspection shows evidence of deterioration or cracking. In the interim, grease the gasket if deterioration or leakage is found to improve seal while waiting on replacement gasket.
- Keep thief hatch in good working order. Verify thief hatch seal is capable of holding pressure in excess of the pressure/vacuum relief device (PRD). The thief hatch spring or weight relief set point should be greater than the set point on the PRD, and both the thief hatch and PRD set points need to be greater than the back pressure set point of the control system.

Standard practice is to implement preventative maintenance during routine inspections including cleaning surfaces and seals, greasing the gasket to improve the seal, and repairing or replacing springs. If a leaking gasket is discovered during inspection, the temporary initial fix is to grease the gasket to improve the seal. If unable to verify a good seal, then replace the gasket within 30 days unless a custom gasket must be fabricated for replacement (e.g. older storage tanks).

Gasket selection

Elastomers nitrile and neoprene appear to be the “standard” gasket materials for oil storage, with Fluoroelastomers for H₂S service. Thermoplastic seals are not commonly used, but can be. There are various grades of seals within each material category for selection in the proper fluid composition and temperature environment the gasket will be used.

Any rulemaking should not mandate specific gasket materials but rather specify gasket material appropriate for type of chemical service and operating conditions including weather.

Oil and Gas Flaring and Issues with 40 CFR §60.18

Introduction

For emissions control in oil and gas production operations, flare design and purpose is varied. Oil and gas flares generally serve one or a combination of several different purposes. Uses include continuous control for process operations, standby for backup to primary control systems, and blowdowns for maintenance startup shutdown (MSS) events or emergency upset events. Each use requires a flare design that is fit for purpose for optimum operational efficiency.

In many cases, especially at newer, larger natural gas compressor stations and gas processing plants, flares are designed to meet 40 CFR §60.18 requirements. Even if there is no applicable NSPS Subpart, permits often refer to §60.18 for flare design. However, depending on operating conditions, additional operating efficiencies would be possible if these sites were not restricted to the continuous pilot and Vmax provisions of §60.18.

For situations or sites that don't presently require a §60.18 compliant flare, flares may not operate with a continuous 24/7 pilot or they may have "sonic" high velocity flare tips that exceed the Vmax of 400 ft/sec in §60.18. In either case, if properly designed, these flares can meet or exceed the control efficiencies of a §60.18 compliant flare. With new NSPS rules that increase the scope of regulated facilities, the default reference to §60.18 for flare design will be impractical and detrimental to many oil and gas sites. Allowances need to be made for alternative flare designs.

Attached to this document is a short white paper from John Zink, a large, well known vendor for flare systems as well as the test study referenced in the Zink paper. The paper argues the value of allowing sonic flare designs for oil and gas applications where high BTU gas will be flared. Sonic flares have destruction efficiencies that exceed conventional flares and are used worldwide in the oil and gas industry. However, due to NSPS limitations from §60.18, efficient sonic flare designs are in limited use in the U. S. You will note that at the end of the Zink paper is a table of recent test results witnessed by the TCEQ in October, 2010 in which all but one of 8 tests achieved 100% destruction efficiency. The one lone test achieved a destruction efficiency of > 99%.

Below is a discussion for making allowances for flares that do not have continuous pilots (24 hours a day/7 days a week).

Flare Pilots

There are a number of operating scenarios where use of a continuous 24/7 pilot is not desirable, and is inefficient. In these cases, pilot fuel gas may be in limited supply or not available, or flaring events are so infrequent, that use of continuous pilot gas is wasteful and creates unnecessary emissions. Unnecessary wear also occurs to the flare tip when a pilot is needlessly lit continuously. Listed below are a few examples of flare uses where these conditions would apply:

Emergency Only/Planned MSS Flare: Flare is designed for control of emergency upsets only, planned MSS events only or both. No continuous process streams are routed to the flare. Use of flare is intermittent with long periods between flaring events that could be less than once per year. A separate conventional flare system may exist to handle process streams.

Low Pressure Backup Flare: Flare is designed for low pressure, low volume burning and may serve as a backup to a primary emissions control or recycling device such as a vapor recovery unit (VRU). Use is intermittent with potentially long periods of time in between uses (e.g., during periods of maintenance or downtime to the primary control or recycling system).

Intermittent Low Pressure Process Control Flare: Flare is designed for controlling intermittent emission periods such as during truck loading when operating conditions warrant emissions control of vapors. Truck loading is a manual operation, so emissions are generated manually, and flare is used only as needed when a truck pulls up to be loaded. This type of flare may have a dual use as a Low Pressure Backup Flare.

Storage Tank Vapor Flare¹: Another low pressure flare that burns storage tank vapors. Pilot gas may not be available due to insufficient produced gas volume associated with oil production and a gas delivery system is unavailable. Purchased gas may have to be used for ignition gas as a substitute for produced gas.

In cases where a 24/7 pilot is not used, it is recognized that a good pilot flame is necessary to ensure combustion efficiency during flaring events. Consequently, a good flare design will have a stream detection system tied to an auto ignition system so that the pilot lights as needed to combust the waste stream going to flare. When the waste stream stops, the pilot shuts off. In effect, the pilot is continuously lit, but only during the flare event itself.

In cases where pilot gas is not available, or use of a separate pilot gas stream is undesirable due to intermittent flaring events, low pressure flare designs exist where the flare stream itself operates as its own pilot so that a separate pilot fuel stream is unnecessary. As an example, below is a technical description from John Zink of how this type of flare might work. Other vendors should have equivalent designs.

- **Model EFF-ZFF Flaring System:** The ZFF is a gas-assisted, pre-mix flare for smokeless burning of waste gas. The flare is highly efficient for the combustion of small waste gas flows; the ZFF is capable of combusting hydrocarbons, low BTU, and toxic gases. An additional feature of the ZFF is that the flare acts as its own pilot. The pre-mix feature allows the ZFF to be utilized in applications with very low available pressure.
- **Purge Gas Reduction:** The ZFF induces a vacuum in the knockout drum when initially being ignited. This reduces the need for venting purge gas continuously through the system, which makes the ZFF more economic during normal operations because gas will not be continuously vented to the atmosphere.
- **Purge Gas:** During operations the ZFF will utilize 1000 scfh of pilot gas.
- **Ignition Gas:** During ignition the ZFF will utilize 250 scfh of ignition gas.
- **Purge Gas Seal:** Due to the aspirating mixer drawing a vacuum on the waste line it is not necessary to have a seal on the flaring system. This is ideal for installing a flare system on a VRU system; The VRU system generally operates at 3-6 ounces.
- **Non-continuous Ignition/ Purge Gas Flare:** The ZFF is not a conventional flare. The flare neither requires continuous purge gas or a seal mechanism to ensure that air does not become entrained in the system. The lack of continuous purge gas or a seal mechanism is possible because of the pre-mix feature. Also, the ZFF does not have continuous ignition, this is possible because the flare acts as its own pilot.
- **ZFF Control Panel Logic:** Once the vapor pressure reaches 5 ounces, and the control valve will send a signal to the control panel to ignite the ZFF. Then the panel will send a signal to the fuel gas control valves to allow pilot gas and ignition gas to the flare. The igniter will continue sparking approximately every ten seconds until the thermocouple

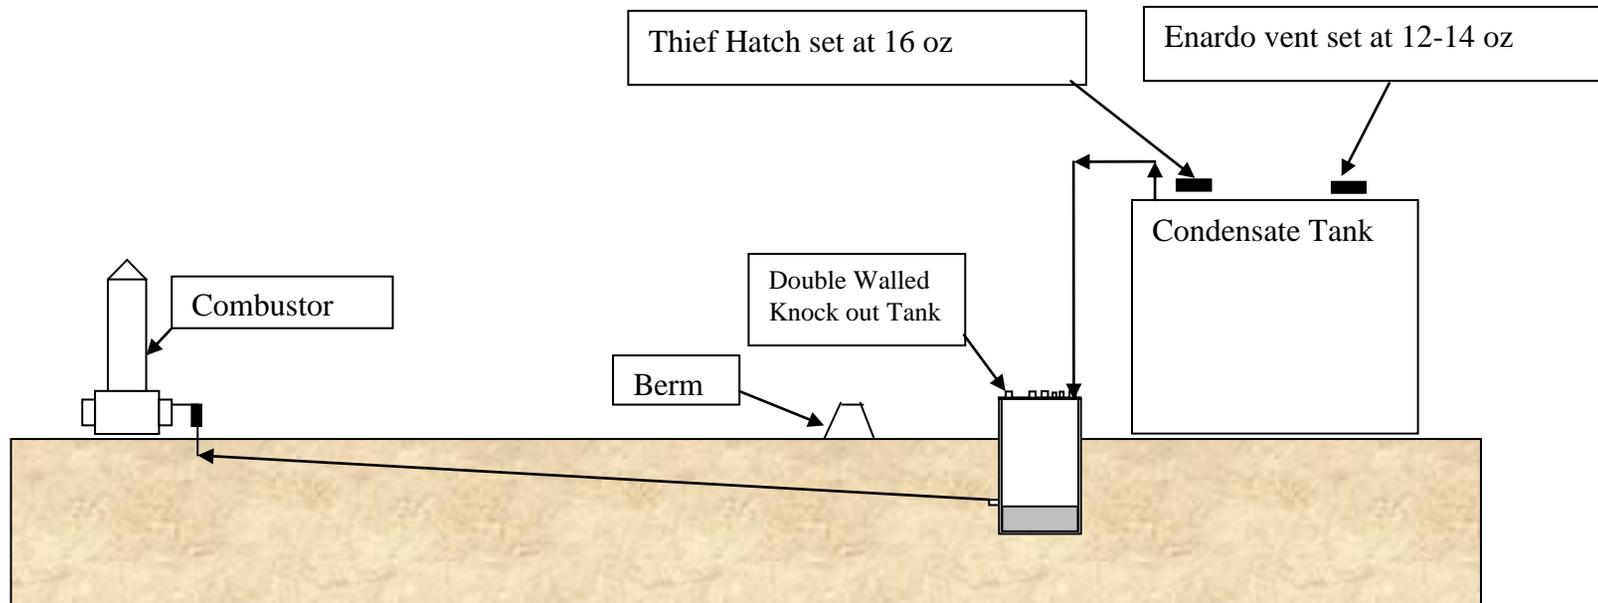

senses it is lit. Once the pilot is lit, the control panel will send a signal to close the ignition gas control valve. The flare will operate until the control valve senses that the system pressure is below 5 ounces.

While the above describes the operation for a low pressure vapor flare application, the control panel logic described in the last paragraph can be applied to more conventional flare designs as well. Intermittent flare streams can be detected by sensors that trigger lighting of the pilot.

¹ To avoid confusion, the flare described here refers to a conventional flare with a flare tip at the end of a vertical stack designed to promote efficient burning. **Another type of combustion unit known within industry as a vapor combustor to control tank emissions is sometimes misnamed as an enclosed flare.** This is not really a flare in the conventional sense. Vapor combustors generally consist of an enclosure/stack, a burner array (typically a ring burner), a pilot (some have dual pilots), a backflash preventer, and a thermal well for temperature monitoring that is mostly tied into the automation system for data archiving and alarms when the combustor fails for any number of reasons. A fair number of these units have a "hot point" element (a metal probe with a high heat holding capacity) which provides "re-light" for momentary flame outages. A much smaller number have UV fire detection and electronic re-light capabilities. These units are generally naturally aspirated with no air or gas assist. Many of these units have been "stack tested" in the Jonah/Pinedale area of Wyoming and have DRE's north of 98-99%. Attachment 1 provides a diagram showing how combustor systems are typically designed.

This rulemaking needs to allow for the use of combustors without reference §60.18.

Pressure Drop Profile for Combustor System Example Design

System Description:

1. *Maximum* flow conditions are detailed in adjacent text box. 400 BBL is sometimes seen on new 5 pad wells, but normal production is less than 100 BBL/day.
2. All lines from the condensate tank to the combustor are 4" pipe.
3. The tank Enardo is set at 12-14 oz. The tank Thief Hatch is set at 16 oz.
4. The knock out tank prevents any liquid head in the underground line
5. The combustor is generally set with 300 feet of the tank.
6. Additional pressure drop – other than piping associated with the combustor system, there is an additional pressure drop at the combustor consisting of an orifice, burner and flash back arrestor, with the majority of the drop across the orifice. If excessive pressure is encountered on the orifice, the orifice size is increased to eliminate any venting of the Enadros.

**Ref.: Review of Federal Air Regulations for the Oil and Natural Gas Sector
40 CFR Part 60, Subparts KKK and LLL
40 CFR Part 63, Subparts HH and HHH**

The American Petroleum Institute (API) is a national trade association with over 400 member companies that are involved with all aspects of the oil and natural gas industry. We are writing to provide commentary on issues pertaining to the pending review by the U.S. Environmental Protection Agency (EPA) of federal air regulations for the Oil and Natural Gas Sector, specifically:

- 40 CFR Part 60 Subpart KKK, Standards of Performance for Equipment Leaks of VOC From Onshore Natural Gas Processing Plants,
- 40 CFR Part 60 Subpart LLL, Standards of Performance for Onshore Natural Gas Processing: SO₂ Emissions,
- 40 CFR Part 63 Subpart HH, National Emission Standards for Hazardous Air Pollutants From Oil and Natural Gas Production Facilities, and
- 40 CFR Part 63 Subpart HHH, National Emission Standards for Hazardous Air Pollutants From Natural Gas Transmission and Storage Facilities.

The attached comments are provided to assist EPA in understanding issues that are critical to the operations of oil and natural gas facilities that would be potentially affected by the pending rulemaking.

We appreciate your consideration of our comments. If you have any questions, please contact me at 202-682-8319 or toddm@api.org.

Sincerely,

/s/ Matthew Todd

Matthew Todd

1. WORKER SAFETY MUST BE CONSIDERED

EPA needs to consider worker safety in this rulemaking. These requirements will mandate control technologies and practices be applied to equipment and/or activities that have never before been regulated and therefore the risk of performing this work has not been fully evaluated. EPA needs to avoid instances where the requirements contained in this rule expose workers unnecessarily to dangers including but not limited to fire and explosion, toxic atmospheres, falling, equipment rupture, and rotating equipment injury.

2. THE FLOORS DO NOT NEED TO BE FIXED

EPA has indicated that it intends to “fix the floors” for some units in the Subpart HH standards and, in particular, the 1 ton/year (or 0.9 megagram per year) of benzene exemption threshold. When EPA says “floor” we assume that means the Clean Air Act requirement where the MACT control level must set at least at the average of the best 12% performing sources in that source category. However, these standards have been in effect for some years and never challenged. The values do not need to be “fixed”. Indeed, as explained below, EPA’s authority under the current review is prescribed by the terms of § 112(d)(6).

2.1. Adjustments to Floors are Limited by Statute

Once EPA establishes a MACT standard for a particular source category, the Agency has the authority (and the obligation) under § 112(d)(6) to “review and revise as necessary (taking into account developments in practices, processes, and control technologies), emissions standards promulgated under this section no less often than every 8 years.” In other words, EPA does not have unfettered discretion to revisit a prior MACT determination once that determination has been issued. Rather, EPA may revise a prior determination only “as necessary” according to explicit statutory criteria.

In 2006, NRDC filed a multi-faceted challenge to EPA’s final residual risk and § 112(d)(6) determinations for the Hazardous Organic NESHAP (“HON”) in the D.C. Circuit. Among numerous other claims, NRDC argued that EPA is required to make a new MACT determination each time an existing standard is reviewed pursuant to § 112(d)(6). The court quickly dispensed with this argument, concluding that “the words “review and revise as necessary” [cannot] be construed reasonably as imposing any such obligation.” *NRDC v. EPA*, 529 F.3d 1077, 1083 (D.C. Cir. 2008).

More specifically, NRDC also asserted that EPA was obligated under § 112(d)(6) to re-determine MACT for certain source types because cost had been considered in

determining the MACT “floor” in the original HON rule. The D.C. Circuit disagreed, reasoning that “EPA squarely found that there were no “significant developments in practices, processes and control technologies” and “[s]ince that is the core requirement of subsection 112(d)(6) and EPA’s finding satisfies that requirement, it is irrelevant whether EPA considered costs in arriving at the initial MACT floor and reaffirming that standard in the residual risk rulemaking.” *Id.* at 1084.

In short, this holding clearly establishes EPA is not required to redetermine MACT under § 112(d)(6) and that EPA cannot be forced pursuant to § 112(d)(6) to revise an existing MACT determination in order to “correct” an alleged deficiency in that determination based on subsequent judicial decisions.

2.2. One ton/year Threshold for Benzene is an Effective Standard

Lastly, the 1 ton/year (or 0.9 megagram per year) of benzene exemption threshold should be considered an “emission standard.” An exemption tied to an emission has the advantage of encouraging the over-control of affected sources (validated by State NSR permits so that the PTE limitation is federally enforceable) to avoid the complexities and continuous monitoring burden of NESHAP regulations. This practice was recognized in the January 3, 2007 proposed revision of the Once-In-Always-In policy. Thus, even at major sources, the use of emission limits to exempt affected sources from regulation under NESHAP is beneficial to the environment.

3. GREEN COMPLETIONS HAVE LIMITED FEASIBILITY

API wishes to reiterate the conditions and criteria that enable “green completions” to be used when completing or re-completing an oil and/or gas well. As context, we are including a short description of well flow-back and clean-up.

3.1. Background on Well Completion, Flow-Back, and Clean-up

As EPA is aware, most oil and gas development in the onshore US is in non-traditional reservoirs, such as shales, coal-beds, and tight sands, and the majority of wells require fracture stimulation to enable production. Hydraulic fracturing is the most common stimulation technique and requires pumping a fluid (such as gelled water or inert gas) carrying a proppent (such as sand) into the well-bore at a high flow rate and pressure to enhance fractures in the reservoir rock which are then propped open by the proppent material and provide a flow path for oil and gas to flow to the low pressure zone created by a well-bore.

After stimulation, a well must be “flowed back” at a rate sufficient to lift fluids and solids in the well-bore to the surface. Wells must be adequately cleaned-up to enable

production and avoid long term reservoir damage caused by foreign fluids and accumulated solids which stay in the formation. The ability of a well to flow back at a pressure and rate sufficient to lift the fluids and adequately clean-up the formation is dictated by the reservoir pressure/energy, the reservoir flow potential, the depth of the well, and the physical characteristics of the fracture fluids.

A common well clean-up technique is a clean-out where a high pressure gas is injected into the wellbore to jet debris from the wellbore and transport the solids to surface along with the gas. This technique is very common and works best with homogenous gases like air, CO₂, nitrogen, or methane. Gases with a wide range of components (like many natural gases) are less effective than homogenous gases due to condensation effects.

The flow rate up a well bore is dependent on the reservoir pressure being higher than the sum of flowing friction losses up the well-bore, the weight of any vertical column of fluid in the well bore, surface equipment and piping pressure losses, and any collection system/flow-line back-pressure. When green completions are used, this resistance to flow is much higher than the resistance observed in traditional completions (that flow against atmospheric pressure rather than collection system/flow-line pressure), which can reduce the flow rate to values inadequate to properly lift liquids and solids from the wellbore.

In the initial stages of a completion flow-back most of the flow is comprised of introduced fluids and proppent with little formation fluids or gas. As a well cleans-up, more formation fluid and gas enters the well-bore and the fluid column in the well-bore becomes “lighter” with less back-pressure on the formation.

3.2. Conditions Necessary for Green Completions

Green completions are the use of surface equipment, often purpose-designed and operated, to separate the introduced fluids, proppent, hydrocarbon liquids, and gas – with the gas routed to a collection line for sales and the hydrocarbon liquids routed to on-site storage for sales. To enable the use of green completion techniques a number of conditions/criteria must be met:

- 3.2.1. Availability of specialized equipment and personnel. Adequate equipment and qualified personnel must be in-place or available to allow the safe implementation of green completion techniques. Often, this will require that sufficient “purpose designed and constructed” surface equipment be available. Equipment and procedures for green completions must be able to safely handle the erosive forces of high rate flow with abrasive proppent without cutting through the surface piping and/or equipment.
- 3.2.2. Not feasible with air, CO₂, or nitrogen. The mixture of gases produced from the wellbore must be such that they can meet gathering-system quality requirements with simple mechanical separation equipment. When air, CO₂, or nitrogen is used in well operations, these gases would require extensive chemical and/or thermodynamic

processes to extract natural gas from the gas stream. This equipment is inappropriate and unsafe for wellsite use, and any of the processes that cannot be done without using these gases must be excluded from any green-completion requirement.

Meeting the gas composition specifications to enable sales is problematic where an inert gas or air is used to “jet” a well for clean-up, where an inert gas, such as CO₂ or N₂ is used to “energize” a hydraulic fracture, and where an inert gas, such as CO₂, is used as the stimulation fluid. In all of these cases, flow-back gas cannot be routed to a collection system for sales until it meets the system operator’s composition specifications and green completions is not an option.

- 3.2.3. Not viable for low pressure reservoirs. The reservoir must have sufficient flow potential and energy to lift fluids and adequately clean-up against the back pressure imposed by flowing to a gas collection line for sales. If the reservoir pressure/energy is too low to lift fluids and overcome the collection line back-pressure the well will not flow to a pipeline. Often in the early stages of a well clean-up, the flow-back is predominantly fracture fluid and the well will not be able to flow to a pipeline until it has partially cleaned-up. For some low pressure and depleted reservoirs green completions is not an available option.
- 3.2.4. Not viable unless collection infrastructure is in place. There must be a collection line in place to receive the flow-back gas. This is only common in in-fill situations where the risk of a dry hole is low and gas collection infrastructure is close. Exploration wells, flank extension wells, and wells having a high risk of being dry typically will not have a flow line in place to receive the gas.

If all of these conditions are met, then green completions may be a valid practice for a particular well. If any of these conditions cannot be overcome, then green completions cannot be used on a particular well.

API is aware that the addition of compression between the outlet of the surface green completion separation equipment and the gas pipeline has been tried in the past to lower back pressure on a well and broaden the pressure range where green completions can be accomplished. In fact, several of our member companies were the operators that piloted these trials – some for multiple years. Due to the unstable flow-back rates and pressures during a well clean-up coupled with compressor’s sensitivity to suction pressure and rate changes these pilots have not been successful yet. API does not consider the addition of compression to a green completion operation to be proven technology and EPA should not consider it as proven or available technology.

In crafting a regulatory program addressing well completions and flow-back, EPA must consider these physical and operational facts and provide the necessary regulatory clarity/ certainty and flexibility to enable companies to continue developing US oil and gas resources while complying with any regulation promulgated.

4. THE EFFECTIVE DATE MUST BE REASONABLE

4.1. Allow One Year for Equipment Supplies to Meet Demand

An appropriate effective date will lessen the production and cost impacts caused by competition for limited supplies of control equipment. API anticipates that compliance with this proposal will place heavy demands on limited supplies of control equipment and this will have significant negative consequences on production and drive up the cost of compliance. The EPA must avoid mandating control requirements before equipment supplies can meet demand.

Emission control equipment is in limited supply because many of the proposal's performance requirements will impact source types that have never before been regulated. It will take time for the supply of this equipment to match demand since the equipment is specialized and only available from a limited number of suppliers. If the EPA does not establish an appropriate effective date for controls, competition for limited supplies of control equipment will drive up cost and will negatively impact production.

As an example, if the proposal contained a requirement for all of industry to begin "green completing" their wells where practical (see "Green Completions" Section) at a time when specialized flowback equipment is in short supply, the result would be a bottleneck, affecting the industry's ability to bring on new production. The economic consequences of this will be significant. Further, in some cases, fluid-caused damage to the reservoir will occur if a company was delayed in flowing back wells because equipment wasn't available. This would result in permanent impacts to production and reserves.

Similarly, when demand for vent and fugitive emission control equipment outpaces supply, a producer's ability to begin operation of new production facilities will be impacted.

To avoid the negative consequences stemming from competition for control equipment, EPA should consider making control requirements effective at least one year after rule promulgation for equipment installed after the proposal date. Relocated equipment should not be considered a new source subject to the rule.

Emission control requirements should also become effective at least one year after rule promulgation for activities such as well flowback or well venting that aren't directly related to the installation of production equipment.

It is anticipated that equipment suppliers will need at least one year to ramp up production to meet demand.

4.2. NSPS Compliance Should be Triggered by the Final Rule, Not the Proposed Rule

Under the NSPS program, typically, any affected unit constructed, modified or reconstructed after the rule proposal date must comply with the NSPS rule. This approach will not work for many oil and gas operations because of the short-term or temporary nature of the operation. For example, if the upcoming O&G NSPS rule includes requirements to control well completion operations, it is unreasonable to require all well-completion jobs carried out between rule proposal date and the final rule date to adopt the control measures in the proposed rule. For the completion jobs performed shortly after the rule is proposed, it is most likely they will be completed or terminated before the final rule takes effect. In addition, the final rule may contain a vastly different requirement than the proposal. To expect and require such well completion projects to comply with the rule while the rule takes effect after the project is concluded is extremely unreasonable. Therefore, EPA should use the final rule effective date as the rule applicability threshold date.

5. A WELL WORKOVER DOES NOT CONSTITUTE A NSPS MODIFICATION

Because the O&G industry's operations are driven by the geology of the reservoirs that they are harvesting, impacts of NSPS and NESHAP General Provisions and definitions can have unintended consequences. The common interpretation of "modification" may be an example of this. EPA has already recognized at least part of this issue by stating that a well workover does not constitute a modification of a facility, even though it will increase the production (O&G flow) of the well. API sees this as a valid approach, since the purpose of a workover is to regain at least some of the original production flow of the well that has been lost to reservoir depletion.

API would like to assure that this approach is extended to other equipment both at the facility and downstream in the gathering system. The actual emissions of equipment (tank, dehydrator, compressor, etc.) decreases as the production flow depletes and correspondingly increases when the production rises due to a workover. API believes that a modification as defined in the NSPS is not triggered when the flow from the well and in the equipment downstream of the well increases as the result of well workover. API also believes that a modification as defined in NSPS is not triggered for equipment in a gathering system when there is an increase of flow from the workover of a well, or even the addition of new wells. Gathering system equipment should be subject to the rule based on the date of construction or the definition of reconstruction.

6. THIEF HATCH REQUIREMENTS APPLY ONLY TO CONTROLLED TANKS

In a short one page brief submitted to EPA in early December, a strawman was provided for developing work practice requirements to maintain thief hatches on storage tanks being controlled for emissions. Four key items were presented for consideration. These were: gasket selection, inspection schedule, replacement/repair of gasket material, and the proper pressure seal of the hatch in relation to the tank PRD or Enardo valve. The key limitation in recommending these practices was to apply them at tanks being controlled for emissions only. Maintaining a good seal at the thief hatch improves efficiency of the control device connected to the tank vent

Applying these practices to uncontrolled tanks will have no impact on reducing emissions and will only increase maintenance costs. If a tank's vent is uncontrolled, no control efficiency is gained by mandating work practices for the thief hatch. Depending on the condition of the hatch, the full stream of uncontrolled emissions will either exit through the tank vent or partial emissions may exit through the thief hatch instead of the vent. In either case, all tank emissions will be vented to atmosphere. No vapors are being captured, condensed, or burned to limit emissions.

7. FLARE REQUIREMENTS NEED TO BE CLARIFIED

7.1. Flare Continuous Pilots and Vmax Limits

Among the several papers provided to EPA in December was a short white paper discussing the various types of flares and their use in the oil and gas industry. Included as an attachment, was a study by John Zink for the TCEQ that demonstrates the efficiency of high velocity sonic flares. The key issues pointed out in the paper were the flare design limitations of 40 CFR §60.18. In particular the requirements of most concern are continuous pilots and Maximum velocity (Vmax). Our request is that continuous pilot requirements be clarified to mean "continuously lit pilot only during flaring events". Additionally, we ask that upper Vmax limits be removed so that more efficient sonic flares can be used for high BTU waste streams.

Changes to NSPS rules that widen the scope of applicability to oil and gas emission sources may also increase the applicability of §60.18 to flares used in the industry. While there is a rulemaking team established to modify flare requirements as a part of the uniform standard effort, the schedule for the oil and gas NSPS rules precedes any new flare standards. Consequently, it's our understanding that any changes to flaring requirements will need to be included in the oil and gas rulemaking directly.

7.2. Enclosed Combustors Need To Be Distinguished From Flares

API would also like to emphasize again that the “enclosed combustor” type of thermal device should be classified as a “burner”, not a “flare” and should not be subject to the requirements of §60.18. These devices are completely different from flares in their design and operation which renders the requirements of §60.18 inappropriate. EPA has recognized this in several past determinations where they have determined that enclosed flame combustors are not flares even if they are termed (enclosed) flares by the manufacturer.

These enclosed combustor types of devices are increasingly being deployed for emission control of streams that would historically have been burned in flares or not controlled. We would also like to emphasize that the type of units typically deployed in the E&P industry are quite different than those which might be deployed at industrial facilities. Specifically, the combustors typically deployed in the E&P segment do not have electricity available and hence depend on natural draft rather than forced air (blower) for combustion, tend to be less complex, and tend to have limited instrumentation. Although simpler in design and dependent on natural draft these units have been shown able to consistently deliver destruction efficiencies in the 98 – 99%+ range in Wyoming areas.

Given the design of these enclosed combustors and the typical materials (fuels) that are burned, API also believes they should be considered as burners rather than thermal oxidation devices.

EPA should not create disincentives to use a broader deployment of these types of devices by requiring unnecessary or infeasible testing and/or monitoring.

7.3. Provisions are Needed for Approval of New Control Technologies

During the last teleconference with the Agency several weeks ago, there was a favorable discussion about inserting provisions in the rulemaking that (with appropriate approvals) would allow for the experimental use and implementation of new control technologies. This would be a welcome provision in the rules. However, the ability to implement new technologies can sometimes be hampered by the approval process and the time it may take to get necessary approvals. Though extensively used worldwide in industry, as flaring rules stand right now, use of a sonic flare would have to get special approval as a new technology (if indeed a new technology provision is put into the new NSPS rule) before implementation. With backing from the Zink paper, it would seem more efficient to include use of sonic flares directly into the rule. This would eliminate the burden of getting special approvals for its use.

8. NSPS RULES SHOULD RETAIN THE VOC 10% EXEMPTION

API believes that the applicability criteria for the entire proposed *Oil & Gas New Source Performance Standards (NSPS)* should be the same cutoff (10 wt% VOC) used in the current NSPS Subpart KKK (which references Subpart VV, 40 CFR 60.481). That subpart (§60.632) states that “For a piece of equipment to be considered not in VOC service, it must be determined that the VOC content can be reasonably expected never to exceed 10.0 percent by weight”. In its analysis EPA determined that it is not cost effective to include equipment that handles liquid or gas with less than 10 wt% VOC.

Since the primary objective of the proposed O&G NSPS regulation is to reduce VOC emissions, the sources to be regulated must be capable of emitting VOC. Therefore, API requests that the 10 wt% VOC criteria apply to all of the O&G source types that are to be regulated by this proposed rule, not just the fugitive sources (i.e., those suitable for a Leak Detection and Repair program).

9. INCREASED REGULATION MAY DECREASE OIL AND GAS PRODUCTION

In prior discussions and presentations EPA has voiced the opinion that NSPS regulation of the E&P industry will not result in less production or reserves (natural gas supply). API believes this position is erroneous and offers the following discussion to underpin our belief.

US onshore oil and gas production is a mature industry with a very large proportion of low rate “marginal” producing wells and an increasing focus hydrocarbon deposits that are more difficult to find and extract in developing resource plays. As an indicator, the average production per new well has been declining for several years.

The US Energy Information Administration’s (EIA) listing of oil and gas wells by production rate bracket illustrates the preponderance of low rate wells in the US E&P industry. Of 363,459 producing US oil wells EIA data shows some 286,109 (78.7%) produce at a rate of 10 barrel-of-oil-equivalent (BOE) or less per day. For gas wells, EIA’s data shows that of 461,388 producing gas wells some 297,371 (64.5%) produce at a rate of 10 barrel-of-oil-equivalent (BOE) or less per day. With these low production rates, these wells are economically marginal and very sensitive to additional costs. Costs imposed by regulation may make the “tail” end of these wells non-economic and result in their shut-in and abandonment. Some proportion of this segment of the well portfolio may be abandoned which will reduce oil and natural gas production, royalty and tax income to mineral owners and government entities, and overall reserves. The extent of this reduction will be dependent on the scale of costs imposed by regulation.

The shift towards non-traditional resource plays for domestic production is illustrated by the focus on and increasing importance of natural gas from shale, coal beds, and tight sands. Not many years ago, these reservoir types were regarded as uneconomic because the technology to produce them didn't exist. At the gas prices of 2006-2007, the Shale Gas plays became economic and the industry began actively acquiring leasehold acreage and began drilling. With the price collapse in 2008, activity in the shale was significantly curtailed back to only those projects that were contractually mandatory. With the cost of drilling and completion under today's regulations, the threshold price is a sustained market price well above today's prices (the exact price level required to sustain production is a matter of much conjecture). Adding significant costs to reach new environmental goals will further delay the development of this resource, and may increase imports of natural gas. The extent of reduction in oil and gas production, reserves, royalties, and tax payments will depend on the scale of the costs imposed by regulation.

These impacts can disproportionately impact small oil and gas companies/operators who tend to have a portfolio of low rate marginal wells that are not economic for larger companies. There are 10,439 operators in the Oil & Gas industry that produced a combined 22 MMCF/d from 233,607 wells in 2008. This average of 0.1 MCF/day/well is very sensitive to costs and many of these operators cannot tolerate any additional costs and remain solvent. With an average of 22 wells (233,607 wells/10,439 operators) per operator it is obvious that most of these low rate wells are operated by small operators and regulatory imposed costs would disproportionately impact these small businesses.

10. ALLOW FLEXIBILITY FOR WELL-BORE DELIQUIFICATION CONTROLS

API has significant concerns with EPA's apparent focus in the December, 2009, CAAAC Multi-pollutant Sector Approach presentation on plunger-lift as a single technology-choice for addressing the challenge of reduced well venting. Deliquification of gas wells is a highly complex and technical subject with many approaches and technologies in use and venting of wells is one technique used. A very large amount of industry focus and attention is applied to gas-well deliquification with innovation and research continually underway. It is not appropriate for EPA to specify a particular technology or approach to the highly complex problem of well-bore deliquification through regulation. API does recognize that well-venting can be a significant source of hydrocarbon pollutant emissions and that there are technologies and techniques in use and available to sharply reduce, but not eliminate, venting of wells to assist in deliquification. In fact, many of API's member companies have been on the forefront of developing and applying innovative solutions for well-bore liquids unloading with no venting or reduced venting.

Specifying a single technology or approach could negatively impact the continued ability to produce low rate gas wells, stifle innovation, shorten the economic life of the majority of US gas wells, and disproportionately impact many small operators who tend to have portfolios of low rate “marginal” wells. Specifying one approach to deliquification will limit the economic life of gas wells and could cause companies to rethink their investment in US gas development. This may negatively impact the clean-fuel natural gas supply and the country’s energy security. Operators must have the flexibility to choose the most appropriate and cost effective approach for each individual well/reservoir/age/production combination and the regulatory certainty to underpin continued investment.

API suggests that EPA take a different approach to reducing venting by providing regulatory dis-incentives for continued venting rather than trying to enter the discipline of production engineering and well deliquification. Additionally, API suggests that EPA fully understand the issue of well liquid-loading and venting control prior to crafting regulations addressing it. API would like to offer assistance, through organizing meetings, workshops, and/or training sessions with well deliquification experts to help EPA gain the necessary understanding to craft a workable and effective regulation.

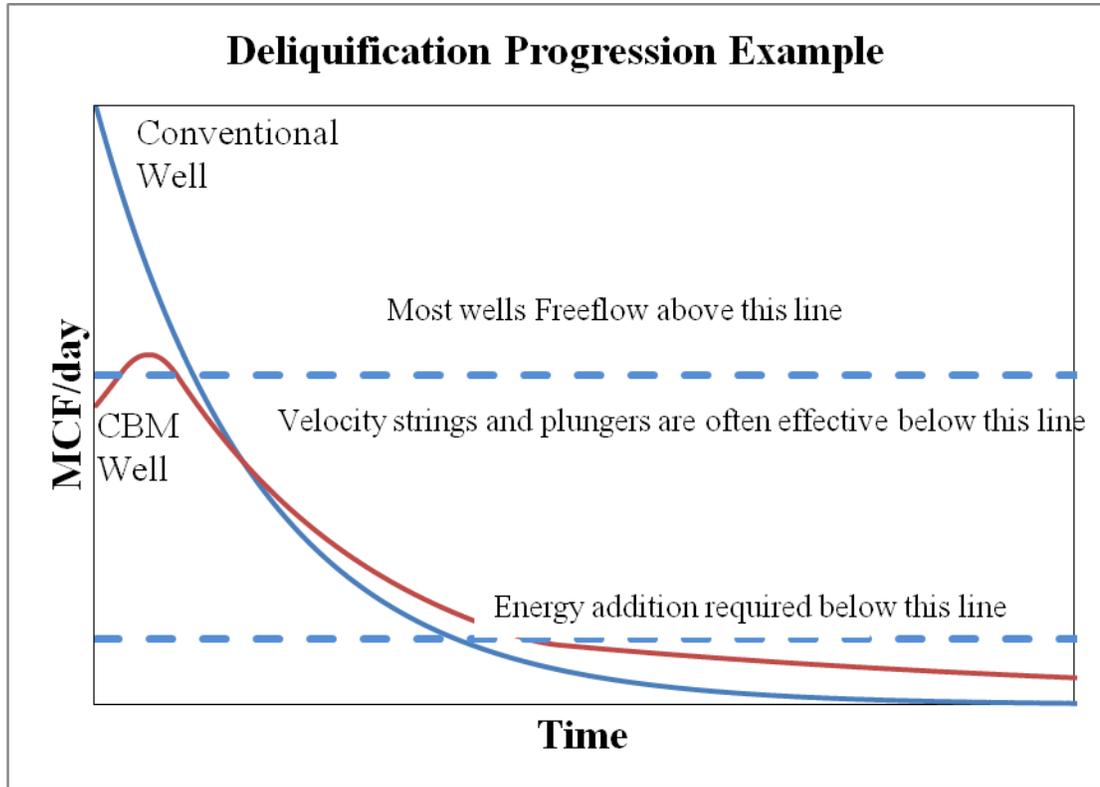

10.1. Background on Well-bore Deliquification (liquids unloading)

It is important to fully understand the fundamental nature of well bore liquid loading or the range of technologies in use to address it – in particular plunger lift and its appropriate use, limitations, and efficacy. API offers the following discussion of well venting and well-bore deliquification to assist EPA in crafting workable, appropriate, and effective requirements for reducing well venting for well-bore deliquification. Additionally, we highly recommend the June, 2009 American Oil and Gas Report article *Artificial Lift Advances Address Challenges, Trends in Gas Well Deliquification* and the February 27, 2006 Oil & Gas Journal article *Low-Pressure Gas Well Deliquification Requires Different Approaches*. Both articles provide a robust discussion of this topic.

Well deliquification is a fundamental challenge for continued production from the majority of US gas wells and the proportion is expected to grow with new growth concentrated in non-traditional gas reservoirs such as shales, coal-beds, and tight-gas sands which are all very susceptible to liquid loading. Liquid loading of well-bores occurs when the gas production-rate up the well-bore is not sufficient to carry liquids out of the well-bore. When a liquid column builds up in the well-bore, the weight of the column puts back-pressure on the producing formation and the production rate declines to the point where the well can quit flowing. According to the Energy Information Administration’s 2009 “Distribution of Wells by Production Rate Bracket” some 338,056 (73%) wells out of a total gas well inventory of 461,388 gas

wells produce 90 mcf of gas (15 BOE or less) or less per day (http://www.eia.doe.gov/pub/oil_gas/petrosystem/us_table.html) . These low rate wells are either impaired by liquids accumulation or are using a deliquification method to produce.

Wells and reservoirs follow a continuum of flow regimes, in their economic life, as the reservoir depletes, production goes down, well-bore (tubing) velocity goes down, and liquid loading begins to occur in the well-bore. In the early stage of a well’s life many (but by no means all) wells can flow freely and with sufficient velocity to avoid liquid loading problems. As the reservoir energy depletes and the production-rate declines, a well will reach the stage where liquid-loading begins to be a problem and one of a portfolio of technologies or techniques will be used to help lift liquids using the reservoirs energy. As a well continues to produce and the reservoir energy declines further, a well will reach the stage where the reservoirs energy is not sufficient to lift liquids and energy, in the form of pumps, gas lift, etc., will have to be added to continue producing. When the expected production from a well cannot support the investment required to enable deliquification, it will reach the end of its economic life and be abandoned. The following figure shows a generalized well life-cycle curve with these different stages of a wells life illustrated.

The production rate of a well, consequent velocity up the well-bore, and hence ability to lift liquids is mostly a function of the differential pressure between the reservoir and the flow-line/collection system and the reservoir's sensitivity to backpressure. In order to flow, the total reservoir pressure must be greater than the total resistance to flow. This resistance is comprised of fluid friction and fluid interference across the reservoir; the flowing friction up the well-bore; the weight of the vertical fluid column in the well-bore; surface equipment and piping pressure losses; and the collection system/flow-line back-pressure. Opening a well-bore to atmospheric pressure (venting a well) removes the surface equipment/piping pressure-loss and the back pressure from the collection line and increases differential pressure to increase flow rates and velocities, which may enable the well to lift the liquid from the well-bore (unload the well). Venting of wells has been a common practice in low rate gas well deliquification for decades and is not restricted to wells without deliquification assist technologies, such as plunger lifts, in place.

To combat this normal well/reservoir depletion and assist liquid lift a number of techniques are used – dependent on the well configuration, reservoir properties, well depth, and surface equipment and collection system. Some of these techniques are:

- The tubing in a well may be changed to smaller diameter “velocity strings” which provide for higher velocity at any given flow rate and provide higher liquid lift capabilities.
- Soap injection may be used to “foam” the liquids to reduce the unit density and enable liquids lifting.
- Wells may be put on a shut-in cycle to allow pressure/energy build-up of the reservoir near the well bore which equals higher production rates/velocity (temporary) and better liquids lifting.
- Plunger lift may be installed in a well. This is generally coupled with a shut-in cycle to build enough pressure under the plunger to lift it and the liquid column.
- Mechanical pumps are selected when liquid rate is too high for plungers to operate or reservoir pressure is too low for plungers to operate without excessive shut-ins for build up.
- Gas lift which raises tubing velocity to lift liquids by injecting gas down the tubing-casing annulus.
- Compression which lowers the surface pressure creating more differential for flow and increasing velocity by lowering pressure.
- Combinations of above approaches such as foaming, gas lift, and compression

The choice of what technique to employ is based on well-by-well and reservoir-by-reservoir analysis and is one of the primary jobs of the production engineering teams. For a typical well, as it moves through the depletion continuum, a series of techniques will be employed. The decision on technology-selection requires a thorough understanding of the conditions that a reservoir is flowing into, the reservoir's sensitivity to backpressure and the volumes and pressures that the deliquification technology must handle, and costs/benefits of applying the technology. This is a matter for engineering analysis and should not be a matter for regulation. For the EPA to mandate or even provide incentives to use a specific technology such as plungers will have the effect of stifling innovation and often deploying inappropriate technology. Saying that venting should be curtailed is a long way from the EPA requiring a broad implementation of a niche technology like plungers. In crafting regulations addressing well venting, EPA must encourage the flexibility to apply engineering analysis while introducing minimum venting as a criterion.

Once wells reach the point where energy must be added, there are many options such as pumps, gas lift, and compressors available to work in gas wells both before and after the brief time that plungers might be applied.

An excellent overview of this subject is Gas Well Deliquification, Second Edition, by Dr. James F. Lea, Dr. Henry V. Nickens, and Mr. Mike R. Wells (Gulf Publishing, 2008, ISBN 978-0-7506.8280-0). This 588 page book does a good job of explaining the basis for choosing among the various technologies, but it does not presume to force a one-size-fits-all solution on the industry.

10.2. Background on Plunger Lift

Plungers work by providing a mechanical barrier between a small volume of water and the gas that is used to transport it. If the gas could flow faster, then that mechanical barrier would not be necessary or helpful. Plunger capacity is limited by well depth, differential between reservoir pressure/surface pressure, and the gas/liquid ratio that the well produces. Even plunger lifted wells reach a point where they lack the reservoir pressure to run a plunger against backpressure often enough to lift the liquid that must be lifted. At that point the operator has the choice of replacing the plunger with a lift method that adds energy to the system or plugging the well. In the case of CBM wells for example, this point is generally reached around 50% of original gas in place (OGIP). Operators look at these wells and have to make the decision to spend capital on a pump or spend capital on drilling a new well—the economics of that decision generally favor installing a pump.

Although plungers are among the most common tools used in middle stage deliquification, plungers do not eliminate the need to vent to atmosphere. In many cases, wells are vented to atmosphere to generate the differential pressure necessary to lift the plunger and liquid column up the well-bore. This can be controlled and minimized but not eliminated.

- One of the primary studies/projects EPA likes to highlight from its Natural Gas Star program is the BP “smart automation” well bore venting control system in the San Juan basin. What is generally misunderstood or not acknowledged is that the majority of the wells which were venting (around 4.2 BCF of gas per year) were plunger equipped and were vented in order to generate the energy necessary to lift the plunger and liquid column.
- The fact that it took nearly 6 years to fully develop the system and achieve 90% + venting reduction is also often ignored. It is technically and operationally very difficult.
- Plungers are not universally applicable to well-bores. For example, a plunger cannot be run in a well-bore with changing tubing sizes, defects or buildups of scale or in coil tubing which has an “internal upset” weld seam. Plungers can only be run where the inside of the well-bore is smooth and in reasonably good condition. They also do not work well in highly deviated directional or horizontal well-bores.
- Although casing plungers are available for wells without tubing, they have had significant reliability problems and it is also difficult to control the velocity up the well-bore to avoid high velocities which have blown the top off of well-heads resulting in uncontrolled release of significant quantities of gas.
- Once a well/reservoir declines sufficiently, plungers will no longer work and energy must be added to the well-bore or the well abandoned. This is an economics decision.

10.3. Industry Research on Well-Bore Deliquification

There is a tremendous amount of research and work focused on well-bore deliquification, from a production and economics perspective alongside emissions reduction, and EPA needs to not discourage this or insert road-blocks. This work is both optimizing and improving existing techniques along with developing entirely new types of systems. Industry needs the flexibility to pilot some of these ideas/developments without regulatory impediments – even if they ultimately do not succeed.

For example, the 9th Annual Gas Well Deliquification Workshop is scheduled for February 28 – March 2, 2011 in Denver, Colorado. This workshop series, along with a portfolio of other venues dedicated to well deliquification and artificial lift, is organized by the Artificial Lift Research and Development Council (ALRDC), and the Southwestern Petroleum Short Course (SWPSC). The 34th Annual ASME/ALRDC International Gas-Lift Workshop was held in Singapore on February 7 - 11, 2011 with past annual workshops at various venues around the world. The ALRDC / SWPSC 2011 Appalachian Basin Gas Well Deliquification Seminar and workshop is scheduled for June 2011. For more information, please visit <http://www.alrdc.com>.

Attachment B
EPA Data Requested Table

Attachment B: EPA Requested Comment – Cross Reference Table

| API Comment Section | EPA Ref. Pre-Pub Page # | Oil & Gas Comment Solicitation List | Specific Data/Comments EPA requests in the preamble |
|---|-------------------------|--|---|
| 18.8 | 48 | 1. On the suitability of a compliance option allowing the use of wet seals combined with routing of emissions from the seal liquid through a closed vent system to a control device as an acceptable alternative to installing dry seals | 1.) EPA is aware that some owners and operators may need to use centrifugal compressors with wet seals, and is soliciting comment on the suitability of a compliance option allowing the use of wet seals combined with routing of emissions from the seal liquid through a closed vent system to a control device as an acceptable alternative to installing dry seals. (pg 48 of pre-publication) |
| 18.3 | 49 | 2. We solicit comment on the appropriateness of a fixed replacement frequency and other considerations that would be associated with regular replacement. | 2.) When the hours of operation reaches 26,000 hours, the owner or operator would be required to change the rod packing immediately. However, to avoid unscheduled shutdowns when 26,000 hours is reached, owners and operators could track hours of operation such that packing replacement could be coordinated with planned maintenance shutdowns before hours of operation reached 26,000. Some operators may prefer to replace the rod packing on a fixed schedule to ensure that the hours of operation would not reach 26,000 hours. EPA solicits comment on the appropriateness of a fixed replacement frequency and other considerations that would be associated with regular replacement. (pg 49 of pre-publication) |
| API had insufficient time to provide detail information | 56 | 3. The EPA has attempted to ensure that we have neither overlooked nor failed to propose to remove from the existing text any provisions that are inappropriate, unnecessary or redundant in the absence of the SSM exemption, nor included any such provisions in the proposed new regulatory language. We are specifically seeking comment on whether there are any such provisions that we have inadvertently overlooked or incorporated. | |
| 15.7 8 – 8.4 | 57 | 4. We discuss some innovative implementation approaches being considered and seek comment on these and other potential methods of streamlining notification and reporting for well completions covered by the proposed rule. p. 58 | |

| API Comment Section | EPA Ref. Pre-Pub Page # | Oil & Gas Comment Solicitation List | Specific Data/Comments EPA requests in the preamble |
|---------------------|-------------------------|--|--|
| 8 – 8.4 8.7 | 67 | | 3.) Under a traditional approach, owners or operators would provide notifications and keep records of information required by the NSPS. In addition, they would certify compliance with the NSPS as part of a required annual report that would include compliance-related information, such as details of each well completion event and information documenting compliance with other requirements of the NSPS. The EPA, state or local agency would then physically inspect the affected facilities and/or audit the records retained by the owner or operator. As an alternative to the traditional approach, EPA is seeking an innovative way to provide for more transparency to the public and less burden on the regulatory agencies and owners and operators, especially as it relates to modification of existing sources through recompletions of hydraulically fractured gas wells. These innovative approaches would provide compliance assurance in light of the absence of requirements for CAA title V permitting of non-major sources. (pg 67 of the pre-publication) |
| 8 – 8.1 | 68 | 5. We are seeking comment regarding the scope of application of one or more of these approaches, i.e., which provisions of the standards being proposed here would be suitable for specific compliance approaches, and whether the approaches should be alternatives to the requirements in the regulations. P.68 | 4.) EPA requests comments and suggestions on all aspects of the innovative compliance approaches discussed below and how they may be implemented appropriately. EPA is seeking comment regarding the scope of application of one or more of these approaches, i.e., which provisions of the standards being proposed here would be suitable for specific compliance approaches, and whether the approaches should be alternatives to the requirements in the regulations. (pgs 68 – 76 of the pre-publication) |
| 8.2-8.2.1, 15.7 | 70 | 6. We seek comment on potential methodologies that would minimize burden on operators, while providing timely and useful information for regulators and the public. P.70 | <u>Registration of Wells and Advance Notification of Planned Completions (pg 69-70)</u> Notification and registration could be streamlined through optional electronic reporting with web-based public access or other methods. 4a.) EPA seeks comment on potential methodologies that would minimize burden on operators, while providing timely and useful information for regulators and the public. |
| 15.7 | 70 | 7. We also solicit comment on provisions for a follow-up notification one or two days before an impending completion via telephone or by electronic means, since it is difficult to predict exactly when a well will be ready for completion a month in advance. However, we would expect an owner or operator to provide the follow-up notification only in cases where the completion date was expected to deviate from the original date provided. P.70 | 4b.) EPA also solicits comment on provisions for a follow-up notification one or two days before an impending completion via telephone or by electronic means, since it is difficult to predict exactly when a well will be ready for completion a month in advance. |
| 15.7 | 70 | 8. We ask for suggestions regarding how much advance notification is needed and the most effective method of providing sufficient and accurate advance notification of well completions. P.70 | |
| 8.7 | 71 | 9. we are considering and seeking comment on the potential use of third party verification to assure compliance. P. 71 | |

| API Comment Section | EPA Ref. Pre-Pub Page # | Oil & Gas Comment Solicitation List | Specific Data/Comments EPA requests in the preamble |
|---|-------------------------|--|--|
| 8.7 | 72 | 10. We seek comment on whether annual reports for well completions would be needed if a suitable third party verification program was in place and already housed that same information. P. 72 | |
| 8.7 | 72 | 11. We also solicit comment on the range of potential activities the third party verification program could handle with regard to well completions. P. 72 | |
| 8.7 | 73 | 12. We are seeking comment on appropriate third party reviewers and qualifications and registration requirements under such a program. P. 73 | <p><u>Third Party Verification (pg 70-73)</u> EPA is considering and seeking comment on the potential use of third party verification to assure compliance.</p> <p>4c.) EPA is seeking comment on appropriate third party reviewers and qualifications and registration requirements under such a program.</p> |
| 8.7 | 73 | 13. We are seeking comment on whether third party verification paid for by industry would result in impartial, accurate and complete data information. P. 73 | 4d.) The cost of third party verification would be borne by the affected industries. EPA is seeking comment on whether third party verification paid for by industry would result in impartial, accurate and complete data information. |
| 8.7 | 73 | 14. We are seeking comment on whether or not the EPA should approve third party verifiers p.73 | 4e.) EPA is seeking comment on whether or not the EPA should approve third party verifiers. |
| 8.4.3 | 74 | 15. We solicit comment on requiring sources to electronically submit their emissions data for the oil and gas rules proposed here. P.74 | <p><u>Electronic Reporting Using Existing Mechanisms (pg 74 -75)</u></p> <p>4f.) EPA solicits comment on requiring sources to electronically submit their emissions data for the oil and gas rules to the EPA's <u>Electronic Greenhouse Gas Reporting Tool (e-GGRT) used to report under Subpart W.</u></p> |
| API had insufficient time to provide detail information | 76 | 16. We seek comment on approaches that may be suitable for allowing temporary field testing of technology in development. These approaches could include not only established procedures under the CAA and its implementing regulations, but new ways to apply or interpret these provisions to avoid impeding innovation while remaining environmentally responsible and legal. P. 76 | <p><u>Provisions for Encouraging Innovative Technology (pg 75 -76)</u> The oil and natural gas industry has a long history of innovation in developing new exploration and production methods, along with techniques to minimize product losses and reduce adverse environmental impacts. As more emission sources in this source category are covered by regulation, as in the case of the action being proposed here, there likely will be situations where innovation and development of new control techniques potentially could be stifled by risk of violation.</p> <p>4g.) EPA seeks comment on approaches that may be suitable for allowing temporary field testing of technology in development. These approaches could include not only established procedures under the CAA and its implementing regulations, but new ways to apply or interpret these provisions to avoid impeding innovation while remaining environmentally responsible and legal.</p> |

|---------------------|-------------------------|--|--|
| 19.2.1 – 19.2.2 | 102 | 17. We request comment on the applicability of a LDAR program based solely on the use of optical gas imaging. Of most use to us would be information on the effectiveness of this and, potentially, other advanced measurement technologies, to detect and repair small leaks on the same order or smaller than specified in the 40 CFR part 60, subpart VVa equipment leak requirements and the effects of increased frequency of and associated leak detection, recording and repair practices. P. 102 | 5.) EPA requests comment on the applicability of a LDAR program based solely on the use of optical gas imaging. Of most use would be information on the effectiveness of this and, potentially, other advanced measurement technologies, to detect and repair small leaks on the same order or smaller than specified in the 40 CFR part 60, subpart VVa equipment leak requirements and the effects of increased frequency of and associated leak detection, recording and repair practices. (pg 102) |
| 21 | 111 | 18. We, therefore, solicit comments on produced water ponds, particularly in the following subject areas: (a) We are requesting comments pertaining to methods for calculating emissions. The State of Colorado currently uses a mass balance that assumes 100 percent of the VOC content is emitted to the atmosphere. Water9, an air emissions model, is another option that has some limitations, including poor methanol estimation. | 6.) EPA solicits comments on produced water ponds, particularly in the following subject areas: 6a) EPA is requesting comments pertaining to methods for calculating emissions. The State of Colorado currently uses a mass balance that assumes 100 percent of the VOC content is emitted to the atmosphere. Water9, an air emissions model, is another option that has some limitations, including poor methanol estimation. |
| 21 | 111 | (b) We are requesting additional information on typical VOC content in produced water and any available chemical analyses, including data that could help clarify seasonal variations or differences among gas fields. Additionally, we request data that increase our understanding of how changing process variables or age of wells affect produced water output and VOC content. | 6b) EPA is requesting additional information on typical VOC content in produced water and any available chemical analyses, including data that could help clarify seasonal variations or differences among gas fields. Additionally, we request data that increase our understanding of how changing process variables or age of wells affect produced water output and VOC content. |
| 21 | 111 | (c) We solicit information on the size and throughput capacity of typical evaporation pond facilities and request suggestions on parameters that could be used to define affected facilities or affected sources. We also seek information on impacts of smaller evaporation pits that are co-located with drilling operations, whether those warrant control and, if so, how controls should be developed. | 6c) EPA solicits information on the size and throughput capacity of typical evaporation pond facilities and request suggestions on parameters that could be used to define affected facilities or affected sources. We also seek information on impacts of smaller evaporation pits that are co-located with drilling operations, whether those warrant control and, if so, how controls should be developed. |
| 21 | 112 | (d) An important factor is cost of emission reduction technologies, including recovery credits or cost savings realized from recovered salable product. We are seeking information on these considerations as well. | 6d) An important factor is cost of emission reduction technologies, including recovery credits or cost savings realized from recovered salable product. EPA is seeking information on these considerations as well. |
| 21 | 112 | (e) We are also seeking information on any limitations for emission reduction technologies such as availability of electricity, waste generation and disposal and throughput and concentration constraints. | 6e) EPA is also seeking information on any limitations for emission reduction technologies such as availability of electricity, waste generation and disposal and throughput and concentration constraints. |
| 21 | 112 | (f) Finally, we solicit information on separator technologies that are able to improve the oil-water separation efficiency. P. 112 | 6f) EPA solicits information on separator technologies that are able to improve the oil-water separation efficiency. |

| API Comment Section | EPA Ref. Pre-Pub Page # | Oil & Gas Comment Solicitation List | Specific Data/Comments EPA requests in the preamble |
|--------------------------------------|-------------------------|--|--|
| 15.2, 15.3, 15.3.2 | 122 | 19. The EPA requests comment on this and seeks input on whether alternative approaches to requiring REC for all operators with access to pipelines may exist that would allow operators to meet a performance-based standard if they can demonstrate that an REC is not cost effective. P.122 | 7.) EPA recognizes that there is heterogeneity in well operations and costs, and that while RECs may be cost effective on average, they may not be for all operators. Nonetheless, EPA is proposing to require an operational standard rather than a performance-based standard (e.g., requiring that some percentage of emissions be flared or captured), because EPA believes there are no feasible ways to demonstrate compliance with a performance-based standard for REC in combination with pit flaring. The EPA requests comment on this and seeks input on whether alternative approaches to requiring REC for all operators with access to pipelines may exist that would allow operators to meet a performance-based standard if they can demonstrate that an REC is not cost effective. (pg 122) |
| 15.3.1, 15.3.3, 15.3.7, | 122 | 20. We solicit comment on whether there are other such situations where flaring would be unsafe or infeasible, and potential criteria that would support venting in lieu of pit flaring. P122 | |
| 5.1.2., 15.3.2, 15.6.3, Attachment B | 122 | 21. We solicit comment on criteria and thresholds that could be used to exempt some well completion operations occurring in coalbed methane reservoirs from the requirements for subcategory 1 wells. | |
| 15.4 | 123 | 22. We request comment on whether sufficient supply of this equipment and personnel to operate it will be available to accommodate the increased number of REC by the effective date of the NSPS | 8.) EPA believes that there will be a sufficient supply of REC equipment available by the time the NSPS becomes effective. However, energy availability could be affected if a shortage of REC equipment was allowed to cause delays in well completions. EPA requests comment on whether sufficient supply of this equipment and personnel to operate it will be available to accommodate the increased number of REC by the effective date of the NSPS. |
| 15.4 | 123 | 23. We also request specific estimates of how much time would be required to get enough equipment in operation to accommodate the full number of REC performed annually | EPA also requests specific estimates of how much time would be required to get enough equipment in operation to accommodate the full number of REC performed annually. (pg 123) |
| 15.4 | 124 | 24. We solicit comment on the phasing of requirements for REC along with suggestions for other ways to address a potential short-term REC equipment shortage that may hinder operators' compliance with the proposed NSPS, while also achieving a comparable level of reduced emissions to the air. P. 124 | 9.) EPA solicits comment on the phasing of requirements for REC along with suggestions for other ways to address a potential short-term REC equipment shortage that may hinder operators' compliance with the proposed NSPS, while also achieving a comparable level of reduced emissions to the air. (pg 124) |
| 15.10, Attachment B | 125 | 25. We request comment and any available technical information to judge whether our assumption of \$33,237 per well completion for this service given the projected number of wells in 2015 subject to this requirement is accurate. P. 125 | 10.) EPA requests comment and any available technical information to judge whether our assumption of \$33,237 per well completion for this service given the projected number of wells in 2015 subject to this requirement is accurate. (pg. 125) |

| API Comment Section | EPA Ref. Pre-Pub Page # | Oil & Gas Comment Solicitation List | Specific Data/Comments EPA requests in the preamble |
|----------------------------|-------------------------|---|--|
| 5.1.2, 15.3.2, 15.6, 15.10 | 125 | 26. We solicit comment and supporting data on appropriate thresholds (e.g., pressure, flowrate) that we should consider in specifying which well completions are subject to the REC requirements for subcategory 1 wells. Comments specifying thresholds should include an analysis of why sources below these thresholds are not cost effective to control. P. 125 | 11.) EPA believes that the proposed rule regulates only significant emission sources for which controls are cost-effective. Nevertheless, EPA solicits comment and supporting data on appropriate thresholds (e.g., pressure, flowrate) that should be considered in specifying which well completions are subject to the REC requirements for subcategory 1 wells. Comments specifying thresholds should include an analysis of why sources below these thresholds are not cost effective to control. (pg. 125) |
| 15.2, 15.3, 15.4 | 126 | 27. We request information on such opportunities and barriers that we should consider and suggestions for how we may take them into account in structuring the NSPS. P.126 | 12.) There may be economic, technical or other opportunities or barriers associated with performing cost-effective REC that EPA did not identified in their review. For example, some small regulated entities may have an increased source of revenue due to the captured product. On the other hand, some small regulated entities may have less access to REC than larger regulated entities might have. EPA requests information on such opportunities and barriers that should be considered and suggestions for how they may take them into account in structuring the NSPS. (pg. 125) |
| 15.3.1, 15.3.3, 15.3.7, | 128 | 28. We solicit comment on whether there are other such situations where flaring would be unsafe or infeasible and potential criteria that would support venting in lieu of pit flaring. P. 128 | 13.) Consistent with requirements for subcategory 1 wells, owners or operators of subcategory 2 wells would be required to document completions and provide justification for periods when gas was vented in lieu of combustion. EPA solicits comment on whether there are other such situations where flaring would be unsafe or infeasible and potential criteria that would support venting in lieu of pit flaring. (pg 128) |
| 15.11 | 130 | 29. EPA seeks comment on the 10 percent per year rate of refracturing for natural gas wells assumed in the impacts analysis found in the TSD. EPA has received anecdotal information suggesting that refracturing could be occurring much less frequently, while others suggest that the percent of wells refractured in a given year could be greater. P, 130 | 14.) EPA seeks comment on the 10 percent per year rate of refracturing for natural gas wells assumed in the impacts analysis found in the TSD. EPA has received anecdotal information suggesting that refracturing could be occurring much less frequently, while others suggest that the percent of wells refractured in a given year could be greater. |
| 15.11 | 130 | 30. We seek comment and comprehensive data and information on the rate of refracturing and key factors that influence or determine refracturing frequency. P.130 | EPA seeks comment and comprehensive data and information on the rate of refracturing and key factors that influence or determine refracturing frequency. (pg 129-130) |

| API Comment Section | EPA Ref. Pre-Pub Page # | Oil & Gas Comment Solicitation List | Specific Data/Comments EPA requests in the preamble |
|---|-------------------------|--|---|
| 17, 17.1, 17.6 | 137 | | 15.) There may be situations where high-bleed controllers and the attendant gas bleed rate greater than 6 cubic feet per hour, are necessary due to functional requirements, such as positive actuation or rapid actuation. An example would be controllers used on large emergency shutdown valves on pipelines entering or exiting compression stations. For such situations, EPA provided in the proposed rule an exemption where pneumatic controllers meeting the emission standards discussed above would pose a functional limitation due to their actuation response time or other operating characteristics. EPA is requesting comments on whether there are other situations that should be considered for this exemption. If you provide such comment, please specify the criteria for such situations that would help assure that only appropriate exemptions are claimed. (pg 137) |
| 18.8.1 | 143 | | 16.) EPA seeks comment on available cost data of a dry seal versus wet seal compressor, including all ancillary equipment costs. (pg 143) |
| 18.8.1 | 144 | 31. We are soliciting comments on the emission reduction potential, cost and any limitations for the option of routing the gas back to a low pressure fuel stream to be combusted as fuel gas. | 17.) Although EPA is proposing to determine dry seal systems to be BSER for centrifugal compressors, EPA is soliciting comments on the emission reduction potential, cost and any limitations for the option of routing the gas back to a low pressure fuel stream to be combusted as fuel gas. |
| 18.8.1 | 144 | In addition, we solicit comments on whether there are situations or applications where wet seal is the only option, because a dry seal system is infeasible or otherwise inappropriate. P.144 | In addition, EPA solicits comments on whether there are situations or applications where wet seal is the only option, because a dry seal system is infeasible or otherwise inappropriate. (pg 144) |
| 18.3.3 | 149 | 32. We are soliciting comments on incorporating a method similar to that in the Natural Gas STAR's Lessons Learned document entitled, Reducing Methane Emissions from Compressor Rod Packing Systems p.149 | 18.) Some industry partners of the Natural Gas STAR program currently conduct periodic testing to determine the leakage rates that would identify economically beneficial replacement of rod packing based on natural gas savings. Therefore, EPA is soliciting comments on incorporating a method similar to that in the Natural Gas STAR's Lessons Learned document entitled, Reducing Methane Emissions from Compressor Rod Packing Systems (http://www.epa.gov/gasstar/documents/ll_rodpack.pdf), to be incorporated in the NSPS. |
| API had insufficient time to provide detail information | 149 | 33. We are soliciting comments on how to determine a suitable leak threshold above which rod packing replacement would be cost effective for VOC emission reduction. | EPA is soliciting comments on how to determine a suitable leak threshold above which rod packing replacement would be cost effective for VOC emission reduction. |
| 18.3 | 149 | 34. We are also soliciting comment on the appropriate replacement frequency and other considerations that would be associated with regular replacement periods. P.149 | EPA is also soliciting comment on the appropriate replacement frequency and other considerations that would be associated with regular replacement periods. (pg 149) |

| API Comment Section | EPA Ref. Pre-Pub Page # | Oil & Gas Comment Solicitation List | Specific Data/Comments EPA requests in the preamble |
|---|-------------------------|---|--|
| API had insufficient time to provide detail information | 166 | 35. We request comment on the applicability of a leak detection and repair program based solely on the use of optical imaging or other technologies. Of most use to us would be information on the effectiveness of advanced measurement technologies to detect and repair small leaks on the same order or smaller as specified in the VVa equipment leak requirements and the effects of increased frequency of and associated leak detection, recording, and repair practices. P.166 | 19.) EPA requests comment on the applicability of a leak detection and repair program based solely on the use of optical imaging or other technologies. Of most use to EPA would be information on the effectiveness of advanced measurement technologies to detect and repair small leaks on the same order or smaller as specified in the VVa equipment leak requirements and the effects of increased frequency of and associated leak detection, recording, and repair practices. (pg 166) |
| 10, 10.12, 10.3, 10.4, 10.6 | 167 | 36. Thus, any comments that contend that sources cannot meet the proposed standard during startup and shutdown periods should provide data and other specifics supporting their claim. P.167 | |
| API had insufficient time to provide detail information | 176 | 37. We are requesting that the public provide a detailed review of the information in this dataset and provide comments and updated information where appropriate. Section X of this preamble provides an explanation of how to provide updated information for these datasets. | 20.) The NEI database was used to evaluate the number of major sources, EPA is requesting that the public provide a detailed review of the information in this dataset and provide comments and updated information where appropriate. Section X of this preamble provides an explanation of how to provide updated information for these datasets. (pg 176) |
| API had insufficient time to provide detail information | 212 | 38. We solicit comment on the use of the occupational values described above in the interpretation of these worst-case acute screening exposure estimates. P.212 | |
| 20.2 | 245 | 39. Pursuant to CAA section 112(f)(4), we are proposing that this change (i.e., removal of the 0.9 Mg/yr compliance alternative) apply 90 days after its effective date. We are requesting comment on whether or not this is sufficient time for the large dehydrators that have been relying on this compliance alternative to come into compliance with the 95-percent control requirement or if additional time is needed. See CAA section 112(f)(4)(A). p. 245 | |
| 20.1, 20.2, 20.3, 20.4 | 246 | 40. We solicit comment on any such impacts and whether such impacts warrant adding a different compliance alternative that would result in less risk than the 0.9 Mg/yr benzene limit compliance option. If a commenter suggests a different compliance alternative, the commenter should explain, in detail, what that alternative would be, how it would work and how it would reduce risk. P.246 | |
| 20.1, 20.2, 20.3, 20.4 | 262 | 41. We solicit comment on any such impacts and whether such impacts warrant adding a different compliance alternative that would result in less risk than the 0.9 Mg/yr benzene limit compliance option. If a commenter suggests a different compliance alternative, the commenter should explain, in detail, what that alternative would be, how it would work, and how it would reduce risk. P262 | |

| API Comment Section | EPA Ref. Pre-Pub Page # | Oil & Gas Comment Solicitation List | Specific Data/Comments EPA requests in the preamble |
|---|-------------------------|--|--|
| API had insufficient time to provide detail information | 283 | 42. We are specifically seeking comment on whether there are any such provisions that we have inadvertently incorporated or overlooked. 0,282 | |
| API had insufficient time to provide detail information | 290 | 43. We are asking for comment regarding the likelihood of this occurrence and data demonstrating the circumstances where it occurs. In light of the potential issue, we are asking for comment regarding the addition of provisions in the NESHAP to require area sources to recalculate their PTE to confirm that they are indeed area sources and whether that calculation should be performed on an annual or biannual basis to verify that changes in gas composition have not increased their emissions. P.290 | 21.) EPA is seeking comment on several PTE related issues. According to the data available to the Administrator, when 40 CFR part 63, subpart HH was promulgated, the level of HAP emissions was predominantly driven by natural gas throughput (i.e., HAP emissions went up or down in concert with natural gas throughput). Since promulgation, EPA has learned that there is not always a direct correlation between HAP emissions and natural gas throughput. EPA has received information suggesting that, in some cases, HAP emissions can increase despite decreasing natural gas throughput due to changes in gas composition. EPA is asking for comment regarding the likelihood of this occurrence and data demonstrating the circumstances where it occurs. In light of the potential issue, EPA is asking for comment regarding the addition of provisions in the NESHAP to require area sources to recalculate their PTE to confirm that they are indeed area sources and whether that calculation should be performed on an annual or biannual basis to verify that changes in gas composition have not increased their emissions. (pg. 290) |
| API had insufficient time to provide detail information | 317 | 44. In particular, the EPA seeks public comments to this proposed rulemaking regarding social cost of methane estimates that may be used to value the co-benefits of methane emission reductions anticipated for the oil and gas industry from this rule. Comments specific to whether GWP is an acceptable method for generating a placeholder value for the social cost of methane until interagency-modeled estimates become available are welcome. Public comments may be provided in the official docket for this proposed rulemaking in accordance with the process outlined earlier in this notice. These comments will be considered in developing the final rule for this rulemaking. P.317 | |
| API had insufficient time to provide detail information | 319 | 45. We are soliciting comments on all aspects of this proposed action. All comments received during the comment period will be considered. | |

| API Comment Section | EPA Ref. Pre-Pub Page # | Oil & Gas Comment Solicitation List | Specific Data/Comments EPA requests in the preamble |
|---|--|--|--|
| API had insufficient time to provide detail information | 319 | In addition to general comments on the proposed actions, we are also interested in any additional data that may help to reduce the uncertainties inherent in the risk assessments. We are specifically interested in receiving corrections to the datasets used for MACT analyses and risk modeling. Such data should include supporting documentation in sufficient detail to allow characterization of the quality and representativeness of the data or information. Please see the following section for more information on submitting data. P. 319 | |

Attachment C
Suggested Rule Text Table

Attachment C

| Ref # | Comment | Regulatory Text |
|---|---|--|
| Subpart 0000-Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution | | |
| § 60.5360 What is the purpose of this subpart? | | |
| 1 | See Section 3. for Title deletion. | § 60.5360 This subpart establishes emission standards and compliance schedules for the control of volatile organic compounds (VOC) and sulfur dioxide (SO ₂) emissions from affected facilities that commenced construction, modification or reconstruction after August 23, 2011. |
| § 60.5365 Am I subject to this subpart? | | |
| 2 | See Section 3.1, 3.2, and 5.1.2. | § 60.5365 If you are the owner or operator of <u>a site prior to the point of custody transfer at which is located</u> one or more of the affected facilities listed in paragraphs (a) through (g) of this section that commenced construction, modification, or reconstruction after August 23, 2011 your affected facility is subject to the applicable provisions of this subpart. <u>Paragraphs §60.5365(a)-(e) apply only to affected facilities in VOC service. For the purposes of this subpart, a well completion operation following hydraulic fracturing or refracturing that occurs at a gas wellhead facility that commenced construction, modification, or reconstruction on or before August 23, 2011 is considered a modification of the gas wellhead facility, but does not affect other equipment, process units, storage vessels, or pneumatic devices located at the well site.</u> |
| 2A | Primary Recommendation: see Section 2. Alternative Recommendation : see Section 4. and regulatory text for 60.5365(a)-(e) below. | Remove 60.5365(a)-(e) and associated sections/paragraphs of Subpart OOOO from this proposal and place in a separate supplemental proposal to be finalized at a later date. |
| 2B | See Section 5.4.3 and 15.6. | § 60.5365 (a) <u>An onshore natural gas wellhead affected facility, is a single natural gas well-, except for one that does not have flowback immediately following hydraulic fracturing stimulation. VOC emissions from flowback immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore is the only activity regulated at this affected facility. For the purposes of this subpart, an existing onshore natural gas wellhead facility is considered modified if it meets the criteria of modification in §60.14. The modification of an existing natural gas wellhead affected facility does not affect the status of other equipment, process units, storage vessels, or pneumatic devices located at the well site.</u> |

| Ref # | Comment | Regulatory Text |
|-------|--|--|
| 3 | See Section 18.1. | § 60.5365 (b) A centrifugal compressor affected facility, which is defined as a single centrifugal compressor <u>in VOC service</u> located between the wellhead and the <u>point of custody transfer eity gate</u> (as defined in § 60.5430), except that a centrifugal compressor located at a well site (as defined in § 60.5430) <u>and prior to the natural gas processing</u> plant is not an affected facility under this subpart. For the purposes of this subpart, your centrifugal compressor is considered to have commenced construction on the date the compressor is installed at the facility. |
| 4 | See Section 18.1 and 18.4. | § 60.5365 (c) A reciprocating compressor affected facility, which is defined as a single reciprocating compressor <u>in VOC service</u> located between the wellhead and the <u>point of custody transfer eity gate</u> (as defined in § 60.5430), except that a reciprocating compressor located at a well site (as defined in § 60.5430) is not an affected facility under this subpart. For the purposes of this subpart, your reciprocating compressor is considered to have commenced construction on the date the compressor is installed at the facility. |
| 5 | See Section 17.4 Process unit affected facility concept from SOCOMI NSPS in 59 FR 46780 <ul style="list-style-type: none"> • Avoids RMRR triggering modification, reconstruction • Significant relief in recordkeeping and reporting • Controllers are a component piece of a process unit, not a standalone emissions source. | § 60.5365 (d) A pneumatic controller affected facility, which is defined as a single pneumatic controller. A continuous bleed gas-driven pneumatically controlled process unit affected facility which is defined as a single continuous bleed gas-driven pneumatically controlled process unit, if it is located before the point of custody transfer. |
| 5A | Alternative Recommendation – See Section 17.4.3 | § 60.5365 (d) A <u>continuous bleed gas-driven</u> pneumatically controller affected facility, which is defined as a single pneumatic <u>controller, if it is located before the point of custody transfer.</u> |
| 5B | See Section 17.1 New sub-paragraphs inserted <ul style="list-style-type: none"> • Intermittent vent pneumatic controllers are not continuous bleed controllers Non-gas driven pneumatic controllers have no regulated emissions | <u>§ 60.5365 (d)(1) Intermittent vent pneumatic controllers are not considered part of an affected facility.</u> |
| 5C | See Section 17.4.2 | <u>§ 60.5365 (d)(2) Non gas-driven pneumatic controllers are not considered part of an affected facility.</u> |
| 6 | See Section 5.2, 5.3, and 16.4 | § 60.5365 (e) A storage vessel affected facility, which is defined as a single storage vessel <u>storing condensate or crude oil</u> and <u>located prior to the point of custody transfer.</u> |
| 7 | See Section 18.2 and 19.3 | § 60.5365 (f) Compressors and e Equipment (as defined in § 60.5430) located at onshore natural gas processing plants. |
| 8 | See Section 18.2 and 19.3 | § 60.5365 (f)(1) Each compressor in VOC service or in wet gas service is an affected facility. |

| Ref # | Comment | Regulatory Text |
|-------|--|--|
| 9 | See Section 18.2 and 19.3 | § 60.5365 (f) (2) <u>(1)</u> The group of all equipment, except compressors , within a process unit is an affected facility. |
| 10 | See Section 19.3 | § 60.5365 (f) (3) <u>(2)</u> Addition or replacement of equipment, as defined in § 60.5430, for the purpose of process improvement that is accomplished without a capital expenditure shall not by itself be considered a modification under this subpart. |
| 11 | See Section 19.3 | § 60.5365 (f) (4) <u>(3)</u> Equipment (as defined in § 60.5430) associated with a compressor station, dehydration unit, sweetening unit, underground storage tank, field gas gathering system, or liquefied natural gas unit is covered by §§ 60.5400, 60.5401, 60.5402, 60.5421 and 60.5422 of this subpart if it is located at an onshore natural gas processing plant. Equipment (as defined in § 60.5430) not located at the onshore natural gas processing plant site is exempt from the provisions of §§ 60.5400, 60.5401, 60.5402, 60.5421 and 60.5422 of this subpart. |
| 12 | See Section 19.3 | § 60.5365 (f) (5) <u>(4)</u> Affected facilities located at onshore natural gas processing plants and described in paragraphs (f)(1) and (f)(2) of this section are exempt from this subpart if they are subject to and controlled according to subparts VVa, GGG or GGGa of this part. |
| 13 | See Section 5.5 | § 60.5365 (g) Sweetening units located <u>at onshore natural gas processing plant</u> that process natural gas produced from either onshore or offshore wells. |
| 14 | | § 60.5365 (g)(1) Each sweetening unit that processes natural gas is an affected facility; and |
| 15 | | § 60.5365 (g)(2) Each sweetening unit that processes natural gas followed by a sulfur recovery unit is an affected facility. |
| 16 | | § 60.5365 (g)(3) Facilities that have a design capacity less than 2 long tons per day (LT/D) of hydrogen sulfide (H ₂ S) in the acid gas (expressed as sulfur) are required to comply with recordkeeping and reporting requirements specified in § 60.5423(c) but are not required to comply with §§ 60.5405 through 60.5407 and paragraphs 60.5410(g) and 60.5415(g) of this subpart. |
| 17 | | § 60.5365 (g)(4) Sweetening facilities producing acid gas that is completely reinjected into oil-or-gas-bearing geologic strata or that is otherwise not released to the atmosphere are not subject to §§ 60.5405 through 60.5407, and §§ 60.5410(g), 60.5415(g), and § 60.5423 of this subpart. |
| 18 | § 60.5370 When must I comply with this subpart? | |
| 19 | See Section 7.1 and 15.4 | § 60.5370 (a) You must be in compliance with the standards of this subpart no later than <u>60 days after</u> the date of publication of the final rule in the Federal Register or upon startup, whichever is later <u>except for the provisions provided in (d) and (e) of this section.</u> |
| 19A | See Section 7.2 and 15.4 | <u>§ 60.5370 (a)(1) Compliance with 60.5375 (natural gas wellhead facility) will begin [two years after the effective date]. From the [effective date] until [two years after the effective date] comply only with § 60.5375 (a)(1)(ii).</u> |

| Ref # | Comment | Regulatory Text |
|-------|---|---|
| 19B | See Section 7.3, 17.10 and 17.11 | <u>§ 60.5370 (a)(2) Compliance with §60.5390 is required beginning [one year after the effective date], except for the following</u> |
| 19C | See Section 17.10 API prefers to remove manufacturer guarantee, but this text is offered as an alternative | <u>§ 60.5370 (a)(2)(i) Compliance with §60.5410(d)(3) is required (for any new, modified, or reconstructed affected facility) beginning two years after the effective date</u> |
| 19D | See Section 17.10 API prefers to remove manufacturer guarantee, but this text is offered as an alternative | <u>§ 60.5370 (a)(2)(ii) Compliance with §60.5410(d)(3) is required (for any new, modified, or reconstructed affected facility) beginning two years after the effective date</u> |
| 19E | See Section 17.10 API prefers to remove manufacturer guarantee, but this text is offered as an alternative | <u>§ 60.5370 (a)(2)(iii) Compliance with §60.5420(c)(4)(iii) is required (for any new, modified, or reconstructed affected facility) beginning two years after the effective date</u> |
| 19F | See Section 7.3 | <u>§ 60.5370 (a)(3) Compliance with §60.5395 is required beginning [three years after the effective date].</u> |
| 19G | See Section 19.6 | <u>§ 60.5370 (a)(4) If your new or reconstructed process unit equipment is subject to §§60.5400, 60.5401, and 60.5402, you must be in compliance no later than 180 days after startup.</u> |
| 19H | See Section 19.6 & 19.7 | <u>§ 60.5370 (a)(5) If you become subject to §§60.5400, 60.5401 and 60.5402 due to modification under provisions of §60.14, the group of all equipment within that process unit must be in compliance with the work practice provisions of §§60.5400, 60.5401, and 60.5402 of this subpart no later than a year after the modification. If any equipment upgrade is required in order to achieve initial compliance (e.g., pump seal and pressure relief device upgrades), you must complete all equipment upgrades and comply with §§60.5400, 60.5401 and 60.5402 for that equipment no later than three years after the modification.</u> |
| 20 | | § 60.5370 (b) The provisions for exemption from compliance during periods of startup, shutdown, and malfunctions provided for in 40 CFR 60.8(c) do not apply to this subpart. |
| 21 | | § 60.5370 (c) You are exempt from the obligation to obtain a permit under 40 CFR part 70 or 40 CFR part 71, provided you are not otherwise required by law to obtain a permit under 40 CFR 70.3(a) or 40 CFR 71.3(a). Notwithstanding the previous sentence, you must continue to comply with the provisions of this subpart. |
| 21A | See Section 19.6 | <u>§ 60.5370(d) If your new or reconstructed process unit equipment is subject to §§60.5400, 60.5401, and 60.5402, you must be in compliance no later than 180 days after startup.</u> |
| 21B | See Section 19.6 and 19.7 | <u>§ 60.5370(e) If you become subject to §§60.5400, 60.5401 and 60.5402 due to modification under provisions of §60.14, the group of all equipment within that process unit must be in compliance with the work practice provisions of §§60.5400, 60.5401, and 60.5402 of this subpart no later than a year after the modification. If any equipment upgrade is required in order to achieve initial compliance (e.g., pump seal and pressure relief device upgrades), you must complete all equipment upgrades and comply with §§60.5400, 60.5401 and 60.5402 for that equipment no later than three years after the modification.</u> |

| 22 | | § 60.5375 What standards apply to gas wellhead affected facilities? |
| 23 | | § 60.5375 If you are the owner or operator of a gas wellhead affected facility, you must comply with paragraphs (a) through (g) of this section. |
| 24 | Preferred Option See Section 15.2 | § 60.5375 (a) Except as provided in paragraph (f) of this section, for flowback immediately following of each well completion operation with hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore , as defined in § 60.5430, you must control emissions by the operational procedures found in paragraphs (a)(1) through and (a)(32) of this section. |
| 24A | Alternative Option See Section 15.2 | § 60.5375 (a) Except as provided in paragraph (f) of this section, for flowback of each well completion operation with immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore , as defined in §60.5430, you must control emissions by the operational procedures found in paragraphs (a)(1) through (a)(3) of this section. |
| 25 | Preferred Option See Section 15.2 | § 60.5375 (a)(1) You must minimize the <u>VOC</u> emissions associated with venting of hydrocarbon fluids and gas over the duration of flowback immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore , as defined in § 60.5430, utilizing one or more of the following options by routing the recovered liquids into storage vessels and routing the recovered gas into a gas gathering line or collection system. |
| 25A | Alternative Option See Section 15.2 | § 60.5375 (a)(1) You must minimize the <u>VOC</u> emissions associated with venting of hydrocarbon fluids and gas over the duration of flowback duration of immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore , as defined in §60.5430, utilizing one or more of the following options: by routing the recovered liquids into storage vessels and routing the recovered gas into a gas gathering line or collection system. |
| 25B | Preferred Option See Section 15.2 | § 60.5375 (a)(1)(i) Route salable natural gas to a natural gas gathering line if available when deemed safe and practicable by the operator. |
| 25C | Alternative Option See Section 15.2 | § 60.5375 (a)(1)(i) Route salable natural gas to a natural gas gathering line if available when deemed safe and practicable by the operator. When the well head pressure (in absolute units) immediately following perforation is four times the static sales meter pressure then the operator is obligated to flow the well to an available sales line or document the reasons for failing to flow to sales. |

|-------|--|---|
| 25D | Preferred Option See Section 15.2 | <u>§ 60.5375 (a)(1)(ii) Capture and route VOC emissions associated with flowback immediately following hydraulic fracturing stimulation that occurs at a natural gas wellhead facility onshore that cannot be directed to the gathering line to a completion combustion device except when conditions may result in an explosion, gas is not combustible, or not allowed by state, tribal, or local requirement. Completion combustion devices must be equipped with a reliable ignition source over the duration of flowback but are not subject to 60.18.</u> |
| 25E | Alternative Option See Section 15.2 | <u>§ 60.5375 (a)(1)(ii) Capture and route flowback emissions that cannot be directed to the gathering line to a completion combustion device except when conditions may result in a fire hazard, or explosion, gas is not combustible, or not allowed by state, tribal, or local requirement. Completion combustion devices must be equipped with a reliable ignition source over the duration of flowback but are not subject to 60.18. For wells meeting the criteria for wildcat, appraisal, or delineation wells or where production equipment or a natural gas gathering line is not reasonably available, reduce emissions by using a completion combustion device when not precluded by one of the conditions described above.</u> |
| 25F | Preferred Option See Section 15.2 | <u>§ 60.5375 (a)(1)(iii) Other method that minimizes VOC emissions associated with flowback immediately following hydraulic fracture stimulation.</u> |
| 26 | Preferred Option See Section 15.2 | <u>§ 60.5375 (a)(2) You must employ sand traps, surge vessels, separators, and tanks during flowback and cleanout operations to safely maximize resource recovery and minimize releases to the environment. All salable-quality gas must be routed to the gas gathering line as soon as practicable. Develop and implement a management plan for each basin for how you will minimize VOC emissions associated with flowback immediately following hydraulic fracturing stimulation at a natural gas wellhead facilities onshore utilizing the options in 60.5375(a)(1). The plan must include:</u> |
| 26A | Alternative Option See Section 15.2 | <u>§ 60.5375 (a)(2) You must employ sand traps, surge vessels, separators, and tanks during flowback and cleanout operations to safely maximize resource recovery and minimize releases to the environment. All salable-quality gas must be routed to the gas gathering line as soon as practicable.</u> |
| 26B | See Section 15.2 | <u>§ 60.5375 (a)(2)(i) Methods and techniques to enhance direction of gas during the flowback immediately following hydraulic fracturing to the natural gas gathering system.</u> |
| 26C | See Section 15.2 | <u>§ 60.5375 (a)(2)(ii) Equipment to be used.</u> |
| 26D | See Section 15.2 | <u>§ 60.5375 (a)(2)(iii) Operating procedures.</u> |
| 26E | See Section 15.2 | <u>§ 60.5375 (a)(2)(iv) Definition of roles and responsibilities for implementation of the plan.</u> |

| Ref # | Comment | Regulatory Text |
|-------|--|---|
| 26F | See Section 15.2 | <u>§ 60.5375 (a)(2)(v) Review of the effectiveness of the plan in minimizing VOC emissions every 2 years.</u> |
| 27 | See Section 15.2 | § 60.5375 (a)(3) You must capture and direct flowback emissions that cannot be directed to the gathering line to a completion combustion device, except in conditions that may result in a fire hazard or explosion. Completion combustion devices must be equipped with a reliable continuous ignition source over the duration of flowback. |
| 28 | See Section 15.2 | § 60.5375 (b) You must maintain <u>a log records</u> for each well completion operation at each gas wellhead affected facility. The log must be completed on a daily basis and must contain the <u>information records</u> specified in § 60.5420(c)(1)(iii). |
| 29 | | § 60.5375 (c) You must demonstrate initial compliance with the standards that apply to gas wellhead affected facilities as required by § 60.5410. |
| 30 | | § 60.5375 (d) You must demonstrate continuous compliance with the standards that apply to gas wellhead affected facilities as required by § 60.5415. |
| 31 | | § 60.5375 (e) You must perform the required notification, recordkeeping, and reporting as required by § 60.5420. |
| 32 | See Section 15.2 | § 60.5375 (f) For wells meeting the criteria for wildcat, <u>appraisal, or delineation wells, or where production equipment or a natural gas gathering line is not reasonably available</u> , each well completion operation with hydraulic fracturing at a gas wellhead affected facility must reduce emissions by using a completion combustion device meeting the requirements of paragraph (a)(3)(1)(ii) of this section. You must also maintain records specified in § 60.5420(e)(1)(iii) for wildcat or delineation wells. |
| 32A | Preferred Option See Section 15.2 | <u>§ 60.5375 (g) The provisions of this Section notwithstanding, a gas wellhead affected facility that commenced construction, modification, or reconstruction after August 23, 2011 but flowback immediately following hydraulic fracturing at a natural gas wellhead facility onshore that ends prior to [two years after the effective date] shall not be required to comply with §60.5375 (a) through (f)</u> |
| 32B | Alternative Option See Section 15.2 | <u>§ 60.5375 (g) The provisions of this Section notwithstanding, a gas wellhead affected facility that commenced construction, modification, or reconstruction after August 23, 2011 but flowback immediately following hydraulic fracturing ends prior to [two years after the effective date] shall not be required to comply with §60.5375 (a) through (f).</u> |
| 33 | | § 60.5380 What standards apply to centrifugal compressor affected facilities? |
| 34 | | § 60.5380 You must comply with the standards in paragraphs (a) through (d) of this section, as applicable for each centrifugal compressor affected facility. |

| Ref # | Comment | Regulatory Text |
|-------|---------------------------|---|
| 35 | See Section 18.7 and 18.8 | <u>§ 60.5380 (a) You must control VOC emissions from centrifugal compressors using one of the methods described in paragraph (a)(1), (a)(2), or (a)(3). equip each rotating compressor shaft with a dry seal system upon initial startup</u> |
| 35A | See Section 18.7 and 18.8 | <u>§ 60.5380 (a)(1) Equip the rotating compressor shaft with a dry seal system upon initial startup.</u> |
| 35B | See Section 18.7 and 18.8 | <u>§ 60.5380 (a)(2) Equip the rotating compressor shaft with a wet seal-oil degassing system and route the separated gas to one of the following:</u> |
| 35C | See Section 18.7 and 18.8 | <u>§ 60.5380 (a)(2)(i) a flare designed and operated in accordance with the requirements of §60.18(b), or</u> |
| 35D | See Section 18.7 and 18.8 | <u>§ 60.5380 (a)(2)(ii) a flare designed and operated in accordance with the requirements of §60.18(b), except §60.18(c)(2) and (f)(2). An electronic flare ignition device shall be used to satisfy the requirement for an ignition system when a VOC stream is sent to the flare.</u> |
| 35E | See Section 18.7 and 18.8 | <u>§ 60.5380 (a)(2)(iii) a combustion device designed to reduce VOC emissions by 95%, or</u> |
| 35F | See Section 18.7 and 18.8 | <u>§ 60.5380 (a)(2)(iv) a fuel system, or</u> |

| 58 | See Section 16.7 | <u>§ 60.5395 (b) (d)</u> This standard does not apply to storage vessels already subject to and controlled in accordance with the requirements for storage vessels in § 63.766(b)(1) or (2) of this chapter. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Ref # | Comment | Regulatory Text |
|-------|---|---|
| 59 | See Section 16.7 | § 60.5395- (e) <u>(e)</u> You must demonstrate initial compliance with standards that apply to storage vessel affected facilities as required by § 60.5410. |
| 60 | See Section 16.7 | § 60.5395- (d) <u>(f)</u> You must demonstrate continuous compliance with standards that apply to storage vessel affected facilities as required by § 60.5415. |
| 61 | See Section 16.7 | § 60.5395- (e) <u>(g)</u> You must perform the required notification, recordkeeping, and reporting as required by § 60.5420. |
| 62 | § 60.5400 What VOC standards apply to affected facilities at an onshore natural gas processing plant? | |
| 63 | See Section 19.3 | § 60.5400 This section applies to each compressor in VOC service or in wet gas service and the group of all equipment (as defined in § 60.5430), except compressors, within a process unit. |
| 64 | See Section 19.3 & 19.8.3. | § 60.5400 (a) You must comply with the requirements of § 60.482-1a(a), (b), and (d), § 60.482-2a, and § 60.482-4a, and § 60.482-6a through 60.482-104a, except as provided in <u>(a)(1) through (a)(4) below and in § 60.5401.</u> |
| 64A | See Section 19.1. | <u>§ 60.5400 (a)(1) In lieu of §60.482-2a(b)(1), a leak in a pump in light liquid service is detected if an instrument reading of 10,000 ppm or greater is measured.</u> |
| 64B | See Section 19.1. | <u>§ 60.5400 (a)(2) In lieu of §60.482-7a(b), a leak in a valve is detected if an instrument reading of 10,000 ppm is measured.</u> |
| 64C | See Section 19.1. | <u>§ 60.5400 (a)(3) In lieu of §60.482-7a(c)(2), if a leak is detected, the valve shall be monitored after it is repaired, and then, quarterly thereafter.</u> |
| 64D | See Section 19.1. | <u>§ 60.5400 (a)(4) If a leak is detected in three of any four consecutive quarters, the valve shall be designated as a chronic leaker. All valves designated as chronic leaker shall be refurbished or replaced during the next process unit shut-down.</u> |
| 65 | See Section 19.1. API is offering to give up alternative standards (skip period and allowable percentage) in lieu of the leak definition of 500 ppm. LDAR 1.1 | § 60.5400 (b) You may elect to comply with the requirements of §§ 60.483-1a and 60.483-2a, as an alternative. |
| 65A | See Section 19.1. API commits to VAO monitoring in lieu of M21 monitoring with a 500 ppm leak definition. LDAR 1.1 | <u>§ 60.5400 (b) Connectors in gas/vapor service or light liquid service shall comply with the monitoring and leak definition provisions of §60.482-8a.</u> |
| 66 | | § 60.5400 (c) You may apply to the Administrator for permission to use an alternative means of emission limitation that achieves a reduction in emissions of VOC at least equivalent to that achieved by the controls required in this subpart according to the requirements of§ 60.5402 of this subpart. |
| 67 | | § 60.5400 (d) You must comply with the provisions of § 60.485a of this part except as provided in paragraph (f) of this section. |
| 68 | | § 60.5400 (e) You must comply with the provisions of §§ 60.486a and 60.487a of this part except as provided in §§ 60.5401, 60.5421, and 60.5422 of this part. |

| Ref # | Comment | Regulatory Text |
|-------|---|--|
| 69 | | § 60.5400 (f) You must use the following provision instead of § 60.485a(d)(1): |
| 70 | Preferred 19.4.2 | § 60.5400 Each piece of equipment is presumed to be in VOC service or in wet gas unless an owner or operator demonstrates that the piece of equipment is not in VOC service or in wet gas service. For a piece of equipment to be considered not in VOC service, it must be determined that the VOC content can be reasonably expected never to exceed 10.0 percent by weight. For a piece of equipment to be considered in wet gas service, it must be determined that it contains or contacts the field gas before the extraction step in the process. For purposes of determining the percent VOC content of the process fluid that is contained in or contacts a piece of equipment, procedures that conform to the methods described in ASTM E169–63, 77, or 93, E168–67, 77, or 92, or E260–73, 91, or 96 (incorporated by reference as specified in § 60.17) must be used. |
| 70A | Alternative 19.4.2 | Each piece of equipment is presumed to be in VOC service or in wet gas service unless an owner or operator demonstrates that the piece of equipment is not in VOC service or in wet gas service. For a piece of equipment to be considered not in VOC service, it must be determined that the VOC content can be reasonably expected never to exceed 10.0 percent by weight. For a piece of equipment to be considered in wet gas service, it must be determined that it contains or contacts the field gas before the extraction step in the process. <u>For a piece of equipment to be considered not in wet gas service, it must be determined that the VOC content can be reasonably expected never to exceed X percent by weight [Note: API recommends X be 5.0 or greater].</u> For purposes of determining the percent VOC content of the process fluid that is contained in or contacts a piece of equipment, procedures that conform to the methods described in ASTM E169–63, 77, or 93, E168–67, 77, or 92, or E260–73, 91, or 96 (incorporated by reference as specified in § 60.17) must be used. |
| 71 | § 60.5401 What are the exceptions to the VOC standards for affected facilities at onshore natural gas processing plants? | |
| 72 | | § 60.5401 (a) You may comply with the following exceptions to the provisions of subpart VVa of this part. |
| 73 | | § 60.5401 (b)(1) Each pressure relief device in gas/vapor service may be monitored quarterly and within 5 days after each pressure release to detect leaks by the methods specified in § 60.485a(b) except as provided in § 60.5400(c) and in paragraph (b)(4) of this section, and § 60.482–4a(a) through (c) of subpart VVa. |
| 74 | Section 19.8.2 EPA should clarify whether it is 5000 or 500 ppm [see 60.5421(b)(2)(iv)] LDAR 1.9.1 | § 60.5401 (b)(2) If an instrument reading of 5000 ppm or greater is measured, a leak is detected. |
| 75 | | § 60.5401 (b)(3)(i) When a leak is detected, it must be repaired as soon as practicable, but no later than 15 calendar days after it is detected, except as provided in § 60.482–9a. |

| Ref # | Comment | Regulatory Text |
|-------|--|---|
| 76 | | § 60.5401 (b)(3)(ii) A first attempt at repair must be made no later than 5 calendar days after each leak is detected. |
| 77 | | § 60.5401 (b)(4)(i) Any pressure relief device that is located in a nonfractionating plant that is monitored only by non-plant personnel may be monitored after a pressure release the next time the monitoring personnel are on-site, instead of within 5 days as specified in paragraph (b)(1) of this section and § 60.482–4a(b)(1) of subpart VVa. |
| 78 | | § 60.5401 (b)(4)(ii) No pressure relief device described in paragraph (b)(4)(i) of this section must be allowed to operate for more than 30 days after a pressure release without monitoring. |
| 79 | | § 60.5401 (c) Sampling connection systems are exempt from the requirements of § 60.482–5a. |
| 80 | See Section 19.8.1. and 19.8.3. Preferred- no VVa connector program | § 60.5401 (d) Pumps in light liquid service, valves in gas/vapor and light liquid service, and pressure relief devices in gas/vapor service that are located at a nonfractionating plant with a design capacity to process 283,200 standard cubic meters per day (scmd) (10 million standard cubic feet per day) or less more of field gas are exempt from the routine monitoring requirements of §§ 60.482–2a(a)(1) and 60.482–7a(a), and paragraph (b)(1) of this section, <u>and the reporting requirements found in §60.5420 and 60.5422.</u> |
| 80A | Alternative- with VVa connector program See Section 19.8.1. and 19.8.3. | § 60.5401 (d) Pumps in light liquid service, valves in gas/vapor and light liquid service, and pressure relief devices in gas/vapor service that are located at a nonfractionating plant with a design capacity to process 283,200 standard cubic meters per day (scmd) (10 million standard cubic feet per day) or less more of field gas are exempt from the routine monitoring requirements of §§ 60.482–2a(a)(1) and 60.482–7a(a), <u>60.482-11a</u> , and paragraph (b)(1) of this section, <u>and the reporting requirements found in §60.5420 and 60.5422.</u> |
| 81 | See Section 19.8.3. | § 60.5401 (e) Pumps in light liquid service, valves in gas/vapor and light liquid service, and pressure relief devices in gas/vapor service within a process unit that is located in the Alaskan North Slope are exempt from the routine monitoring requirements of §§ 60.482–2a(a)(1), 60.482–7a(a), and paragraph (b)(1) of this section, <u>and the reporting requirements found in §60.5420 and 60.5422.</u> |
| 81A | | |
| 82 | See Section 9.3. and 60.5414(i) | § 60.5401 (f) Flares used to comply with this subpart must comply with the requirements of § 60.18 (b) , <u>except as provided in § 60.5415 (i)(1) and (2).</u> |
| 83 | | § 60.5401 (g) An owner or operator may use the following provisions instead of § 60.485a(e): |
| 84 | | § 60.5401 (g)(1) Equipment is in heavy liquid service if the weight percent evaporated is 10 percent or less at 150 °C (302 °F) as determined by ASTM Method D86–78, 82, 90, 95, or 96 (incorporated by reference as specified in § 60.17). |

| Ref # | Comment | Regulatory Text |
|-------|--|--|
| 85 | | § 60.5401 (g)(2) Equipment is in light liquid service if the weight percent evaporated is greater than 10 percent at 150 °C (302°F) as determined by ASTM Method D86–78, 82, 90, 95, or 96 (incorporated by reference as specified in § 60.17). |
| 85A | See Section 19.5 | <u>§ 60.5401 (h) In addition to the provisions of 60.482-9a, delay of repair for valves and connectors will be allowed if:</u> |
| 85B | See Section 19.5 | <u>§ 60.5401 (h)(1) Initial (within 5 days of the leak being detected) and follow-up (within 15 days of the leak being detected) repair attempts using routine methods have been completed and were unsuccessful and</u> |
| 85C | See Section 19.5 | <u>§ 60.5401 (h)(2) Further on-line repair attempts require the use of a specialized repair contractor, and</u> |
| 85D | See Section 19.5 | <p><u>§ 60.5401 (h)(3) Further specialized repair attempts are completed as soon as practicable, but not later than 90 days after the leak was detected. If a repair attempt using a specialized technique is unsuccessful, repair shall occur before the end of the next process unit shutdown or as otherwise allowed by 60.482-9a(e).</u></p> <p><u>A specialized repair contractor provides repair services not available from the facility or contractor maintenance personnel who perform routine repairs of most facility equipment leaks. An example of a specialized repair contractor is a contractor who provides valve gland drill and tap services.</u></p> |
| 85E | See Section 19.1.4 | <u>§ 60.5401 (i) Any existing reciprocating pump in a process unit which becomes an affected facility under the provisions of §60.14 or §60.15 is exempt from§60.482-2a of this part, provided the owner or operator demonstrates that recasting the distance piece or replacing the pump are the only options available to bring the pump into compliance with the provisions of §60.482-2a of this part.</u> |
| 86 | § 60.5402 What are the alternative emission limitations for equipment leaks from onshore natural gas processing plants? | |
| 87 | | § 60.5402 (a) If, in the Administrator’s judgment, an alternative means of emission limitation will achieve a reduction in VOC emissions at least equivalent to the reduction in VOC emissions achieved under any design, equipment, work practice or operational standard, the Administrator will publish, in the Federal Register, a notice permitting the use of that alternative means for the purpose of compliance with that standard. The notice may condition permission on requirements related to the operation and maintenance of the alternative means. |
| 88 | | § 60.5402 (b) Any notice under paragraph (a) of this section must be published only after notice and an opportunity for a public hearing. |

| Ref # | Comment | Regulatory Text |
|-------|--|---|
| 89 | | § 60.5402 (c) The Administrator will consider applications under this section from either owners or operators of affected facilities, or manufacturers of control equipment. |
| 90 | | § 60.5402 (d) The Administrator will treat applications under this section according to the following criteria, except in cases where the Administrator concludes that other criteria are appropriate: |
| 91 | | § 60.5402 (d)(1) The applicant must collect, verify and submit test data, covering a period of at least 12 months, necessary to support the finding in paragraph (a) of this section. |
| 92 | | § 60.5402 (d)(2) If the applicant is an owner or operator of an affected facility, the applicant must commit in writing to operate and maintain the alternative means so as to achieve a reduction in VOC emissions at least equivalent to the reduction in VOC emissions achieved under the design, equipment, work practice or operational standard. |
| 93 | § 60.5405 What standards apply to sweetening units at onshore natural gas processing plants? | |
| 94 | | § 60.5405 (a) During the initial performance test required by § 60.8(b), you must achieve at a minimum, an SO ₂ emission reduction efficiency (Z _i) to be determined from Table 1 of this subpart based on the sulfur feed rate (X) and the sulfur content of the acid gas (Y) of the affected facility. |
| 95 | | § 60.5405 (b) After demonstrating compliance with the provisions of paragraph (a) of this section, you must achieve at a minimum, an SO ₂ emission reduction efficiency (Z _c) to be determined from Table 2 of this subpart based on the sulfur feed rate (X) and the sulfur content of the acid gas (Y) of the affected facility. |
| 96 | 60.5406 What test methods and procedures must I use for my sweetening units affected facilities at onshore natural gas processing plants? | |
| 97 | | § 60.5406 (a) In conducting the performance tests required in § 60.8, you must use the test methods in Appendix A of this part or other methods and procedures as specified in this section, except as provided in paragraph § 60.8(b). |
| 98 | | § 60.5406 (b) During a performance test required by § 60.8, you must determine the minimum required reduction efficiencies (Z) of SO ₂ emissions as required in § 60.5405(a) and (b) as follows: |
| 99 | | § 60.5406 (b)(1) The average sulfur feed rate (X) must be computed as follows:[Equation]Where:X = average sulfur feed rate, Mg/D (LT/D).Q _a = average volumetric flow rate of acid gas from sweetening unit, dscm/day (dscf/day).γ = average H ₂ S concentration in acid gas feed from sweetening unit, percent by volume, expressed as a decimal.K = (32 kg S/kg-mole) / ((24.04 dscm/kgmole) (1000 kg S/Mg)) = 1.331 × 10 ⁻³ Mg/dscm, for metric units = (32 lb S/lb-mole) / ((385.36 dscf/lb-mole) (2240 lb S/long ton)) = 3.707 × 10 ⁻⁵ long ton/dscf, for English units. |
| 100 | | § 60.5406 (b)(2) You must use the continuous readings from the process flowmeter to determine the average volumetric flow rate (Q _a) in dscm/day (dscf/day) of the acid gas from the sweetening unit for each run. |

| Ref # | Comment | Regulatory Text |
|-------|---------|---|
| 101 | | <p>§ 60.5406 (b)(3) You must use the Tutwiler procedure in § 60.5408 or a chromatographic procedure following ASTM E-260 (incorporated by reference—see § 60.17) to determine the H₂S concentration in the acid gas feed from the sweetening unit (Y). At least one sample per hour (at equally spaced intervals) must be taken during each 4-hour run. The arithmetic mean of all samples must be the average H₂S concentration (Y) on a dry basis for the run. By multiplying the result from the Tutwiler procedure by 1.62×10^{-3}, the units gr/100 scf are converted to volume percent.</p> |
| 102 | | <p>§ 60.5406 (b)(4) Using the information from paragraphs (b)(1) and (b)(3) of this section, Tables 1 and 2 of this subpart must be used to determine the required initial (Z_i) and continuous (Z_c) reduction efficiencies of SO₂ emissions.</p> |
| 103 | | <p>§ 60.5406 (c) You must determine compliance with the SO₂ standards in § 60.5405(a) or (b) as follows:</p> |
| 104 | | <p>§ 60.5406 (c)(1) You must compute the emission reduction efficiency (R) achieved by the sulfur recovery technology for each run using the following equation:[Equation]</p> |
| 105 | | <p>§ 60.5406 (c)(2) You must use the level indicators or manual soundings to measure the liquid sulfur accumulation rate in the product storage tanks. You must use readings taken at the beginning and end of each run, the tank geometry, sulfur density at the storage temperature, and sample duration to determine the sulfur production rate (S) in kg/hr (lb/hr) for each run.</p> |
| 106 | | <p>§ 60.5406 (c)(3) You must compute the emission rate of sulfur for each run as follows:[Equation]Where: E = emission rate of sulfur per run, kg/hr. C_e = concentration of sulfur equivalent (SO₂ + reduced sulfur), g/dscm (lb/dscf). Q_{sd} = volumetric flow rate of effluent gas, dscm/hr (dscf/hr). K₁ = conversion factor, 1000 g/kg (7000 gr/lb).</p> |
| 107 | | <p>§ 60.5406 (c)(4) The concentration (C_e) of sulfur equivalent must be the sum of the SO₂ and TRS concentrations, after being converted to sulfur equivalents. For each run and each of the test methods specified in this paragraph (c) of this section, you must use a sampling time of at least 4 hours. You must use Method 1 of Appendix A to part 60 of this chapter to select the sampling site. The sampling point in the duct must be at the centroid of the cross-section if the area is less than 5 m² (54 ft²) or at a point no closer to the walls than 1 m (39 in) if the cross-sectional area is 5 m² or more, and the centroid is more than 1 m (39 in.) from the wall.</p> |
| 108 | | <p>§ 60.5406 (c)(4)(i) You must use Method 6 of Appendix A to part 60 of this chapter to determine the SO₂ concentration. You must take eight samples of 20 minutes each at 30-minute intervals. The arithmetic average must be the concentration for the run. The concentration must be multiplied by 0.5×10^{-3} to convert the results to sulfur equivalent.</p> |

| Ref # | Comment | Regulatory Text |
|-------|--|--|
| 109 | | <p>§ 60.5406 (c)(4)(ii) You must use Method 15 of appendix A to part 60 of this chapter to determine the TRS concentration from reduction-type devices or where the oxygen content of the effluent gas is less than 1.0 percent by volume. The sampling rate must be at least 3 liters/min (0.1 ft³/min) to insure minimum residence time in the sample line. You must take sixteen samples at 15-minute intervals. The arithmetic average of all the samples must be the concentration for the run. The concentration in ppm reduced sulfur as sulfur must be multiplied by 1.333×10^3 to convert the results to sulfur equivalent.</p> |
| 110 | | <p>§ 60.5406 (c)(4)(iii) You must use Method 16A or Method 15 of appendix A to part 60 of this chapter to determine the reduced sulfur concentration from oxidation type devices or where the oxygen content of the effluent gas is greater than 1.0 percent by volume. You must take eight samples of 20 minutes each at 30-minute intervals. The arithmetic average must be the concentration for the run. The concentration in ppm reduced sulfur as sulfur must be multiplied by 1.333×10^3 to convert the results to sulfur equivalent.</p> |
| 111 | | <p>§ 60.5406 (c)(4)(iv) You must use Method 2 of appendix A to part 60 of this chapter to determine the volumetric flow rate of the effluent gas. A velocity traverse must be conducted at the beginning and end of each run. The arithmetic average of the two measurements must be used to calculate the volumetric flow rate (Q_{sd}) for the run. For the determination of the effluent gas molecular weight, a single integrated sample over the 4-hour period may be taken and analyzed or grab samples at 1-hour intervals may be taken, analyzed, and averaged. For the moisture content, you must take two samples of at least 0.10 dscm (3.5 dscf) and 10 minutes at the beginning of the 4-hour run and near the end of the time period. The arithmetic average of the two runs must be the moisture content for the run.</p> |
| 112 | <p>§ 60.5407 What are the requirements for monitoring of emissions and operations from my sweetening unit affected facilities at onshore natural gas processing plants?</p> | |
| 113 | | <p>§ 60.5407 (a) If your sweetening unit affected facility is located at an onshore natural gas processing plant and is subject to the provisions of § 60.5405(a) or (b) you must install, calibrate, maintain, and operate monitoring devices or perform measurements to determine the following operations information on a daily basis:</p> |

| Ref # | Comment | Regulatory Text |
|-------|---------|---|
| 114 | | § 60.5407 (a)(1) The accumulation of sulfur product over each 24-hour period. The monitoring method may incorporate the use of an instrument to measure and record the liquid sulfur production rate, or may be a procedure for measuring and recording the sulfur liquid levels in the storage tanks with a level indicator or by manual soundings, with subsequent calculation of the sulfur production rate based on the tank geometry, stored sulfur density, and elapsed time between readings. The method must be designed to be accurate within ± 2 percent of the 24-hour sulfur accumulation. |
| 115 | | § 60.5407 (a)(2) The H ₂ S concentration in the acid gas from the sweetening unit for each 24-hour period. At least one sample per 24-hour period must be collected and analyzed using the equation specified in § 60.5406(b)(1). The Administrator may require you to demonstrate that the H ₂ S concentration obtained from one or more samples over a 24-hour period is samples collected at equally spaced intervals during the 24-hour period. In instances where the H ₂ S concentration of a single sample is not within ± 20 percent of the average of the 12 equally spaced samples, the Administrator may require a more frequent sampling schedule. |
| 116 | | § 60.5407 (a)(3) The average acid gas flow rate from the sweetening unit. You must install and operate a monitoring device to continuously measure the flow rate of acid gas. The monitoring device reading must be recorded at least once per hour during each 24-hour period. The average acid gas flow rate must be computed from the individual readings. |
| 117 | | § 60.5407 (a)(4) The sulfur feed rate (X). For each 24-hour period, you must compute X using the equation specified in § 60.5406(b)(3). |
| 118 | | § 60.5407 (a)(5) The required sulfur dioxide emission reduction efficiency for the 24-hour period. You must use the sulfur feed rate and the H ₂ S concentration in the acid gas for the 24-hour period, as applicable, to determine the required reduction efficiency in accordance with the provisions of § 60.5405(b). |
| 119 | | § 60.5407 (b) Where compliance is achieved through the use of an oxidation control system or a reduction control system followed by a continually operated incineration device, you must install, calibrate, maintain, and operate monitoring devices and continuous emission monitors as follows: |
| 120 | | § 60.5407 (b)(1) A continuous monitoring system to measure the total sulfur emission rate (E) of SO ₂ in the gases discharged to the atmosphere. The SO ₂ emission rate must be expressed in terms of equivalent sulfur mass flow rates (kg/hr (lb/hr)). The span of this monitoring system must be set so that the equivalent emission limit of § 60.5405(b) will be between 30 percent and 70 percent of the measurement range of the instrument system. |

| Ref # | Comment | Regulatory Text |
|-------|---------|---|
| 121 | | <p>§ 60.5407 (b)(2) Except as provided in paragraph (b)(3) of this section: A monitoring device to measure the temperature of the gas leaving the combustion zone of the incinerator, if compliance with § 60.5405(a) is achieved through the use of an oxidation control system or a reduction control system followed by a continually operated incineration device. The monitoring device must be certified by the manufacturer to be accurate to within ± 1 percent of the temperature being measured.</p> |
| 122 | | <p>§ 60.5407 (b)(3) When performance tests are conducted under the provision of § 60.8 to demonstrate compliance with the standards under § 60.5405, the temperature of the gas leaving the incinerator combustion zone must be determined using the monitoring device. If the volumetric ratio of sulfur dioxide to sulfur dioxide plus total reduced sulfur (expressed as SO₂) in the gas leaving the incinerator is equal to or less than 0.98, then temperature monitoring may be used to demonstrate that sulfur dioxide emission monitoring is sufficient to determine total sulfur emissions. At all times during the operation of the facility, you must maintain the average temperature of the gas leaving the combustion zone of the incinerator at or above the appropriate level determined during the most recent performance test to ensure the sulfur compound oxidation criteria are met. Operation at lower average temperatures may be considered by the Administrator to be unacceptable operation and maintenance of the affected facility. You may request that the minimum incinerator temperature be reestablished by conducting new performance tests under § 60.8.</p> |
| 123 | | <p>§ 60.5407 (b)(4) Upon promulgation of a performance specification of continuous monitoring systems for total reduced sulfur compounds at sulfur recovery plants, you may, as an alternative to paragraph (b)(2) of this section, install, calibrate, maintain, and operate a continuous emission monitoring system for total reduced sulfur compounds as required in paragraph (d) of this section in addition to a sulfur dioxide emission monitoring system. The sum of the equivalent sulfur mass emission rates from the two monitoring systems must be used to compute the total sulfur emission rate (E).</p> |
| 124 | | <p>§ 60.5407 (c) Where compliance is achieved through the use of a reduction control system not followed by a continually operated incineration device, you must install, calibrate, maintain, and operate a continuous monitoring system to measure the emission rate of reduced sulfur compounds as SO₂ equivalent in the gases discharged to the atmosphere. The SO₂ equivalent compound emission rate must be expressed in terms of equivalent sulfur mass flow rates (kg/hr (lb/hr)). The span of this monitoring system must be set so that the equivalent emission limit of § 60.5405(b) will be between 30 and 70 percent of the measurement range of the system. This requirement becomes effective upon promulgation of a performance specification for continuous monitoring systems for total reduced sulfur compounds at sulfur recovery plants.</p> |

|-------|---|--|
| 125 | | § 60.5407 (d) For those sources required to comply with paragraph (b) or (c) of this section, you must calculate the average sulfur emission reduction efficiency achieved (R) for each 24-hour clock interval. The 24-hour interval may begin and end at any selected clock time, but must be consistent. You must compute the 24-hour average reduction efficiency (R) based on the 24-hour average sulfur production rate (S) and sulfur emission rate (E), using the equation in § 60.5406(c)(1). |
| 126 | | § 60.5407 (d)(1) You must use data obtained from the sulfur production rate monitoring device specified in paragraph (a) of this section to determine S. |
| 127 | | § 60.5407 (d)(2) You must use data obtained from the sulfur emission rate monitoring systems specified in paragraphs (b) or (c) of this section to calculate a 24-hour average for the sulfur emission rate (E). The monitoring system must provide at least one data point in each successive 15-minute interval. You must use at least two data points to calculate each 1-hour average. You must use a minimum of 18 1-hour averages to compute each 24-hour average. |
| 128 | | § 60.5407 (e) In lieu of complying with paragraphs (b) or (c) of this section, those sources with a design capacity of less than 152 Mg/D (150 LT/D) of H ₂ S expressed as sulfur may calculate the sulfur emission reduction efficiency achieved for each 24-hour period by:[Equation]Where: R = The sulfur dioxide removal efficiency achieved during the 24-hour period, percent. K ₂ = Conversion factor, 0.02400 Mg/D per kg/hr (0.01071 LT/D per lb/hr). S = The sulfur production rate during the 24-hour period, kg/hr (lb/hr). X = The sulfur feed rate in the acid gas, Mg/D (LT/D). |
| 129 | | § 60.5407 (f) The monitoring devices required in paragraphs (b)(1), (b)(3) and (c) of this section must be calibrated at least annually according to the manufacturer's specifications, as required by § 60.13(b). |
| 130 | | § 60.5407 (g) The continuous emission monitoring systems required in paragraphs (b)(1), (b)(3), and (c) of this section must be subject to the emission monitoring requirements of § 60.13 of the General Provisions. For conducting the continuous emission monitoring system performance evaluation required by § 60.13(c), Performance Specification 2 of appendix B to part 60 of this chapter must apply, and Method 6 must be used for systems required by paragraph (b) of this section. |
| 131 | § 60.5408 What is an optional procedure for measuring hydrogen sulfide in acid gas—Tutwiler Procedure? | |
| 132 | | § 60.5408 (a) When an instantaneous sample is desired and H ₂ S concentration is ten grains per 1000 cubic foot or more, a 100 ml Tutwiler burette is used. For concentrations less than ten grains, a 500 ml Tutwiler burette and more dilute solutions are used. In principle, this method consists of titrating hydrogen sulfide in a gas sample directly with a standard solution of iodine. |

| Ref # | Comment | Regulatory Text |
|-------|---------|--|
| 133 | | § 60.5408 (b) Apparatus. (See Figure 1 of this subpart) A 100 or 500 ml capacity Tutwiler burette, with two-way glass stopcock at bottom and three-way stopcock at top which connect either with inlet tubulature or glass-stoppered cylinder, 10 ml capacity, graduated in 0.1 ml subdivision; rubber tubing connecting burette with leveling bottle. |
| 134 | | § 60.5408 (c) Reagents. |
| 135 | | § 60.5408 (c)(1) Iodine stock solution, 0.1N. Weight 12.7 g iodine, and 20 to 25 g cp potassium iodide for each liter of solution. Dissolve KI in as little water as necessary; dissolve iodine in concentrated KI solution, make up to proper volume, and store in glass stoppered brown glass bottle. |
| 136 | | § 60.5408 (c)(2) Standard iodine solution, 1 ml = 0.001771 g I. Transfer 33.7 ml of above 0.1N stock solution into a 250 ml volumetric flask; add water to mark and mix well. Then, for 100 ml sample of gas, 1 ml of standard iodine solution is equivalent to 100 grains H ₂ S per cubic feet of gas. |
| 137 | | § 60.5408 (c)(3) Starch solution. Rub into a thin paste about one teaspoonful of wheat starch with a little water; pour into about a pint of boiling water; stir; let cool and decant off clear solution. Make fresh solution every few days. |
| 138 | | § 60.5408 (d) Procedure. Fill leveling bulb with starch solution. Raise (L), open cock (G), open (F) to (A), and close (F) when solutions starts to run out of gas inlet. Close (G). Purge gas sampling line and connect with (A). Lower (L) and open (F) and (G). When liquid level is several ml past the 100 ml mark, close (G) and (F), and disconnect sampling tube. Open (G) and bring starch solution to 100 ml mark by raising (L); then close (G). Open (F) momentarily, to bring gas in burette to atmospheric pressure, and close (F). Open (G), bring liquid level down to 10 ml mark by lowering (L). Close (G), clamp rubber tubing near (E) and disconnect it from burette. Rinse graduated cylinder with a standard iodine solution (0.00171 g I per ml); fill cylinder and record reading. Introduce successive small amounts of iodine thru (F); shake well after each addition; continue until a faint permanent blue color is obtained. Record reading; subtract from previous reading, and call difference D. |
| 139 | | § 60.5408 (e) With every fresh stock of starch solution perform a blank test as follows: Introduce fresh starch solution into burette up to 100 ml mark. Close (F) and (G). Lower (L) and open (G). When liquid level reaches the 10 ml mark, close (G). With air in burette, titrate as during a test and up to same end point. Call ml of iodine used C. Then, Grains H ₂ S per 100 cubic foot of gas = 100 (D-C) |
| 140 | | § 60.5408 (f) Greater sensitivity can be attained if a 500 ml capacity Tutwiler burette is used with a more dilute (0.001N) iodine solution. Concentrations less than 1.0 grains per 100 cubic foot can be determined in this way. Usually, the starch-iodine end point is much less distinct, and a blank determination of end point, with H ₂ S-free gas or air, is required. |

| 141 | | <p>§ 60.5410 How do I demonstrate initial compliance with the standards for my gas wellhead affected facility, my centrifugal compressor affected facility, my reciprocating compressor affected facility, my <u>continuous bleed gas-driven pneumatically controlled process unit pneumatic controller</u> affected facility, my storage vessel affected facility, and my affected facilities at onshore natural gas processing plants?</p> |
| 142 | | <p>§ 60.5410 You must determine initial compliance with the standards for each affected facility using the requirements in paragraphs (a) through (g) of this section. The initial compliance period begins on the date of publication of the final rule in the Federal Register or upon initial startup, whichever is later, and ends on the date the first annual report is due as specified in § 60.5420(b).</p> |
| 143 | | <p>§ 60.5410 (a) You have achieved initial compliance with standards for each well completion operation conducted at your gas wellhead affected facility if you have complied with paragraphs (a)(1) and (a)(2) of this section.</p> |
| 144 | See Section 15.7.2 | <p>§ 60.5410 (a)(1) You have notified the Administrator <u>monthly of all the well flowbacks immediately following hydraulic fracturing stimulation that are scheduled to occur at any gas wellhead facilities onshore during the upcoming month if you have one or more fracs including within 30 days of the commencement of the well completion operation</u>, the <u>tentative scheduled start date of the well flowback and of the well completion operation</u>, the latitude and longitude coordinates of the well in decimal degrees to an accuracy and precision of five (5) decimals of a degree using the North American Datum (NAD) of 1983</p> |
| 145 | | <p>§ 60.5410 (a)(2) You have maintained a log of records as specified in § 60.5375(b) or (f) for each well completion operation conducted during the initial compliance period.</p> |
| 146 | | <p>§ 60.5410 (a)(3) You have submitted the initial annual report for your wellhead affected facility as required in § 60.5420(b).</p> |
| 147 | See Section 18 | <p>§ 60.5410 (b) You have achieved initial compliance with standards for your centrifugal compressor affected facility if the centrifugal compressor is fitted <u>with a dry seal system</u> upon initial startup as required by § 60.5380.</p> |
| 148 | | <p>§ 60.5410 (c) You have achieved initial compliance with standards for each reciprocating compressor affected facility if you have complied with paragraphs (c)(1) and (c)(2) of this section.</p> |
| 149 | | <p>§ 60.5410 (c)(1) During the initial compliance period, you have continuously monitored the number of hours of operation.</p> |
| 150 | | <p>§ 60.5410 (c)(2) You have included the cumulative number of hours of operation for your reciprocating compressor affected facility during the initial compliance period in your initial annual report required in § 60.5420(b).</p> |

| Ref # | Comment | Regulatory Text |
|-------|---|--|
| 151 | See Section 17.4 | § 60.5410 (d) You have achieved initial compliance with emission standards for your <u>continuous bleed gas-driven pneumatically controlled process unit pneumatic controller</u> affected facility if you comply with the requirements specified in paragraphs (d)(1) through (d)(43) of this section. |
| 152 | See Section 17.1 and 17.7 (Note: typo, should be 60.5390(a), there is no 5490 section.) As in 60.5390(a), “Administrator’s satisfaction” suggests prior approval. Removed for consistency and clarity. | § 60.5410 (d)(1) You have demonstrated to the Administrator’s satisfaction, the use of a high bleed <u>gas-driven pneumatic controller device</u> is predicated as specified in § 60.54390(a). |
| 153 | See Section 17.5.1 Remove for consistency and clarity. If pneumatic controllers are non-gas driven they are not part of an affected facility, therefore this paragraph is unnecessary | § 60.5410 (d)(2) You own or operate a pneumatic controller affected facility located at a natural gas processing plant and your pneumatic controller is driven other than by use of natural gas and therefore emits zero natural gas. |
| 154 | See Section 17.10 Uncertain if use “guarantee” is for descriptive purposes or means an actual certified guarantee <ul style="list-style-type: none"> If an actual guarantee required, manufacturers not prepared to provide this on effective date. “Guarantee” should be replaced with “verify” if an actual statement of guarantee not required. | § 60.5410 (d)(3) You own or operate a <u>continuous bleed gas-driven pneumatically controlled process unit affected facility pneumatic controller affected facility</u> not located at a natural gas processing plant and the manufacturer’s design specifications <u>verify guarantee</u> the <u>low bleed gas-driven pneumatic controller weak stream</u> emits less than or equal to 6.0 standard cubic feet of gas per hour. |
| 155 | See Section 17 | § 60.5410 (d)(4) You have included the information in paragraphs (d)(1) through (d)(3) of this section in the initial annual report submitted for your <u>continuous bleed gas-driven pneumatically controlled process unit affected facility pneumatic controller</u> affected facilities according to the requirements of § 60.5420(b). |
| 156 | See Section 16 | § 60.5410 (e) You have demonstrated initial compliance with emission standards for your storage vessel affected facility if you are complying with paragraphs (e)(1), (2), or (3) through (e)(7) of this section. |
| 157 | See Section 16 | § 60.5410 (e)(1) You have equipped the storage vessel with a closed vent system that meets the requirements of § 63.771(e) of this chapter connected to and a control device that meets the conditions specified in § 63.771(d) 60.5395(b). |
| 158 | See Section 9.5 | § 60.5410(e)(2) You have <u>a copy of the performance test results for a performance test conducted by the manufacturer as specified in §60.772(h)</u> conducted an initial performance test as required in § 63.772(e) of this chapter within 180 days after initial startup or the date of publication of the final rule in the Federal Register and have conducted the compliance demonstration in § 63.772(f). |

| Ref # | Comment | Regulatory Text |
|-------|------------------|---|
| 159 | | § 60.5410 (e)(3) You have conducted the initial inspections required in § 63.773(e) of this chapter. |
| 160 | See Section 16.7 | § 60.5410 (e)(4) You have installed and operated continuous parameter monitoring systems in accordance with § 63.773(d) of this chapter. |
| 161 | See Section 16.7 | § 60.5410 (e) (5) <u>(3)</u> If you are exempt from the standards of § 60.5395 according to § 60.5395(a) (1) or (a)(2) , you have determined the condensate or crude oil throughput, <u>pressure, and emissions according to 60.5395(c)</u> , as applicable, according to paragraphs (e)(5)(i) or (e)(5)(ii) of this section and demonstrated to the Administrator's satisfaction that your annual average condensate throughput is less than 1 barrel per day per tank and your annual average crude oil throughput is less than 20 barrels per day per tank. |
| 162 | See Section 16.7 | § 60.5410 (e)(5)(i) You have installed and operated a flow meter to measure condensate or crude oil throughput in accordance with the manufacturer's procedures or specifications. |
| 163 | See Section 16.7 | § 60.5410 (e)(5)(ii) You have used any other method approved by the Administrator to determine annual average condensate or crude oil throughput. |
| 164 | See Section 16.7 | § 60.5410 (6) <u>(4)</u> You have submitted the information in paragraphs (e)(1) through (e) (5) <u>(3)</u> of this section in the initial annual report for your storage vessel affected facility as required in § 60.5420(b). |
| 165 | | § 60.5410 (f) For affected facilities at onshore natural gas processing plants, initial compliance with the VOC requirements is demonstrated if you are in compliance with the requirements of § 60.5400. |
| 166 | | § 60.5410 (g) For sweetening unit affected facilities at onshore natural gas processing plants, initial compliance is demonstrated according to paragraphs (g)(1) through (g)(3) of this section. |
| 167 | | § 60.5410 (g)(1) To determine compliance with the standards for SO ₂ specified in § 60.5405(a), during the initial performance test as required by § 60.8, the minimum required sulfur dioxide emission reduction efficiency (Z _i) is compared to the emission reduction efficiency (R) achieved by the sulfur recovery technology as specified in paragraphs (g)(1)(i) and (g)(1)(ii) of this section. |
| 168 | | § 60.5410 (g)(1)(i) If $R \geq Z_i$, your affected facility is in compliance. |
| 169 | | § 60.5410 (g)(1)(ii) If $R < Z_i$, your affected facility is not in compliance. |
| 170 | | § 60.5410 (g)(2) The emission reduction efficiency (R) achieved by the sulfur reduction technology must be determined using the procedures in § 60.5406(c)(1). (3) You have submitted the results of paragraphs (g)(1) and (g)(2) of this section in the initial annual report submitted for your sweetening unit affected facilities at onshore natural gas processing plants. |

|-------|---------|---|
| 185 | | § 60.5415 (h) Excess emissions resulting from SSM activities Affirmative defense for exceedance of emission limit during malfunction. In response to an action to enforce the standards set forth in §§ 60.5375, 60.5380, 60.5385, 60.5390, 60.5395, 60.5400, and 60.5405, you may assert an affirmative defense to a claim for civil penalties for exceedances of such standards that are caused by malfunction, as defined at § 60.2. Appropriate penalties may be assessed, however, if you fail to meet your burden of proving all of the requirements in the affirmative defense. The affirmative defense shall not be available for claims for injunctive relief. |
| 186 | | § 60.5415 (h)(1) To establish the affirmative defense in any action to enforce such a limit, you must timely meet the notification requirements in § 60.5420(a), and must prove by a preponderance of evidence that: |
| 187 | | § 60.5415 (h)(1)(i) The excess emissions: |
| 188 | | § 60.5415 (h)(1)(i)(A) Were caused by a sudden, infrequent, and unavoidable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner, and |
| 189 | | § 60.5415 (h)(1)(i)(B) Could not have been prevented through careful planning, proper design or better operation and maintenance practices; and |
| 190 | | § 60.5415 (h)(1)(i)(C) Did not stem from any activity or event that could have been foreseen and avoided, or planned for; and |
| 191 | | § 60.5415 (h)(1)(i)(D) Were not part of a recurring pattern indicative of inadequate design, operation, or maintenance; and |
| 192 | | § 60.5415 (h)(1)(ii) Repairs were made as expeditiously as possible when the applicable emission limitations were being exceeded. Off-shift and overtime labor were used, to the extent practicable to make these repairs; and |
| 193 | | § 60.5415 (h)(1)(iii) The frequency, amount and duration of the excess emissions (including any bypass) were minimized to the maximum extent practicable during periods of such emissions; and |
| 194 | | § 60.5415 (h)(1)(iv) If the excess emissions resulted from a bypass of control equipment or a process, then the bypass was unavoidable to prevent loss of life, personal injury, or severe property damage; and |
| 195 | | § 60.5415 (h)(1)(v) All possible steps were taken to minimize the impact of the excess emissions on ambient air quality, the environment and human health; and |
| 196 | | § 60.5415 (h)(1)(vi) All emissions monitoring and control systems were kept in operation if at all possible, consistent with safety and good air pollution control practices; and |
| 197 | | § 60.5415 (h)(1)(vii) All of the actions in response to the excess emissions were documented by properly signed, contemporaneous operating logs; and |
| 198 | | § 60.5415 (h)(1)(viii) At all times, the facility was operated in a manner consistent with good practices for minimizing emissions; and |

|-------|--------------------|---|
| 199 | | § 60.5415 (h)(1)(ix) A written root cause analysis has been prepared, the purpose of which is to determine, correct, and eliminate the primary causes of the malfunction and the excess emissions resulting from the malfunction event at issue. The analysis shall also specify, using best monitoring methods and engineering judgment, the amount of excess emissions that were the result of the malfunction. |
| 200 | | § 60.5415 (h)(2) The owner or operator of the facility experiencing an exceedance of its emission limit(s) during a malfunction shall notify the Administrator by telephone or facsimile (FAX) transmission as soon as possible, but no later than 2 business days after the initial occurrence of the malfunction, if it wishes to avail itself of an affirmative defense to civil penalties for that malfunction. The owner or operator seeking to assert an affirmative defense shall also submit a written report to the Administrator within 45 days of the initial occurrence of the exceedance of the standards in §§ 60.5375, 60.5380, 60.5385, 60.5390, 60.5395, and 60.5400 to demonstrate, with all necessary supporting documentation, that it has met the requirements set forth in paragraph (a) of this section. The owner or operator may seek an extension of this deadline for up to 30 additional days by submitting a written request to the Administrator before the expiration of the 45-day period. Until a request for an extension has been approved by the Administrator, the owner or operator is subject to the requirement to submit such report within 45 days of the initial occurrence of the exceedance. |
| 200A | See Section 9.3 | <u>§ 60.5415 (i) Flares used for compliance of this section will comply with 60.18(b), except as provided in § 60.5415 (i)(1) and (2).</u> |
| 200B | See Section 9.1.1. | <u>§ 60.5415 (i)(1) “flame present at all times” required in 60.18(c)(2) means that a pilot that must be present at all times while a VOC or waste stream is being sent to the flare for emissions destruction, or</u> |
| 200C | See Section 9.1.2. | <u>§ 60.5415 (i)(2) or thru the use of an electronic ignition device.</u> |
| 200D | See Section 9. | <u>§ 60.5415 (j) For the purposes of this subpart if the vapors from the affected facility are routed back to process and meet the definition provided for routed to process in § 60.5430 then this equipment is not considered a control device or closed vent system.</u> |
| 201 | | § 60.5420 What are my notification, reporting, and recordkeeping requirements? |
| 202 | See Section 15.7.2 | § 60.5420 (a) You must submit the notifications required in § 60.7(a)(1), (a)(3) and (a)(4), and according to paragraphs (a)(1) and (a)(2) of this section, if you own or operate one or more of the affected facilities specified in § 60.5365. For the purposes of this subpart, a workover that occurs after August 23, 2011 at each affected facility for which construction, reconstruction, or modification commenced on or before August 23, 2011 is considered a modification for which a notification must be submitted under § 60.7(a)(4). |

| 272 | | § 60.5423 (e) The requirements of paragraph (b) of this section remain in force until and unless the EPA, in delegating enforcement authority to a state under section 111(c) of the Act, approves reporting requirements or an alternative means of compliance surveillance adopted by such state. In that event, affected sources within the state will be relieved of obligation to comply with paragraph (b) of this section, provided that they comply with the requirements established by the state. |
| 273 | § 60.5425 What part of the General Provisions apply to me? | |
| 274 | | § 60.5425 Table 3 to this subpart shows which parts of the General Provisions in §§ 60.1 through 60.19 apply to you. |
| 275 | § 60.5430 What definitions apply to this subpart? | |
| 276 | | As used in this subpart, all terms not defined herein shall have the meaning given them in the Act, in subpart A or subpart VVa of part 60; and the following terms shall have the specific meanings given them. |
| 277 | | <i>Acid gas</i> means a gas stream of hydrogen sulfide (H ₂ S) and carbon dioxide (CO ₂) that has been separated from sour natural gas by a sweetening unit. |
| 278 | | <i>Alaskan North Slope</i> means the approximately 69,000 square-mile area extending from the Brooks Range to the Arctic Ocean. |
| 279 | | <i>API Gravity</i> means the weight per unit volume of hydrocarbon liquids as measured by a system recommended by the American Petroleum Institute 279(API) and is expressed in degrees. |
| 279A | See Section 6.2 | <u><i>Appraisal well</i> means a well drilled in an area where the reservoir has not been classified for that area as containing proved reserves of a natural gas.</u> |
| 279B | See Section 20.6.1 | <u><i>Boiler</i> means an enclosed device using controlled flame combustion and having the primary purpose of recovering and exporting thermal energy in the form of steam or hot water. Boiler also means any industrial furnace as defined in 40 CFR 260.10. This definition excludes line heaters and glycol reboilers.</u> |

| Ref # | Comment | Regulatory Text |
|-------|--|--|
| 279C | <p>See Section 22.4.4.</p> <p>New Definition</p> <p>LDAR 1.4.4</p> | <p><u>Capital expenditure means, in addition to the definition in 40 CFR 60.2, an expenditure for a physical or operational change to an existing facility that:</u></p> <p><u>(a) Exceeds P, the product of the facility's replacement cost, R, and an adjusted annual asset guideline repair allowance, A, as reflected by the following equation: $P = R \times A$, where:</u></p> <p><u>(1) The adjusted annual asset guideline repair allowance, A, is the product of the percent of the replacement cost, Y, and the applicable basic annual asset guideline repair allowance, B, divided by 100 as reflected by the following equation:</u></p> <p><u>$A = Y \times (B \div 100)$;</u></p> <p><u>(2) The percent Y is determined from the following equation: $Y = 1.0 - 0.575 \log X$, where X is 2011 minus the year of construction; and</u></p> <p><u>(3) The applicable basic annual asset guideline repair allowance, B, is 4.5.</u></p> |
| 280 | See Section 18.9.2 | <p><u>Centrifugal compressor means a dynamic machines in which one or more rotating impellers, usually shrouded on the sides, accelerate the flow of natural gas or field gas. The main gas flow is radial. The pressure increase is achieved by converting kinetic energy to static energy. Centrifugal compressor does not include compressors associated with a vapor recovery unit or any other pollution control device.</u>means a piece of equipment that compresses a process gas by means of mechanical rotating vanes or impellers.</p> |
| 281 | | <p><i>City gate</i> means the delivery point at which natural gas is transferred from a transmission pipeline to the local gas utility.</p> |
| 281A | See Section 18.1 | <p><u>Commenced means, with respect to the definition of new source in section 111(a)(2) of the Act, that an owner or operator has undertaken a continuous program of construction or modification or that an owner or operator has entered into a contractual obligation to undertake and complete, within a reasonable time, a continuous program of construction or modification.</u></p> |
| 282 | | <p><i>Completion combustion device</i> means any ignition device, installed horizontally or vertically, used in exploration and production operations to combust otherwise vented emissions from completions or workovers.</p> |
| 283 | | <p><i>Compressor</i> means a piece of equipment that compresses process gas and is usually a centrifugal compressor or a reciprocating compressor.</p> |
| 284 | | <p><i>Compressor station</i> means any permanent combination of compressors that move natural gas at increased pressure from fields, in transmission pipelines, or into storage.</p> |

| Ref # | Comment | Regulatory Text |
|-------|--|--|
| 285 | See Section 5.1.1 and (Storage Vessels). Definition from EIA glossary. | Condensate means a hydrocarbon liquid separated from natural gas that condenses due to changes in the temperature, pressure, or both, and remains liquid at standard conditions, as specified in § 60.2. For the purposes of this subpart, a hydrocarbon liquid with an API gravity equal to or greater than 40 degrees is considered condensate natural gas-natural gas liquid recovered from associated and non associated gas wells from lease separators or field facilities, reported in barrels of 42 U.S. gallons at atmospheric pressure and 50 degrees Fahrenheit. |
| 285A | See Section 20.6.2 | Condenser means any equipment using an internal temperature change to facilitate condensation. Condensers do not affect non-condensable vapors and cannot be considered a device to control VOC or HAP. |
| 285B | See Section 18.1 | Construction means fabrication, erection, or installation of an affected facility. |
| 285C | Missing Definition | Continuous bleed pneumatic controller means a pneumatic controller that does not have a mechanical barrier between the pressure source and the end device and controls the signal to the end device by adjusting the magnitude of the flow rate of the bleed gas to the atmosphere (weak stream) through an adjustable port. |
| 285D | See Section 17.3.4 Primary Option Missing definition that is needed because of API proposed change to pneumatic controller affected facility | Continuous bleed gas-driven pneumatically controlled process unit means the group of equipment required to operate all pneumatically controlled valves that regulate a process variable (such as flow, fluid level, pressure, or temperature of gas and liquids) located at a single site such as a well site, tank battery, or compressor station. This group of equipment includes instrument gas supply lines, filters, pressure regulators, floats and switches, continuous bleed gas-driven pneumatic controllers, valve actuators, and valves. |
| 285E | See Section 17.3.5 Secondary Option Used if site wide process unit is unacceptable to EPA | Pneumatically controlled process unit means the group of equipment required to operate a single pneumatically controlled valve that regulates a process variable (such as flow, fluid level, pressure, or temperature of gas and liquids) located at a single site such as a well site, tank battery, or compressor station. This group of equipment includes instrument gas supply lines, filters, pressure regulator, float and switch, continuous bleed gas-driven pneumatic controller, valve actuator, and valve.” |

| Ref # | Comment | Regulatory Text |
|-------|--|---|
| 286 | Definition from Energy Information Administration glossary | <p><i>Crude oil</i> means crude petroleum oil or any other hydrocarbon liquid, which are produced at the well in liquid form by ordinary production methods, and which are not the result of condensation of gas before or after it leaves the reservoir. For the purposes of this subpart, a hydrocarbon liquid with an API gravity less than 40 degrees is considered crude oil. <u>a mixture of hydrocarbons that exists in the liquid phase in natural underground reservoirs and remains liquid at atmospheric pressure after passing through surface separating facilities. Crude oil may also include:</u></p> <ul style="list-style-type: none"> <u>Small amounts of hydrocarbons that exist in the gaseous phase in natural underground reservoirs but are liquid at atmospheric pressure after being recovered from oil well (casinghead) gas in lease separators, and that subsequently are comingled with the crude stream without being separately measured.</u> <u>Small amounts of nonhydrocarbons produced with the oil.</u> |
| 286A | See Section 3.1 | <p><u><i>Custody transfer</i> means the last point of custody transfer of crude oil, condensate, or natural gas before it leaves the production field or basin and enters pipelines or any other forms of transportation. Typical custody transfer points include truck loading facilities or pipeline metering stations for crude oil or condensate, and the tail gate of natural gas processing plants or pipeline metering stations for natural gas.</u></p> |
| 286B | See Section 3.2 | <p><u><i>Custody Transfer Station</i> means a facility where custody of natural gas is transferred from an interstate transmission pipeline or local producer to a natural gas local distribution utility.</u></p> |
| 287 | | <p><i>Dehydrator</i> means a device in which an absorbent directly contacts a natural gas stream and absorbs water in a contact tower or absorption column (absorber).</p> |
| 288 | | <p><i>Delineation well</i> means a well drilled in order to determine the boundary of a field or producing reservoir.</p> |
| 288A | See Section 19.1. New Definition | <p><u><i>Distance piece</i> means an open or enclosed casing through which the piston rod travels, separating the compressor or pump cylinder from the crankcase.</u></p> |
| 289 | Preferred Regulatory Text See Section 19.4.3 | <p><i>Equipment</i> means each pump, pressure relief device, open-ended valve or line, valve, compressor, and flange or other connector that is in VOC service or in wet gas service, and any device or system required by <u>the equipment leak provisions of</u> this subpart.</p> |
| 289A | Alternative Regulatory Text See Section 19.4.3 | <p><i>Equipment</i> means each pump, pressure relief device, open-ended valve or line, valve, compressor, and flange or other connector that is in VOC service or in wet gas service, and any device or system required by <u>the equipment leak provisions of</u> this subpart.</p> |
| 290 | | <p><i>Field gas</i> means feedstock gas entering the natural gas processing plant.</p> |
| 291 | | <p><i>Field gas gathering</i> means the system used to transport field gas from a field to the main pipeline in the area.</p> |

| Ref # | Comment | Regulatory Text |
|-------|--|---|
| 291A | See Section 6.3 | <p><u>First Date of Production</u> means the date permanent production equipment is in place and product is consistently flowing to sales lines, gathering lines or storage tanks. Production occurring during well completion activities which is routed to temporary production equipment is considered to occur prior to the First Date of Production. If extended periods of time pass between zone completions but production initially completed zones is consistently flowing to permanent production equipment, the First Date of Production is the date when production from the initial zones began consistently flowing to the permanent production equipment, even though more zones will be completed later.</p> |
| 292 | See Section 8.1.3 or 15.3.9 | <p><i>Flare</i> means a thermal oxidation system using an open (without enclosure) flame. <u>A completion combustion device is not a flare.</u></p> |
| 293 | | <p><i>Flowback</i> means the process of allowing fluids to flow from the well following a treatment, either in preparation for a subsequent phase of treatment or in preparation for cleanup and returning the well to production. <u>Flowback immediately following hydraulic fracture stimulation may occur in conjunction with a well completion, recompletion, or workover.</u></p> |
| 294 | | <p><i>Flow line</i> means surface pipe through which oil and/or natural gas travels from the well.</p> |
| 294A | See Section 5.1.3 and 19.4.1. | <p><u>Forced extraction of natural gas liquids</u> means removal of ethane or higher carbon number hydrocarbons existing in the vapor phase in natural gas, by removing ethane or heavier hydrocarbons derived from natural gas into natural gas liquids by means of a forced extraction process. <u>Forced extraction processes include but are not limited to refrigeration, absorption (lean oil), cryogenic expander, and combinations of these processes. Forced extraction does not include in and of itself; natural gas dehydration, or the collection or gravity separation of water or hydrocarbon liquids from natural gas at ambient temperature or heated above ambient temperatures, or the condensation of water or hydrocarbon liquids through passive reduction in pressure or temperature, or portable dewpoint depression skids or fuel treatment skids.</u></p> |
| 295 | Controllers are not “powered by” the gas stream. | <p><i>Gas-driven pneumatic controller</i> means a pneumatic controller <u>powered by that directs a signal to an end device using</u> pressurized natural gas.</p> |
| 296 | See Section 6.1.3 | <p><i>Gas processing plant</i> process unit means equipment assembled for the forced extraction of natural gas liquids from field gas, the fractionation of the liquids into natural gas products, or other operations associated with the processing of natural gas products. A process unit can operate independently if supplied with sufficient feed or raw materials and sufficient storage facilities for the products.</p> |
| 297 | Definition from Energy Information Administration glossary | <p><i>Gas well</i> means a well, <u>the principal production of which at the mouth of the well is gas, completed for production of natural gas from one or more gas zones or reservoirs. Such wells contain no completions for the production of crude oil.</u></p> |

| Ref # | Comment | Regulatory Text |
|-------|--|--|
| 298 | The end devices are not the issue. The emission quantity is absolutely controlled by the controller and any end-device can be driven by either a continuous bleed controller or an intermittent vent controller. | <i>High-bleed pneumatic devices controller</i> means <u>a automated, continuous bleed pneumatic controller which controls flow control devices powered by</u> pressurized natural gas <u>that has the ability to vent the weak stream and used for maintaining a process condition such as liquid level, pressure, delta pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents continuously (bleeds) to the atmosphere at a rate greater than in excess of</u> six standard cubic feet per hour. |
| 299 | See Section 6.2 | <i>Hydraulic fracturing</i> means the process of directing pressurized liquids, containing water, proppant, and any added chemicals, to penetrate tight sand, shale, or coal formations that involve high rate, extended back flow to expel fracture fluids and sand during completions and well workovers. <u>a stimulation treatment routinely performed on oil and gas wells in low-permeability reservoirs. Specially engineered fluids are pumped at a high pressure and rate into the reservoir interval to be treated, causing a fracture(s) to open. The wings of the fracture extend away from the wellbore in opposing directions according to the natural stresses within the formation. Proppant, such as grains of sand of a particular size, is mixed with the treatment fluid to keep the fracture open when the treatment is complete. Hydraulic fracturing creates high-conductivity communication with a large area of formation and by passes any damage that may exist in the near-wellbore area.</u> |
| 300 | | <i>In light liquid service</i> means that the piece of equipment contains a liquid that meets the conditions specified in § 60.485a(e) or § 60.5401(h)(2) of this part. |
| 300A | Copied from NSPS Subpart VVa | <i>In VOC service</i> means that the piece of equipment contains or contacts a process fluid that is at least 10 percent VOC by weight. |
| 301 | See Section 4.1 | <i>In wet gas service</i> means that a compressor or piece of equipment contains or contacts wet gas, the field gas before the extraction step at a gas processing plant process unit. |
| 301A | Missing definition that is needed because of reference to API proposed §60.5365(d)(1) | <i>Intermittent vent pneumatic controller</i> means <u>a pneumatic controller that has an internal mechanical barrier between the source of gas pressure and the end device. In response to an input signal, these devices will shut the vent and open the mechanical barrier to send gas pressure to the end device. When the input signal has been satisfied it shuts the mechanical barrier and opens a vent to remove pressure from the end device.</u> |
| 302 | | <i>Liquefied natural gas unit</i> means a unit used to cool natural gas to the point at which it is condensed into a liquid which is colorless, odorless, noncorrosive and non-toxic. |

| Ref # | Comment | Regulatory Text |
|-------|--|---|
| 303 | The end devices are not the issue. The emission quantity is absolutely controlled by the controller and any end-device can be driven by either a continuous bleed controller or an intermittent vent controller. | <i>Low-bleed pneumatic controller</i> means a <u>continuous bleed pneumatic controller which controls automated flow control devices powered by</u> pressurized natural gas <u>that has the ability to vent the weak stream and used for maintaining a process condition such as liquid level, pressure, delta pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents continuously (bleeds)</u> to the atmosphere at a rate equal to or less than six standard cubic feet per hour. |
| 304 | Preferred Option See Section 15.6.2 | <i>Modification</i> means any physical change in, or change in the method of operation of, an affected facility which increases the amount of VOC or natural gas emitted into the atmosphere by that facility or which results in the emission of VOC or natural gas into the atmosphere not previously emitted. For the purposes of this subpart, each recompletion of a fractured or refractured existing gas well is considered to be a modification. |
| 304A | Alternative Option See Section 15.6.2 | <i>Modification</i> means any physical change in, or change in the method of operation of, an affected facility which increases the amount of VOC or natural gas emitted into the atmosphere by that facility or which results in the emission of VOC or natural gas into the atmosphere not previously emitted. For the purposes of this subpart, each recompletion of a fractured or existing gas well is considered to be a modification. |
| 304B | Basis of this definition is NSPS Subpart Da | <u><i>Natural gas</i> means a naturally occurring mixture of hydrocarbons and non-hydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane. LNG is not considered natural gas, since impurities such as VOCs and HAPs have been removed.</u> |
| 305 | | <i>Natural gas liquids</i> means the hydrocarbons, such as ethane, propane, butane, and pentane that are extracted from field gas. |
| 306 | See Sections 5.1.3 and 19.4.1. | <i>Natural gas processing plant (gas plant)</i> means any processing site engaged in the <u>forced</u> extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both. |
| 307 | | <i>Nonfractionating plant</i> means any gas plant that does not fractionate mixed natural gas liquids into natural gas products. |
| 308 | See Section 17.2.1 | <i>Non gas-driven pneumatic <u>controller device</u></i> means <u>a pneumatic controller that directs a signal to an end device in a medium other than natural gas. The signal can include compressed air, electric power, or hydraulic power.</u> an instrument that is actuated using other sources of power than pressurized natural gas; examples include solar, electric, and instrument air. |
| 309 | | <i>Onshore</i> means all facilities except those that are located in the territorial seas or on the outer continental shelf. |
| 310 | An orphaned definition that is not used in the subpart and should be removed. See Section 5.6. | <i>Plunger lift system</i> means an intermittent gas lift that uses gas pressure buildup in the casing-tubing annulus to push a steel plunger, and the column of fluid ahead of it, up the well tubing to the surface. |

| Ref # | Comment | Regulatory Text |
|-------|--|---|
| 311 | Imprecise definition | <i>Pneumatic controller</i> means an automated instrument <u>that is able to sense the state of a process variable and send a pressure signal to an end device to affect a change in that process variable. used for maintaining a process condition such as liquid level, pressure, delta pressure and temperature.</u> |
| 311A | Missing definition needed to complement API proposed change to pneumatic controller affected facility. | <i>Pneumatically controlled process unit</i> means the group of <u>equipment required to operate all pneumatically controlled valves that regulate a process variable (such as flow, fluid level, pressure, or temperature of gas and liquids) located at a single site such as a well site, tank battery, or compressor station. This group of equipment includes instrument gas supply lines, filters, pressure regulators, floats and switches, pneumatic controllers, valve actuators, and valves.</u> |
| 312 | An orphaned definition that is not used in the subpart and should be removed. See Section 5.6. | <i>Pneumatic pump</i> means a pump that uses pressurized natural gas to move a piston or diaphragm, which pumps liquids on the opposite side of the piston or diaphragm. |
| 313 | LDAR 1.4.1 | <i>Process unit</i> means components assembled for the <u>forced</u> extraction of natural gas liquids from field gas, the fractionation of the liquids into natural gas products, or other operations associated with the processing of natural gas products. A process unit can operate independently if supplied with sufficient feed or raw materials and sufficient storage facilities for the products. |
| 313A | See Section 6.2 | <u><i>Proven reserves</i> of a natural gas are reserves which analysis of geological and engineering data demonstrate with reasonable certainty to be recoverable in future years from known reservoirs under existing economic and operating conditions. Reservoirs are considered proved if economic producibility is supported by actual production or conclusive formation test (drill stem or wire line), or if economic producibility is supported by core analyses and/or electric or other log interpretations. The area of a gas reservoir considered proved includes: (1) that portion delineated by drilling and defined by gas – oil and/or gas – water contacts, if any; and (2) the immediately adjoining portions not yet drilled, but which can be reasonably judged as economically productive on the basis of available geological and engineering data. In the absence of information on fluid contacts, the lowest known structural occurrence of hydrocarbons is considered to be the lower proved limit of the reservoir.</u> |
| 314 | See Section 18.5 | <i>Reciprocating compressor</i> means a <u>positive-displacement machines in which the compressing and displacing element is a piston having a reciprocating motion within a cylinder. The pressure increase is achieved by reducing the volume of a fixed amount of natural gas or field gas.</u> means a piece of equipment that increases the pressure of a process gas by positive displacement, employing linear movement of the driveshaft. |
| 315 | | <i>Reciprocating compressor rod packing</i> means a series of flexible rings in machined metal cups that fit around the reciprocating compressor piston rod to create a seal limiting the amount of compressed natural gas that escapes to the atmosphere. |

| Ref # | Comment | Regulatory Text |
|-------|--|---|
| 316 | An orphaned definition that is not used in the subpart and should be removed. See Section 5.6. | Reduced emissions completion means a well completion where gas flowback that is otherwise vented is captured, cleaned, and routed to the sales line. |
| 317 | An orphaned definition that is not used in the subpart and should be removed. See Section 5.6. | Reduced emissions recompletion means a well completion following refracturing of a gas well where gas flowback that is otherwise vented is captured, cleaned, and routed to the sales line. |
| 318 | | Reduced sulfur compounds means H ₂ S, carbonyl sulfide (COS), and carbon disulfide (CS ₂). |
| 319 | See Section 9.4 | Routed to a process or route to a process means the emissions are conveyed to any enclosed portion of a process unit where the emissions are predominantly recycled and/or consumed in the same manner as a material that fulfills the same function in the process and/or transformed by chemical reaction into materials that are not regulated materials and/or incorporated into a product; and/or recovered. |
| 320 | | Salable quality gas means natural gas that meets the composition, moisture, or other limits set by the purchaser of the natural gas. |
| 321 | | Sales line means pipeline, generally small in diameter, used to transport oil or gas from the well to a processing facility or a mainline pipeline. |
| 321A | See Section 15.5 | <u>Standard of Performance means a standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction</u> |
| 322 | See Section 6.3 | Storage vessel or Tank means a stationary vessel or series of stationary vessels that are either manifolded together or are located at a single well site and that have potential for VOC emissions equal to or greater than 10 tpy. unit that is constructed primarily of nonearthen materials (such as wood, concrete, steel, fiberglass, or plastic) which provide structural support and is designed to hold an accumulation of liquids or other materials. Storage vessel or Tank does not include: <u>(1) Process tanks, including vessels used for a process function such as reactions, blending, or separation, vessels such as sumps used to collect discharged material such that it can be transferred to a process or to storage, vessels used for surge control, and vessels used as knockouts,</u> <u>(2) Vessels with a design capacity less than or equal to 472 barrels with a maximum true vapor pressure less than 11.1 psia.</u> <u>(3) Vessels storing wastewater,</u> <u>(4) Pressure vessels designed to operate without emissions to the atmosphere,</u> <u>(5) Subsurface caverns and porous rock reservoirs, and</u> <u>(6) Vessels that do not remain at a given site for more than 90 consecutive days.</u> |
| 323 | | Sulfur production rate means the rate of liquid sulfur accumulation from the sulfur recovery unit. |
| 324 | | Sulfur recovery unit means a process device that recovers element sulfur from acid gas. |

| Ref # | Comment | Regulatory Text |
|-------|--|--|
| 325 | | <i>Surface site</i> means any combination of one or more graded pad sites, gravel pad sites, foundations, platforms, or the immediate physical location upon which equipment is physically affixed. |
| 326 | | <i>Sweetening unit</i> means a process device that removes hydrogen sulfide and/or carbon dioxide from the natural gas stream. |
| 327 | | <i>Total Reduced Sulfur (TRS)</i> means the sum of the sulfur compounds hydrogen sulfide, methyl mercaptan, dimethyl sulfide, and dimethyl disulfide as measured by Method 16 of appendix A to part 60 of this chapter. |
| 328 | | <i>Total SO2 equivalents</i> means the sum of volumetric or mass concentrations of the sulfur compounds obtained by adding the quantity existing as SO2 to the quantity of SO2 that would be obtained if all reduced sulfur compounds were converted to SO2 (ppmv or kg/dscm (lb/dscf)). |
| 329 | | <i>Underground storage tank</i> means a storage tank stored below ground. |
| 329A | Missing definition needed because term is referenced in API §60.5410(d)(3) and §60.5420(c)(4)(iii) | <u><i>Weak stream</i> means the stream of gas that is vented when the end device is “at rest” in its idle position (e.g., when the end device is shut on a pressure-to-open system).</u> |
| 330 | | <i>Well</i> means an oil or gas well, a hole drilled for the purpose of producing oil or gas, or a well into which fluids are injected. |
| 331 | See Section 15.8.3 | <i>Well Completions</i> means the process that allows for the flow of petroleum or natural gas from newly drilled wells to expel drilling and reservoir fluids and tests the reservoir flow characteristics, steps which may vent produced gas to the atmosphere via an open pit or tank. Well completion also involves connecting the well bore to the reservoir, which may include treating the formation or installing tubing, packer(s), or lifting equipment. of making a new oil or natural gas well ready for production. It allows for the flow of petroleum or natural gas from newly drilled wells to expel drilling and reservoir fluids and test the reservoir flow characteristics and also involves connecting the well bore to the reservoir, which may include treating the formation or installing tubing, packers(s), or lifting equipment. This process may also include high-rate flowback of injected gas, water, oil, and proppant used to fracture stimulate and prop open new fractures in lower permeability reservoirs. <i>Well completion operation</i> means any well completion occurring at a gas wellhead affected facility <u>onshore.</u> |
| 331A | See Section 6.2 | <u><i>Well recompletion</i> means completing a well again. See the definition of well completion.</u> |
| 332 | | <i>Well site</i> means the areas that are directly disturbed during the drilling and subsequent operation of, or affected by, production facilities directly associated with any oil well, gas well, or injection well and its associated well pad. |

| Ref # | Comment | Regulatory Text |
|-------|---|--|
| 332A | See Section 6.2 | <p><u>Well workover means the work conducted on wells with a rig or coiled tubing unit after the initial completion is over. Such process(es) may include performing one or more of a variety of remedial operations on producing petroleum and natural gas wells to try to increase production or return the well to its normal production rate. This process may also include high-rate flowback of injected gas, water, oil, and proppant used to re-fracture and prop-open new fractures in existing low permeability reservoirs or re-complete an existing well to a new production zone/horizon. A well workover does not include routine maintenance activities that are performed on the well with the tree installed (See 30 CFR Part 250.601 Definitions for further details). Such routine activities may include maintenance, repair, or replacement of equipment such as rods, pumps, tubing, packers, or other mechanical devices.</u></p> |
| 333 | | <p><i>Wellhead</i> means the piping, casing, tubing and connected valves protruding above the earth's surface for an oil and/or natural gas well. The wellhead ends where the flow line connects to a wellhead valve. The wellhead does not include other equipment at the well site except for any conveyance through which gas is vented to the atmosphere.</p> |
| 334 | <p>See Section 4.1 New Definition LDAR 1.4.2 <i>[API recommends X be 5.0 or greater.]</i></p> | <p><u>Wet gas means the field gas before the extraction step at a gas processing plant process unit that is >X% VOC by weight or does not include gas streams that are >50% by weight inert gases (e.g. nitrogen or carbon dioxide).</u></p> |
| 335 | | <p><i>Wildcat well</i> means a well outside known fields or the first well drilled in an oil or gas field where no other oil and gas production exists.</p> |

Re: Comments on Proposed Standards of Performance for New Stationary Sources and Emission Guidelines for Existing Sources: Sewage Sludge Incineration Units, Docket ID No. EPA-HQ-OAR-2009-0559

Dear Sir or Madam:

This letter provides comments of the SSM Coalition on EPA's proposal to promulgate National Standards of Performance for New Stationary Sources under Clean Air Act ("CAA") sections 111(b) and 129(a) and emission guidelines for existing sources under CAA sections 111(d) and 129(b) for sewage sludge incineration units ("SSIs"), as published on October 14, 2010, 75 Fed. Reg. 63260 (the "Proposed Rule" or the "Proposed Standards").

The SSM Coalition is an *ad hoc* coalition of trade associations and business organizations interested in the methodologies EPA uses to develop stationary source emission standards under the CAA and the way those standards are expressed in EPA regulations. SSM Coalition's current members are the American Chemistry Council, American Forest & Paper Association, American Home Furnishings Alliance, American Iron and Steel Institute, American Petroleum Institute, American Wood Council, Brick Industry Association, Coalition for Responsible Waste Incineration, Council of Industrial Boiler Owners, Florida Sugar Industry, National Association of Manufacturers, National Petrochemical & Refiners Association, Rubber Manufacturers Association, Treated Wood Council, and the Vegetable Oil SSM Coalition (consisting of the Corn Refiners Association, the National Cotton Council, the National Cottonseed Products Association, the National Oilseed Processors Association, and Sessions Peanut Company).

The members of the SSM Coalition have an interest in, and many of the associations' members are directly affected by, various rules that are in the active rulemaking stage or that are scheduled for review in the near future. The SSM Coalition objects to the new manner in which EPA is proposing to address periods of startup, shutdown, or malfunction ("SSM") in the SSI rulemaking and in several other recently proposed and final rules. SSM Coalition members believe EPA has failed to account adequately for emissions that occur during SSM periods. EPA bases its action on an improperly narrow reading of the D.C. Circuit's *Sierra Club v. EPA*

decision and on unreasonable or insufficiently supported assumptions about SSM events and emissions during SSM periods. EPA should revise the proposed standards to account better for SSM events, rather than rely on an “affirmative defense” to make up for its failure to do so. The affirmative defense EPA describes in the Proposed Rule inappropriately shifts the burden to the source to disprove alleged violations during malfunctions. In addition, the limitations and requirements EPA proposes for the affirmative defense are unreasonable and impracticable. It would require substantial modification and streamlining if EPA persists on relying on it.

1. EPA Misreads *Sierra Club v. EPA*

EPA has recognized for decades that generally it is unreasonable to require sources to meet technology-based emission standards, such as NSPS promulgated under section 111, during SSM periods. See 40 C.F.R. § 60.8(c). Despite that fact, the Proposed Standards, to be issued under sections 111 and 129, state that they are applicable at all times, even during SSM events. Proposed section 60.5180. EPA suggests that its treatment of excess emissions during SSM events in the Proposed Standards is supported, perhaps even compelled, by the D.C. Circuit’s decision in *Sierra Club v. EPA*, 551 F.3d 1019 (D.C. Cir. 2008), *cert. denied*, 130 S. Ct. 1735 (2010), which vacated the exemption¹ for excess emissions during SSM events contained in the 40 C.F.R. part 63, subpart A General Provisions for emission standards for hazardous air pollutants under CAA section 112. Since that decision involved the Court’s interpretation of the definition of “emission standards,” which appears in CAA section 302(k), and which EPA asserts “applies equally” to “emission standards” under CAA section 112 and “performance standards” under section 129, EPA states that “the legality of source category-specific SSM exemptions in rules promulgated pursuant to section 129 is questionable.” See 75 Fed. Reg. at 63,282 col. 3.

The D.C. Circuit’s *Sierra Club* decision manifestly is not binding on EPA’s establishment of performance standards for SSI units under CAA sections 111 and 129. First, the *Sierra Club* decision interpreted section 112, not section 129 (which incorporates by reference section 111). This is not merely a technical distinction. The language that the D.C. Circuit considered dispositive in interpreting EPA’s standards-setting authority under section 112 — the statement in the definition of “emission limitation” and “emission standard” that it “limits the quantity, rate, or

¹ Although the D.C. Circuit (and EPA in the preamble to the Proposed Rule) referred to the provision vacated in the *Sierra Club* decision as an “exemption” from hazardous air pollutant standards during SSM events, in fact other portions of the NESHAP General Provisions impose various requirements that apply to sources during SSM events (including the obligation to minimize excess emissions), and in anticipation of and following SSM events (including requirements to prepare a plan to address SSM events and to report SSM events).

concentration of emissions of air pollutants on a continuous basis” — has been in the statute since 1977. Throughout that time, EPA has exempted emissions during SSM events from compliance with NSPS under CAA section 111. See 40 C.F.R. § 60.8(c). In fact, Congress enacted the “continuous basis” language in section 302(k) knowing that EPA’s emissions standards under section 111 exempted SSM periods. There is nothing in the legislative history of the 1977 amendments to the CAA that suggests Congress intended to overturn that practice.² Moreover, court decisions both before and after the Clean Air Act Amendments of 1977, some of which are cited below, have affirmed the appropriateness of including an SSM exemption in standards issued under section 111.

Secondly, the *Sierra Club* decision did not address whether EPA could use a “design, equipment, work practice or operational standard,” as authorized under CAA section 112(h) [and 111(h)] and included in the definition of “emission limitation” and “emission standard” in CAA section 302(k), in lieu of a numerical emission limitation during SSM events. EPA told the Court that the General Provisions SSM exemption struck down in *Sierra Club* was not an alternative standard based on that work practice, etc. authority. See 551 F.3d at 1028. Indeed, EPA argued in that case that section 112(h) was irrelevant to its authority to exempt excess emissions during SSM events. *Id.* at 1030 (Randolph, J. dissenting).

EPA’s assertion that “the legality of source category-specific SSM exemptions in rules promulgated pursuant to section 129 is questionable” does not acknowledge, much less contradict, these facts. See 75 Fed. Reg. at 63,282 col. 3. Although EPA claims that by requiring that the Proposed Standards be met at all times—and basically ignoring or assuming away SSM events—it is acting “consistent with *Sierra Club*,” this claim does not justify EPA’s actions in the Proposed Rule, since the *Sierra Club* opinion relates to a different type of action (exempting emissions from any standard) under a different statutory provision (section 112). See *id.* Even if *Sierra Club* were relevant to and binding upon EPA’s promulgation of performance standards for SSI units under sections 111 and 129, however, it would not compel EPA to eschew distinct requirements applicable during SSM events.

EPA claims that the D.C. Circuit’s interpretation of the definition of “emission standards” “requires EPA to apply MACT emission standards on a continuous basis, thereby precluding exemptions applied for malfunctions or other singular events.” 75 Fed. Reg. at 63,282 col. 2 (emphasis added). While a blanket exemption from any standard under sections 111 and 129 may be inconsistent with the *Sierra Club* panel

² Rather, the “continuous basis” language related to a debate in Congress about whether sources should be allowed to use temporary or intermittent pollution control technologies, as the *Sierra Club* court recognized. See 551 F.3d at 1027, citing *Kamp v. Hernandez*, 752 F.2d 1444, 1452 (9th Cir.1985). It had nothing to do with limitations applied during SSM nor with EPA’s established practice of exempting excess emissions during SSM events from its performance standards.

holding that, for section 112 maximum achievable control technology (MACT) standards, “there must be continuous section 112-compliant standards” (551 F.3d at 1027), *Sierra Club* does not preclude EPA from applying different standards during SSM events than apply during normal operations. In fact, the opinion acknowledges that section 302(k)’s “inclusion of [the] broad phrase” “any requirement relating to the operation or maintenance of a source to assure continuous emission reduction” in the definition of “emission standard” suggests that EPA need not “necessarily continuously apply [] a single standard.”³

Thus, EPA cannot hide behind the *Sierra Club* decision as a justification for ignoring the inability of even the “best performers” to achieve the proposed emission standards during SSM events. CAA section 129 (a)(2), which incorporates the same MACT requirements for solid waste incinerators as CAA section 112(d) applies to sources of hazardous air pollutants, mandates that the emission standards be “achievable.” Moreover, if EPA sets the emission standards based on the “best performing 12% of units in the category” (the “MACT floor”), those limitations must on average be “achieved” by the best performers.

An emission limitation that applies during SSM events does not meet the requirement of CAA section 129(a)(2) that “emission standards” under that section be “achievable” if in fact EPA has not demonstrated that the limitation is “achievable” with available technology, “taking into consideration the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements.” Similarly, an emission limitation that applies during SSM events has not been demonstrated to be “achieved” by the best-performing 12% of units in the category” unless EPA can show that those best performers actually meet that emission limitation during SSM events.

Similarly, CAA section 111(a)(1), which also applies to emission standards promulgated under section 129, requires that any emission limitation be “achievable through the application of” emission reduction technology that “the Administrator determines has been adequately demonstrated.” EPA therefore must demonstrate that a numerical limitation, if it is to apply even during SSM events, is in fact achievable with available technology during such events.

³ 551 F.3d at 1027. “Indeed, this reading is supported by the legislative history of section 302(k).” *Id.* See also *id.* at 1021 (“accepting that ‘continuous’ for purposes of the definition of ‘emission standards’ under CAA section 302(k) does not mean unchanging”); *id.* (referring to “the CAA’s requirement that some section 112 standard apply continuously”) (emphasis added). Moreover, since it was addressing only a generic SSM exemption, the *Sierra Club* decision did not consider whether EPA, in the context of individual categorical standards, could determine that it is infeasible to apply the same limits, or any limits on the mass or concentration of pollutants emitted at all, during SSM events, or that it would lead to absurd results to do so.

These plain-language readings of the applicable statutory requirements are echoed by extensive case law. The courts have long recognized that a “technology based standard discards its fundamental premise when it ignores the limits inherent in technology.” *NRDC v. EPA*, 859 F.2d 156, 208 (D.C. Cir. 1988). For example, the D.C. Circuit recognized, in *Portland Cement Ass’n v. Ruckelshaus*, 486 F.2d 375, 398 (D.C. Cir. 1973), a decision reviewing standards under CAA section 111, that “‘start-up’ and ‘upset’ conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated.” *Id.* at 399. Similarly, in *Essex Chem. Corp. v. Ruckelshaus*, 486 F.2d 427, 432 (D.C. Cir. 1973), *cert. denied*, 416 U.S. 969 (1974), another section 111 case, the court held that SSM provisions are “necessary to preserve the reasonableness of the standards as a whole.” *Id.* at 433. In *National Lime Ass’n v. EPA*, 627 F.2d 416 (D.C. Cir. 1980), another case reviewing emission standards promulgated under CAA section 111, the court held CAA technology-based standards must be capable of being met “under most adverse circumstances which can reasonably be expected to recur,” such as during periods of SSM. 627 F.2d at 431 n.46.

Courts have reached a similar conclusion when considering the analogous Clean Water Act requirements that EPA establish technology-based effluent limitations based on the best available control technology. Knowing that there would be periods where a discharger, even with “exemplary use of” the identified best technology, would exceed the effluent limitations because of conditions “beyond the control of the permit holder,” EPA violated the Clean Water Act by failing to provide an “upset provision” to address those periods. *Marathon Oil Co. v. EPA*, 564 F.2d 1253, 1273-74 (9th Cir. 1977). See also, e.g., *NRDC v. EPA*, 859 F.2d at 207 (distinguishing between technology-based effluent limitations, where some provision for “upsets” is required, and water-quality-based effluent limitations, which are tied to achieving water quality standards rather than based on available technology, and therefore need not include an upset provision).⁴

As noted above, the *Sierra Club* decision does not prevent EPA from adopting emission standards for SSM periods that are different from those required during periods of normal operation. Nor did the *Sierra Club* court conclude that EPA is barred from using a “requirement relating to the operation or maintenance of a source to assure continuous emission reduction” as the emission standard that applies during such events. See 551 F.3d at 1027. The *Sierra Club* decision only

⁴ *Weyerhaeuser Co. v. Costle*, 590 F. 2d 1011 D.C. Cir. 1078), does not support EPA’s position. In that case, the court was discussing a “technology forcing” standard, rather than one, like MACT and NSPS, that is to be based on what is already being “achieved” or has been demonstrated to be achievable. Also, the decision came long before *NRDC v. EPA*, 859 F.2d 156 (D.C. Cir. 1988) which, as noted above, affirmed the need for an upset provision to address circumstances where compliance with effluent limitations is impossible through no fault of the permittee, and which endorsed *Marathon Oil*.

rejected EPA's assertion that it had discretion to decide not to impose *any* emission standard whatsoever during SSM periods. See *id.* at 1027-28, 1030 (noting that EPA was not claiming that the General Provisions SSM exemption was either an emission standard under CAA section 112(d) or a design, equipment, work practice, or operational standard under section 112(h)).⁵ Thus, despite EPA's suggestions to the contrary, the *Sierra Club* decision expressly recognizes that different standards, including non-numerical standards, may (and in some cases must) apply during non-standard operating conditions, such as SSM.

2. EPA Has Not Justified Applying the Same Emission Limitations During Startup and Shutdown

In the Proposed Rule, EPA does not say that it is precluded from adopting different emission limitations that would apply during startup and shutdown periods. Rather, EPA asserts that it is not necessary to do so in this case, because EPA "believes" that SSI units will be able to comply with the emission limitations proposed for normal operations, even during periods of startup and shutdown. See 75 Fed. Reg. at 63,282 col. 3.

SSM Coalition members do not have sufficient information to comment on whether in fact the emission limitations EPA has proposed for normal operations of SSI units can also be met during startup and shutdown. However, SSM Coalition members do have considerable experience with and emissions data for similar types of combustion units (i.e., boilers), and these data clearly demonstrate that emissions during startup and shutdown are much different than during normal operation. While mass emissions of pollutants can be lower during startup and shutdown events, emissions in terms of concentration (ppmvd, gr/dscf, mg/dscm, etc., which are the units of the proposed standards) can be much higher during these periods, because of lower exhaust gas volumes. It is reasonable to believe that SSI units would experience similar conditions during startup and shutdown, since they are enclosed combustion devices like boilers.

EPA, on the other hand, presents no information in either the preamble or in the docket supporting the contention that the proposed emission limitations for normal operations can also be met by the best performing SSI units during startup and shutdown. In fact, so far as the SSM Coalition can determine, EPA presents no

⁵ The statement in the majority opinion that "Congress gave no indication that it intended the application of MACT standards to vary based on different time periods," 551 F.3d at 1028: (1) is contradicted by other statements in the opinion, referenced above, that a MACT standard need not continuously apply a single emission limitation, (2) is *dicta*, because that was not the situation presented by the challenged regulations and argued by EPA, (3) ignores the extensive case law about technology-based limitations referenced above, and (4) does not in any event say that the CAA precludes EPA from adopting different emission limitations that apply during SSM events.

data at all about emissions from the best performing units during SSM events, or about best practices for minimizing emissions during SSM events. Instead, EPA simply asserts that emissions from burning natural gas, landfill gas, or distillate oil before adding waste to the SSI unit “are expected to generally be lower than from burning solid wastes” and that emissions during shutdowns “are also generally lower than emissions during normal operations because the materials in the incinerator would be almost fully combusted before shutdown occurs.” 75 Fed. Reg. at 63,282 col. 3, 63,283 col. 1.

These bare assumptions that emissions are “expected” to be lower, “generally,” do not constitute a demonstration that applying the proposed emission limitations during startup and shutdown reflects the performance of the best-performing SSI units under CAA section 129(a)(2) or is “adequately demonstrated” to be “achievable through the application of the best system of emission reduction” under CAA section 111(a)(1). EPA cannot conclude that special provisions for emissions during startup and shutdown are not needed based on “mere speculation.” See *NRDC v. EPA*, 859 F.2d 156, 210 (D.C. Cir. 1988).

The CAA does not authorize EPA to set limitations that only “generally” are achieved by the best performers or achievable with demonstrated technology. Moreover, the general assertions EPA has offered as support for insisting that emission limitations developed for normal operations must apply even during startup and shutdown are not even superficially persuasive. For example, EPA’s statement that emissions should be lower during startup before waste is added to an SSI unit fails to consider whether emissions will be higher than during normal, steady-state operations when the incinerator is first charged with sludge and before operations have stabilized. Nor is it obvious that the atypical combustion conditions occurring when the SSI unit is shutting down necessarily will result in lower emissions of all pollutants than during normal operations, especially pollutants that may be degraded at high stack temperatures.⁶ In some pollution control configurations, it is not possible to route exhaust gases to control equipment until the control equipment is fully operational, or until pollutants in the exhaust gases are sufficiently concentrated to be above the upper explosive limit. EPA’s undocumented “expectations” that the amount and/or concentration of all regulated pollutants emitted during startup or shutdown will be less than during normal operations simply ignore these possibilities.

⁶ To the contrary, a document in the docket for this rulemaking indicates that “NO_x and CO emissions are inversely proportional” and “[b]oth THC and CO emissions decrease with temperature, while NO_x emissions increase.” EPA-HQ-OAR-2009-0559-0032.pdf, at p. 2. Also, as noted above, low exhaust gas flows during shutdown may result in higher concentrations of pollutants even if the mass emitted is less. These facts appear directly to contradict EPA’s assumption that emissions of all of the regulated pollutants will be less under startup and shutdown conditions than at normal operating conditions.

EPA also claims that, because it has accounted for emissions variability in setting emissions standards based on actual performance of existing units, those emission standards “have adequately addressed any minor variability that may potentially occur during startup or shutdown.” 75 Fed. Reg. at 63,283 col. 1. There is no apparent basis for EPA’s assertion that there will only be “minor variability” during startup or shutdown. But in any event, EPA has not, in its variability analysis for setting the Proposed Standards, taken into account variability associated with startup or shutdown.

When developing technology-based emission standards, EPA often will not have emissions data that reflect startup and shutdown conditions. To the extent emissions data come from required performance tests, the applicable regulations generally prohibit testing during SSM conditions, and require that data not be used for compliance purposes if obtained during a startup, shutdown, or malfunction event.⁷ To the extent EPA evaluates emissions data collected through continuous monitoring, the applicable regulations generally require or allow the source to exclude from its reporting of continuous monitoring data those data reflecting SSM conditions. So in most cases, when EPA performs its variability analyses on emissions data for existing units, it assesses the variability only of a data set that already excludes SSM events.

In the case of the SSI rulemaking, EPA based the Proposed Standards, and conducted its variability analysis, solely based upon stack test data from nine publicly-owned treatment works that were targeted by EPA’s information collection request. See EPA-HQ-OAR-2009-0559-0006, pp. 5-9, 10-12 and Attachment J. In other words, the variability EPA used in setting the Proposed Standards—because the analysis was performed on emissions data from performance tests, when the source is being operated at normal levels and when efforts are being made to maintain steady-state conditions—reflects at most only the normal variation in emissions experienced during normal operations. Since performance test data are not collected during SSM events, the variability factors EPA derived to establish the Proposed Standards could not possibly incorporate emissions variability experienced during SSM events. Thus, by virtue of the variability analysis itself, the Proposed Standards are representative of emissions achieved during normal (very stable) operations and are not representative of emissions during SSM events (which can be highly variable). (For the same reasons, EPA’s attempt to consider variability in setting emission standards does not eliminate the need for different standards that apply during malfunctions.)

⁷ See, for example, the General Provisions applicable to NSPS, which state that performance tests can only be conducted under representative conditions and which specify that: “Operations during periods of startup, shutdown, and malfunction shall not constitute representative conditions for the purpose of a performance test....” 40 C.F.R. § 60.8(c).

EPA has a number of options for promulgating performance standards for SSI units under CAA sections 111 and 129. First, EPA could conduct stack testing during startup and shutdown events, just as it required stack testing at existing sludge incinerators for purposes of deriving the Proposed Standards. (Emissions testing during startup and shutdown will not be an option in all cases, because it may not be possible to obtain accurate sampling of exhaust gases during startup or shutdown of certain types of process or pollution control equipment. Stack sampling procedures may not apply or produce accurate results during the abnormal flow and concentration conditions present during startup or shutdown.) If sources are so equipped, EPA also may be able to analyze continuous monitoring data for some parameters that would include monitoring during startup or shutdown periods.⁸ These data could enable EPA to set alternative emission standards that apply during startup and shutdown, or to conclude that sources with the identified control technology will be able to meet emission limitations established for normal operations during startup and shutdown periods, as well. It would be appropriate for EPA to defer promulgating any emission limitations that apply during periods of startup or shutdown until after EPA obtains such data. EPA also could study facilities' operational logs to determine an averaging time for an emission standard sufficiently long that typical startups and shutdowns would not cause an exceedance of the standard. EPA also might determine, based on infeasibility of collecting representative data during startup and shutdown events, that it is necessary and appropriate to promulgate a design, equipment, work practice, or operational standard, pursuant to CAA section 111(h) and/or section 302(k), in lieu of deriving limitations on the mass or concentration of pollutants emitted during startup or shutdown.

Any one of these approaches would be consistent with the CAA. What EPA has done instead—merely assuming the problem away without conducting the necessary analysis of the performance actually achieved—is not. EPA should defer establishing any standards under CAA sections 111 and 129 for startup and shutdown periods until EPA can collect the necessary data and/or determine the appropriate work practice or operational standards to establish “emission limitations or other limitations” for SSI units during startup and shutdown. See CAA section 129(a)(1).

⁸ If the Proposed Regulations are adopted, EPA should be able to use continuous monitoring data reflecting at least some SSM events for the next review of SSI emission standards, from those facilities that opt to use the continuous emission monitor option in the Proposed Rule, since the Proposed Rule would require such facilities to operate and report data from continuous monitors even during SSM events (other than during monitor malfunction or downtime). See 75 Fed. Reg. at 63,281 col. 1.

3. EPA Is Required To Take Malfunctions into Account when Adopting Emission Standards

EPA asserts that it “is reasonable to interpret section 129 as not requiring EPA to account for malfunctions in setting emissions standards.” 75 Fed. Reg. at 63,283 col. 1. EPA offers little support for that assertion, however, other than its *ipse dixit*. For example, EPA says it “has determined that malfunctions should not be viewed as a distinct operating mode and, therefore, any emissions that occur at such times do not need to be factored into development of CAA section 129 standards, which, once promulgated, apply at all times.” *Id.* EPA provides no explanation of how it “determined” that malfunctions are not a distinct operating mode. Moreover, EPA offers no explanation of how it “determined” that, even though it believes malfunctions are not a distinct operating mode, emissions during malfunctions should not be used to characterize the source’s operating mode. On its face, asserting that malfunctions are part of normal operations, but then excluding emissions during malfunctions when determining emission limitations for normal operations, makes no sense.

EPA acknowledges that the best performing SSI units (like any technologies), are subject to a wide variety of potential malfunctions (e.g., power failures, equipment breakdowns). The operators of these processes and equipment must treat malfunctions as very distinct events from steady-state operations, depending on the severity of the malfunction, requiring anything from shutdown of the unit to emergency fire response actions. The SSM Coalition agrees with EPA’s conclusion that the factual complexity of differing processes and of the severity, frequency, and duration of malfunctions makes standard-setting difficult. In addition, it is often impossible to gather emission data during malfunctions – either for standard-setting or for compliance demonstration purposes. Malfunctions are by definition unexpected, so it is not possible to plan to have test equipment in place to measure emissions when one occurs. Even if test or monitoring equipment is in place, emissions during malfunctions often are not routed to a stack where they can be measured, and upsets during stack testing invalidate the test results under EPA’s approved test methods.

These findings should lead EPA to the authority under section 111(h) to prescribe alternative design, equipment, work practice or operational standards where it is not feasible to set or enforce a numerical emission limit. EPA cannot rationally defend its articulated view that applying the concept of “best performing” is inconsistent with a source experiencing a malfunction. See 75 Fed. Reg. at 63,283 col. 1. This ignores that there are work practices – such as monitoring combustion parameters to identify a malfunction and stopping the charging of materials to an incinerator – that represent the best practices for minimizing emissions during a malfunction. While the measures that represent these best practices will depend on facility-specific issues, such as incinerator design, pollution control train, and other

factors, they are nonetheless the “best technological system of continuous emission reduction ... adequately demonstrated.”

EPA claims that it somehow “presents significant difficulties” to attribute malfunctions to a “best performing” source. *Id.* But what really presents significant difficulties is EPA ignoring the undisputed existence of malfunctions even at best-performing sources, and claiming that the best-performing sources “achieve” emission levels that they undisputedly do not achieve part of the time. Since EPA describes malfunctions as being sometimes unavoidable or “not reasonably preventable,” despite proper design and maintenance of equipment, there is no basis for EPA’s conclusion that malfunction events are not representative of best-performing sources. See 75 Fed. Reg. 63,283 cols. 1 and 2. True, one goal (although not “the goal”) “of best performing sources is to operate in such a way as to avoid malfunctions of their units.” But that is all the more reason why EPA must acknowledge the fact that those sources nevertheless experience malfunction events, rather than assume those emissions away. *Cf.* 75 Fed. Reg. 63,283 col. 1.

By proposing a standard that EPA recognizes even the best-performing SSI units cannot achieve part of the time, EPA really is going beyond the MACT floor, yet without making the demonstrations that the statute and case law require EPA to make in order to impose beyond-the-floor MACT standards. (This is especially obvious when one considers the multitude of conditions EPA proposes to impose on sources during malfunctions, in order to be excused from civil penalties: EPA makes no attempt to justify those conditions as reasonable “taking into consideration the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements.” See CAA section 129(a)(2).)

Nor does EPA present any substantiation for its “belief” that “it would be impracticable to take malfunctions into account in setting CAA section 129 standards for SSI.” *Id.* EPA cannot defensibly acknowledge that malfunctions are inevitable, even for the best performing sources, yet refuse to include emissions data during malfunctions from its MACT floor calculations. If it is possible to gather sufficient representative data reflecting emissions during malfunctions, then EPA is obligated to consider these data in its MACT floor calculations for steady-state operating conditions. To the extent EPA has access to continuous monitoring data for SSI units, EPA could have conducted analyses of emissions levels during malfunction events.⁹ Also, although the SSM Coalition does not have information about sewage sludge incinerators in particular, many types of sources are required by many state agencies to submit deviation reports or malfunction reports when they experience a malfunction that causes an exceedance of an applicable limitation. EPA does not

⁹ Even if the continuous monitoring data are for parameters not regulated by the Proposed Standards, analysis of monitoring data for those other parameters during malfunction events might form a reasonable basis for EPA’s assessment of what standards are achieved or achievable during malfunctions.

appear to have made any attempt to obtain and analyze such reports, in order to assess what type of requirement might reasonably apply to SSI units during malfunctions.

There are several options EPA could use for setting performance standards under CAA sections 111 and 129 that would apply during malfunction events. For example, EPA could establish an emission limitation that applies at all times, but that has an averaging time of sufficient duration that short, infrequent spikes in emissions due to malfunctions would not cause the source to exceed the emission limitation (while at the same time assuring that the source does not operate in a way that causes frequent, lengthy excursions above the normal information rate). EPA could expand the Operator Training and Certification portion of the rules, issued under authority of CAA section 129(d), to provide greater specificity about the procedures the operator must follow to avoid and minimize excess emissions during malfunctions. Cf. proposed 40 C.F.R. § 60.4814(c)(1). EPA could use the flexibility accorded by CAA section 129(a)(1)(A) (performance standards “shall include emissions limitations and other requirements”) (emphasis added) and section 302(k) (defining “emission limitation” and “emission standard” to include “any requirement relating to the operation or maintenance of a source to assure continuous emission reduction, and any design, equipment, work practice or operational standard promulgated under” the CAA) to address emissions during malfunction events through operational requirements rather than by applying the limits on pollutant concentrations in exhaust gases that apply during normal operations. EPA could have concluded, as explained above, that it has grounds to exercise its authority under CAA section 111(h) to promulgate a design, equipment, work practice, or operational standard, or combination thereof, because it is not feasible to prescribe or enforce a standard of performance. EPA might also use several of these approaches in combination.

There is no indication in the Proposed Rule that EPA gave much if any consideration to these types of options. In short, there are ample reasons to reject EPA’s conclusory assertions that it cannot take malfunctions into account when setting performance standards for SSI units. EPA’s failure to evaluate these options thoroughly renders the Proposed Rule arbitrary and requires EPA to develop a new proposal.

4. The Proposed Affirmative Defense Is Not a Substitute for Setting Emission Standards for SSM Periods

EPA acknowledges that SSI units sometimes will be unable to comply with the Proposed Standards because of malfunctions, even if their equipment is properly designed and maintained, through no fault of the source. See 75 Fed. Reg. at 63,283. Rather than promulgate an emission standard that eliminates that situation, so that SSI units will be subject to differentiated requirements, achievable with the

identified best technology, during SSM events, EPA offers instead an “affirmative defense.” The proposed affirmative defense shifts the burden to the source to prove that a myriad number of criteria are met and actions were taken by the source (which bear no direct relation to the statutory factors for performance standards under CAA sections 111 and 129), in order to avoid “civil penalties.” Inclusion of the affirmative defense does not cure EPA’s failure to set emission standards that are achievable during SSM events. The Proposed Standards, incorporating the affirmative defense, still do not meet the criteria of CAA sections 111 and 129.

It is unclear where EPA finds the legal authority in the CAA to shift the burden to the regulated community of proving (or disproving) essential elements of an alleged violation. The statute is silent as to the issue and “the ordinary default rule [is] that plaintiffs bear the risk of failing to prove their claims.” *Shaeffer v. Weast*, 546 U.S. 49 (2005), quoting McCormick on Evidence §337, at 412 (“The burdens of pleading and proof with regard to most facts have and should be assigned to the plaintiff who generally seeks to change the present state of affairs and who therefore naturally should be expected to bear the risk of failure or proof or persuasion”); C. Mueller & L. Kirkpatrick, Evidence § 3.1, p. 104 (3d ed. 2003) (“Perhaps the broadest and most accepted idea is that the person who seeks court action should justify the request, which means that the plaintiffs bear the burdens on the elements in their claims”). While the Supreme Court has recognized exceptions such as affirmative defenses, courts retain the authority to establish such rules unless Congress acts to delegate that authority. In this instance, EPA has not provided any justification for requiring a source to prove its innocence; in fact, to fully demonstrate its innocence within 30 days of the event, without even being charged. Rather, if EPA adopts an approach along the lines of the proposed affirmative defense, it should be stated instead in terms that, once a source has claimed that its excess emissions were related to a malfunction, it will not be considered to be in violation of the standards unless the enforcement authority demonstrates that the source is not entitled to claim the malfunction.

EPA’s rationale for excluding startup and shutdown events from the proposed affirmative defense is unclear, as well. As noted above, EPA has for decades recognized in NSPS regulations that it may not be possible to meet normally applicable emission limitations, even using the best demonstrated technology, during startup, shutdown, and malfunction events. If EPA persists in its proposal not to provide separate emission limitations for startup and shutdown of the SSI units, and if in fact excess emissions from an SSI unit cannot reasonably be avoided during a startup or shutdown, not because of failure of a process or equipment but because of the nature of conditions while starting up or shutting down the source, there is no apparent reason why EPA would not provide the same kind of affirmative defense that it proposes to provide for malfunctions.

Even if the proposed affirmative defense were not unreasonably restrictive, as discussed in the following portion of these comments, being able to assert a defense obviously is not the same as complying with emission limitations that are properly set in accordance with sections 111 and 129. Although a source believes it qualifies for the affirmative defense, it may be considered to have violated the standards—and may have to report violations, certify noncompliance, etc.—until there has been an enforcement proceeding and the source has successfully asserted the affirmative defense. The affirmative defense places the source in the position of proving its innocence, rather than EPA or another enforcement authority having to prove that the source violated the CAA.

Furthermore, it is not even clear what the affirmative defense covers. In the Proposed Rule, EPA states that the affirmative defense is “to a claim for civil penalties for exceedances of such standards that are caused by malfunction, as defined in section 60.2.”¹⁰ Is the term “civil penalties,” which is not defined in the Proposed Rule, intended to apply as well to a “civil administrative penalty” imposed by EPA under CAA section 113(d)? (The term “civil penalty” in other contexts means only penalties imposed by a court.) Does the affirmative defense apply to “noncompliance penalties” under CAA section 120 (which apply, *inter alia*, to noncompliance with a section 111 NSPS)? To meet the purported purpose of the affirmative defense, which is to provide relief from emission limitations that cannot be met at times even with equipment that is properly designed and maintained (see 75 Fed. Reg. 63,283 col. 2), the affirmative defense would need to apply to civil and administrative penalties, including noncompliance penalties.

It is unclear as well how the affirmative defense would apply to enforcement actions by state and local governments, or to private citizen enforcement actions under CAA section 304. The preamble to the Proposed Rule, for example, speaks only in terms of application of the affirmative defense in an EPA enforcement action.¹¹ An affirmative defense should clearly state that it is applicable to enforcement actions by states or citizen-suit plaintiffs, as well.

¹⁰ Proposed 40 C.F.R. § 60.4861. (These comments refer to sections of proposed Subpart LLLL; nearly identical language is also included in proposed Subpart MMMM.) Note that the reference here to the definition of “malfunction” in section 60.2 is confusing, and its purpose is unclear, given that the proposed SSI standards themselves contain a definition of “malfunction.” See proposed 40 C.F.R. § 60.4930. But that definition in itself is unclear, since it states that: “During periods of malfunction the operator shall operate within established emissions and operating limits and shall continue monitoring of all applicable operating parameters until all waste has been combusted or until the malfunction ceases, whichever comes first.” *Id.* This language—indicating that an event can only be a malfunction if the source operates within its normal emission limitations—is circular and nonsensical and must be removed.

¹¹ See, e.g., 75 Fed. Reg. at 63,283 col. 2 (“In any judicial or administrative proceeding, the Administrator may challenge the assertion of the affirmative defense....”).

In a November 5, 2010 notice, EPA clarified its intent behind the October 14, 2010 proposal concerning how the affirmative defense would apply to injunctive relief. See 75 Fed. Reg. 68,296. Although that notice says that EPA is merely clarifying its intention in the original proposal that operators not be able to assert the affirmative defense to a claim for injunctive relief (see *id.* at 60,297), in fact the preamble to the Proposed Rule does not give any explanation for why the affirmative defense would not apply to injunctive relief. If in fact the excess emissions associated with the equipment or process failure are not reasonably preventable, then there is no apparent reason why injunctive relief should be available either. In fact, as a matter of law, injunctive relief may not be available in cases where a civil penalty cannot be imposed. See *Sierra Club v. Otter Tail Power Co.*, 615 F.3d 1008 (8th Cir. 2010) (under concurrent remedy doctrine, injunctive relief for a CAA violation is barred when civil penalty is barred by statute of limitations).

Maintaining liability for injunctive relief renders the affirmative defense particularly ineffective with respect to citizen suits. If the source is even potentially subject to injunctive relief, and therefore could be required to pay the citizen-plaintiff's attorneys fees even if the source successfully demonstrated that it otherwise qualified for the affirmative defense, then the affirmative defense would not accomplish EPA's stated objective of providing relief in situations where the emission limitations cannot be met despite proper design and operation of process and control equipment.

EPA has not addressed these and other apparent limitations and shortcomings of the affirmative defense, which make it an entirely inadequate substitute for setting standards that include provisions for SSM events. Moreover, EPA has provided no analysis that would supersede its previous and long-standing determination that it is not desirable to rely on enforcement, rather than regulatory language, to address the inability to comply with section 111 performance standards during SSM events.¹²

At a minimum, then, EPA should state that the affirmative defense applies to civil penalties, civil administrative penalties, noncompliance penalties, and injunctive relief. EPA also should reword the "affirmative defense," so that it states that a

¹² See 37 Fed. Reg. 17,214, 17,214 (Aug. 25, 1972). See also *Marathon Oil Co. v. EPA*, 564 F.2d at 1273 (explaining why EPA's statement that it would not take enforcement action against sources that exceeded effluent limitations because of upset events was "not an adequate response" to the argument that standards that cannot be met during unavoidable upsets fail to reflect available technology). Also for these reasons, EPA's statements in the Proposed Rule preamble about EPA "determining an appropriate response" to reported exceedances of the Proposed Standards, based on whether the exceedances were avoidable, minimized, etc. (which seems to be in addition to providing the affirmative defense) are not in any way a substitute for EPA setting the standards at an achievable level to begin with. See 75 Fed. Reg. at 63,283 cols. 1-2.

source “will not be deemed in violation of” the Part LLLL or Part MMMM standards for excess emissions unless the event, and the source’s response to the event, do not meet the criteria spelled out in the regulations.¹³ Configured in that way, this provision for malfunction should be called something other than an “affirmative defense,” such as an “alternative standard for SSM events.”

5. The Proposed Affirmative Defense As Written Is Unreasonable and Impracticable

If EPA refuses to set alternative emission standards that apply during SSM periods and continues to rely instead on the proposed affirmative defense, the affirmative defense must be substantially modified for it to provide any significant relief. First, as noted above, the affirmative defense needs to state clearly that a source that qualifies for the affirmative defense shall not be deemed to have violated the applicable standards during that time. If EPA does that, it may be unnecessary to state also that the affirmative defense relieves the source from liability for all types of penalties and injunctive relief (save criminal penalties), but that should be the clear effect of qualifying for the affirmative defense.

The affirmative defense should be available not only for malfunctions, but also for excess emissions during startup and shutdown. Although EPA asserts that the Proposed Standards are set at a level that should be achievable by SSI units during startup and shutdown, there is no logical reason why a source that experiences excess emissions during startup or shutdown that were not reasonably preventable (either because it experienced conditions EPA did not anticipate in setting the standards, or because EPA’s assumption about the achievability of those standards during startup and shutdown periods was wrong) should be excluded from the affirmative defense.

Additionally, many aspects of the affirmative defense would make it unavailable as a practical matter for many, if not most malfunctions. Many of these limitations on the affirmative defense also are not directly related to the question of whether an exceedance of the emission limitations due to a malfunction should be excused. EPA needs to substantially revise and streamline the proposed affirmative defense for it to be of practical value.

Several of the conditions for establishing an affirmative defense in proposed 40 C.F.R. § 60.4861(a) and 40 C.F.R. § 60.5181(a)¹⁴ list numerous items which may

¹³ Cf. 40 C.F.R. § 80.613 (stating that persons demonstrating specified defenses “will not be deemed in violation” and are not “deemed liable for a violation” of diesel fuel sulfur program regulations).

¹⁴ EPA is proposing the same affirmative defense requirements for new sources (40 C.F.R. § 60.4861) and existing sources (40 C.F.R. § 60.5181.) Our comments cite the proposed

be appropriate considerations in determining whether excess emissions during a malfunction should be considered a violation, but which ought not to be listed as mandatory criteria, all of which have to be met in order for an exceedance to be excused. For example, proposed section 60.4861(a)(1)(i) states that the excess emissions must have been “caused by a sudden, short, infrequent, and unavoidable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner.” There is no practical reason why a sudden, infrequent, and unavoidable equipment failure should be exempted if it was “short” but considered a violation if it was not “short.” Similarly, why should a malfunction be considered a violation of the standards if it is not “infrequent,” even though it is “not part of a recurring pattern indicative of inadequate design, operation, or maintenance” (see proposed section 60.4861(a)(1)(iv))?

Several of the conditions for establishing an affirmative defense use phrases that are subject to a wide range of interpretations, and that on their face do not recognize any need for reasonableness or cost-effectiveness. How will the enforcement authority, or a judge, determine whether “proper design” or “better operation and maintenance practices” could have prevented a malfunction (section 60.4861(a)(1)(ii)), whether a recurring malfunction is a result of “inadequate design” (section 60.4861(a)(1)(iv)), whether repairs were made “as expeditiously as possible” (section 60.4861(a)(2)), whether the source took “all possible steps” to minimize the impact of the excess emissions (section 60.4861(a)(5)), *and* whether emissions control systems “were kept in operation if at all possible” (section 60.4861(a)(6))? In many, if not most cases, it may have been possible to avoid the malfunction, or to do more to reduce the magnitude of the excess emissions, if the source had spent huge amounts of money or had imposed economically impracticable constraints on its operation. The affirmative defense, as proposed, leaves open the possibility that a source will be considered to be in violation because the enforcement authority decides that in one or more respects it would have been “proper” or “possible” for the source to take further steps to prevent or minimize the malfunction. In effect, EPA or the court may impose an extreme version of MACT during malfunction periods, without any application of the beyond-the-floor factors in CAA section 129(a)(2). At a minimum, the vague and unqualified descriptors in the criteria for demonstrating the affirmative defense will inevitably lead to varying conclusions as to whether a violation has occurred, resulting in inconsistency from one jurisdiction to the next.

Proposed section 60.4861(a)(6) requires, as a condition for the affirmative defense, that all emissions “control systems were kept in operation if at all possible.” Besides the fact that “if at all possible” is an extreme term that bears no relation to good air pollution control practices, this provision, as well as proposed sections 60.4861(a)(1)(ii) and (iv), should be qualified, as EPA has qualified similar provisions in the NESHAP General Provisions in 40 C.F.R. § 63.6. For example, these

regulatory provisions for new SSI units but are equally applicable to the proposed regulatory provisions for existing SSI units.

conditions should be qualified with caveats that the operation must be consistent with safety and good air pollution control practices, that it does not require the source to make further efforts to reduce emissions below what the standards require, and that it does not require regular operation of backup or standby pollution control equipment.¹⁵ Similarly, EPA has long recognized, in the General Provisions applicable to NSPS, that it is appropriate to require sources to operate the affected facility and related air pollution control technology “to the extent practicable...consistent with good air pollution control practice for minimizing emissions” during SSM periods, not “if at all possible.” See 40 C.F.R. § 60.11(d). EPA cannot abandon those rational approaches and adopt the kind of absolute requirements implied by the Proposed Rule, without an explanation of why it is necessary and appropriate to do so.

Proposed section 60.4861(a)(4) would preclude a facility from taking advantage of the affirmative defense if the malfunction involved bypassing control equipment or a process and the bypass was not “unavoidable to prevent loss of life, severe personal injury, or severe property damage.” This language is stated in such extreme terms that it may be difficult or impossible to meet this criterion, even though bypassing the control equipment or the process was an appropriate exercise of good air pollution control practices. For example, a bypass can be the appropriate response to an upset in order to prevent excess emissions, e.g., fouling of pollution control equipment media that in turn would result in reduced pollution control equipment efficiency or increased pollution control equipment downtime. There can be substantial room for disagreement about what constitutes “severe” property damage. And what degree of injury to employees must the bypass avoid in order to qualify as avoiding “severe” personal injury? Besides the unclear and subjective nature of these criteria, there is nothing inherent to standards under CAA sections 111 and 129 that require a source to avoid bypassing control equipment to such a degree. Lastly, it is not apparent at all why the CAA would disfavor bypassing “a process” in this way.

Under proposed section 60.4861(a)(6), a source claiming the affirmative defense must prove that: “All possible steps were taken to minimize the impact of the excess emissions on ambient air quality, the environment and human health.” In addition to the subjective term “all possible steps,” this provision again presents a disconnect between the absolute and extreme requirement of the affirmative defense and the provisions of the CAA designed to attain ambient air quality standards and protect human health and the environment. The CAA does not require sources to take “all possible steps” to control emissions, even to minimize the impact of hazardous air pollutant emissions on human health under CAA section 112(f). In addition, it is unclear how this criterion for qualifying for the affirmative defense

¹⁵ EPA also determined it was appropriate to include those kinds of caveats in its regulation requiring proper operation and maintenance of wastewater treatment facilities, in 40 C.F.R. § 122.41(e).

differs from proposed section 60.4861(a)(2), which requires that the frequency, amount, and duration of excess emissions “were minimized to the maximum extent practicable.” Unless EPA explains what additional showing would be needed by section 60.4861(a)(6), it should be eliminated.

The requirement proposed in section 60.4861(a)(8) that the source must show that “at all times, the facility was operated in a manner consistent with good practices for minimizing emissions” (emphasis added) could be read to go way beyond an analysis of why equipment may have malfunctioned and place an insurmountable burden on the source to meet a “good practices” standard (undefined) for the whole sewage treatment plant, industrial plant, or commercial premises. (The problem is that EPA has used “facility” in some aspects of the Proposed Rule to indicate something much larger than the SSI unit subject to the Proposed Standards. See proposed 40 C.F.R. §60.4780.) This factor could allow a regulatory enforcement official to potentially measure the entirety of operations at a site against a multitude of arbitrary “good practices” and subjectively find the source lacking, thereby denying the source the ability to assert an affirmative defense. If EPA retains this condition for the affirmative defense, of demonstrating operation consistent with good practices for minimizing emissions, EPA must clarify that this condition applies to the “affected facility” or “existing facility,” as those terms are defined in 40 C.F.R. §60.2. EPA also must not include a requirement such as this in an affirmative defense unless it defines the terms used. If EPA really does intend for this condition to apply to operation of the entire site, and not just the SSI unit, then EPA must justify why EPA has the statutory authority to shift its focus from the SSI unit to the plant as a whole.

The requirement in proposed section 60.4861(a)(9) that the source “have prepared a written root cause analysis to determine, correct, and eliminate the primary causes of the malfunction and the excess emissions resulting from the malfunction event at issue” again does not implement the statutory criteria for standard-setting under sections 111 and 129. Moreover, read literally it would mean that a source could never take advantage of the affirmative defense if the source was unable to determine the primary cause of the malfunction or was unable to correct that cause. EPA has defined a malfunction as an event that is “unavoidable” and unforeseeable. See proposed section 60.4861(a)(1)(i)-(iii). It therefore should be expected that in many cases the primary cause of the malfunction will not be ascertainable, or it will not be possible to identify a way to ensure the malfunction will not recur.¹⁶ In addition, requiring the facility to eliminate the primary causes of the malfunction, without regard to “taking into consideration the cost of achieving such” elimination and the “non-air quality health and environmental impacts and energy requirements” associated with its elimination is unreasonable and entirely

¹⁶ EPA has long acknowledged this reality in the General Provisions applicable to NSPS, which requires that written reports of excess emissions include the “nature and cause of any malfunction, if known....” 40 C.F.R. § 60.7(b)(2) (emphasis added).

inconsistent with the criteria for standards established under CAA sections 111(a)(1) and 129(a)(2).

Finally, the requirement in proposed section 60.4861(b) to notify the Administrator by telephone or fax as soon as possible, but no later than two business days after the malfunction begins, and then to submit a written report within 30 days of the initial occurrence of the malfunction that demonstrates, "with all necessary supporting documentation," that the source met all of the multitude of criteria for the affirmative defense, is unreasonable and unnecessary. It is novel at best for a person to be determined to have acted unlawfully unless the person has submitted his entire defense before he is even notified of a potential enforcement action. In many cases, it would be obvious to the enforcement authority (not "the Administrator"), based on the kind of short malfunction or deviation report that sources already submit under many air programs, that an exceedance of the Proposed Standards resulted from an unforeseen and unavoidable equipment failure or process upset. It is extremely inefficient and burdensome for both sources and regulators to require a complete justification of the affirmative defense before the enforcement authority has indicated any need for further investigation. Additionally, allowing only 30 days to provide the kind of extensive documentation required by the affirmative defense as currently written, including a completed root cause analysis, is unreasonable. Ninety days is the minimum time that should be allowed, unless EPA substantially streamlines the criteria for the affirmative defense, consistent with these comments.

6. Conclusion

In summary, the SSM Coalition urges EPA to withdraw the Proposed Rule, so that EPA can give serious consideration to alternative emission limitations, or other requirements, that would apply during startup and shutdown events or during malfunctions. EPA must consider the variety of options, as described in these comments, that it has for addressing excess emissions during SSM events, rather than merely assuming they will not occur or providing an "affirmative defense" in lieu of setting standards and other requirements that comply with the criteria for standard-setting in CAA sections 111 and 129. If EPA retains the affirmative defense in lieu of setting appropriate, achievable standards, EPA must modify it substantially so that it does not require the source to prove its innocence (before it is even charged) and does not impose unreasonable or impracticable conditions.

If you have any questions about these comments or wish to discuss these issues further with members of the SSM Coalition, please contact our counsel, Russell Frye, at 202-572-8267 or rfrye@fryelaw.com.

Re: Comments of the Residual Risk Coalition on the National Emission Standards for Hazardous Air Pollutant Emissions: Hard and Decorative Chromium Electroplating and Chromium Anodizing Tanks; Group I Polymers and Resins; Marine Tank Vessel Loading Operations; Pharmaceuticals Production; The Printing and Publishing Industry; and Steel Pickling – HCl Process Facilities and Hydrochloric Acid Regeneration Plants; Proposed Rule.

To Whom It May Concern:

The Residual Risk Coalition (“R2C”) appreciates this opportunity to submit comments on the above-referenced proposed rule, which was published at 75 Fed. Reg. 65068 (Oct. 21, 2010). The R2C is an ad-hoc group comprised of the American Chemistry Council, the American Forest & Paper Association, the American Petroleum Institute, the American Wood Council, the National Oilseed Processors Association, the National Petrochemical and Refiners Association, the Portland Cement Association, and the Rubber Manufacturers Association. Each R2C organization has members that are subject to “MACT” standards that will undergo residual risk review pursuant to § 112(f), including standards that are the subject of this rulemaking. The R2C is dedicated to working constructively with the Environmental Protection Agency in developing a practical and environmentally responsible approach to satisfying the Agency’s obligations under § 112(f).

We offer comments on eight specific aspects of the proposed rule. These comments address the cross-cutting issues that likely will arise in many of the residual risk assessments for rules applicable to our members. We do not provide comments on the particular details of the source categories addressed in the subject proposal. Overall, our interest is in establishing a reasonable residual risk methodology that identifies and appropriately addresses remaining risk associated with hazardous air pollutant (“HAP”) emissions from MACT-regulated source categories and subcategories, while avoiding additional emissions limitations where they are not needed to assure an ample margin of safety.

1. The “total facility” approach to conducting risk assessment exceeds EPA’s authority under § 112(f).

EPA explains in the RTR Proposal that “in contrast to past [residual risk] determinations” the Agency has decided to consider “additional measures of health information to support our decision-making,” including “[e]stimates of “total facility” cancer and non-cancer risk (risk from all HAP emissions from the facility at which the source category is located.”¹ Because the CAA requires residual risk determinations to be conducted on a category by category basis, EPA does not have authority to consider the combined emissions from entire facilities when making a § 112(f) risk assessment for a given source category.

Section 112(f)(2)(A) unambiguously requires EPA, within eight years after adopting a MACT standard for a given source category or subcategory, to “promulgate standards for such category or subcategory if promulgation of such standards is required in order to provide an ample margin of safety to protect public health.” Section 112(f)(2)(A) further dictates that, “Emissions standards promulgated under this subsection shall provide an ample margin of safety to protect public health.” It is not reasonable to construe these provisions as authorizing EPA to consider emissions from entire facilities in conducting risk assessments and potentially revising the underlying rule for the simple reason that the Congress clearly envisioned that full implementation of the MACT program would take longer than eight years. Consequently, it would be impossible for EPA to fulfill its unambiguous obligation for § 112(f) standards to protect public health with an ample margin of safety in cases where facilities contain sources in a category where the eight year deadline for conducting the § 112(f) risk review precedes the adoption of MACT standards for other sources at the facilities.

This is not mere hypothetical conjecture. The standards under review in this proposal provide a case in point. Many of the facilities containing sources affected by one of the standards under review in this proposal also contain industrial boilers that will be subject to the upcoming MACT standard for industrial boilers. As a result, EPA currently is without authority to conduct a § 112(f) risk assessment for co-located industrial boilers because those boilers are not yet subject to a MACT standard. Thus, it is impossible for EPA to assure an ample margin of safety from total facility emissions for sources affected by the standards covered by this proposal. This demonstrates why the statute cannot be interpreted to allow consideration of emissions from entire facilities when conducting a § 112(f) risk review.

In addition, § 112(f)(2)(A) further provides that, “If standards promulgated pursuant to subsection (d) of this section and applicable to a category or subcategory of sources emitting a pollutant (or pollutants) classified as a known, probable or possible human carcinogen do not reduce lifetime excess cancer risks to the individual most exposed to *emissions from a source in the category or subcategory* to less than one in one million, the Administrator shall promulgate

¹ 75 Fed. Reg. at 65073.

standards under this subsection for such source category” (emphasis added). This provision unambiguously requires the § 112(f) risk assessment to be focused exclusively on “emissions from a source in the category or subcategory.” For this reason alone, EPA does not have authority to consider emissions from any sources other than those in the source category or subcategory under review at that time.

2. Demographics may not be considered in conducting risk assessments under § 112(f).

EPA explains that “in contrast to past [residual risk determinations], this notice presents and considers additional measures of health information to support our decision-making” – including “[d]emographic analyses (analyses of the distributions of HAP-related cancer risks and non-cancer risks, across different social, demographic, and economic groups within the populations living near the facilities where these source categories are located).”² In other words, EPA proposes to consider in making § 112(f) risk determinations “the potential for any environmental justice issues that might be associated with each source category.”³

Although EPA conducted a “demographic analysis” for each of the six rules covered by this proposal, those analyses do not provide a basis for imposing additional control measures in order to assure an ample margin of safety. However, for one source category – chromium electroplating and anodizing – EPA expresses concern “that there are disparities in risks for some demographic groups” and specifically requests comment “on whether there are any cost-effective controls that may be able to reduce these risks.”⁴

Because the term “public health” cannot reasonably be interpreted to include consideration of environmental justice in the § 112(f) context, EPA’s proposal to consider demographic analyses in conducting risk reviews under § 112(f) is not a proper exercise of Agency authority. Section 112(f)(2)(A) expressly instructs EPA to impose additional emissions controls if needed to provide an ample margin of safety “to protect public health.” The term “public health” is not defined in § 112 or in EPA’s Part 63 regulations.

In the context of EPA’s national ambient air quality program (“NAAQS”), the Supreme Court has observed that the “primary definition of the term” should be applied – *i.e.*, public health means “the health of the public.”⁵ This conclusion emphasizes that the scope of the term “public health” should be dictated by the meaning of the word “public.” In relevant part, Websters Free Dictionary defines the adjective “public” to mean “of, relating to, or affecting all of the people or the whole area of a nation or state” and “of or relating to people in general.”

² *Id.*

³ *Id.* at 65080.

⁴ *Id.* at 65093.

⁵ *Whitman v. American Trucking Associations, Inc.*, 531 U.S. 457, 465 (2001).

These definition emphasize that the word “public” should be construed expansively as describing the people as a whole, and not particular demographic segments.

EPA’s established approach to assessing potential impacts on public health under the NAAQS program is consistent with this meaning. EPA reasonably interprets the term “public health” to include consideration not only of potential impacts on the population as a whole, but also on sensitive subpopulations – recognizing that the objective is to protect the group rather than any particular individual in the group.⁶ But, sensitive subpopulations are identified according to their particular health-based sensitivities (*e.g.*, asthmatics) rather than demographic classifications unrelated to particular health-based sensitivities (*e.g.*, population without a high school diploma).

With this backdrop, it is not reasonable to construe the term “public health” as used in § 112(f) as allowing consideration of demographic classifications that bear no relationship to the potential health effects presented by the HAPs at issue for the given source category or subcategory. EPA’s proposal would unreasonably inject racial, ethnic, and other policy considerations into a program designed to provide protection for the public at large. For example, EPA suggests that the population without a high school diploma should receive extra scrutiny, yet does not afford the same scrutiny to other reasonably definable educational groups, such as those with a high school diploma, those with college degrees, and those with advanced degrees. There is simply no principled way to identify and define those groups that should receive extra scrutiny from those that do not. In short, EPA’s approach would inappropriately cause arbitrary policy and political considerations to trump objective scientific analysis. This is patently unreasonable and, as such, is not a supportable interpretation of § 112(f).

3. EPA fails to provide a rational basis for using allowable emissions in conducting risk assessments under § 112(f).

EPA coins the term “MACT allowable” emissions in the preamble, and explains that this term “represents the highest emission level that could be emitted by the facility without violating the MACT standard.”⁷ The Agency asserts that considering MACT allowable emissions in determining residual risk under § 112(f) “is inherently reasonable since these risks reflect the maximum level sources could emit and still comply with national emission standards.”⁸ Without further explanation as to why it might be appropriate to determine and apply MACT allowable emissions in § 112(f) risk assessments, the Agency goes on to explain that it developed a ratio method of estimating MACT allowable emissions and “applied these ratios on a facility-by-facility basis to the maximum chronic risk values from the inhalation risk assessment to obtain

⁶ *See, e.g.*, 71 Fed. Reg., 61144, 61145 fn. 2 (Oct. 17, 2006).

⁷ 75 Fed. Reg. at 65077.

⁸ *Id.*

facility-specific maximum risk values based on MACT-allowable emissions.”⁹ The Agency considered risks based on MACT allowable emissions in its proposed risk assessments for the six subject source categories.¹⁰

EPA cannot lawfully use MACT allowable emissions in the proposed risk assessments and residual risk determinations because the Agency has failed to provide any reasoned explanation for why risk assessments based on actual emissions estimates are inadequate.¹¹ The Agency’s risk assessment methodology already is rife with conservative assumptions. For example, health benchmarks, such as acute reference doses, typically incorporate two to three orders of magnitude of conservatism to account for uncertainties, such as the extrapolation of animal toxicity testing data to humans. Similarly, the dispersion models used to predict off-site ambient HAP concentrations attributable to emissions from affected sources incorporate numerous conservative assumptions to simplify the analysis of highly complex factors, such as meteorology and atmospheric chemistry. In addition, risk assessments assume exposure to the most exposed individual on a continuous basis for an entire lifetime.

In light of the conservatism that already is inherent to EPA’s risk assessment methodology, it makes no sense to apply yet another layer of conservatism – this time based on the hypothetical assumption that affected sources should be expected to emit more than the actual data indicate – to § 112(f) risk assessments. EPA has provided no data or analyses indicating that its current methodology results in negative bias. EPA has provided no data demonstrating that affected sources actually do emit at levels significantly higher than the actual data show for any significant period of time. In short, EPA’s proposal to use hypothetical emissions levels in § 112(f) risk assessments is justified on nothing more than the bald assertion that sources *might* emit at these higher levels. The failure to provide a reasoned explanation as to why this approach is justified and the failure to provide any record evidence supporting the use of MACT allowable emissions render this proposal insupportable under the law.

⁹ *Id.*

¹⁰ *See, e.g., id.* at 65087 (risk assessment for the chromium electroplating and anodizing source category).

¹¹ Note that § 112(f)(1)(A) required EPA to report to Congress on “methods of calculating the risk to public health *remaining, or likely to remain*, from sources subject to regulation under this section after the application of standards under subsection (d) of this section” (emphasis added). Section 112(f)(1)(B) required EPA also to report on “the *actual health effects* with respect to persons living in the vicinity of” affected sources” (emphasis added). These requirements clearly signal that Congress expected EPA to focus on actual risk and not hypothetical risk in implementing the requirements of § 112(f). Thus, it is not reasonable in the first instance for EPA to construe § 112(f) as authorizing the Agency to conduct risk assessments based on hypothetical “MACT allowable” emissions.

4. EPA is without authority to eliminate the startup, shutdown, and malfunction provisions unless the underlying MACT standards accommodate emissions during those periods.

EPA observes in the preamble to the proposed rule that the startup, shutdown, and malfunction (“SSM”) provisions contained in the Part 63 General Provisions were vacated by the D.C. Circuit in *Sierra Club v. EPA*, 551 F.3d 1019 (D.C. Cir. 2008) (“*Sierra Club*”).¹² The Agency then explains that, “We are proposing to eliminate the SSM exemption in each of the six MACT standards addressed in this proposal. Consistent with *Sierra Club v. EPA*, we are proposing that the established standards in these rules apply at all times.”¹³

The proposal to eliminate the SSM provisions in the six subject rules is not based on an accurate reading of *Sierra Club*, is not supported by any rational explanation as to why the elimination of the SSM provisions is justified, and is arbitrary and capricious given that EPA fails to provide any analysis of why affected sources reasonably can be expected to meet the emissions limitations and standards that the Agency proposes to apply during periods of SSM.

To begin, EPA’s proposal “that the standards in these rules apply at all times” is not, as EPA claims, “[c]onsistent with *Sierra Club v. EPA*. The decision in that case was grounded in the court’s assertion that § 112 requires emissions standards to apply at all times.¹⁴ Based on this, the court held the SSM General Provisions do not comport with § 112 because, in the eyes of the court, the SSM provisions are not “section 112-compliant” emissions standards.¹⁵ Notably, the court did not hold that EPA is prohibited from setting separate standards for periods of SSM. It simply held that standards for such periods must be developed according to the § 112(d) MACT process.

Thus, the proposal to eliminate the SSM provisions from the six source categories subject to this proposal is not “consistent” with *Sierra Club* because there is nothing in that case that supports the conclusion that vacatur of the Part 63 General Provisions necessarily requires “the established standards in these rules [to] apply at all times.” EPA’s flawed legal analysis provides no support for the proposal to eliminate the SSM provisions in the six subject rules.

¹² 75 Fed. Reg. at 65074.

¹³ *Id.*

¹⁴ *Sierra Club* at 1027 (“Congress has required that there must be continuous section 112-compliant standards.”).

¹⁵ *Id.* at 1028 (“Because the general duty is the only standard that applies during SSM events — and accordingly no section 112 standard governs these events — the SSM exemption violates the CAA’s requirement that some section 112 standard apply continuously.”).

This fundamental legal flaw is magnified by the Agency's failure to provide any explanation whatsoever as to why it is appropriate to now apply the existing emissions standards to periods of SSM. For example, EPA made no effort to obtain emissions information from the six source categories for periods of SSM and provides no other evidence or analysis supporting its assertion that it is appropriate to apply the existing standards to periods of SSM. Moreover, EPA fails to investigate the record data developed during the promulgation of the existing standards to assess whether those data are characteristic and representative of emissions during periods of SSM. In short, the Agency simply asserts with no record basis that the existing standards should apply to periods of SSM. This unsupported assertion provides no basis for extending the existing standards to periods of SSM – this failure to seek relevant data, assess existing data, and investigate whether the existing standards should appropriately apply to periods of SSM is facially arbitrary and capricious and provide wholly inadequate support for the Agency's proposal.¹⁶

5. EPA is without authority to impose new standards under §§ 112(d)(2) and (3) for emissions sources in source categories for which a MACT standard already has been promulgated – § 112(d)(6) provides the Agency's only authority to adjust existing MACT standards.

Once EPA establishes a MACT standard for a particular source category, the Agency has the authority under § 112(d)(6) to “review and revise as necessary (taking into account developments in practices, processes, and control technologies), emissions standards promulgated under this section no less often than every 8 years.” In other words, EPA does not have unfettered discretion to revisit a prior MACT determination once that determination has been issued. Rather, EPA may revise a prior determination only “as necessary” according to explicit statutory criteria.¹⁷

¹⁶ In any event, we also note that EPA's proposal to provide an affirmative defense for periods of malfunction is without merit. Comments recently submitted by the “SSM Coalition” on EPA's proposed standards for Sewage Sludge Incinerators explain in detail that: (1) EPA must take malfunctions into accounts when setting § 112 emissions standards; (2) the proposed affirmative defense is not a permissible substitute for setting emissions standards for periods of malfunction; and (3) the proposed affirmative defense is unreasonable and impracticable. See Letter to EPA Docket Center (EPA/DC) from the American Chemistry Council, *et al.*, Comments on Proposed Standards of Performance for New Stationary Sources and Emission Guidelines for Existing Sources: Sewage Sludge Incineration Units, Docket ID No. EPA-HQ-OAR-2009-0559, at 6-20 (Nov. 29, 2010). We incorporate these comments by reference. For these reasons, EPA should set aside the proposed affirmative defense for periods of malfunction and, instead, set a work practice standard for such periods.

¹⁷ Cf. *New Jersey v. EPA*, 517 F.3d 574, 582 (D.C. Cir. 2008) (Thus, EPA can point to no persuasive evidence suggesting that section 112(c)(9)'s plain text is ambiguous. It is therefore bound by section 112(c)(9) because “for [] EPA to avoid a literal interpretation at *Chevron* step

In the proposal, EPA explains that, “For eight source categories subject to three of the MACT standards, we identified significant emission sources within the categories for which standards were not previously developed” and that, “We are proposing MACT standards for these emission sources pursuant to CAA section 112(d)(2) and (3).”¹⁸ This explanation makes it clear that EPA is not invoking § 112(d)(6) as the authority for the new proposed standards – indeed, the preamble provides no analysis of “developments in practices, processes, and control technologies” to justify the proposed standards, as would be required if EPA were relying on § 112(d)(6). And, there is no mention of § 112(d)(6) in relation to the proposed new standards. Instead, the Agency is invoking §§ 112(d)(2) and (3) directly, as if a MACT standard for these sources categories does not already exist.

EPA does not have such authority. As explained above, once EPA makes a MACT determination for a particular category, § 112(d)(6) provides the only authority for the Agency to later review and possibly revise the determination. Section 112(d)(6) expressly authorizes EPA to review existing determinations and provides specific criteria to guide and constrain the review. The existence of this express authority forecloses the Agency’s ability to directly invoke §§ 112(d)(2) and (3) for a given source category when a MACT determination has already been issued for the source category.

Notably, even if the Agency had invoked § 112(d)(6) as authority for revising the existing MACT standards, it still would not have authority to regulate the emissions points for which standards were not established in the first round of MACT rulemaking. Prior MACT determinations may be revised only “as necessary (taking into account developments in practices, processes, and control technologies).” Perceived “gaps” in the original MACT determinations are not “practices, processes, and control technologies” that are properly within the scope of a § 112(d)(6) review.

6. In any event, it is not a reasonable exercise of authority to establish new emissions limitations under existing MACT standards when there is no significant risk associated with emissions from sources in the given source category.

In the proposed rule, EPA asserts the proposition that standards must be established for “significant emissions points” not currently regulated under existing MACT standards – even in circumstances where the Agency has determined that the existing MACT standard protects

one, it must show either that, as a matter of historical fact, Congress did not mean what it appears to have said, or that, as a matter of logic and statutory structure, it almost surely could not have meant it,” *Engine Mfrs. Ass’n v. EPA*, 88 F.3d 1075, 1089 (D.C. Cir. 1996), showings EPA has failed to make.”).

¹⁸ 75 Fed. Reg. at 65074.

health and the environment with an ample margin of safety. Establishing new standards under these circumstances is patently unreasonable and cannot be justified under § 112(d)(6).

For example, in its review of the existing MACT standards for the epichlorohydrin elastomers production source category, EPA explains that, based on a detailed assessment of risk to health and the environment due to HAP emissions from this source category under the existing Polymers and Resins I MACT standard, “we continue to propose that the current MACT standard provides an ample margin of safety to protect public health and the environment, and we are proposing to re-adopt the existing MACT standard to satisfy section 112(f) of the CAA.”¹⁹ Yet, just paragraphs later in the same section of the preamble, the Agency proposes a new MACT emissions limitation for back end process operations in this source category.²⁰

As explained above, EPA has no direct authority under §§ 112(d)(2) and (3) to create new limits in source categories for which a MACT standard already has been promulgated. But, even if EPA had invoked § 112(d)(6) as authority for adopting the new standard for back end process operations, such a standard would not be justified because EPA’s own analysis demonstrates that the existing MACT standard provides an ample margin of safety to health and the environment. In fact, EPA plainly admits that “the MACT standard, prior to the implementation of the proposed emission limitation to the back-end process operations discussed in this section, provides an ample margin of safety to protect public health.”²¹

In these circumstances, it is patently unreasonable for EPA to regulate beyond the point that the standard has been found to already provide an ample margin of safety. This is regulation for the sake of regulation and, as such, contradicts Congress’s clear intent that an ample margin of safety is an appropriate stopping point for emissions limitations under § 112.²²

¹⁹ *Id.* at 65098.

²⁰ *Id.* at 65097.

²¹ *Id.* at 65099.

²² EPA also explains in the context of the proposed new limit for back end process operations that, because the existing MACT standard already provides an ample margin of safety, “we do not believe it will be necessary to conduct another residual risk review under CAA section 112(f) for this source category 8 years following promulgation of new back-end process limitations, merely due to the addition of this new MACT requirement.” Implicit in this statement is the suggestion that a residual risk review under § 112(f) may be needed for new emissions limits that are established for existing MACT standards. As with setting MACT standards in the first instance, § 112(f) provides a one-time opportunity for conducting a residual risk review of a MACT standard. There is no basis under the law for the suggestion that a revision to an existing MACT standard triggers the need for another § 112(f) residual risk review. Indeed, the proposal provides no explanation whatsoever as to why such a subsequent review could be required under the law.

7. EPA is without authority to consider non-HAP emissions reductions in conducting a review of existing MACT standards under § 112(d)(6).

In the context of the § 112(d)(6) review of the existing MACT standard for Marine Tank Vessel Loading Operations (“MTVLO”), EPA assesses the possibility of lowering the existing applicability threshold for that rule from 10 million barrels per year (bbl/yr) gasoline to a lower threshold of 5, 1, or 0.5 million bbl/yr. The Agency’s analysis shows that the cost effectiveness of establishing a 1 million bbl/yr threshold would be \$74,000 per ton of HAP controlled and \$5,500 per ton of VOC controlled.²³ Based on this analysis, the Agency proposes to lower the applicability threshold to 1 million bbl/yr on the grounds that, “While the HAP cost-effectiveness is higher than our historical values, the VOC cost-effectiveness is within the range of acceptability.”²⁴ In other words, EPA purports to expand the HAP control requirements under the existing rule based on a finding that the expanded control requirements would be cost effective for VOC control.

This conclusion cannot be supported under the CAA. When setting MACT standards in the first instance, the CAA expressly forbids EPA from considering the co-benefits of non-HAP emissions reductions – the “floor” must be based on the HAP emissions reductions achieved by the better performing sources in the category (or the best controlled similar source in the case of new source MACT) and any “above the floor” standard may be based only on consideration of “the cost of achieving such [HAP] emission reduction, and any non-air quality health and environmental impacts and energy requirements.”²⁵ It would not be reasonable to conclude that § 112(d)(6) enables consideration of non-HAP emissions reductions in making control requirements when such reductions cannot be considered in setting the standard in the first instance. Congress unambiguously designed § 112 to provide the authority and obligation for EPA to regulate HAP emissions. There is no indication in §§ 112(d)(2), (3), or (6) that EPA may impose HAP emissions limitation based solely on an assessment of collateral non-HAP emissions reductions.

Therefore, in the case of the MTVLO standard, EPA has no cognizable basis for changing the existing 10 million-bbl/yr applicability threshold.

²³ 75 Fed. Reg. at 65115.

²⁴ *Id.*

²⁵ CAA §§ 112(d)(2) and (3).

8. EPA has not provided justification or any rational basis for departing from the risk assessment methods established in prior § 112(f) residual risk determinations.

As explained in detail above, EPA proposes at least three significant departures from its established methods of conducting risk analyses in support of § 112(f) determinations: (1) EPA seeks to include consideration of total facility HAP emissions at a given site, and has expressed the belief that region-wide analyses would be appropriate if adequate data were available; (2) the Agency proposes to consider allowable emissions from affected facilities rather than relying on quality-assured actual emissions data; and (3) EPA seeks to consider demographics in deciding whether an ample margin of safety has been achieved.

Where legal discretion otherwise exists, the Agency is not prevented from charting a new course on established regulatory principles. However, EPA must do more than outline its purported legal authority for the new approach. EPA has the additional burden of providing a rational basis for abandoning its prior approach. In this case, even assuming EPA has discretion on these key points (which, for the reasons described above, the R2C contends the Agency does not), EPA has provided no explanation at all as to why such fundamental changes to the established contours of the program are necessary or appropriate. As a result, these changes lack foundation and are not supported as a reasonable exercise of Agency discretion.

Reservoir Performance for Reduced Emissions
Completions

Attachment F

Reservoir Performance for Reduced Emissions Completions

By David A. Simpson, PE

EPA has proposed under 40 CFR 60.5375 that “*Except as provided in paragraph (f) of this section, for each well completion operation with hydraulic fracturing, as defined in §60.5430, you must control emissions by the operational procedures found in paragraphs (a)(1) through (a)(3) of this section.*”

- (1) *You must minimize the emissions associated with venting of hydrocarbon fluids and gas over the duration of flowback by routing the recovered liquids into storage vessels and routing the recovered gas into a gas gathering line or collection system.*
- (2) *You must employ sand traps, surge vessels, separators, and tanks during flowback and cleanout operations to safely maximize resource recovery and minimize releases to the environment. All salable quality gas must be routed to the gas gathering line as soon as practicable.*
- (3) *You must capture and direct flowback emissions that cannot be directed to the gathering line to a completion combustion device, except in conditions that may result in a fire hazard or explosion. Completion combustion devices must be equipped with a reliable continuous ignition source over the duration of flowback.”*

This regulation requires that flow-back emissions must be controlled. Industry practice has long been to flow wells back to flares where allowed by local regulations because unburned natural gas presents a safety hazard to workers on location. There is an evolving trend to flow this gas to sales where technically feasible. In effect, the regulatory language above is setting proscriptive language to require an evolving practice. The discussion below is directed at clarifying the issues surrounding the technical choices that must be made during a flow back to maximize the potential for success.

API conversations with Halliburton, Schlumberger, and BJ Services (the three largest oilfield service companies) and Aztec Well Services a regional drilling company indicates that essentially every well that is drilled is evaluated for hydraulic fracture stimulation and has been for many years. There are fields where this evaluation results in different stimulation techniques, but these fields are reasonably rare. Consequently, the population for this requirement is approximately every gas well.

To support these conversations, the online databases for Colorado¹, New Mexico², and Wyoming³ were searched for information on hydraulic fractures. Permit data is stored as scanned images and a review of a random selection of wells completed since 1960, showed that the data is mostly silent on stimulation techniques, but where such techniques were mentioned every well that was looked at had been hydraulically fractured regardless of the formation.

The benefits of Reduced Emissions Completions (REC) stated in the Regulatory Impact Analysis (RIA) depend heavily the data contained in EPA’s Natural Gas Star Program⁴. This reliance may be less justified than the EPA expects. First, the data within the Natural Gas Star Program has been carefully

¹ Website of Colorado database <http://cogcc.state.co.us/>

³ Website of Wyoming database <http://wogcc.state.wy.us/>

⁴ EPA Energy Star Program at <http://www.energystar.gov/>

selected initially by the contributing company and finally by the EPA itself to present environmental successes in the best possible light. The success stories described within the program represent techniques that have worked on the projects referenced, and contributing companies have not claimed that the techniques reported are in any way universally applicable to the industry. To assume that a few dozen or even a few hundred successful reduced emissions completions means that 53% of all completions, fractures and re-fractures will benefit from this technique is extrapolating a limited data set far outside the parameters supported by the original sample size.

The requirements for REC are: (1) that any inert gases used in the fracture will be diluted to acceptable levels for sales gas before the end of the flow back; and (2) that the well has adequate reservoir pressure to flow at rates appropriate for transporting solids and liquids into an imposed back pressure. The first requirement is easily satisfied for hydraulic fracture stimulations using a liquid as the carrier fluid—the large number of procedures that use nitrogen or CO₂ foam will rarely meet the requirements during the flowback period. The second requirement is problematic.

First, let me clarify some terms commonly used in describing flow from a reservoir.

- **“Reservoir pressure”** is the pressure within the reservoir rock at a point where the pressure is largely undisturbed by well flow. When a well is first completed (i.e., the production casing is installed, cemented, and perforated), the pressure seen on surface is a reasonable surrogate for reservoir pressure as long as care is taken to take the static pressure gradient into account. As fluids are removed from the reservoir, surface pressure becomes progressively less representative of reservoir pressure. For determining if a well will flow into line pressure, the pressure experienced immediately after perforations (before any stimulation) is typically used for “reservoir pressure”. After that initial point, reservoir pressure is rarely known with certainty again, but can be estimated through pressure build up tests or material balance calculations.
- **“Near wellbore pressure traverse”** is an estimate of the pressure moving away from the bottom of the well to a position within the reservoir that is experiencing “reservoir pressure”. This gradient represents the resistance of the reservoir to flow, so the faster you flow the well the steeper the gradient becomes; which tends to be a limiting parameter in flow rate. This is because of the resistance of the reservoir rock to flow which can be very high. We don’t measure “resistance” to flow, but instead we measure “ability” to flow or “permeability”. The industry goes to great lengths to predict permeability in every reservoir, but permeability tends to change with time and with spatial position so it is never known with precision.
- **“Flowing bottomhole pressure”** is the pressure that can be measured on the well side of the perforations while the well is flowing. This is the “hinge” pressure that determines both the flow rate into the well and the flow rate out of the well for a given set of wellbore tubulars and a fixed surface pressure.
- **“Flowing tubinghead pressure”** is the pressure measured in the production tubing at the surface while the well is flowing. The difference between line pressure and flowing tubing pressure is the pressure drop in the flow lines and surface equipment. This pressure drop can be very large especially at high flow rates or in scaling/plugging situations. It is rare to be able to reliably substitute “line pressure” for “flowing tubing pressure”.
- **“Line pressure”** is the pressure at the sales meter and represents the pressure of the gathering line. Data from line pressure instruments is always the most accurate and available information on a wellsite, but is rarely appropriate for reservoir-flow calculations.

- “**Superficial velocity**” is the velocity that a fluid would demonstrate if it were the only fluid contained in a multiphase flow stream. The interactions between fluids in a multiphase flow conduit are extremely complex and estimating the actual velocity of any given component within the stream has proven to be impossible to date. Researchers have found that superficial velocity leads to conclusions that do an adequate job of reflecting actual performance of a multiphase line.

Velocity is required to shift liquids and solids. The magnitude of required bottom-hole superficial velocity is somewhere between 50 ft/sec and 150 ft/sec depending on the free solids that must be transported. Plotting bottom-hole superficial gas velocity vs. flowing tubing pressure for an example well with 4,000 ft of 2-3/8, 4.7 lbm/ft, J-55 tubing yields:

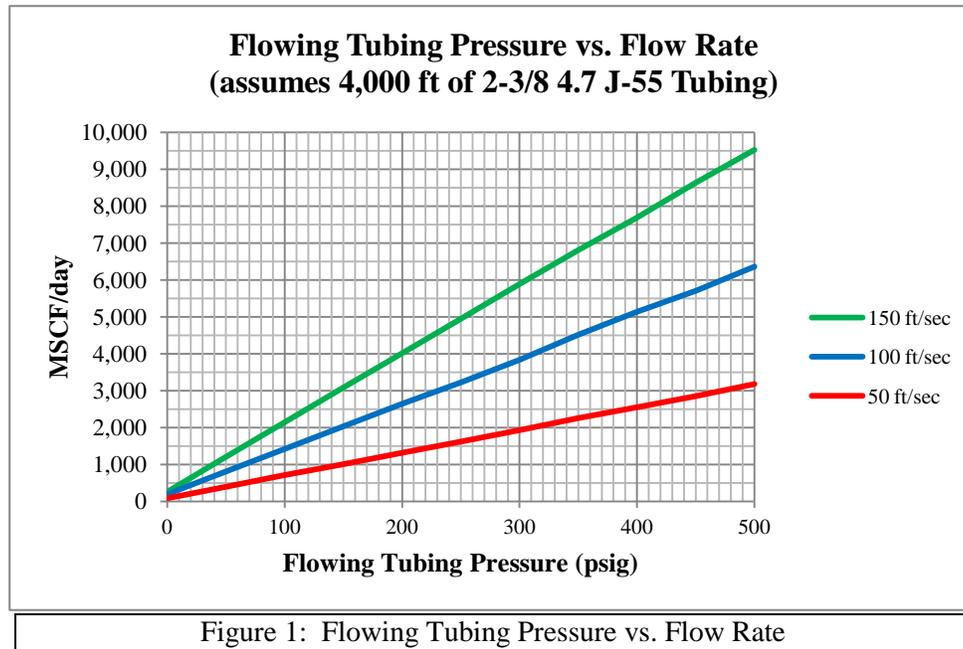

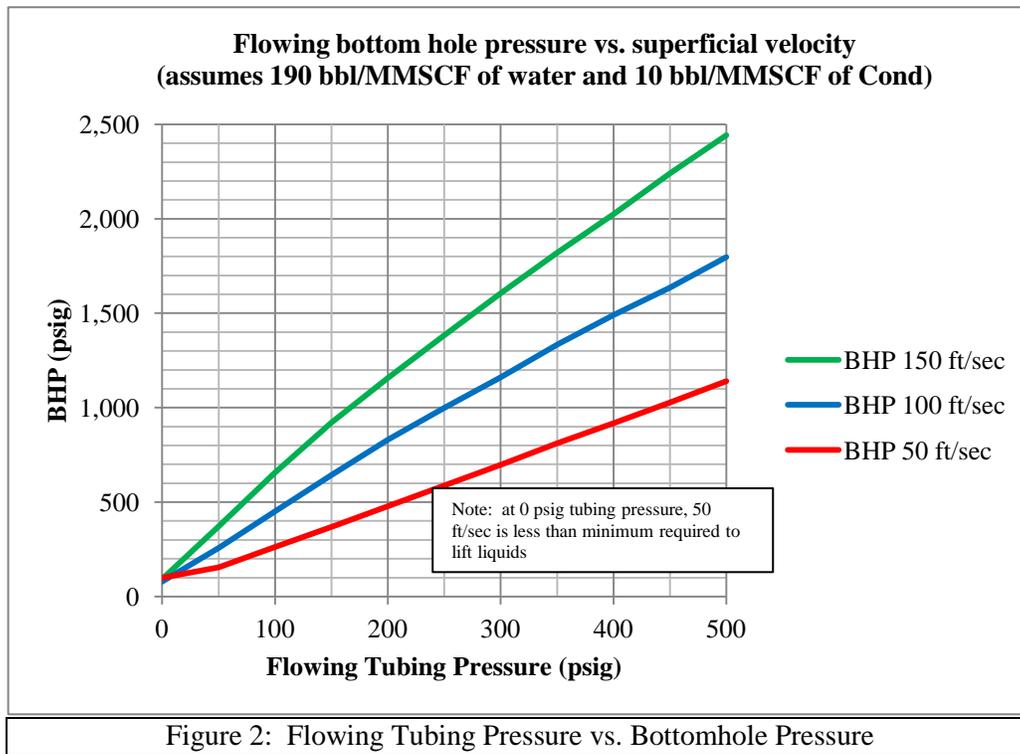

Figure 1 shows that imposed backpressure has a significant impact on velocity. If the flow back can exhaust to atmosphere, then the flow rate required to achieve adequate velocity is 200 to 264 MSCF/day depending on the amount of solids that have to be moved. This flow rate is achievable in a significant number of new wells. If the well sees 100 psig, which is often considered a “low” line pressure, then the minimum required flow rate moves up to a range of 700 to 2,100 MSCF/day which exceeds the ability of a large proportion of new wells. In the frontier Shale Gas plays, the line pressures are currently tending to be in the neighborhood of 450 psig which would require the wells to flow 2.8 to 8.6 MMSCF/d, with the sand load requiring velocities well toward the high end of that range.

The other piece of this puzzle is the flowing bottom-hole pressure required to achieve a superficial gas velocity of 50-150 ft/sec. To determine that pressure you have to assume a liquid flow rate. If you assume that while the well is cleaning up it will flow about 190 bbl water/MMSCF and 10 bbl condensate/MMSCF then you can get an example of the bottom hole pressures required:

There is no universal correlation to relate a flowing bottom hole pressure and a flow rate to reservoir pressure because the relationship is very much dependent on the efficiency of the transport paths within the near wellbore. That being said, it is not unusual for the required reservoir pressure to be more than twice the bottom hole pressure, so to flow 150 ft/sec into 450 psig gathering pressure would require reservoir pressures in the neighborhood of 4,400 psig. Reservoir pressures this high are certainly not unheard of, but at the same time they are not particularly common either.

Determining reservoir pressure is a challenge. For flowing wells, reservoir pressure is rarely known with any confidence. Sometimes a pressure build-up test is used to allow engineering tools to be applied to predict reservoir pressure, but the shut-in periods are rarely long enough to allow the near wellbore pressure to reach reservoir pressure. Occasionally, engineers have enough information to perform a reliable material balance to compute reservoir pressure. This is exceedingly rare. When a new well is drilled, the area around the wellbore will have approximate reservoir pressure because that region of the reservoir will not have been subject to any velocity or depletion effects yet. After stimulation and flowback, the reservoir pressure becomes progressively more difficult to determine with time. After setting production casing and cementing it into the well bore, the casing and cement are perforated to allow the wellbore to access the reservoir. At that point, the reservoir pressure is equal to the bottom-hole pressure and until liquids accumulate in the wellbore, surface pressure is reasonably close to flowing bottomhole and reservoir pressure. This number is generally recorded and reported to state agencies as “Initial Pressure” and is reasonable to accept as “reservoir pressure” at completion.

After stimulation, wellhead pressure is no longer a reasonable representation of reservoir pressure. Stimulation fluids add a hydrostatic component that makes determination of reservoir pressure from the surface less accurate. During the flow back, friction effects within the reservoir, through the well bore tubulars, through surface equipment, to the gathering system are very complex and change constantly. In other words, the comparison of surface pressure immediately after perforation to the line pressure prior to

flow back represent a data point that could inform a decision whether to set REC equipment or not, but it doesn't ensure that the well will clean up to sales. The decision of how to flow a well back after a stimulation procedure is generally based on the experience of the people on the ground and to dictate specific equipment or specific procedures across the board has a very high potential to lead to sub-optimum results.

If a line pressure of half the flowing bottom hole pressure and a flowing bottom hole pressure of half of reservoir pressure are required to reliably clean up a well, then the only wells that you can have confidence will clean up while flowing to sales are wells with reservoir pressure at least four times line pressure. Some wells will clean up with reservoir pressure less than that, but that decision must be based on the training and experience of the operators on the ground. A well that is too weak to flow into an imposed backpressure will rapidly accumulate liquids and solids within the wellbore that can damage the well's ability to produce gas at economic flow rates. This is a decision that can only be made after the well is completed. To require REC equipment to be set prior to perforating the casing is imposing a cost that will frequently be wasted.

Author Biography

David Simpson has 31 years experience in Oil & Gas and is currently the Proprietor and Principal Engineer of MuleShoe Engineering. Based in the San Juan Basin of Northern New Mexico, MuleShoe Engineering addresses issues in Coalbed Methane, Low Pressure Operations, Gas Compression, Gas Measurement, Field Construction, Gas Well Deliquification, and Produced Water Management.

A Professional Engineer with his Master's degree, David has had numerous articles published in professional journals, has contributed a chapter on CBM to the 2nd edition of Gas Well Deliquification, by Dr. James Lea, et al, and has spoken at various conferences, including the 2000 SPE *International Conference on Health, Safety, and the Environment in Oil & Gas Production* in Stavanger, Norway where he presented a paper on the transition from continuous bleed pneumatic controllers to intermittent vent pneumatic controllers (SPE61030). He has been a featured speaker at the bi-annual *Four Corners Oil & Gas Conference* for the last 6 years and is a regular instructor at short courses at the annual ALRDC *Gas Well Deliquification Workshop* in Denver. David was Program Chair for the highly successful SPE Advanced Technology Workshop titled "Managing the Performance of Low Pressure Gas Wells and Associated Facilities" held in Ft Worth, TX in October, 2008. His consulting practice includes clients in 12 countries.

Peer Review. This document was peer reviewed by experienced Reservoir Engineers to ensure that the conclusions reached were consistent with the conclusions that would normally be reached by someone experienced in the field.

Review of the Regulatory Impact Analysis (RIA) for the Well Completions Portion of the Proposed New Source Performance Standards for the Oil and Natural Gas Industry

By David A. Simpson, PE

EPA has proposed under 40 CFR 60.5375 that “*Except as provided in paragraph (f) of this section, for each well completion operation with hydraulic fracturing, as defined in §60.5430, you must control emissions by the operational procedures found in paragraphs (a)(1) through (a)(3) of this section.*”

- (1) *You must minimize the emissions associated with venting of hydrocarbon fluids and gas over the duration of flowback by routing the recovered liquids into storage vessels and routing the recovered gas into a gas gathering line or collection system.*
- (2) *You must employ sand traps, surge vessels, separators, and tanks during flowback and cleanout operations to safely maximize resource recovery and minimize releases to the environment. All salable quality gas must be routed to the gas gathering line as soon as practicable.*
- (3) *You must capture and direct flowback emissions that cannot be directed to the gathering line to a completion combustion device, except in conditions that may result in a fire hazard or explosion. Completion combustion devices must be equipped with a reliable continuous ignition source over the duration of flowback.”*

API conversations with Halliburton, Schlumberger, and BJ Services (the three largest oilfield service companies) and Aztec Well Services, a regional drilling company, indicates that essentially every well that is drilled is evaluated for hydraulic fracture stimulation and has been for many years. There are fields where this evaluation results in different stimulation techniques, but these fields are reasonably rare. Consequently, the population for this requirement is approximately every gas well.

To support these conversations, the online databases for Colorado¹, New Mexico², and Wyoming³ were searched for information on hydraulic fractures. Permit data is stored as scanned images and a review of a random selection of wells completed since 1960, showed that the data is mostly silent on stimulation techniques, but where such techniques were mentioned every well that was looked at had been hydraulically fractured regardless of the formation.

Companies Affected: Data from IHS for 2008 showed that there were 14,289 companies with at least one producing well⁴. There were 5,873 companies with 10 or more producing wells. RIA Table 7-18 claims that this number is 128 companies. While there are a smaller number of companies that are drilling new wells, all of these companies will be subject to this rule.

³ Website of Wyoming database <http://wogcc.state.wy.us/>

⁴ Reference for IHS company data <http://www.ihs.com/products/oil-gas-information/production-data/>

Company Survey: API asked member companies to provide information about their 2012 development plans. Nine companies provided data on 29 producing areas where they expected to drill 6,159 wells in 2012. The companies that responded represented all of the largest producers in the major shale-gas plays⁵, so it is likely that this survey encompassed a significant portion of the Shale-gas development for 2012. Extrapolating the data to the population of companies is difficult and of limited value, but the best we were able to do is predict that 30% of the 2012 drilling will be shale-gas, 70% will be CBM, tight-gas, and conventional. Table G-1 summarizes the results of the API survey. Within a single play with several companies reporting, the variability was significant. The only conclusion that can be drawn is that each company has their own strategy for performing reduced emissions completions (REC) and the equipment required (and its cost and supplier) reflects that variability. A weighted average of this data puts the cost/day very close to \$5,000.

Table G-1: Summary of API Survey Results

| Type Reservoir | 2012 Well Count | Minimum Reported Cost/day | Maximum Reported Cost/day |
|-----------------------|------------------------|----------------------------------|----------------------------------|
| Conventional REC | 1,060 | \$2,150 | \$5,900 |
| CBM REC | 625 | \$4,286 | \$30,000 |
| Shale REC | 2,698 | \$1,530 | \$10,500 |
| Tight Gas REC | 74 | \$6,000 | \$15,000 |
| Non-REC | 1,702 | | |

Applicability of Reduced Emissions Completions (REC): The Table 3-2 of the RIA expects that 9,313 wells will meet the requirements for REC in 2015 (out of 17,453 new gas wells). In the same table they expect that there will be 12,050 refracs that meet the criteria for REC and 42,352 conventional wells that will not meet the criteria. The benefits of REC stated in the RIA depend heavily the data contained in EPA’s Natural Gas Star Program.

First, the data within the Natural Gas Star Program has been carefully selected initially by the contributing company and finally by the EPA itself to present environmental successes in the best possible light. The success stories described within the program represent techniques that have worked on the projects referenced, and contributing companies have not claimed that the techniques reported are in any way universally applicable to the industry. In fact, the Natural Gas Star Partner reported successes for reduced emission completions have been targeted to specific areas where the reservoir characteristics and infrastructure enable reduced emission completions. The limitations on use of reduced emission techniques have been clearly articulated and communicated to EPA, both through the Natural Gas Star Program and in various other communications. To ignore these limitations and assume that a few dozen

⁵ Companies responding were Anadarko Petroleum Corp, BP Production Co, Chesapeake Energy Corp., Chevron Corp., ConocoPhillips, Devon Energy, Noble Energy Inc., Shell, Talisman Energy Inc., and XTO Energy

or even a few hundred successful reduced emissions completions means that 53% of all completions, frac's, and re-frac's will benefit from this technique is extrapolating a limited data set far outside the parameters supported by the original sample size.

The technical support document (TSD) for reduced emissions completions relied heavily on data from the Wyoming Department of Environmental Quality (WYDEQ) Air Quality Division and claimed that "The State of Wyoming's Air Quality Division (WAQD) requires operators to complete wells without flaring or venting where the following criteria are met: (1) the flowback gas meets sales line specifications and (2) the pressure of the reservoir is high enough to enable REC. If the above criteria are not met, then the produced gas is to be flared". According to the WYDEQ's March 2010 Oil and Gas Production Facilities Permitting Guidance ⁶ this is a requirement in only 7 counties of the state.

Second, the number of refracs is assumed to be 10% of the population of gas wells each year. Data from industry puts that number well under 1%.

Third, the requirements for REC are: (1) that any gases used in the frac will decline to acceptable levels for sales gas before the end of the flow back; and (2) that the well has adequate reservoir pressure to flow at rates adequate for transporting solids and liquids into an imposed back pressure. The first requirement is easily satisfied for hydraulic fracture stimulations using a liquid as the carrier fluid—the large number of procedures that use nitrogen or CO₂ foam will never meet the requirements during the flowback period. The second requirement is very dependent on reservoir pressure and line pressure. The industry direction is to flow to sales if it is cost effective, but many wells will not clean up at observed pressures.

The TSD estimates that wellsite dehydrators and sand separators are "often" included on completions and that "many" REC wellsites will only add \$806/day (2006 estimate inflated to 2008) to the cost of completion. On sites that have to bring in temporary equipment this number increases to \$7,486 (2008 dollars) per day. They further claim that flowbacks will be done in 3-10 days (average of 7 days) and that an average incremental cost is \$4,146/day. This includes a one-time cost of \$691 for transportation, placement, and removal of equipment. This results in a total cost of \$29,713/well.

The companies who responded to API's survey described above represented the majority of the most active shale-gas operators. This group of companies is doing REC on approximately 70% of the wells they reported. This data is very much skewed toward shale-gas. Evaluating the companies that responded to the survey relative to the population of companies in the industries indicates that the industry will likely drill 30% shale gas and 70% CBM, tight-gas, and conventional wells. Data from the API member survey showed that the average cost per day is about \$5,000 (reasonably close to the EPA estimate). The EPA estimated that flow back periods will typically be 3-10 days with 7 being a reasonable average. The API survey is largely in agreement with those estimates. The problem is that the equipment does not magically appear on day one and instantly disappear on day 7. It has to be staged before the flowback can be scheduled, gas control must have advance notice to nominate the gas to the gathering system, and some contingency time is generally needed. Then at the end of the flowback, crews must be scheduled to demobilize the equipment, trucks must be scheduled to pick it up, and it has to have a place to go. The front-end/back-end non-productive time must be paid for. To account for this, the

⁶ Wyoming Department of Environmental Quality, Oil and Gas Production Facilities Chapter 6, Section 2 Permitting Guidance, Revised March 2010, <http://deq.state.wy.us/aqd/Oil%20and%20Gas/March%202010%20FINAL%20O&G%20GUIDANCE.pdf>

majority of flowback companies have a 30 day minimum rental period which makes the average cost per well \$150,000 plus \$30,000 for mobilization/demobilization for an average total of \$180,000. Also, the API Survey reported that the storage vessels and combustion equipment for REC costs on the order of \$2,000/day, but again requires a 30 day commitment so the rental cost per well is \$60,000 and the mobilization/demobilization costs are \$30,000.

In the TSD, the authors consistently claim that REC is only applicable to unconventional gas, then on page 4-16, they claim that every completion will recover 34 bbl of condensate at a value of \$70/bbl which adds \$2,380 to the benefit of REC—but most unconventional wells produce no condensate. They also assume that each well will recover 8.258 MMSCF during the flowback. This says that for a 7 day average flowback, wells will average 1.2 MMSCF/day. For the wells that can flow to sales, this is a reasonable assumption since only the strongest formations will be able to flow to sales.

The number of wells that can successfully be cleaned up by flowing into a gathering system is closer to 30% or 5,230 wells instead of 9,313. Evaluating reservoir pressure requirements to flow into typical gathering systems, a number around 1.2-1.4 MMCF/d is reasonable. However, the condensate recovery factor is unreasonably high. This leads to the cost per REC shown on Table G-2.

Table G-2: Cost per REC

| | RIA | API Survey |
|--|-------------------------|------------------------|
| Rental cost of equipment | \$29,022 | \$150,000 |
| Variable cost per installation | \$691 | \$30,000 |
| Total cost per job | \$33,239 | \$180,000 |
| Sales recovered per job | \$35,410 | \$32,900 |
| Net Cost (benefit) per well | (\$2,171) | \$147,100 |
| Number of jobs in 2015 | 9,313 | 5,230 |
| Total cost (benefit) in 2015 of REC | (\$20.2 million) | \$782.6 million |

EPA estimated that 53% of the wells drilled would be able to sell gas. The remainder of the population was broken into hydraulically fractured wells that could not sell gas (3%) and “conventional wells” (44%) which they mistakenly suggest are not hydraulically fractured. They estimate that the equipment and reporting requirements will add \$3,523 per well to the cost of the well. However, the requirements for non-sales wells are extensive and very expensive. EPA is requiring that companies capture gas that “can not be directed to the gathering line to a completion combustion device” with a “reliable continuous ignition source”. When the gas is not combustible, this will require supplemental fuel. Also, this prohibits the use of electronic igniters to minimize the use the waste of pilot gas. Furthermore, EPA is also requiring that for wildcat or delineation wells, that companies supply “the distance, in miles, of the nearest gathering line”, the “latitude and longitude coordinates of the well in decimal degrees to an accuracy and precision of five (5) decimals of a degree using the North American Datum (NAD) of

1983”, etc. All the new information required will require new data-storage and collection systems, which will require administrative staff to assemble several new reporting obligations, and will require environmental professionals to comply with additional strict reporting requirements. Once adequate data collection systems are in place, this rule can be expected to add 100 man-hours of administrative effort per well and 20 hours for an environmental professional. At a fully-burdened cost of administrative staff of \$50/hour and professional staff of \$110/hour, this adds \$7,200/well which will apply even to wells that can not recover sales gas. Table G-3 summarizes the cost for completions using flaring versus recover to sales. Table G-4 summarizes the overall expenditures for REC. The cost of this regulation has the potential to create the same devastation to the Oil & Gas industry as the New Mexico Pit Rule has created in New Mexico. The costs in the “API Survey” column above would not be sustainable in most of the industry and this regulation will result in a large number of wells that will not be drilled, and a large number of wells that could otherwise benefit from a production restoring “workover” to be plugged and abandoned.

Table G-3: Cost of Completions with Flaring

| | RIA | API Survey |
|---|---------------|-------------------|
| Costs of equipment and installation | \$3,523 | \$90,000 |
| Administrative cost per installation | 0 | \$7,200 |
| Total cost per job | \$3,523 | \$97,200 |
| Sales recovered | \$0 | \$0 |
| Net Cost (benefit) | \$3,523 | \$97,200 |
| Number of jobs in 2015 (Frac’d & Flared) | 446 | 12,230 |
| Total cost (benefit) in 2015 of Frac’d & Flared (\$million) | \$1.6 | \$997.0 |
| Number of Jobs in 2015 (Conventional) | 7,694 | 7,694 |
| Total cost in 2015 of Conventional (\$million) | \$27.1 | \$747.9 |

Table G-4: Summary Expenditures

| | RIA | API Survey |
|---|----------------------|--------------------------|
| REC wells | (\$20.2 million) | \$782.6 million |
| Frac’d and Combusted Wells | \$1.6 million | \$997.0 million |
| Conventional Wells (Combusted) | \$27.1 million | \$747.9 million |
| Total cost (benefit) of regulation | \$8.5 million | \$2,527.5 million |

Emissions Reductions

VOC content varies from well to well, field to field, and basin to basin. With 400,000 gas wells there are 400,000 unique gas analyses that are in place at any given time. Regulations require that each of the wells will be periodically re-sampled because the mix of components in a well stream changes. The mix will change with pressure changes, temperature changes, and with changes in the portion of the reservoir that is currently available to the wellbore (which changes minute-to-minute). The VOC content of the mix of wells on production at any given time is one of the most volatile parameters in this industry. The EPA based their rule making on 7 wells out of 400,000. These 7 wells were handpicked based on parameters other than an effort to provide a random sample.

To determine the mass of VOC in any given stream, you must first determine the mass of the stream and apply the weight percent VOC to that total mass. For the tables below, we assumed that the EPA estimate of 1.2 MMCF/day and 7 days of flowback are as reasonable an estimate as anyone is likely to develop. Collapsing 20,000 flowbacks into a single number is statistically invalid, but for the sake of this discussion we will accept EPA's number.

Table 3-3 in the RIA has detailed emissions reductions for gas wells that assume 83% (by volume) Methane and 3% (by volume) VOC. These percentages are the same for all the categories of gas wells, including conventional wells and disregard the fact that a significant portion of current and future drilling is in CBM and Shale Gas plays.

An article published in *Oil & Gas Journal* March 9, 2009 titled "Compositional variety complicated processing plans for US shale gas" written by Keith A Bullin and Peter E Kroushop both of Bryan Research and Engineering had a series of tables that are summarized on Table G-5.

Table G-5: Shale Gas Composition

| | C1 | C2 | C3+ | CO2 | N2 | Total |
|---------------------------|-----------|-----------|------------|------------|-----------|--------------|
| Barnett Average | 86.8% | 6.7% | 2.0% | 1.7% | 2.9% | 100.0% |
| Marcellus Average | 85.2% | 11.3% | 2.9% | 0.4% | 0.3% | 100.0% |
| Fayetteville Average | 97.3% | 1.0% | 0.0% | 1.0% | 0.7% | 100.0% |
| New Albany Average | 89.9% | 1.1% | 1.1% | 7.9% | 0.0% | 100.0% |
| Haynesville Shale Average | 95.0% | 0.1% | 0.0% | 4.8% | 0.1% | 100.0% |
| Shale Gas Average | 90.8% | 4.0% | 1.2% | 3.1% | 0.8% | 100.0% |

A similar analysis of CBM would show C2+ to be approximately zero. Adding the Shale Gas analysis to the GRI analysis provided in the docket yields Table G-6. The "tonne VOC/MMSCF" column is simply the density of the gas at standard temperature and pressure times 1,000,000 SCF. The "tonne VOC/flowback" column is the "tonne VOC/MMSCF" column times the 8.4 MMSCF which would have

been produced from a well making 1.2 MMSCF/day for 7 days. The “cost effectiveness” column is the cost of the flowback (\$180,000 discussed above) divided by the “tonne VOC/flowback” column.

Table G-6: Gas Composition

| | MW | SG | VOC (Vol %) | VOC (W%) | Tonne VOC/ MMSCF | Tonne VOC/ flowback | Cost Effective- ness (\$/tonne) |
|----------------------|---------------|---------------|----------------|--------------|------------------------|---------------------------|--|
| GRI1 | 16.661 | 0.5752 | 0.45% | 1.39% | 0.277 | 2.327 | \$63,214 |
| GRI2 | 17.637 | 0.6090 | 2.20% | 6.84% | 1.447 | 12.155 | \$12,102 |
| GRI3 | 18.373 | 0.6344 | 3.93% | 11.94% | 2.631 | 22.100 | \$6,656 |
| GRI4 | 29.356 | 1.0136 | 28.13% | 52.72% | 18.569 | 155.980 | \$943 |
| GRI5 | 20.509 | 0.7081 | 7.15% | 18.62% | 4.583 | 38.497 | \$3,821 |
| GRI6 | 20.911 | 0.7220 | 8.64% | 21.39% | 5.366 | 45.074 | \$3,264 |
| GRI7 | 20.665 | 0.7135 | 7.01% | 10.09% | 2.502 | 21.016 | \$8,564 |
| GRI8 | 20.665 | 0.7135 | 7.01% | 17.95% | 4.451 | 37.388 | \$4,814 |
| GRI9 | 19.558 | 0.6753 | 6.22% | 16.31% | 3.828 | 32.155 | \$4,575 |
| GRI10 | 17.791 | 0.6143 | 2.41% | 7.47% | 1.595 | 13.398 | \$10,979 |
| GRI11 | 18.565 | 0.6410 | 3.21% | 9.80% | 2.183 | 18.337 | \$8,022 |
| GRI12 | 20.550 | 0.7096 | 2.30% | 6.78% | 1.671 | 14.036 | \$10,480 |
| Barnett Avg | 18.355 | 0.6337 | 2.00% | 4.81% | 1.058 | 8.887 | \$16,552 |
| Marcellus Avg | 18.605 | 0.6424 | 2.90% | 6.87% | 1.534 | 12.886 | \$11,415 |
| Fayetteville Avg | 16.547 | 0.5713 | 0.00% | 0.00% | - | 0 | infinite |
| New Albany Avg | 18.715 | 0.6462 | 1.10% | 2.59% | 0.582 | 4.889 | \$30,088 |
| Haynesville Avg | 17.411 | 0.6012 | 0.00% | 0.00% | - | 0 | Infinite |
| Shale Gas Avg | 17.915 | 0.6186 | 1.20% | 2.95% | 0.635 | 5.334 | \$27,578 |

In Table G-6, only eight of the seventeen analyses would meet a cost effectiveness target of less than \$10,000/tonne. Further, 77% of the proposed 2012 wells from the API survey are unconventional gas; therefore, the shale gas average would be the most representative of wells being drilled.

If we look just at the group of wells that the RIA claims can sell gas, then the emissions reductions and cost effectiveness would be as shown in the API Survey VOC column of Table G-7.

Table G-7: Emissions Reduction and Cost Effectiveness

| | | RIA VOC | API Survey VOC |
|----------------------------------|---------------|--------------------|-------------------------------|
| Shale Gas Wells | tons/well | 22.0 | 5.3 |
| Number of Wells | | 7,171 | 4,027 |
| Annual Sales | BSCF | 60.2 | 33.8 |
| Annual Emissions Savings | tons/yr | 157,182 | 21,480 |
| Annual Cost | \$million | \$238.4 | \$724.9 |
| Annual Sales | \$million | (\$253.9) | (\$132.5) |
| Effectiveness (w/o sales) | \$/ton | \$1,516 | \$33,748 |
| Effectiveness (w/sales) | \$/ton | (\$99) | \$27,579 |

Finally, looking at the conventional wells where the mix of gases used in the RIA is defensible, but the assumption that they will not be frac'd is not defensible. It is curious to note in the RIA that while conventional wells are not required to conform to Subpart OOOO, the EPA is claiming significant VOC reductions in Table 3-3 of the RIA as shown here on Table G-8.

Table G-8: RIA Table 3-3

| | | RIA | | |
|----------------------------------|---------------|-----------------|-------|-------|
| | | VOC | CH4 | HAP |
| Conventional Wells | tons/well | 0.11 | 0.76 | 0.01 |
| Number of Wells | | 7,694 | 7,694 | 7,694 |
| Annual Sales | BSCF | 0 | 0 | 0 |
| Annual Emissions Savings | tons/yr | 857 | 5,875 | 62 |
| Annual Cost | \$million | \$27.1 | | |
| Annual Sales | \$million | 0 | | |
| Effectiveness (w/o sales) | \$/ton | \$31,619 | | |

From this data, it is not cost effective to do REC on conventional wells even at EPA’s understated cost/procedure, but the wells are hydraulically fractured so they would be subject to Subpart OOOO and would be required to do REC.

Technical Review of WCI Proposals to Meter Fuel and Control Gas

I. Executive Summary

The Western Climate Initiative (WCI) makes the assumption that Operators would be reporting the “most accurate” volumes if the gas was metered as a “fuel” stream and a “control” stream instead of applying theoretical factors and Engineering approaches to estimate these volumes. The reports make this assertion without discussing the technology that would be deployed to measure these streams to “provide the rigor required for either cap-and-trade or offset programs”. The review below categorically rejects their basic assumption and asserts that the act of installing meters on the streams considered will provide a **false sense of security** and a **net deterioration in the quality of data reported**.

There is no gas measurement technology currently existing that would provide better data in the field than is currently being reported using manufacturer’s numbers and theoretical calculations. In addition to making the data less representative of reality, the costs that would be imposed are staggering—industry would be required to spend billions of dollars to report gas emissions data that is demonstrably worse than the data they are reporting today.

A. Summary Expenditures

The “Per Company” column below assumes 2,000 wells per company, “Total WCI” column assumes 100,000 wells affected in the WCI States and Provinces (breakdown is included under “Cost of Implementation” below). Many wells cannot sustain either the increased operating cost or the capital expenditure so they would be plugged instead of spending this money—there is no way to predict this mix of expenditure vs. plugging.

| | Per well (\$k) | Per Company (\$million) | Total WCI (\$million) |
|------------------------|----------------|-------------------------|-----------------------|
| RTU Replacement | \$3.5 | \$7 | \$350 |
| Host/Database | | \$15 | \$750 |
| Site Modifications | \$30.0 | \$60 | \$3,000 |
| Total Capital | \$33.5 | \$82 | \$4,100 |
| | | | |
| Annual Operating Costs | \$1.5 | \$3 | \$150 |

His consulting practice includes clients in 10 countries.

II. Discussion

The Western Climate Initiative has developed at least two documents that each reach the conclusion that gas consumed on wellsites must be measured to achieve adequate “accuracy” in accounting for emissions. The documents further require that gas used for pneumatic controls must be measured separately from gas burned because vented gas has a different “emissions factor” on the environment than burned gas has.

The industry has long said and demonstrated that measuring either fuel gas or control gas represents a very large cost for a very small return. The discussion below supports that position.

A. Magnitude of Gas Consumed

1. *Engine Fuel*

The industry has an excellent understanding of engine fuel. Where engine fuel is measured, the theoretical correlations match very well with measured data. The added value of measuring this fuel-gas stream is not clear to most wellhead compressor operators; consequently it is rare to see a fuel meter on a wellhead compressor or pump jack. The various stakeholders in the gas production process (including regulatory agencies and mineral owners) have accepted that these volumes are both small and adequately represented by the theoretical usage factors.

Engines utilized in field locations range from a single-cylinder Arrow running a pump jack (smallest is the Arrow C-46 which is rated at 6 hp at 500 rpm at sea level with 70,000 BTU/hp-hr fuel consumption) to a nominal 1,000 hp compressor (such as the Waukesha P48 GLD which is rated at 1,200 hp at 1,400 rpm at sea level with 7,720 BTU/hp-hr fuel consumption). This equates to a required measurement range of 5 MCF/day to 220 MCF/day (3.5 to 153 SCFM) assuming a pump jack at ½ load and a GLD at full load.

2. *Separator/Tank Heaters*

I recently did a review of 536 tank and separator burners in the San Juan Basin. Burner nameplate capacity ranged from 50,000 BTU/hr to 500,000 BTU/hr. The average capacity was 340,000 BTU/hr. Since these burners only operate 5-6 months out of the year, this number equates to less than 170,000 BTU/hour on an annual basis. For some perspective, the on-demand hot water heater in my house is rated at 185,000 BTU/hour. This is a fair comparison since both devices are classed as “on demand” in that they will each turn off when conditions warrant—while in service, tank heaters only run a fraction of the time to maintain the tank at the set temperature.

The current method of reporting fuel consumed in burners is to determine if the heater had gas to it during the month, if it did then most operators

take the nameplate energy consumption times 24 hours per day for every day of the month. For a 340,000 BTU/hour burner this equates to 253 MMBTU in a 31 day month. I have worked with several operators who would report this number even if the burner only had gas to it for a single day.

In reality, the water or condensate entering a tank is usually substantially warmer than the burner set point so the burner will tend to run less than 15 minutes out of an hour on the coldest night. This means that if you shut your heater down at noon on April 1 you would have burned 1 MMBTU for the month and reported 253 MMBTU. Even if the burner has gas to it for an entire month, you burn the gas in the pilot for 744 hours in a 31 day month (typical pilot lights burn approximately 1,700 BTU/hr), but you only run the main burner for something like 186 hours—for a 340,000 BTU/hr burner you consume less than 70 MMBTU and report 253 MMBTU.

The main challenge of measuring the gas consumed in a burner is that the device must measure the pilot flow with the same level of uncertainty as you apply to the main burner flow. For a common 500,000 BTU/hr burner this means that you have to have a 294:1 “turndown ratio”. Turndown ratio is a measure of ability of a measurement device to provide similar “accuracy” over the expected operating range. According to Wikipedia, a Square Edged Orifice meter has a turndown ratio of 3:1. Even a Diaphragm Meter (similar to residential gas meters) only has a turndown ratio on the order of 80:1. A meter that can measure full burner flow would register zero with pilot flow.

With burner on/off control, there is a rapid transient in the flow as the line fills upstream of the burner followed by steady flow. A device that could successfully capture both the transient and the steady flow would have to be able to go from “off “ to the top end of its range in less than 1 second, and then hold steady for up to 15 minutes, then go to zero in a fraction of a second. There is so much uncertainty in this transient flow that any available gas measurement technology would yield a worse result than manufacturer’s estimates and Engineering calculations.

Required measurement range 0.04 to 12 MSCF/day (0.02 to 8.3 SCFM).

3. *Dehydrator Reboilers, Heater/Treaters, and Line Heaters*

These devices are similar in specific energy-use to the tank/separator heaters, but they tend to run continuously.

Dehydrators are used to remove water-vapor from a gas stream. This water vapor is adsorbed to a liquid that must then be regenerated. Regeneration takes place in a reboiler that is used to add enough heat to the liquid to cook the water out (about 8,000 BTU/lbm of water on average). Since “rich” liquid (i.e., liquid containing high levels of water) is continuously entering the reboiler, the heater is always on.

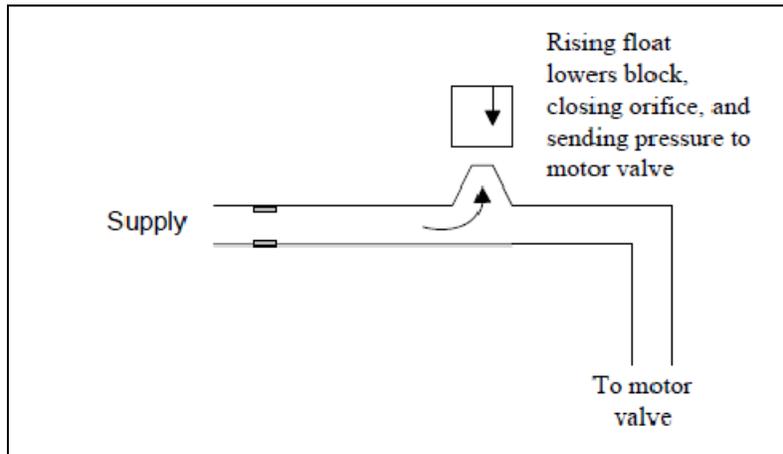

Both Heater/Treaters and Line heaters are designed to add heat to a process stream to control a process variable. For example, Line Heaters are often used in waxy crude to prevent precipitation of paraffin in the pipe causing a clogged line. A Heater/Treater is used to flash light hydrocarbons for further processing into Natural Gas and Natural Gas Liquids streams. Both of these classes of equipment have burners on the high end of the expected range for tank/separator heaters, and both operate around the clock, year-round.

Many technologies could be used to meter any of these streams with adequate repeatability and uncertainty. Whether you meter this stream or use engineering calculations, you will get very similar volumes burned.

4. *Pneumatic devices*

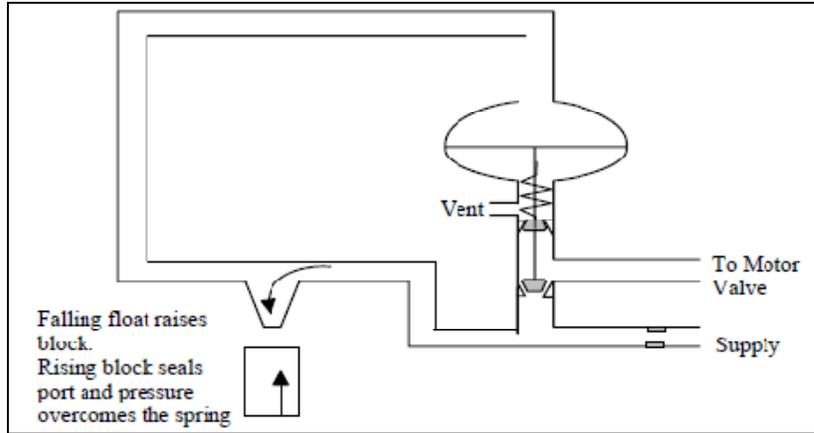

I did a study in the year 2000 (see SPE 61030) that quantified the gas used in high-bleed pneumatic devices. The project described in that paper was an economic success because we were able to replace high-bleed CEMCO throttling level-controllers with no-bleed, snap acting level controllers. The replacement controllers were markedly less effective, but they were marginally good enough and we were able to sell the gas that would have been vented in the CEMCO.

When talking about controllers (level, temperature, etc.), there are two parameters that have to be clarified: (1) Signal Type and (2) Bleed characteristics. Signal type is either “Throttling” or “Snap Acting”. Bleed characteristic is either “continuous bleed” or “no bleed”. An example of a Continuous Bleed, Throttling controller is shown below

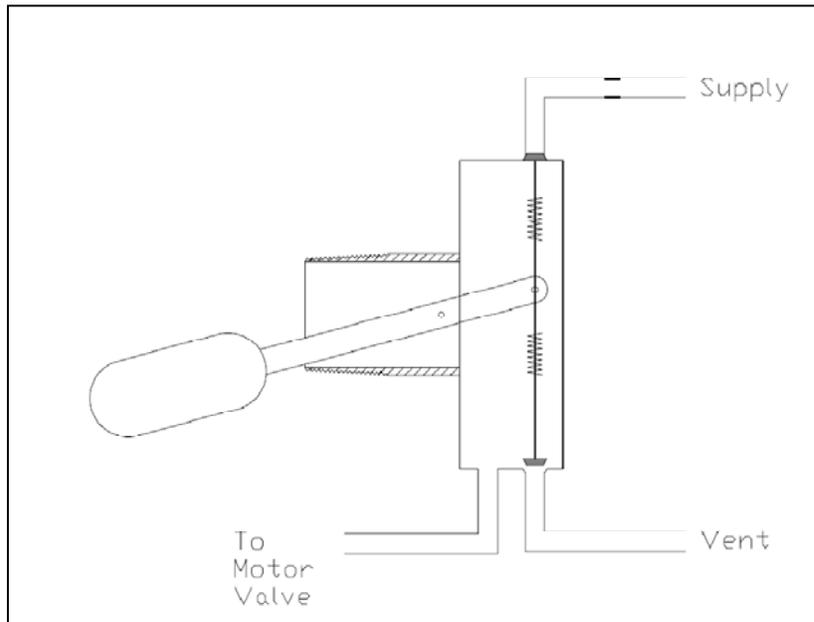

In this device, supply gas is provided through a restrictive orifice to the vent. As the block (attached to a level float for example) descends, it begins restricting the flow through the vent and sends pressure to the controlled device (a motor valve in this case). The beauty of this device is that it operates the controlled device very gently and tends to produce very stable performance. The downside is that you are venting gas anytime that the controlled device is other than fully open. Since many controlled

devices are shut most of the time (e.g. in the referenced study, we determined from a sample of over 4,000 wells that the average well cycled the separator dump valve 5 times per hour for 3 minutes each cycle) some operators have tried to reduce the amount of vented gas by turning the process over like:

In this case, the block closes the vent most of the time. When the fluid level increases, the vent opens some. When the vent is opened far enough to drop the pressure on top of the pilot below the spring setting, the pilot snaps open and sends gas to the motor valve very rapidly. At the end of the cycle, the pilot goes shut and vents the motor valve through the top valve seat. Instead of venting for 45 minutes each hour, it vents about 15 minutes per hour at the cost of throttling the flow.

A “No Bleed” controller would look something like:

This simplified example shows that when the float is down, the supply valve is shut tight and the vent valve is open. As the float starts rising, the

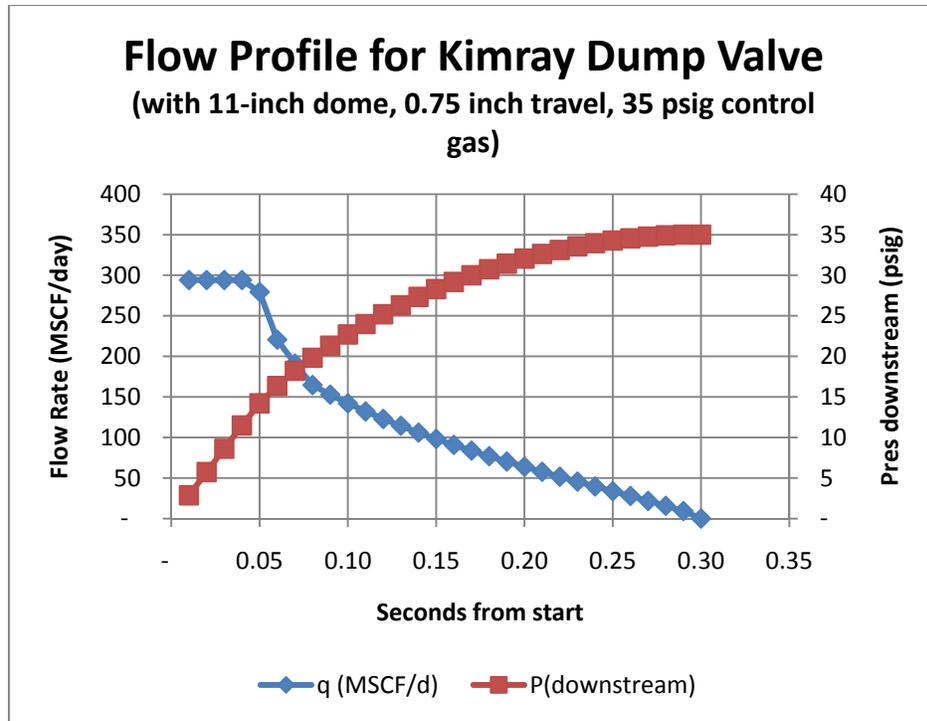

vent is closed. As it continues to rise it reaches a point where the spring tension is inadequate to hold the supply valve shut and it “snaps” open. At the end of the cycle the falling float reaches the point where it can close the supply. As it continues to fall it eventually reaches the point where the vent opens and the motor valve shuts. Most snap acting controllers are applied in service this simple and it is rare to require a pilot in this on/off service.

Notice in the description of the action of the no-bleed controller, the supply gas is used to operate the valve against a dead-end. At the end of the process the supply is shut off before the vent opens. The only gas that is vented in a no-bleed controller is the volume of the piping and the motor-valve bonnet. The supply system is never directly exposed to an open vent, so there is no ongoing “bleeding” of gas.

It is possible to throttle a controlled device with a no-bleed controller with an external pilot, but the control tends to be poor and can't be controlled very long (i.e., the devices used to sense an intermediate position are cumbersome and tend to have a “jerky” action). For practical purposes, when you decide to go to no-bleed you are locking the device into snap acting.

Continuous-bleed controllers are reasonably easy to meter the gas (a CEMCO continuous bleed, throttling level controller vents about 800 SCF/day at 35 psig supply pressure assuming that it is not venting or is venting at a reduced rate for 15 minutes per hour).

For a no-bleed controller, each time the dump valve cycles, control pressure is applied to a diaphragm to counteract spring tension and open the dump valve. At the end of the cycle, the line from the controller to the diaphragm and the diaphragm dome are vented to atmosphere. If we assume that the two devices are connected by 12 ft of 3/8 tubing (0.0092 ft³) and the diaphragm dome is 0.04 ft³ (assuming 11-inch diameter, and 0.75 inches of travel) then the volume vented each dump is 0.049 ft³. At 35 psig and 60°F then this volume is 0.157 SCF/dump. At 5 dumps per hour this equates to 19 SCF/day (2% of a high-bleed device). The flow and pressure profile will look like:

Notice that the entire cycle takes something on the order of 0.3 seconds. This flow is made up of a period of sonic velocity (Reynolds Number 996,000) followed by a period of a significant fraction of sonic velocity (Reynolds Number ends up at 648,000 for 0.65 Mach), and finally a period of flow in a normal turbulent flow regime ending with a Reynolds Number of 10,000 just before the level control is closed. A measurement device would have to be able to go from offline to 294 MSCF/d within 5 ms, and be able to do a 100:1 turndown ratio. No meter ever made has that kind of latency or turndown ratio. Some meter technologies would give you numbers (most would never register), but none will give you measurement.

B. Gas Measurement Technologies

When I talked about “meter accuracy” above I always said “accuracy”. “Accuracy” is an amazingly imprecise term that is never used by competent gas measurement professionals. The layman/advertising concept of “accuracy” is encompassed in the terms “repeatability” and “uncertainty” which have precise definitions that can be measured and used to compare the performance of a device relative to a standard or to another device.

“Repeatability” is a measure of a device’s ability to report the same output for a given set of inputs. Many things can impact a device’s repeatability. For example, turbine meters have the worst repeatability of all industrial gas measurement devices because gear lash is a random parameter that can change the speed of the turbine rotor by several percentage points independent of the magnitude of the change in measured input parameters. Acceptable

repeatability occurs when the standard deviation of the sample data is within $\pm 0.05\%$ of the mean value.

“Uncertainty” is the “dead band” of the instruments. Each component of a gas-measurement station has a defined uncertainty, usually expressed in a range around the device’s calibrated span. For example, a digital pressure transducer may have a stated uncertainty of $\pm 0.5\%$ which means that if the device has a calibrated span of 0-10,000 psig and reads 450 psig then the reading represents a value between 400 and 500 psig. Recalibrating the same device to 0-500 psig would change the meaning of 450 psig to 447.5-452.5 psig. Uncertainty is just that—you do not know where the actual number resides within the uncertainty range. A gas-measurement device is generally considered acceptable if the cumulative effect of each end-devices’ uncertainty is less than $\pm 2.0\%$ (this is based on government requirements which were set before digital instruments, about 1% of the total uncertainty is uncertainty in manual chart integration, 0.5% is from using average temperatures). Electronic Flow Measurement (EFM) devices and digital temperature/pressure instruments make normal uncertainty less than 0.5% in most square-edged orifice (AGA 3) stations today.

Another important gas-measurement concept is “latency”. Latency is a measure of the time lag between a change in flow and that change being reliably represented in the measurement device output. Every technology has some amount of latency. For example, a stopped turbine meter requires flow to overcome static friction before it starts spinning, and once it starts spinning it will tend to spool up to a high angular velocity before coming back down to report the actual flow rate. Consequently, turbine meters perform best in very steady flows—putting a turbine on the gas line to a separator dump valve would result in the meter not registering most dump events and over ranging on the few that it does register.

All gas measurement technologies are “inferential” technologies. This means that the equations infer a flow rate from some unrelated, but measurable, parameter. For example, Square Edged Orifice Measurement uses the *Bernoulli Equation* published by Daniel Bernoulli in 1738 to relate the pressure drop across a known flow restriction to a velocity, and then uses specific correlations developed for gas measurement to convert the velocity into a volume flow rate at standard conditions. The first assumption in Mr. Bernoulli’s development of his famous equation is that the fluid is both incompressible and inviscid. Neither of these assumptions is literally true in a gas flow, but the industry has proven that both assumptions are close enough to being true to allow meaningful flow rates to be estimated. At commercial velocities, highly compressible natural gas does indeed act like an incompressible fluid unaffected by fluid friction over short distances. As velocity increases toward the speed of sound or decreases to result in a Reynolds Number under 4,000 the incompressible assumption becomes progressively less valid and the uncertainty in a measurement device increases dramatically.

1. *Gas Analysis*

Many states and the federal government have agreed that small wells (typically wells making less than 100 MCF/day) would be exempt from requirements for semi-annual analysis of the gas. This decision has not caused wholesale inaccuracies and I get the impression that all the stakeholders are satisfied with annual or even less frequent gas analysis.

For the Western Climate Initiative to re-introduce semi-annual analysis requirements and to propose quarterly analysis on small streams is not a reasonable imposition.

2. *Square Edged Orifice Meters*

The operating principle is to infer a flow rate from the differential pressure across a known restriction based on measured pressure and temperature. For a clean, well conditioned flow stream the uncertainty of the reported volume is on the order of 0.5-2%. Both uncertainty and repeatability are adversely affected by 2 phase flow, dirt, and changes in flow profile and in small-volume and/or intermittent service the uncertainty can exceed $\pm 25\%$.

These meters are the most common type of gas measurement in upstream gas operations. One of the reasons for their popularity is the extensive body of research that has gone into defining the meter configuration and operating limits. This research is documented in the series of reports collected into API 14.3 (also published as AGA 3).

The standards indicate that Square Edged Orifice measurement is only appropriate in meter tubes equal to or greater than 2.000 inches internal diameter (ID) and for Reynolds Numbers above 4,000. This means that the smallest volume that can be reliably measured with this technology at 35 psig is 5 SCFM (7.2 MSCF/day).

Latency in this technology is caused by the chaos in the flow as it moves to establish a pseudo-steady-state condition. I have evaluated carefully-controlled flows at the Colorado Engineering Experiment Station (CEESI) during start-up using instruments that record pressures 100 times per second and have found that reaching repeatable flow in a Square Edged Orifice Meter can take as much as 5 minutes from a dead stop.

3. *V-Cone Meters*

The operating principle is to infer a flow rate from the differential pressure across a known restriction based on measured pressure and temperature. These meters are self-conditioning and tolerant of solids. The total uncertainty is on the order of 0.5-1%. Turndown is 10:1, and it is advertised to work down to Reynolds Numbers of 6,000 or greater.

This device has potential, but the smallest meter (1/2" ID) would register zero during pilot flow and would have a dP less than 7 inH₂O (0.25 psi)

while supplying gas to a 500,000 BTU/hr burner which would increase the uncertainty to several percent.

Latency of these meters is similar to Square Edged Orifice Meters.

4. *Turbine Meters*

The operating principle is to relate a rotor’s angular velocity to a volume flow rate. Turbine meters assume reasonably steady flow with respect to time. Changes in rate take considerable time to steady out. Latency for a change to a flowing stream can be up to a minute, for a start/stop flow it can be many minutes.

Turbine meters rely on considerable mass to spin the rotors and they rarely provide adequate results in gas flows below 50 psig.

5. *Coriolis Meters*

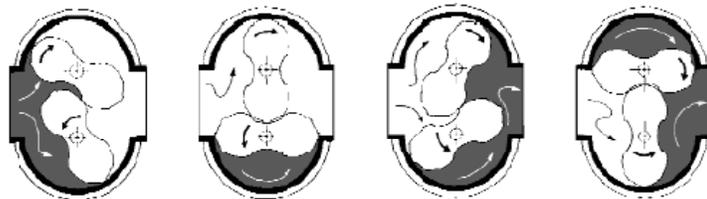

The operating principle is that the momentum of a flowing fluid will vibrate a piping loop, and that the frequency of the vibration is a function of the mass flow rate and density of the fluid. Low velocities and low pressures have a serious negative impact on uncertainty and repeatability. The MicroMotion division of Emerson has some fairly new instruments that can handle quite low flows, but the latency is similar to a turbine meter.

6. *Ultrasonic Meters*

The operating principle of Ultrasonic Meters is that there will be a Doppler Shift in the speed of sound as fluid moves away from a fixed sound-pickup point. The magnitude of this shift is a function of fluid density and fluid velocity. Low velocities and low pressures have a serious negative impact on uncertainty and repeatability.

7. *Roots Rotary Meters*

The operating principle of these positive displacement meters is to trap a fixed volume of gas within each revolution of a pair of lobes. Counting revolutions yields a volume.

This device is quite close to “measuring” gas volumes instead of “inferring” a volume from a tenuous mathematical relationship, but it is still counting revolutions instead of gas molecules.

Latency in Rotary Meters is very high due to having to start the rotors spinning again and leakage past the rotors before they start spinning.

8. *Diaphragm Meters*

The operating principle of these positive displacement meters is to fill a resilient chamber to line pressure, then that chamber is shifted to the demand side while a second chamber is filled. Each time the meter shifts chambers it records a pulse that represents a known volume.

The uncertainty, repeatability, and latency of these devices is excellent. Turndown ratio is on the order of 80:1. “Household quality” meters would handle the low flows, but materials of construction are generally inappropriate for field gas (e.g., they have considerable brass that is rapidly deteriorated by any H₂S in the flow; all of the Household meters have aluminum casings which have not stood up well to condensate service). “Industrial quality” meters are considerably more expensive and many of them still have inappropriate materials. A meter with no aluminum or “yellow metal” is difficult to find and is very expensive.

9. *Exotic/Laboratory instruments*

The volume of gas discussed in this application kept leading me to devices like “Thermal Dispersion Meters” (this meter has two probes, one is heated and one is a temperature sensor, the dT can be correlated to a mass flow rate, very long latency); and laboratory quality devices that are absolutely intolerant of free liquids and/or solids. None of these devices has a published standard for construction, installation, and operation and none has a reasonable chance of success.

10. *Conclusion*

In conclusion, the act of installing meters on the streams considered will provide a false sense of security and a net deterioration in the quality of data reported. Specifically:

- a) Engine fuel can be measured by dP inferential devices (either Square-Edged Orifice Meters or V-Cone meters), but the resulting metered volume will be very close to the theoretical data that is being collected today. Where the two numbers are significantly different I would expect that there is a measurement device error (such as an incorrect meter parameter or a backwards orifice plate) before I would expect the theoretical calculation is incorrect.
- b) No meter exists that can reliably measure both pilot flow and burner flow on a tank or separator heater if the burner is the only load on the system. If measuring these volumes becomes mandatory, then a diaphragm meter could be used to measure the pilot flow and either a Roots Meter or another diaphragm meter could be used for the burner flow. A fuel gas system with multiple engines and multiple burners could be metered with a V-Cone or Square-Edged orifice meter, but the burner volumes would only be able to be measured while the engine was consuming fuel—when the engine is not running, the burner is unlikely to register as an increment from zero.

The theoretical values for burners could be improved by putting a “valve open” clock on the supply line, which (in conjunction with manufacturer’s data and Engineering analysis) would result in a better volume than attempting to meter the gas.

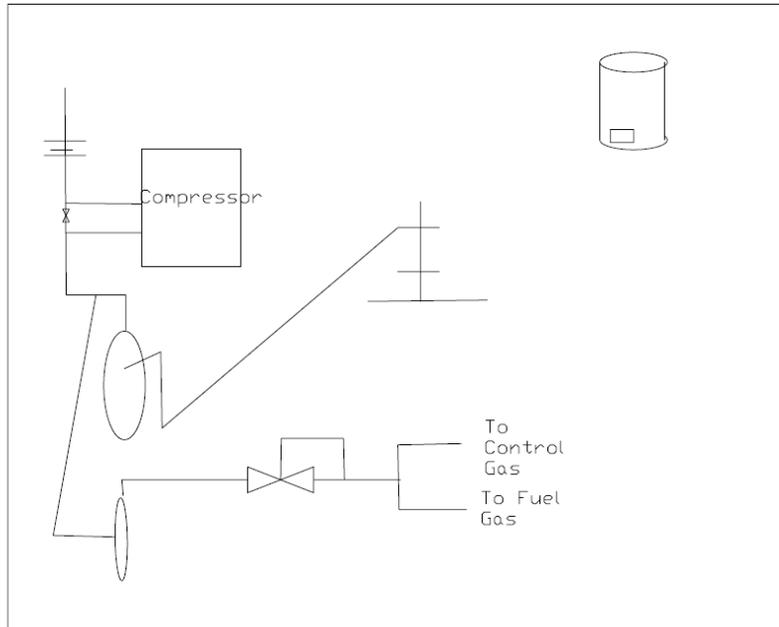

- c) Heater/Treaters, Dehy Reboilers, and Line heaters are reasonably constant loads that could be metered by several of the technologies above (the diaphragm meter would be preferred, but the small V-cone and the smallest Coriolis meter would work), but again the data would be of a similar magnitude of the data being reported today.
- d) No meter exists that can reliably measure the flow to a single dump valve or even a dozen dump valves off the same no-bleed controller. Even if a group of dump valves (three or more) were controlled off the same controller, the flow and pressure traverse would be similar to the one above and the meter would have to go from zero to 900 MCF/d in a few milliseconds then back to zero within about 1/3 second. It can’t be done.

The diaphragm meter comes the closest, but it will tend to either be over ranged for most of the flow period or will fail to register a significant portion of the tail. I would guess that the total uncertainty would be on the order of 20-30%.

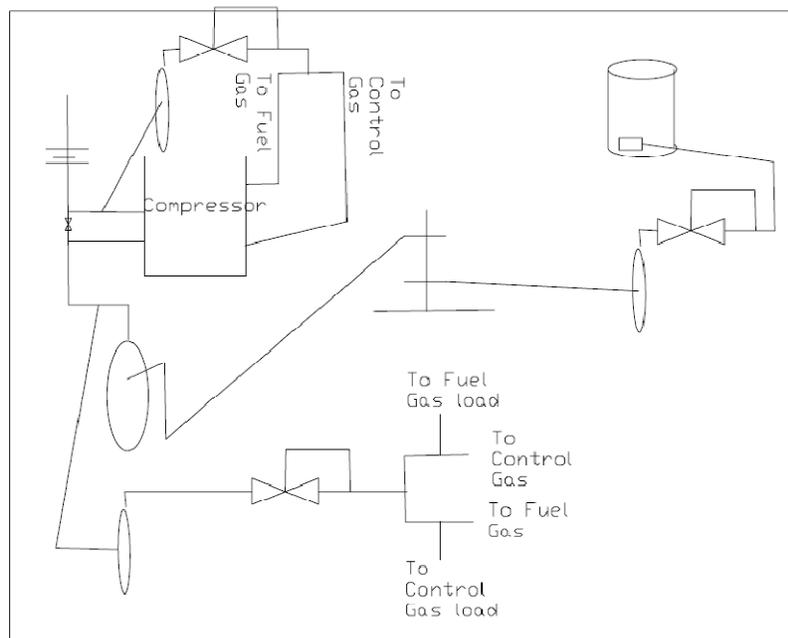

On the other hand, the flow to a continuous-bleed controller could be measured successfully with either a Roots meter or a diaphragm meter.

C. Wellsite Configurations

The reports from the Western Climate Initiative start with an assumption that there is something that can be reasonably termed a “standard” wellsite where fuel-gas measurement equipment can be “relatively easily” installed. This is patently false. The implication is that every site looks something like:

This layout brings gas from the wellbore tubing to a single separator, and then takes fuel gas off the separator outlet to supply both control requirements and fuel requirements. While there are wells that are configured like this, they are rare. A layout that would be equally as likely to occur would look like:

This layout did not suffer the expense of running a fuel gas line across the location to supply gas to the tank heater from the separator; it pulled that fuel stream from the casing valve and put a second fuel pot as a less expensive alternative to laying a line. Also, the compressor takes its fuel and control gas from an on-skid fuel-gas system. This is the normal configuration since

compressor-discharge gas is far better suited to both fuel gas and control gas applications than suction gas is.

This distributed fuel-gas supply scenario has evolved over the decades because the regulations in place at the time of site facilities-construction did not presume to tell operators how to build their sites.

III. Costs of Implementation

It is difficult to develop costs for a “typical” wellsite, “typical” automation system, or “typical” host/database modification because there is no such thing. There are companies within the WCI area of operation that don’t have any automation or measurement on their wellsites today and use Excel spreadsheets to allocate sales volumes back to wells. There are companies with home-grown automation systems that have zero flexibility and cannot be retrofit for two additional volume calculations and would have to be discarded and replaced. There are companies with purchased systems that they do not have the license to modify. There are wellsites that will be trivial to retrofit. There are wellsites that will require laying new lines and replacing production equipment.

My approach to cost estimates is to try to address the wellsites, field automation equipment, and host/database systems that I’ve worked with at my clients operations over the years. I am certain that this technique will be representative of a large number of wellsites and a number of operators, but it will not be all encompassing because it is impossible to assess all of the permutations.

Accessing EIA data at

http://www.eia.doe.gov/pub/oil_gas/petrosystem/petrosysog.html and CAPP data at <http://www.capp.ca/GetDoc.aspx?DocID=146286> for 2006 (the last year that has both US and Canadian well counts) I get the following counts of wells (after deducting 31,000 wells from California to account for Kern County):

| | Gas | Oil | Total |
|------------|--------|--------|---------|
| New Mexico | 36,202 | 15,456 | 51,658 |
| California | 3,692 | 16,197 | 19,889 |
| Utah | 5,259 | 2,574 | 7,833 |
| Montana | 6,207 | 4,199 | 10,406 |
| BC | 6,608 | 1,122 | 7,730 |
| Manitoba | 0 | 2,692 | 2,692 |
| | | | 100,208 |

For the economic analysis I’ll use 100,000 wells.

A. RTU costs

Looking at the specifications on a number of RTU's, there are high-end RTU's like the Fisher FloBoss 107/107E that can accept multiple gas-measurement inputs. These devices are not the norm for wellsite use. More common are units like the Kimray DACC 500 RTU that can only accept one flow calculation. At least 75% of the RTU's currently installed will need to be upgraded at a per-unit cost of \$4,000-5,000. Assuming that 25% of the locations do not need RTU replacement then the average for the wells is approximately \$3,500/site.

B. Host/Database costs

Host databases are very difficult to modify. Changing the Host requires that you: (1) have a place to put the new data; (2) change the data polling logic to pull the new data off the RTU to populate the new database fields; (3) add the new data to EFM editing programs; and (4) modify reporting systems to show the new data. I spent 12 years managing projects similar to this for Amoco and was involved when Amoco was making some significant changes to their host database. Amoco's changes were far less extensive than adding two measurement points that have to be reported to regulatory agencies and those changes cost \$15 million and took almost 2 years. If the average impacted user has 2,000 wells then for 100,000 wells in WCI you could expect to spend \$750 million.

C. Installation costs

After interviewing several operators and several roust-about service providers, modifying control and fuel gas systems to allow measurement and installing measurement equipment should be budgeted at 10 days of work per site. At \$1,200/day that is \$12,000/well labor. Jobs like this one are typically 60% materials (including the cost of a meter run of undecided technology) and 40% labor so total budgetary cost should be \$30,000/well—100,000 wells would cost \$3 billion.

This does not address the gas volume vented during the site blowdown and purge or the vented gas during semi-annual meter calibrations. To put that volume in perspective, for a small location without a compressor operating at 150 psig, the volume vented and later purged would be on the order of 2.5 MSCF—the same volume that would be vented in 131 days of operating a single no-bleed dump valve at 35 psig and 5 cycles/hour. The amount vented and purged during meter calibrations will depend on meter technology selected, but it is far from zero for any technology.

These costs also do not address the 2 weeks of lost production (call it 12 days at an average production rate of 100 MSCF/d) of something like 1,200 MSCF that was either deferred or more likely in competitive reservoirs was allowed to migrate to offset wells. At a \$5/MMBTU sales price the cost of this lost production is \$600 million across 100,000 wells.

D. Operating costs

Operating costs are the easiest to assess. A measurement tech can handle approximately 200 meter stations. The cost of a measurement tech with vehicle and benefits is \$150,000/year which works out to about \$750/meter/year or \$1,500/site/year.

IV. Conclusion

The idea that there would be any benefit to society from requiring gas measurement of control gas and fuel gas is patently false regardless of your position on the risk to society of gases being released to the atmosphere. A project to put this measurement in place would result in considerable vented gas, excessive capital expenditures, and excessive increases in operating costs. On the other hand the data from this expensive equipment would actually be less representative of the gases released than the current methods. In short, you would be implementing a very large cost to develop less precise data.

EPA Office: Region 3
Date: 02/13/2001
Title: Approval of Derate Proposal
Recipient: Charles Bennett
Author: Judith Katz

Subparts: Part 60, Dc, Small Indust.-Comm.-Inst. Steam Gen. Units

References: 60.40c

Abstract:

Q: Will EPA approve a boiler deration proposal from a company to limit the size of boilers at two facilities?

A: Yes. EPA Region III approves the deration proposal because it meets EPA's Policy on boiler deration for limiting the steam generation capacity of the boilers.

Re: Derate Proposal for Company Boilers

Dear Mr. Bennett:

The Philadelphia Regional Office of the U.S. Environmental Protection Agency (Region III) has received and reviewed your information submittals, dated August 22, 2000, September 21, 2000, and January 19, 2001 proposing an alternative boiler deration method for the Biglerville and Gardners plant boilers of Knouse Foods in Adams County, Pennsylvania under the New Source Performance Standards (NSPS) program, 40 CFR Part 60, Subpart Dc. EPA had previously approved a different deration method for Knouse Foods back in 1991 which entailed modifying the cam on the oil flow control valve to limit the oil fuel flow to the boilers, therefore, limiting the heat input capacity of the boilers to less than 30 million BTUs per hour, thereby, avoiding certain NSPS requirements such as the installation of continuous monitors etc. Currently, Knouse Foods has applied for a different deration procedure involving the use of the "Autoflame " combustion management system which is supposed to be able to improve the combustion efficiency of the boilers and, through the use of a microprocessor, be able to limit the heat input capacity of these emission sources. Also, Knouse is proposing to replace the generic oil flow valve with a specially-fabricated control valve specific to Knouse's flow limitation needs to reduce the maximum design heat input capacity of the Biglerville and Gardner plant boilers to less than 30 million BTUs per hour.

EPA's Policy on boiler deration in connection with the NSPS program has always required that a physical/design change be made that is both permanent and as close to impossible to modify as is technically achievable. Based on our review of the submitted materials by Knouse Foods, to date, EPA, hereby, approves Knouse's deration proposal consisting of the following elements, at a minimum:

1. Installation of two (2) Autoflame microprocessor-based burner control systems to replace the mechanical linkage systems currently in use per previous EPA approval. One is to be retrofitted onto the 1000 horsepower Johnston boiler at the Biglerville, Pennsylvania facility and one onto the 1000 horsepower Johnston boiler at the Gardners, Pennsylvania facility. The Autoflame system is comprised of two major components, namely, the Control Module containing the microcomputer and power supply and the individual servomotors for modulating the fuel valves and air damper. The commissioning mode of the computer can only be accessed by entering a proprietary password which is unknown to the facility personnel and maintained by CSI Services, the technology vendor being used to install the technology.
2. Installation of a specially fabricated oil flow control valve having an orifice manufactured by Autoflame which will only pass a compliant volume of oil and effectively limit the operation of the boilers to a compliant high end heat input of less than 30 million BTUs per hour.

This deration will physically make it impossible for these boilers to combust fuel at a rate of 30 million BTUs per hour or greater meeting EPA's current policies on boiler derating and the Company will maintain monthly records of fuel usage and fuel quality/heat content for the regulatory agencies to be able to assess Company compliance with the heat input limit. All physical changes will be made in conformance with the plans/specifications contained in the information submitted to EPA, to date.

If you should have any comments or questions in regard to this matter, do not hesitate to contact James W. Hagedorn, of my staff, at (215) 814-2161.

Sincerely,

Judith M. Katz, Director
Air Protection Division

Re: Johnston Boiler Derate Proposal

Dear Mr. Weaver:

The Philadelphia Regional Office of the U.S. Environmental Protection Agency (Region III) has received and reviewed your most recent boiler derating proposal, dated July 11, 2001, for your new Johnston boiler at your Lebanon County, Pennsylvania facility consisting of two elements; (1) Installation of Autoflame Control System Technology which utilizes a computer control scenario for fuel flow to the boiler burner limiting the maximum design heat input capacity and (2) a redesigned, resized control valve specifically machined to only allow enough oil flow to the burner to maintain a heat input capacity of 30 million BTUs per hour or less. The Company desired to do this based on the New Source Performance Standards program regulations for small boilers, codified at 40 C.F.R. Part 60, Subpart Dc, which specify certain requirements, such as the installation of a continuous opacity monitor, to be complied with if the heat input capacity to the boiler is greater than 30 million BTUs per hour.

Based on EPA's review of the proposal, and the fact that it meets the conditions provided in existing EPA Policy on the matter requiring that a permanent, physical change be made to limit the boiler steam generation capability, Region III has decided to approve the deration proposal as submitted by Keystone Protein in conjunction with the boiler manufacturer representative, CSI Services. The approved plan consists of the described equipment and procedures as delineated in Keystone Protein's submissions to the Agency dated July 11, 2001 and April 30, 2001. This response was coordinated with both Pennsylvania DEP and EPA Research Triangle Park personnel.

If you should have any comments or questions in regard to this matter, do not hesitate to contact James W. Hagedorn, of my staff, at (215) 814-2161.

Sincerely,

Judith M. Katz, Director
Air Protection Division

North Carolina Department of Environment,
Health, and Natural Resources
P.O. Box 29580
Raleigh, NC 27626-0580

SUBJ: Proposed Boiler Derate for U.S. Marine Corps Base, Camp Lejeune, NC

Dear Mr. Klimek:

We have received a letter dated October 28, 1998, from the Marine Corps Base in Camp Lejeune which requests approval of a method for derating a boiler. The proposed method is described in an October 12, 1998, letter from the Coen Company. A copy of these letters is enclosed. The proposed derate is for Boiler No. 5 at the Main Street Plant (Building HP-17), and the purpose for the derate is to exempt the boiler from the requirements of 40 CFR Part 60, Subpart Db - Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units. The boiler presently has a maximum heat input of 121 mmBtu/hr. Camp Lejeune proposes to physically reduce the capacity of the boiler by removing the existing burner and installing a new burner to permanently limit the boiler heat input capacity to 95 mmBtu/hr. Following the boiler derate, the boiler would be subject to the requirements of 40 CFR Part 60, Subpart Dc - Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units. The boiler is primarily used as an auxiliary boiler to supplement loads during start-ups and peak sharing and typically operates at 50 percent of its rated capacity. EPA has determined that the derating method proposed by Camp Lejeune, as described below, would be acceptable.

The method proposed to derate boiler no. 5 involves the removal of the existing Coen CPF-32 burner and replacement with a new burner rated at 95 mmBtu/hr. The burner will be designed to use No. 2 fuel oil or natural gas. The existing Coen windbox will be used, and the new burner will be designed to bolt to the same studs on the existing windbox. The proposed derate method also includes changes to the fuel feed systems. The new burner will provide the same or lower NOx emission levels as the existing burner, using the same induced flue gas recirculation system currently installed.

Each proposal for a boiler derate is evaluated on a case-by- case basis. An acceptable derate must consist of a permanent physical change which prevents the boiler from operating at a capacity greater than the derated value. The physical change cannot be easily undone, and a system shutdown must be required to make the change or to reverse it. The capacity of the boiler must be reduced to constitute an appropriate derate. However, changes which are made only to fuel feed systems are not acceptable for derates. Based on these criteria, the modification proposed by Camp Lejeune is acceptable for a derate. The heat input of the boiler will be limited by the installation of a new burner, which is considered part of the steam generating unit affected facility. The maximum heat input capacity should be demonstrated by operating the boiler at maximum capacity for a 24 hour period with each fuel.

Steam generating units that have a design firing rate of 90 to 100 mmBtu/hr should be required to continuously monitor fuel feed rates and maintain information regarding the fuel heat content in order to ensure that the unit does not exceed 100 mmBtu/hr of heat input. We recommend that fuel feed rates be reported as hourly averages. If any hourly fuel feed rate and corresponding heat content indicate a heat input of greater than 100 mmBtu/hr, then the steam generating unit would be considered subject to Subpart Db from the date a heat input of 100 mmBtu/hr is exceeded.

This approval of the derate method for Boiler No. 5 will become void if Camp Lejeune fails to follow the proposed procedure. If the facility wants to increase the capacity of the boiler after it has been derated, a notification of the proposed modifications must be submitted to EPA.

If there are any questions regarding the contents of this letter, please contact Keith Goff of my staff at (404)562-9137.

Sincerely yours,

R. Douglas Neeley

SUBJ: Proposed Boiler Derate for Wellman, Inc. - Johnsonville, SC

Dear Mr. Joy:

This is to acknowledge receipt of the letter from Mr. Joe Eller of your office dated July 29, 1998, and the July 21, 1998, submittal from Wellman, Inc. which proposes a boiler derate method. The proposed derate is for a Clever Brooks boiler (Boiler No. 3), which was installed in 1994 and is rated at 29.3 mmBtu/hr. The boiler is fueled by natural gas with propane or fuel oil as backup fuel. The boiler is subject to 40 CFR Part 60, Subpart Dc - Standards of Performance for Small Industrial- Commercial-Institutional Steam Generating Units. During a periodic source test, one test run resulted in actual boiler operation at 30.49 mmBtu/hr, which is above the rated capacity. In order to be exempt from the opacity standard in Sec. 60.43(c)c and the requirement in Sec. 60.47c to monitor opacity by using a continuous emission monitoring system (CEMS), Wellman proposes to derate the boiler to less than 30.0 mmBtu/hr. The opacity standard applies to the boiler during oil-fired operation. As a result of the proposed derate, the boiler heat input rating would be 25.1 mmBtu/hr. EPA has determined that the derating method proposed by Wellman, as described below, would be acceptable.

The method proposed by Wellman to derate Boiler No. 3 includes the installation of one 20 horsepower (hp) 600 volt blower motor with base spacer, one 600 hp combustion air impeller with mounting hardware, one 600 hp oil metering stem, three fuse blocks with properly sized fuses, three thermal over loads for the starter, and revised wiring diagrams. A new nameplate will be provided to relate the new reduced boiler input rating (i.e., 25.1 mmBtu/hr). The relative motor horsepower and the fixed impeller size will limit the maximum capacity of the boiler by reducing the air volume into the boiler. The modification will reduce the capacity during both natural gas and oil-fired operation, and a complete combustion tune up with both natural gas and oil will be performed.

Each proposal for a boiler derate is evaluated on a case-by- case basis. An acceptable derate must consist of a permanent physical change which prevents the boiler from operating at a capacity greater than the derated value. The physical change cannot be easily undone, and a system shutdown must be required to make the change or to reverse it. The capacity of the boiler must be reduced to constitute an appropriate derate. However, changes which are made only to fuel feed systems are not acceptable for derates. Based on these criteria, the modification proposed by Wellman is acceptable for a derate. The maximum heat input capacity should be demonstrated by operating the boiler at maximum capacity for a 24 hour period with each fuel. An ongoing program will also need to be implemented to monitor the actual heat input of the boilers by maintaining records of fuel consumption (as already required by Sec. 60.48c(g)) and fuel heating value.

This approval of the derate method for Boiler No. 3 will become void if Wellman fails to follow the proposed procedure. If the facility wants to increase the capacity of the boiler after it has been derated, a notification of the proposed modifications must be submitted to EPA.

If there are any questions regarding the contents of this letter, please contact Keith Goff of my staff at (404)562-9137.

Sincerely yours,

R. Douglas Neeley

Re: Non Applicability to NSPS Subpart Db

Dear Mr. Bloom:

This letter responds to your letters dated September 19, 2000, and January 8, 2001, which request EPA's applicability determination on Lamb-Weston's Boiler #1 at American Falls, Idaho.

Based on the information you have provided, the 133 million Btu/hour burner in the boiler had been replaced with a new low-NOx burner whose manufacturer's rating is 98 million Btu/hour. Results from performance tests conducted by Lamb-Weston also confirm that the boiler's heat input does not exceed 98 million Btu/hour. EPA has determined that NSPS Subpart Db ceases to apply to this boiler due to this change in heat input and because the boiler has met the following boiler derate criteria:

1. Be accomplished through a permanent physical change which will preclude it from operating at a capacity greater than the derated value;
2. Be a change that cannot be easily undone;
3. Requires a system shutdown to make the change or to reverse the change; and,
4. Reduced the capacity of the boiler without the installation of a feed rate governor.

In addition, information you have provided indicates this boiler was installed in 1986, and has not been "modified" within the meaning of 40 C.F.R. Sec. 60.14, or "reconstructed" within the meaning of 40 C.F.R. Sec. 60.15. Therefore, EPA also determines that this boiler is not subject to NSPS, Subpart Dc.

In summary, based on information you have provided, EPA has determined that Lamb-Weston's Boiler #1 at American Falls, Idaho, is no longer subject to NSPS Subpart Db, and is also not subject to NSPS Subpart Dc. In the event Lamb-Weston changes the boiler's capacity to above 100 million Btu/hour, then this applicability determination becomes invalid.

If you have any questions regarding this response, please contact Mr. Kai Hon Shum of my staff at (206) 553-2117.

Sincerely,

Douglas E. Hardesty, Manager
Federal and Delegated Air Programs Unit

Subparts: Part 60, D, Fossil Fuel Fired Steam Gen. (post 8/17/71)

Abstract:

Q: Will EPA allow a facility to derate a boiler to less than 250 mmBtu/hr by limiting the feed rate of coal and fuel oil?

A: No. Changes which are made only to fuel feed systems are not acceptable for derating boilers.

Letter:

December 30, 2002

4APT-ATMB

Mr. Mike Aldridge
Environmental Engineering Supervisor
Technical Services Division
North Carolina Department of Environment
and Natural Resources
Division of Air Quality
1641 Mail Service Center
Raleigh, North Carolina 27699-1641

Dear Mr. Aldridge:

We have received a November 4, 2002, letter from Weyerhaeuser Company in Plymouth, North Carolina requesting approval of a method for derating a boiler. The proposed derate is for Hog Fuel Boiler (HFB) No. 1 at the Weyerhaeuser pulp and paper manufacturing facility. Approval of the derate would prevent applicability of New Source Performance Standards (NSPS) Subpart D - "Standards of Performance for Fossil-Fuel-Fired Steam Generators for Which Construction is Commenced After August 17, 1971." The boiler is presently permitted to fire coal, No. 6 fuel oil, waste oil and sludge, hog fuel (wood) and High Volume Low Concentration non-condensable gases. Hog fuel is the primary fuel, and coal and oil are auxiliary fuels. The maximum heat input rate from fossil fuel is greater than 250 million Btu/hour. Based on our review of Weyerhaeuser's request, the proposed method of derating the boiler, as described below, is not acceptable. Guidance concerning an acceptable derate is provided in this letter.

Weyerhaeuser's proposed derate is based on limiting the fossil fuel heat input to HFB No.1 by using the following methods. The coal feeder rate (tons/hour) is now variable depending on the speed of the feeder, which is controlled by a variable speed drive. The company proposes to make the drive a constant speed drive, which would limit the coal feed to a constant rate. The change can be completed in about two weeks. Weyerhaeuser has indicated that the pumps used to deliver No. 6 fuel oil to HFB No. 1 are positive displacement pumps, which deliver fuel to the boiler at a constant flow rate regardless of the pressure in the system, up to the point of pump failure. The company plans to change the pumps to restrict the flow through the oil guns. The change to the oil pumps may take three to five months to complete. The company may also reduce the number of oil guns in the boiler from six to two or three, depending on the outcome of engineering design work.

Based on previous determinations concerning boiler derates, an acceptable derate must consist of a permanent physical change which prevents the boiler from operating at a capacity greater than the derated value. The physical change cannot be easily undone, and a system shutdown must be required to make the change or to reverse it. The capacity of the boiler must be reduced to constitute an appropriate derate. As indicated in previous determinations concerning derates, changes which are made only to fuel feed systems are not acceptable. It has previously been determined that changes in system capacity such as switching to smaller fans with smaller capacity in combination with the use of smaller pipes and pumps to control fuel feed rate would be acceptable. Based on these criteria, we have determined that the method proposed by Weyerhaeuser for derating HFB No. 1 is not acceptable since it only results in changes to fuel feed systems.

This determination has been provided with assistance from the United States Environmental Protection Agency's Office of Enforcement and Compliance Assurance (OECA). If there are any questions regarding this letter, please contact Keith Goff of the EPA Region 4 staff at (404) 562-9137.

Sincerely,

Beverly H. Banister
Director
Air, Pesticides & Toxics Management Division

Re: NSPS Subpart Db Applicability

Dear Mr. Bloom:

This letter responds to your January 21, 2000, request to the United States Environmental Protection Agency, Region 10 (Region 10), to derate Boiler No. 1. The boiler commenced construction after June 19, 1984, and its heat input capacity is greater than 100 MMBtu/hr. Thus, the requirements of 40 C.F.R. Part 60, Subpart Db - Standards of Performance for Industrial - Commercial - Institutional Steam Generating Units currently apply. You indicate, however, that the replacement of the original burner with a Forney Corporation NOx Miser natural gas burner has decreased the boiler's heat input capacity such that it is now less than 100 MMBtu/hr. You propose to conduct a performance test to determine the boiler's new maximum heat input capacity.

It is our understanding that the installation of the Forney burner is a permanent physical change which will preclude the boiler from operating at a capacity greater than 98 MMBtu/hr. The burner installation is a change that cannot be easily undone, and requires a system shutdown to accomplish or reverse. Therefore, Region 10 has determined that you are eligible to derate the boiler's heat input capacity. The derated value shall be determined by conducting a performance test in accordance with procedures approved by Region 10.

Submit a test plan to Region 10 for approval prescribing the methods to determine the boiler's heat input capacity. Region 10 shall act upon your test plan within 30 calendar days of receipt.

If you have any questions regarding our response, please contact Dan Meyer of my staff at (206) 553-4150.

Sincerely,

Douglas E. Hardesty, Manager Federal and Delegated Air Programs Unit

Subparts: Part 60, Db, Indust.-Comm.-Inst. Steam Gen. Units

Abstract:

Q: Due to a permanent physical change to a boiler, its heat input capacity decreased to less than 100 MMBtu/hr. Will the boiler be subject to the requirements of NSPS Subpart Db?

A: No. The boiler is no longer subject to the requirements of NSPS Subpart Db. However, given that the boiler commenced construction after June 9, 1989, the requirements of NSPS Subpart Dc apply.

Letter:

Reply To
Attn Of: OAQ-107

Mr. Dave Kubosumi
Engineering Manager
Lamb Weston, Inc.
856 Russet Street
Twin Falls, Idaho 83303-0128

Re: NSPS Subpart Db Applicability

Dear Mr. Kubosumi:

This letter responds to your November 8, 1999, request to the United States Environmental Protection Agency, Region 10 (Region 10), for an applicability determination for Boiler No. 1. The boiler commenced construction after June 19, 1984, and its heat input capacity is greater than 100 MMBtu/hr. Thus, the requirements of 40 C.F.R. Part 60, Subpart Db - Standards of Performance for Industrial - Commercial - Institutional Steam Generating Units applied. Subsequent to a recent permanent physical change to the boiler, its heat input capacity decreased such that it is now less than 100 MMBtu/hr. For the reasons discussed below, Region 10 has determined that the boiler is no longer subject to the requirements of 40 C.F.R. Part 60, Subpart Db.

Lamb Weston has successfully demonstrated that the boiler's heat input capacity is less than 100 MMBtu/hr. On November 3, 1999, the boiler was operated at full load during four 15- minute periods. The draft fan motor was operating at full speed and air inlet dampers were fully open. Maximum natural gas flow rates were maintained so as to optimize combustion efficiency. The highest 15-minute heat input value recorded by the facility was 96.6 MMBtu/hr.

Lamb Weston has also successfully documented that the boiler's heat input capacity has been reduced by replacing a 200 horsepower (hp) draft fan motor with a 75 hp motor, effectively reducing fan speed from 1725 revolutions per minute (rpm) to 840 rpm. As prescribed in our June 30, 1999, letter to Lamb-Weston, a boiler derate must be accomplished in accordance with the following criteria:

1. Be accomplished through a permanent physical change which will preclude it from operating at a capacity greater than the derated value.
2. Be a change that cannot be easily undone
3. Require a system shutdown to make the change or to reverse it
4. Reduce the capacity, not the feed rate, of the boiler.

The replacement of the draft fan motor satisfies all four criteria.

Pursuant to the conditions of our June 30, 1999, letter, you shall continue to monitor and maintain records of the natural gas flow rate on a continuous basis. Read and record natural gas flow rate (ft³/min), no less frequently than on a continuous basis. Report to Region 10 and the Idaho Division of Environmental Quality on a quarterly basis the natural gas fired heat input of the boiler (MMBtu/hr) for each boiler operating day.

Given that the boiler commenced construction after June 9, 1989, the boiler is subject to the requirements of 40 C.F.R. Part 60, Subpart Dc - Standards of Performance for Small Industrial - Commercial - Institutional Steam Generating Units, effective the date of this letter. Please note the monitoring and recordkeeping requirements for natural gas fired boilers in 40 C.F.R. Sec. 60.48c(g).

In summary, Region 10 has determined that Boiler No. 1 is no longer subject to the requirements of NSPS Subpart Db. In the event you ever intend to undo the aforementioned physical change such that the boiler's capacity increases above 100 MMBtu/hr, then this applicability determination becomes invalid.

If you have any questions regarding our response, please contact Dan Meyer of my staff at (206) 553-4150.

Sincerely,

Douglas E. Hardesty, Manager Federal and Delegated Air Programs Unit

Abstract:

Q: Will EPA approve a proposal under New Source Performance Standards (NSPS) subpart Db to derate a boiler at North Carolina Baptist Hospital which consists of limiting the combustion air flow by welding a mechanical stop to limit the travel of the inlet valve dampers?

A: No. The proposed derate does not meet the criteria specified in other proposals approved by EPA. In order to be an acceptable derate, a permanent physical change must be made. The proposed method is not considered permanent and could be reversed rather easily.

Letter:

October 27, 2003

4APT-ARB

Mr. Robert R. Fulp
Director
Forsyth County Environmental Affairs Department
537 North Spruce Street
Winston-Salem North Carolina 27101

Dear Mr. Fulp:

We have received the enclosed September 30, 2003, request from North Carolina Baptist Hospital in Winston-Salem, North Carolina for approval of a proposed method for derating a boiler. The proposed derate is for a boiler which has a heat input capacity of 105 million Btu/hour and is subject to New Source Performance Standards (NSPS) Subpart Db - "Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units." As indicated in conversations with Mr. Greg Nichols, from North Carolina Baptist Hospital, the primary fuel for the boiler is natural gas, and fuel oil is used as a backup fuel. By derating the boiler to less than 100 million Btu/hour, it would no longer be subject to NSPS Subpart Db but would be subject to NSPS Subpart Dc - "Standards of Performance for Small Industrial-Commercial- Institutional Steam Generating Units." Based on our review of the proposed boiler derate, we have determined that it is not acceptable. Guidance concerning an acceptable derate is provided in this letter.

Based on previous determinations concerning boiler derates, an acceptable derate must consist of a permanent physical change which prevents the boiler from operating at a capacity greater than the derated value. The physical change cannot be easily undone, and a system shutdown must be required to make the change or to reverse it. The capacity of the boiler must be reduced to constitute an appropriate derate. As indicated in previous determinations, changes which are made only to fuel feed systems are not acceptable. It has previously been determined that changes in system capacity such as switching to smaller fans with smaller capacity in combination with the use of smaller pipes and pumps to control fuel feed rate would be acceptable.

The boiler derate proposed by North Carolina Baptist Hospital is based on limiting the combustion air flow to the boiler to reduce the capacity. The facility has proposed to do so by welding a mechanical stop to limit the travel of the inlet valve dampers. The proposal indicates that along with the mechanical stop, the control span of the actuator will be adjusted. To support their proposal, the facility enclosed with their request a previous Environmental Protection Agency (EPA) Region 4 determination dated December 14, 1998. That determination approved a boiler derate proposal which was also based on limiting the capacity of the boiler by reducing the combustion air volume. While limiting the combustion air flow is an acceptable method of derating a boiler, the particular method described by North Carolina Baptist Hospital is not acceptable. Since the method proposed by North Carolina Baptist Hospital does not constitute a permanent physical change to the affected facility, it is not acceptable. The proposed changes to the boiler could also be reversed rather easily, unlike the changes approved in the December 14, 1998, determination.

If there are any questions regarding this letter, please contact Keith Goff of the Region 4 staff at (404)562-9137.

Category: NSPS
EPA Office: CAMPD
Date: 12/21/2004
Title: Autoflame Control System Technology for Boiler Derate
Recipient: R. Douglas Neeley
Author: Michael S. Alushin
Comments: This comment supercedes previous determinations filed as ADI Control Nos. 0100016 and 0100055.

Subparts: Part 60, D, Foss. Fuel Fired Steam Gen. (post 8/17/71)
Part 60, Da, Elec. Util. Steam Gen. Units (post 9/18/78)
Part 60, Db, Indust.-Comm.-Inst. Steam Gen. Units
Part 60, Dc, Small Indust.-Comm.-Inst. Steam Gen. Units

References: 60.40a
60.40b
60.40c

Abstract:

Q: Will EPA approve the Autoflame Control System Technology to derate a boiler for purposes of determining applicability of the NSPS subparts for boilers (40 CFR part 60, subparts D, Da, Db, and Dc)?

A: No. EPA will not approve the Autoflame Control System Technology because derate methods that are based solely on fuel feedrate control, as the Autoflame Control System Technology is, are not acceptable derate methods for determining the rated capacity of a boiler under NSPS subparts D, Da, Db, and Dc.

Letter:

MEMORANDUM

SUBJECT: New Source Performance Standards for Industrial-Commercial-Institutional Steam Generating Units - Use of Autoflame for Boiler Derates

FROM: Michael S. Alushin, Director Compliance Assessment and Media Program Division
Office of Compliance

TO: R. Douglas Neeley, Chief
Air Toxics and Monitoring Branch
EPA Region 4

This memorandum is in response to a request for assistance from Keith Goff of your staff regarding a letter received on December 22, 2003, from the North Carolina Baptist Hospital (NCBH) located in Winston-Salem, North Carolina. NCBH seeks approval for the use of the Autoflame Control System Technology as a boiler derate method to avoid compliance requirements under the New Source Performance Standards (NSPS) for steam generating units. In their request, NCBH relies upon prior approval of the Autoflame Control System Technology given by EPA Region 3.

According to information provided to us by EPA Region 3, the Autoflame Control System Technology consists of two elements: 1) the installation of a control module (microcomputer and power supply) to control fuel flow to the boiler burner limiting the maximum design heat input capacity; and 2) the installation of a redesigned, resized control valve specifically machined to limit the maximum fuel flow to the boiler. The combination of these two elements limits the fuel feedrate to a boiler.

Beginning in 1977, EPA policy regarding boiler derates has been communicated in several applicability determinations. According to these applicability determinations, approval of a boiler derate is based on the following requirements. The derate must:

- 1) Be accomplished through a permanent physical change which will preclude it from operating at a capacity greater than the derated value;
- 2) Be a change that can not be easily undone;
- 3) Require a system shutdown to make the change or to reverse the change;
- 4) Reduce the capacity of the boiler, not the fuel feedrate to the boiler.

Based on these requirements, the Autoflame Control System Technology would not qualify as an acceptable derate since this system is solely used for fuel feedrate control. In addition, existing EPA applicability determinations have concluded that the installation of a weld plate or orifice, such as a resized control valve, to control fuel flow, would not be an acceptable derate method because it is neither permanent, nor difficult to reverse. Therefore, EPA cannot approve the use of the Autoflame Control System Technology, as described above, as a method for derating boilers to avoid requirements under any of the NSPS for steam generating units (i.e., Subparts D, Da, Db, and Dc).

The two EPA Region 3 determinations approving the use of the Autoflame Control System

Technology as a derate method were based on erroneous technical advise and are in conflict with our current EPA policy regarding boiler derates. Since we have no intention of changing our current boiler derate policy, the EPA Region 3 applicability determinations are not precedence for the NCBH request or any future requests.

The two EPA Region 3 applicability determinations will remain available through the EPA Applicability Determination Index (ADI). However, a statement will be added to these applicability determinations indicating that they were issued erroneously and do not represent official EPA policy.

If you have any questions concerning this response, please contact Gregory Fried at (202) 564-7016.

Title: Boiler Derate Proposal
Recipient: Robert Fulp
Author: Beverly Banister
Comments: See referenced determinations filed as ADI Control Nos. 0400003 and 0500017.

Subparts: Part 60, Db, Indust.-Comm.-Inst. Steam Gen. Units
Part 60, Dc, Small Indust.-Comm.-Inst. Steam Gen. Units

References: 60.40b
60.40c

Abstract:

Q: Will EPA approve a boiler derate proposal, under 40 CFR part 60, subpart Db, which is based on changes made to limit the fuel feed rate?

A: No. EPA will not approve this boiler derate proposal under NSPS subpart Db because it is based only on a reduction in the fuel feed rate and does not result in a reduction in boiler capacity, thus failing to comply with EPA's policy on derates.

Letter:

4APT-ATMB

Mr. Robert R. Fulp
Director
Forsyth County Environmental Affairs Department
537 North Spruce Street
Winston-Salem North Carolina 27101

Dear Mr. Fulp:

We have received the enclosed December 1, 2003, request from North Carolina Baptist Hospital (NCBH) in Winston-Salem, North Carolina for approval of a proposed method for derating a boiler. The proposal is for a boiler which has a heat input capacity of 105 million Btu/hour and is subject to New Source Performance Standards (NSPS) Subpart Db - "Standards of Performance for industrial-Commercial- Institutional Steam Generating Units." The primary fuel for the boiler is natural gas, and fuel oil is used as a backup fuel. By derating the boiler to less than 100 million Btu/hour, it would no longer be subject to NSPS Subpart Db but would be subject to NSPS Subpart Dc - "Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units." Based on a review of the NCBH proposal, we have determined that it does not comply with the Environmental Protection Agency's (EPA's) policy on derates and is not acceptable.

The derate method proposed by NCBH consists of the installation of two Autoflame microprocessor- based burner control systems to replace the mechanical linkage systems currently in use. The Autoflame system is comprised of two major components, which are the control module containing the microcomputer and power supply and the individual servomotors for modulating the fuel valves and air damper. The commissioning mode of the computer can only be accessed by entering a proprietary password which is unknown to the facility personnel and maintained by CSI Services, the vendor which would install the technology. The proposed derate also consists of the installation of a specially fabricated oil flow control valve having an orifice manufactured by Autoflame. The oil flow control valve will restrict the volume of oil and limit the operation of the boilers to a heat input of less than 100 million BTUs per hour. As justification for their proposal, NCBH has referenced previous EPA Region 3 determinations approving this method for derating boilers.

EPA's policy concerning boiler derates has been described in prior EPA determinations and in our October 27, 2003, response to a previous NCBH proposal for a derate. An acceptable derate must consist of a permanent physical change which prevents the boiler from operating at a capacity greater than the derated value. The physical change cannot be easily undone, and a system shutdown must be required to make the change or to reverse it. The capacity of the boiler must be reduced to constitute an appropriate derate. Changes which are made only to fuel feed systems are not acceptable.

Since the NCBH proposal is based only on a reduction in the fuel feed rate and does not result in a reduction in boiler capacity, it does not comply with EPA's policy on derates. To ensure compliance with EPA's policy, this determination is being provided with assistance from EPA's Office of Enforcement and Compliance Assurance (OECA). Enclosed with this letter is a December 21, 2004, memorandum from OECA regarding their review of the NCBH proposal and EPA's policy on derates.

If there are any questions regarding this determination, please contact Keith Goff of the Region 4 staff at (404)562-9137.

Sincerely yours,

Beverly H. Banister

Abstract:

Q: Will EPA approve under 40 CFR part 60, subparts Db and Dc, a boiler derate proposal from North Carolina Baptist Hospital in Winston-Salem, North Carolina, which is based on changes made to the natural gas burner?

A: Yes. EPA approves the proposed derate method under NSPS subparts Db and Dc, as it will reduce the capacity of the boiler and will comply with EPA's policy on derates.

Letter:

4APT-ARB

Mr. Robert R. Fulp
Director
Forsyth County Environmental Affairs Department
537 North Spruce Street
Winston-Salem North Carolina 27101

Dear Mr. Fulp:

We have received the enclosed April 26, 2005, request for a boiler derate from North Carolina Baptist Hospital (NCBH) in Winston-Salem, North Carolina. The proposal is for a boiler which has a heat input capacity of 105 million Btu/hour and is subject to New Source Performance Standards (NSPS) Subpart Db - "Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units." The primary fuel for the boiler is natural gas, and fuel oil is used as a backup fuel. By derating the boiler to less than 100 million Btu/hour, it would no longer be subject to NSPS Subpart D b but would be subject to NSPS Subpart Dc - "Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units." NCBH proposes to modify the gas burner in the boiler by installing new burner tips, which will limit the heat input capacity to less than 100 mmBtu/hr. The oil supply to the boiler and the oil burner will be removed, so the boiler will no longer be capable of burning fuel oil. We have determined that the NCBH proposal complies with the Environmental Protection Agency's (EPA's) policy on derates and is acceptable.

The proposal is described in more detail in the enclosed May 5, 2005, letter from the Coen Company, the manufacturer of the boiler. As described in the proposal, new gas burner tips will be provided which will limit the flow of natural gas to the burner to less than 100 mmBtu/hr. The burner tips will be redesigned with smaller orifices. To replace the burner tips, the boiler will need to be shutdown and then cooled for about two days. A contractor will enter the furnace to replace the old burner tips with the new ones. The unit will then be re-calibrated by a Coen service engineer to adjust the new air/fuel ratio curves based on the new maximum capacity, which can take up to five more days. To eliminate the capability of firing fuel oil, the oil supply and the oil burner will be removed from the boiler.

Each proposal for a boiler derate is evaluated on a case-by-case basis. An acceptable derate must consist of a permanent physical change which prevents the boiler from operating at a capacity greater than the derated value. The physical change cannot be easily undone, and a system shutdown must be required to make the change or to reverse it. The capacity of the boiler must be reduced to constitute an appropriate derate. Changes which are made only to fuel feed systems are not acceptable. Based on these criteria, the modification proposed by NCBH is acceptable for a derate. The heat input of the boiler will be limited by modifying the burner, which is considered part of the steam generating unit affected facility. The maximum heat input capacity should be demonstrated by operating the boiler at maximum capacity for a 24 hour period.

Steam generating units that have a design firing rate of 90 to 100 mmBtu/hr should be required to continuously monitor fuel feed rates and maintain information regarding the fuel heat content in order to ensure that the unit does not exceed a heat input of 100 mmBtu/hr. We recommend that fuel feed rates be reported as hourly averages. If any hourly fuel feed rate and corresponding heat content indicate a heat input of greater than 100 mmBtu/hr, the steam generating unit would then be considered subject to Subpart Db from the date a heat input of 100 mmBtu/hr is exceeded.

This approval of the derate method will become void if NCBH fails to follow the proposed procedure. If the facility wants to increase the capacity of the boiler after it has been derated, a

notification of the proposed modifications must be submitted to EPA.

This determination has been provided with assistance from the EPA's Office of Enforcement and Compliance Assurance (OECA). If there are any questions regarding this determination, please contact Mr. Keith Goff of the Region 4 staff at (404)562-9137.

Sincerely yours,

Beverly H. Banister

60.40c

Abstract:

Q: Does EPA approve a boiler derate proposal, under 40 CFR part 60, subpart Db, based on changes made to the natural gas burner at North Carolina Baptist Hospital in Winston-Salem, North Carolina?

A: Yes. EPA approves this proposal under NSPS subpart Db because it has determined that the proposed derate method, which includes installing new boiler tips limiting the heat input capacity to 100mmBtu/hr and eliminating the burning of fuel oil, will reduce the capacity of the boiler and will comply with EPA's policy on derates.

Letter:

4APT-ARB

Mr. Robert R. Fulp
Director
Forsyth County Environmental Affairs Department
537 North Spruce Street

Winston-Salem North Carolina 27101

Dear Mr. Fulp:

We have received the enclosed April 26, 2005, request for a boiler derate from North Carolina Baptist Hospital (NCBH) in Winston-Salem, North Carolina. The proposal is for a boiler which has a heat input capacity of 105 million Btu/hour and is subject to New Source Performance Standards (NSPS) Subpart Db - "Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units." The primary fuel for the boiler is natural gas, and fuel oil is used as a backup fuel. By derating the boiler to less than 100 million Btu/hour, it would no longer be subject to NSPS Subpart Db but would be subject to NSPS Subpart Dc - "Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units." NCBH proposes to modify the gas burner in the boiler by installing new burner tips, which will limit the heat input capacity to less than 100 mmBtu/hr. The oil supply to the boiler and the oil burner will be removed, so the boiler will no longer be capable of burning fuel oil. We have determined that the NCBH proposal complies with the Environmental Protection Agency's (EPA's) policy on derates and is acceptable.
