PREFACE

The California Air Resources Board (ARB) released a Draft Environmental Analysis (EA) for the Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities (Proposed Regulation) on June 3, 2016 for a 45-day public review and comment period that concluded July 18, 2016. A total of 47 comment letters were received on the Proposed Regulation during the public comment periods, 2 of which addressed the Draft EA. None of the comments received at the Board Hearing held on July 21, 2016 mentioned or raised an issue related to the EA or an environmental issue discussed in the Draft EA.

ARB staff made minor modifications to the EA based on responses to comments and other updates. To facilitate identifying modifications to the document, modified text is presented in the final EA with strike-through for deletions and underline for additions. None of the modifications alter any of the conclusions reached in the EA, introduce new significant effects on the environment, or provide new information of substantial importance relative to the EA. As a result, these minor revisions do not require recirculation of the draft document pursuant to the California Environmental Quality Act (CEQA) Guidelines, California Code of Regulations, title 14, section 15088.5, before the Board considers the Proposed Regulation.
This page intentionally left blank.
1. INTRODUCTION

The California Air Resources Board (ARB) staff prepared and circulated for public review a Draft EA (EA) for the Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities (Proposed Regulation). The Proposed Regulation and EA were released for public review on June 3, 2016. The public comment period concluded on July 18, 2016. Minor changes to the Proposed Regulation, which did not impact the EA, were also released for an additional public comment on February 3, 2017. This public comment period ended on February 21, 2017.

ARB received a total of 47 comment letters through the comment docket opened for the Proposed Regulation during that time. Comments are available on the ARB website at: https://www.arb.ca.gov/lispub/comm/bccommlog.php?listname=oilandgas2016. Pursuant to ARB’s certified regulatory program, staff carefully reviewed all the comment letters received to determine which ones raised substantive environmental issues related to the EA requiring a written response.

This document presents those comments and ARB staff’s written responses for the Board to consider for approval prior to taking final action on the Proposed Regulation. Although this document includes written responses only to those comments related to the EA, all of the public comments were considered by staff and provided to the Board members for their consideration. The full comment letters, which mentioned or raised an issue related to the EA or an environmental issue discussed in the Draft EA, are provided in Attachment 1 of this document. For reference purposes, this document includes a summary of each comment followed by the written response.

Following consideration of the comments received on the EA and during the preparation of the responses to those comments, ARB revised the EA to prepare the Final EA released March 10, 2017.

A. Requirements for Responses to Comments

These written responses to public comments on the EA are prepared in accordance with ARB’s certified regulatory program to comply with the California Environmental Quality Act (CEQA). ARB’s certified regulatory program states in part:

California Code of Regulations, title 17 section 60007. Response to Environmental Assessment

(a) If comments are received during the evaluation process which raise significant environmental issues associated with the proposed action, the staff shall summarize and respond to the comments either orally or in a supplemental written report. Prior to taking final action on any proposal for which significant environmental issues have been raised, the decision maker shall approve a written response to each such issue.
Public Resources Code section 21091 also provides guidance on reviewing and responding to public comments in compliance with CEQA. While this section refers to environmental impact reports, proposed negative declarations, and mitigated negative declarations, rather than an EA, it contains useful guidance for preparing a thorough and meaningful response to comments.

Public Resources Code section 21091, subdivision (d) states:

1. The lead agency shall consider comments it receives … if those comments are received within the public review period.

2. (A) With respect to the consideration of comments received …, the lead agency shall evaluate any comments on environmental issues that are received from persons who have reviewed the draft and shall prepare a written response pursuant to subparagraph (B). The lead agency may also respond to comments that are received after the close of the public review period.

(B) The written response shall describe the disposition of each significant environmental issue that is raised by commenters. The responses shall be prepared consistent with section 15088 of Title 14 of the California Code of Regulations.

California Code of Regulations, title 14, section 15088 (CEQA Guidelines) also includes useful information and guidance for preparing a thorough and meaningful response to comments. It states, in relevant part, that specific comments and suggestions about the EA that are at variance from the lead agency’s position must be addressed in detail with reasons why specific comments and suggestions were not accepted. Responses must reflect a good faith, reasoned analysis of the comments.

California Code of Regulations, title 14, section 15088 (a – c) states:

(a) The lead agency shall evaluate comments on environmental issues received from persons who reviewed the draft EIR and shall prepare a written response. The Lead Agency shall respond to comments received during the noticed comment period and any extensions and may respond to late comments.

(b) The lead agency shall provide a written proposed response to a public agency on comments made by that public agency at least 10 days prior to certifying an environmental impact report.

(c) The written response shall describe the disposition of significant environmental issues raised (e.g., revisions to the proposed project to mitigate anticipated impacts or objections). In particular, the major environmental issues raised when the Lead Agency’s position is at variance with recommendations and objections raised in the comments must be addressed in detail giving reasons why specific comments and suggestions were not accepted. There must be good faith, reasoned analysis in response. Conclusory statements unsupported by factual information will not suffice.
B. Comments Requiring Substantive Responses

ARB is required to prepare substantive responses only to those comments that raise “significant environmental issues” associated with the proposed action, as outlined in California Code of Regulations, title 17, section 60007(a). As stated above, of the total 47 comment letters submitted on the comment docket for the Proposed Regulation, staff determined that 2 of the letters mentioned or raised an issue related to the EA or an environmental issue discussed in the Draft EA. Staff was conservatively inclusive in determining which letters warranted a written response.

Comments on the Draft EA were considered by staff and provided to the Board members for their consideration.
This page intentionally left blank.
2.0 RESPONSES TO COMMENTS

The comment letters were coded by the order in which they were received. Table 2-1 provides the list of comment letters that contain substantive environmental comments. Responses to these comments are provided below. Responses are not provided to comments which do not raise substantive environmental issues. Comment letters, bracketed to indicate individual comments, are provided in Attachment 1.

General Overview: Commenter raises a series of issues that are primarily related to the Proposed Regulation’s treatment of gauge tanks and circulation tanks. The commenter asserts that regulation of smaller gauge tanks would result in a series of difficult technical challenges and environmental impacts, and may result in displacement of production beyond California. Similarly, the commenter states that controls for circulation tanks are not currently available and that attempts to control emissions may cause environmental impacts, including displacement of production.

General Response: ARB staff has provided further clarification to the proposed rule in regards to gauge tanks and circulation tanks. The clarifications make clear that only gauge tanks that would already have been controlled as storage vessels are covered by the rule – that is, the smaller tanks that commenters were concerned with are not covered, and so no controls for them would be required, or result in environmental impacts. Similarly, the rule has been modified for circulation tanks to primarily require a testing and best practices regime consistent with feasible industry practice, with controls required only if they are feasible. The testing regime includes detailed analysis of emissions results, including potential criteria pollutant, GHG, and toxic air contaminant emissions associated with controls. The ARB Executive Officer would make the determination to require controls only after reviewing this information. That determination would not authorize controls contrary to AB 32’s direction to avoid interfering with criteria pollutant and toxic air contaminant control efforts. With these clarifications, the general issues raised by the commenter are even less likely to occur, though the Draft EA determined that those concerns – including concerns over displaced oil or gas production – were otherwise unlikely to occur and were not reasonably foreseeable. While these clarifications within the proposed rule generally address the issues raised by the commenter, specific responses are provided to each comment below.

10-25 Comment: The comment states that the EA does not take into account gauge tanks and the potential environmental impacts associated with the Proposed Regulation’s requirement to control emissions from those tanks.

Agency Response: See response to comment 10-105 through 10-124.

10-47 Comment: The comment states that the requirement to control vapors from circulation tanks by using portable vapor recovery compressors would result in additional greenhouse gas (GHG) and criteria pollutant emissions.

Agency Response: The requirement to control vapors from circulation tanks is that owners/operators must control emissions with at least 95 percent vapor collection and
control efficiency. Any vapor collection system or vapor control device that meets the standards in Section 95671 can be used. Owners/operators are not required to use portable diesel generator-powered vapor recovery compressors to control vapors from circulation tanks. See page 18 of the Draft EA for a discussion of the reasonably foreseeable compliance responses associated with vapor collection.

Furthermore, amendments to the Regulation would address 95 percent vapor control feasibility. Section 95668(b)(2), as amended, directs owners/operators to prepare a technology assessment and emissions testing of equipment used to control emissions from circulation tanks. The report must include an evaluation of vapor control efficiency, and methane, criteria pollutant, and toxic air contaminant emissions before and after installation of equipment. ARB will review and evaluate the technology assessment to determine if the emissions controls are technically feasible and achieve the proposed emissions standards. In the event that emissions controls for circulation tanks are not technically feasible or that controls are not appropriate because of emissions concerns, owners/operators would not be required to install vapor control equipment at that time.

10-48 Comment: The comment states that flaring vapors from circulation tanks will produce additional emissions due to the need to add supplemental fuel to meet Federal flare combustion efficiency requirements.

Agency Response: Staff disagrees that supplemental fuel would be needed to flare vapors from circulation tanks. The regulation does not allow for the use of supplemental fuel and staff believes this is feasible. A manufacturer reported that their devices are used for destroying low quality waste gas (footnotes 52, 53 of Initial Statement of Reasons [ISOR]). For situations where only a small amount of gas is collected, they may be able to temporarily store gas in what is called a “bladder” until enough volume of gas is collected for incinerations. This method of vapor control does not require using supplemental fuel.

See response to comment 10-47. In addition, Staff is proposing that facilities using circulation tanks in conjunction with well stimulation treatments develop a best management practices plan to reduce emissions from the tanks and provide ARB with the results of a technical demonstration of vapor control equipment. This would provide time for industry and equipment manufacturers to work together to develop and test all necessary equipment, and help to ensure that industry is taking steps to reduce emissions while the equipment is being designed and tested.

10-49 Comment: The comment states that emissions from the capture and control of vapors from circulation tanks, as proposed, will be greater than the emissions from uncontrolled circulation tanks.

Agency Response: ARB staff disagrees with the commenter’s analysis of emissions from uncontrolled versus controlled circulation tanks. See response to comment 10-47 regarding the types of vapor control systems/devices that can be used, and regarding
the proposed amendment to require a technical assessment (including an evaluation of feasibility and emissions) prior to requiring circulation tank vapor collection and control.

10-50 Comment: The comment states that controlling circulation tanks will result in significant additional criteria pollutant emissions, outweighing the proposed methane emission reductions, making the controls unjustified.

Agency Response: See response to comment 10-49.

ARB staff made no changes to the provision based upon the above recommendation.

10-105: Comment: The comment states that ARB prepared this Draft EA under its CEQA certified regulatory program, in compliance with Public Resources Code [PRC] 21159, and provided a succinct analysis of impacts. The commenter asserts that the Draft EA does not meet requirements and is inadequate.

Agency Response: This comment is general in nature and does not require a specific response, although ARB responds generally that the Draft EA does meet the applicable requirements of ARB’s certified regulatory program and is adequate. See responses to comments 10-106 through 10-124.

10-106 Comment: The comment states that an EA must include a project description and statement of objectives. The comment references several cases, but does not indicate that the EA is inconsistent with relevant guidance from these cases.

Agency Response: An overview of ARB’s certified regulatory program is provided in Section 1.E.1 in the Draft EA. Chapter 2 of the Draft EA provides a description of the reasonably foreseeable compliance responses that could occur as a result of implementation of the Proposed Regulation. It also includes a description of the primary objectives of the Proposed Regulation. No further response is necessary.

10-107 Comment: The commenter asserts that the EA’s project description does not fully inform the public of the scope of the project. The commenter asserts that the regulation would require owners and operators to install vapor collection systems on certain gauge tanks.

Agency Response: “Gauge” tanks are certain tanks used to measure characteristics of produced oil. When these tanks are large, they present essentially the same pollution risks, and have the same emission control options, as do other storage tanks. However, low-volume tanks (of 100 barrels capacity or less in size) are not a pollution risk of the same sort. ARB has modified the proposed rule to make clear that these low-volume tanks are exempted. Accordingly, the scope of the regulation has not expanded to a large new class of small gauge tanks, with any resulting environmental impacts, despite commenters’ assertion. To the extent this was commenters’ concern, it has been substantively addressed. In any event, the reasonably foreseeable compliance responses associated with gauge tanks’ vapor collection systems covered by the
regulation would be similar to those described for other elements of the Proposed Regulation. Furthermore, gauge tanks larger than 100 barrel capacity (non-exempt gauge tanks) were originally included in the inventory as storage tanks. Gauge tanks of 100 barrels or less capacity (exempt gauge tanks) were not originally nor are they now included in the inventory. While the types of activities and environmental impacts would be the same as discussed in the Draft EA, the text of the last paragraph on page 16 of the EA has been modified as follows (new text is underlined):

The Proposed Regulation would require that uncontrolled separators, tanks (including large gauge tanks), or sumps (i.e., not sealed or controlled with a vapor collection system) either install a vapor collection system or conduct flash analysis testing to determine whether additional vapor collection and disposal methods must be employed. Importantly, gauge tanks of 100 barrels in size and smaller are not subject to this requirement. For tanks that are subject to this requirement, regulated entities would likely choose to conduct flash analysis testing before installing a vapor collection system. If any one of the regulated components in the separation and tank system is uncontrolled (i.e., a partially controlled system), testing must be completed. In addition to the exemption for gauge tanks 100 barrels in size and smaller, the Proposed Regulation exempts systems under certain production levels from testing as they are expected to be well below the threshold for controls. If the measured flash emission rate is less than or equal to 10 metric tons per year of methane, no further action would be required other than periodic flash testing and reporting. If the measured flash emission rate is greater than 10 metric tons per year of methane, vapor collection and disposal methods must be employed.

Accordingly, ARB has modified the EA to clarify that gauge tanks subject to the Proposed Regulation are included in the project description and impact analysis. These modifications do not require recirculation of the EA, because they do not deprive the public of a meaningful opportunity to comment upon a substantial adverse environmental effect or a feasible way to mitigate or avoid such an effect (Cal. Code Regs. tit. 14., § 15088.5(a)). There are no new significant effects identified nor substantial increases in previously identified significant effects, as the project description has merely been clarified to expressly reference gauge tanks subject to the Proposed Regulation.

10-108 Comment: The commenter states that reasonably foreseeable methods of compliance with the requirements of vapor collection at gauge tanks are not discussed.

Agency Response: See response to comment 10-107. The methods for controlling of vapors from gauge tanks are described in Section 2.C.2 of the Draft EA, and are included in the analysis in Section 4 of the Draft EA. As described in this section, recovered vapors would be disposed using the same methodology described in 2.C.1.a, or they are compressed and transferred offsite.
10-109 Comment: The comment states that Section 95668(b)(3) requires that by January 1, 2020, owners or operators of circulation tanks used in conjunction with well stimulation treatments shall control emissions from the tanks with at least 95 percent vapor control efficiency of the equipment, but states that it is unclear how these vapors are controlled because there are not current technologies available to control them.

Agency Response: The control of vapors from uncontrolled well stimulation circulation tanks is discussed in Section 2.C.2 of the Draft EA. As described in this section, ARB anticipates that recovered vapors could be disposed of using the same methodology described in 2.C.1.a, or they can be compressed and transferred offsite. However, ARB is aware that other technologies for circulation tank controls are still being developed. This is why the regulation requires a series of control demonstrations, rather than immediate controls. The regulation has been modified to make clear that no controls will be required after January 1, 2020 (other than best practices) if controls are not demonstrated to be available. Please see response to comment 10-47 for a discussion related to vapor control feasibility.

10-110 Comment: The comment questions whether air districts will permit additional combustion devices for use at circulation tanks, regardless of if they are low-NOx devices. The comment states that some air districts do not want any additional flaring to occur in response to the Proposed Regulation. If low-NOx flares are not allowed by air districts, the commenter asserts that this is not a reasonably foreseeable method of compliance and should be addressed in the EA. The comment also states that since the proposed regulation requires existing equipment to be taken out of service if none of the compliance options is feasible, the EA should consider a reasonably foreseeable compliance response to be shutting down production in California and transferring it to other areas.

Agency Response: See the Response to Comment 10-109 to the extent commenter is asserting that control technology is not available. Further, should these sorts of controls ultimately be required, as described in the last paragraph on page 17 of the Draft EA, “In areas classified as nonattainment with, or which have not been classified as in attainment of, all State and federal ambient air quality standards (i.e., ozone, respirable particulate matter [PM₁₀], fine particulate matter [PM₂.₅], carbon monoxide [CO], nitrogen dioxide [NO₂], sulfur dioxide [SO₂]), allowable devices would be limited to non-destructive vapor control devices¹, or low-NOx² vapor control devices. In areas classified as in attainment with all State or federal ambient air quality standards, allowable devices would be limited to those that achieve 95 percent vapor control efficiency of total emissions.”

¹ A device that achieve 95 percent vapor control efficiency and does not result in emissions of NOx
² A device that achieves 95 percent vapor control efficiency and does not generate more than 15 parts per million volume NOx when measured at 3 percent oxygen.
As described in Impact 3.b, under subheading c) emissions impacts, regulated entities in areas designated as nonattainment with State and federal ambient air quality standards could comply with the Proposed Regulation with the local air district-approved installation of a non-destructive (e.g., non-combustion) or a low-NOx vapor control device. In areas where a combustion device is not approved, other control options are available (e.g., disposal of vapors by routing to an existing sales or fuel gas system or gas disposal well [see page 18 of the Draft EA]). Further, as described above under response to comment 10-47, ARB has proposed modifications to the regulation to address the circulation tank issues that commenters asserted might result in displaced production. ARB staff believe, based on a thorough analysis of affected sources, that there are a range of options available to control emissions such that oil and gas facilities would not need to close or leave the state.

Moreover, displacement of oil operations itself is inherently unlikely for various economic and geographic reasons. For instance, oil field operations, which are geographically-limited, are located in California where considerable investments in these fields have already been made. The costs associated with closure of facilities and development elsewhere would be prohibitive compared to remaining in California and complying with regulations. Thus, the controls at issue in this rule do not render displacement reasonably foreseeable.

Further, ARB expects that permitting low-NOx vapor devices will be possible. The installation of any new vapor control device or replacement of an existing vapor control device must comply with all applicable federal, State, and local air district requirements. These devices are permitted through local air districts in compliance with New Source Review (applies to stationary sources of designated nonattainment pollutants) requirements under the Clean Air Act, or local rules to control emissions from flares, or both. In addition, installation of any flares here, including, enclosed low-NOx combustion devices would be subject to the requirements of any existing or future district flare minimization plans. The proposed rule generates a net benefit by replacing existing, dirtier flares, with cleaner low-NOx vapor combustion devices, when they are used, which should expedite permitting when needed. Operators may also be able to secure appropriate offsets or other emission credits, or pay into district mitigation programs if necessary. ARB is committed to working with regulated parties and with the air districts to support implementation of the rule, and to ensuring that controls are consistent with district NOx control efforts.

In sum, it is not anticipated that oil and gas facilities would be closed and/or transferred outside of California. Thus, the potential for installation of new low-NOx combustion devices is accurately portrayed in the Draft EA. No changes are required.

10-111 Comment: The comment addresses oil production impacts discussed in the Department of Oil, Gas, and Geothermal Resources’ (DOGGR’s) Draft EIR on the “Analysis of Oil and Gas Well Stimulation Treatments in California.” Commenter
appears to assert that this discussion, if accurate, might describe impacts of displaced production as a result of the Proposed Regulation.

**Agency Response:** The Proposed Regulation would not change the process for permitting crude oil and natural gas wells; these permits are issued by DOGGR. The Proposed Regulation would not require an additional permit for well stimulation treatments, nor would it authorize well stimulation treatments or other methods of oil and gas extraction. DOGGR’s well stimulation treatment regulations are not subjects of the EA.

To the extent that the commenter suggests that production restrictions (which DOGGR did not, in any event, adopt) are somehow germane to production behavior under the Proposed Regulation, it has based this concern on potential production responses to circulation tank and gauge tank controls. As staff has explained in these response to comments, the Proposed Regulation has been modified in ways that fully address commenters’ concerns, and displaced production was not, and is not, reasonably foreseeable (see response to comment 10-110).

**10-112 Comment:** The comment addresses issues related to statements made in DOGGR’s Draft EIR on the “Analysis of Oil and Gas Well Stimulation Treatments in California and the potential for displacing oil production.

**Agency Response:** DOGGR’s well stimulation treatment regulations are not subjects of the EA. As described in Response to Comment 10-110, the controls at issue in this rule do not render oil production displacement reasonably foreseeable. No further response is necessary.

**10-113 Comment:** The comment claims the Air Quality analysis in the EA is deficient for not addressing the installation and replacement of gathering lines and piping, flanges, valves, low-NOx combustion devices, and other similar features associated with adding vapor collection systems to gauge tanks; and must estimate potential construction related emissions in as much detail as feasible with data from the 2009 Oil and Gas Industry Survey and Economics Analysis.

**Agency Response:** See response 10-107. ARB is adding more specific gauge tank language to the EA to clarify that the EA is consistent with the Proposed Regulation. In addition, Section 2.C.1.b. of the Draft EA addresses reasonably foreseeable compliance responses to vapor collection, which would be the same for gauge tanks.

The short-term construction-related air emissions associated with the installation and replacement of equipment such as gathering lines, piping, and vapor collection system are discussed under Impact 3.a of the EA. At the time of the environmental review, the specific location, type, and number of construction activities across the state were not known and would be dependent upon a variety of factors that are not within the control or authority of ARB and not within its purview. Thus, ARB has not quantified the
Potential construction-related emission impacts as these would be too speculative to provide a useful evaluation tool. The specific time and locations across the state where each type of equipment may be installed are not known, and ambient air quality varies from district to district. Nonetheless, the analysis presented in the Draft EA provides a good-faith disclosure of the general types of construction emission impacts that could occur with implementation of these reasonably foreseeable compliance responses. Any such impacts would be short-term, and the types of upgrades and modifications to oil and gas facilities that could be required under the Proposed Regulation would be minimal in comparison to the infrastructure already present at the sites. No further response is required.

10-114 and 10-115 Comment: The comment states that in the EA, one option for compliance with the Proposed Regulation “requires that regulated entities operating an existing vapor control device route newly collected vapors into the existing vapor collection system and then replace the existing vapor control device that would receive increased vapor throughput with a non-destructive or low-NOx vapor control device.” Based on this assertion, commenter states that construction emissions from replacing existing flares with low-NOx vapor control devices can be reasonably projected by ARB and must be considered in the EA.

Agency Response: Section 2.C.1.b of the EA includes the reasonably foreseeable compliance responses associated with vapor collection systems. Section 4.B.3 of the EA includes an analysis of short-term construction-related impacts on air quality associated with the reasonably foreseeable compliance responses that would occur under the Proposed Regulation, including installation of vapor collection systems. See response to comment 10-113 for further details.

10-116 Comment: The comment states that the EA does not address the possibility that some air districts may not permit additional flaring, causing compliance with the vapor control devices provision of the Proposed Regulation to be infeasible.

Agency Response: See responses to comments 10-47 and 10-110. New vapor control devices would be installed only if collected vapors cannot feasibly be collected and conveyed into existing sales lines, existing fuel lines, or existing injection wells first with the use of existing vapor control devices, as stated in Section 2.C. While the installation of any vapor control device would be subject to all applicable federal, state, and local requirements, ARB anticipates that most oil or gas production facilities in the state are not subject to prohibitions on permitting newer, more efficient vapor combustion devices, particularly where there is a resulting net decrease in emissions.

10-117 Comment: The comment states that there is not a guarantee that potential control devices for circulation tanks will be available in time for compliance deadlines in the regulation, leading to a cease in some production, which would cause indirect impacts that have not but must be addressed in the EA.

Also, staff has proposed amendments to Section 95668(b) of the regulation which require owner/operators of circulation tanks used for well stimulation treatment to complete a technical assessment of control techniques and technologies. ARB will review and evaluate the technical assessment to determine if the emissions controls are technically feasible and achieve the proposed emissions standards. In the event that emissions controls for circulation tanks are not technically feasible, owners/operators would not be required to install vapor control equipment at that time.

In sum, as described in this response to comments document, ARB has provided for a range of alternative control devices, which would reasonably be available to control emissions even in the absence of non-combustion devices, making it reasonable to assume that production would not be displaced. In any event, ARB has also modified the circulation tank requirement to ensure that it will not be imposed in ways that could limit production if controls are not available. Therefore, the issue identified by the commenter will not occur.

10-118 Comment: The comment states that it is not clear that recovered vapors would be in a form sufficient to use for onsite equipment fueling, therefore assumptions in the EA that recovered vapors could reduce fuel use and thus reduce emissions are unwarranted.

Agency Response: As specified in the Proposed Regulation, owners/operators should first attempt to use recovered vapor, of sufficient quality, for onsite equipment fueling. As is stated in Section 2.C.1.b. of the EA, if the vapors recovered are not suitable for onsite use and do not meet pipeline quality standards, destruction of vapors or disposal in an underground gas disposal well would likely be used. If vapors are destroyed, a low-NOx device must be used in areas that are not in attainment for all state and federal ambient air quality standards. See response to comment 10-48 regarding low-NOx vapor control devices.

10-119 Comment: The comment states that ARB’s calculation of potential emissions impacts, does not consider emissions from gauge tanks and must be corrected. This includes emissions of criteria pollutants, from combustion of additional vapors collected and routed to vapor control devices as a response to the regulation.

Agency Response: Gauge tanks smaller than 100 barrels (bbls) are excluded from the regulation. Gauge tanks larger than 100 bbls were included in the emissions calculations, and therefore were considered in the EA.

10-120 Comment: The comment does not agree with ARB staff’s characterization of NOx emissions in San Joaquin Valley Air Pollution Control District (SJVAPCD), citing differences in assumptions. The comment goes on to state that make-up gas would be
required in low NOx incinerators and thus, the Proposed Regulation may be infeasible in some instances.

Agency Response: As stated in Impact 3.b in the Draft EA, ARB staff employed the most comprehensive and detailed data and information available, collected directly from oil and gas operators in California, to estimate NOx emissions that might result from the Proposed Regulation, and disagrees with SJVAPCD staff’s conclusion for the following reasons:

- SJVAPCD staff assumed that all tank systems are currently uncontrolled except for those owned by the three largest operators, which is contrary to the robust data contained within the oil and gas survey results, and used by ARB staff.
- SJVAPCD staff assumed all captured gas would require an equal amount of supplemental make-up gas before combustion in a flare would be possible. However, ARB’s research (footnotes 52 and 53 of the ISOR) indicates that low-NOx incinerators exist which can handle waste gas and likely would not require additional make-up gas. As such, the regulation does not allow for the use of supplemental or make-up gas.
- SJVAPCD staff also assumed that all additional gas collected as a result of the Proposed Regulation would be routed to a flare, whereas ARB survey data reveals that only four percent of all tank systems currently have vapor recovery flares and the vast majority of tank systems use other vapor control methods.
- The SJVAPCD staff assumed that all gas produced on the lease would go into one large tank system, whereas ARB staff was able to estimate the number of tank systems using the survey data. The District staff’s assumption does not use the available survey data and therefore overestimates the impact.

Thus, the analysis provided in Draft EA correctly characterizes NOx emissions that might result from the Proposed Regulation. No changes to the document are necessary.

10-121 Comment: The comment states that the impacts related to biological resources are understated in the Draft EA because the project description did not include vapor collection systems associated with gauge tanks.

Agency Response: The reasonably foreseeable compliance responses associated with vapor collection systems for gauge tanks would be similar to those discussed for uncontrolled separators, tanks, and sumps. To provide clarification, the term "gauge tanks" has been added to the Project Description of the EA (see response to comment 10-107). These modifications do not require recirculation of the EA, because they do not deprive the public of a meaningful opportunity to comment upon a substantial adverse environmental effect or a feasible way to mitigate or avoid such an effect (Cal. Code Regs. tit. 14., § 15088.5(a)). There are no new significant effects identified nor substantial increases in previously identified significant effects with the addition of the
term “gauge tanks” to the project description. Because gauge tanks smaller than 100 bbls are exempt, there are no additional tanks or associated emissions with the inclusion of gauge tanks in the Regulation that were not included in the EA. Non-exempt gauge tanks were included in the EA, inventory, and emissions calculation as “storage tanks.”

10-122 Comment: The comment directs ARB staff to include an increase in vehicle emissions associated with the Leak Detection and Repair (LDAR) requirements of the regulation.

Agency Response: As stated in the EA (Impact 3.b, subheading a) Vehicle Emissions), the additional miles to and from the oil and gas facilities to comply with the LDAR component of the Regulation, would not be substantial and would be infrequent in nature.

Attachment 3 of the EA, Description of Vehicle Emission Calculations Associated with the Leak Detection and Repair Provisions, details this analysis.

10-123 Comment: The comment states that the number of vehicle trips described in the EA is superficial and purely qualitative, and points to a more quantitative analysis in the air quality discussion.

Agency Response: The air quality discussion notes that the additional vehicle miles traveled (VMT) associated with equipment repairs or replacement is expected to be minimal (second paragraph, page 36 of the Draft EA), and does not attempt to determine the specific roadways that could be affected by implementation of the Proposed Regulation. This analysis is necessarily general and consistent with the programmatic nature of the Proposed Regulation. Attempting to predict decisions by entities regarding the specific location and timing of monitoring activities would be speculative (if not impossible) at this stage, given the influence of other business and market considerations in those decisions. Regardless, as discussed under Impact 17.b: Long-Term Operational Impacts on Transportation and Traffic, which states that, “trips to and from the oil and gas facilities would not require a substantial number of vehicles and would be infrequent (i.e., quarterly), as a result these activities would not result in substantial changes to transportation and traffic plans, air traffic patterns, roadway designs, emergency access, or other traffic-related issues.” Thus, because there would not be a substantial increase in vehicle trips related to implementation of the Proposed Regulation, this analysis is adequate. No changes to the document are required. See also response to comment 10-122.

10-124 Comment: The comment recommends that gauge tanks and recirculation tank controls be removed from the Proposed Regulation. The comment also asserts that the EA must be revised and recirculated to consider the potential environmental implications of all of the requirements in the regulation before ARB can adopt the
Proposed Regulation. It is assumed that this comment is in reference to inclusion of gauge tanks and recirculation tanks in the analysis.

Agency Response: See Response to Comment 10-107 for a discussion of the types of gauge tanks that are subject to the Proposed Regulation. The reasonably foreseeable compliance responses associated with vapor collection systems for gauge tanks would be similar to those discussed for uncontrolled separators, tanks, and sumps. To provide clarification, reference to “gauge tanks” has been added to the Project Description of the EA (see Response to Comment 10-107). These modifications do not require recirculation of the EA because they do not deprive the public of a meaningful opportunity to comment upon a substantial adverse environmental effect or a feasible way to mitigate or avoid such an effect (Cal. Code Regs. tit. 14., § 15088.5(a)). There are no new significant effects identified nor substantial increases in the severity of previously identified significant effects from this modification to the project description. Thus, recirculation of the EA is not necessary.
16-14 Comment: The comment asserts that the Draft EA does not adequately analyze the project because it does not provide data on current and future GHG emissions for context regarding the expected reductions from the regulations. The comment claims that the alternatives analysis omits any alternative that would provide greater environmental benefit in terms of greater emissions reductions. The comment also states that the Draft EA uses faulty or imprecise analysis of data and also refers to the certified regulatory program under which the Draft EA was prepared.

Agency Response: In regard to adequately analyzing current and future GHG emissions, please see response to comment 16-15. For discussion on alternatives, please see response to comment 16-18. The Draft EA was prepared in accordance with all requirements of ARB’s certified regulatory program under CEQA, including providing a thorough and meaningful analysis of all reasonably foreseeable compliance responses associated with the Proposed Regulation. As discussed in Section 1.E.2 of the Draft EA, the degree of specificity required in a CEQA document corresponds to the degree of specificity inherent in the underlying activity it evaluates. The EA for broad programs cannot be as detailed as for specific projects (Cal. Code Regs., tit.14, § 15146.) For example, because the specific location, extent, and design of potential new or modified facilities or activities that may occur in response to implementation of the recommended actions cannot be known at this time, the EA’s discussion of these impacts is necessarily generalized and reflects a conservative assessment to describe the type and magnitude of effects that may occur (i.e., conservative in that the conclusions tend to discuss the potential adverse effects related to a worst-case scenario). These impact discussions are followed by the types of mitigation measures that could typically be required to reduce potentially significant environmental impacts.

Nonetheless, ARB did estimate emissions reductions. Table 4-3 of the Draft EA outlines the estimated statewide emission reductions of toxic air contaminants and criteria air pollutants as benefits of the Proposed Regulation. Table 4-4 of the Draft EA outlines the estimated statewide methane emission reductions that will result from the Proposed Regulation. The total estimated statewide methane emission reduction from the Proposed Regulation is approximately 1.4 million metric tons carbon dioxide equivalent per year (MT CO₂e/year). The total estimated statewide methane emissions from the Oil & Gas Sector are approximately 3.4 million MT CO₂e/year³.

³ Using the 20-yr global warming potential, 72, from the IPCC’s Fourth Assessment Report (AR4) for methane.
Because the programmatic level of analysis associated with this Draft EA does not attempt to address project-specific details of mitigation, there is inherent uncertainty in the degree of mitigation that may ultimately be implemented to reduce potentially significant impacts. ARB has made best efforts to identify likely reductions at this programmatic level of detail. Further calculations of the effects of reductions of this regulation, beyond those provided, cannot reasonably be made at a greater degree of detail at this time. Thus, the appropriate level of review is provided in the EA.

16-15 Comment: The comment states that the EA must provide a direct comparison between baseline GHG emission levels and targeted reductions, including statewide oil and gas climate pollutants, to allow decision makers to fully evaluate the impacts of the Proposed Regulation.

Agency Response: Chapter I.D. in the ISOR states that implementing the measure in the Proposed Regulation would reduce methane emissions by 40-45 percent from the oil and gas sector as a whole by 2025. Table 4-3 of the EA outlines the estimated statewide emission reductions of toxic air contaminants and criteria air pollutants as benefits of the Regulation. Table 4-4 of the EA outlines the estimated statewide GHG emission reductions that will result from the Regulation. The total estimated statewide methane emissions reductions from the Proposed Regulation are approximately 1.4 million MT CO2e/year. The total estimated statewide methane emissions from the Oil & Gas Sector are approximately 3.4 million MT CO2e/year. Pursuant to CEQA, the baseline for determining the significance of environmental impact would normally be the existing conditions at the time the environmental review is initiated (Cal. Code Regs., tit. 14, § 15125(a)). The potential environmental consequences of the Regulation are determined based on the regulatory setting and physical conditions in 2015, which is the appropriate baseline for the analysis because this is when the environmental review was initiated.

16-16 Comment: The comment states that the projected future GHG emissions from the oil and gas sector in the EIR are incorrect, and ARB should use Kern County’s recent EIR and California Council on Science and Technology’s recent analysis of well stimulation.

Agency Response: See Response to Comment 16-15. This comment does not identify any potential environmental impacts, but rather questions the EA’s stated level of otherwise-occurring future GHG emissions from the oil and gas sector. As described above, significance determinations reflected in the Draft EA are based on a comparison of the potential environmental consequences of the Proposed Regulation with the regulatory setting and physical conditions in 2015. Because the Proposed Regulation would limit methane emissions from all regulated sources, the Proposed Regulation would provide substantial GHG emissions reductions from the oil and gas sector.

---

4 Using the 20-yr global warming potential, 72, from the IPCC’s Fourth Assessment Report (AR4) for methane.
regardless of the total number of regulated sources in existence. Therefore, under no scenario would the Proposed Regulation have the potential to increase GHG emissions.

16-17 Comment: Even though the rule will result in net GHG emission reductions, the public and decision makers have been denied the opportunity to assess the significance of those reductions as well as the relative impact of the increases in CO₂ emissions that will result from increased flaring as a result of compliance actions.

Agency Response: As discussed in response to comment 16-15, ARB did, in fact, provide best estimates of emission reductions from the Proposed Regulation and the emissions from industry at this programmatic stage. ARB also provides an ongoing inventory of statewide GHG emissions annually, and collects detailed information from large oil and gas GHG sources via its Mandatory Reporting Regulation; the Proposed Regulation also has reporting provisions. ARB will continue to track reported emissions of GHG, criteria, and toxics pollutants, and disclose them to the public. In view of the extensive analyses already provided, these ongoing programs, and the fact that the commenter identifies no legal duty to undertake new speculative analyses, ARB has fulfilled its obligations in this EA.

The Proposed Regulation is designed to reduce methane emissions from oil and gas facilities in California. The Proposed Regulation would result in slight CO₂ emission increases from the combustion of collected vapors; however, these emissions would be in lieu of the release of methane into the atmosphere, which has a substantially higher global warming potential than CO₂. The relative impact of a slight increase of CO₂ emissions is much less than uncontrolled release of methane without the Proposed Regulation. In terms of CO₂e, there is a net annual reduction of 1.4 million MT CO₂e achieved by the Proposed Regulation.

16-18 Comment: The commenter suggests that the Draft EA does not analyze a sufficient range of alternatives and that the three alternatives considered do not represent increased reductions over the proposed rule.

Agency Response: Section 15126.6 (c) of the CEQA Guidelines addresses the selection of a range of reasonable alternatives. It explains, “[t]he range of potential alternatives to the proposed project shall include those that could feasibly accomplish most of the basic objectives of the project and could avoid or substantially lessen one or more of the significant effects. The EIR should briefly describe the rationale for selecting the alternatives to be discussed. The EIR should also identify any alternatives that were considered by the lead agency but were rejected as infeasible during the scoping process and briefly explain the reasons underlying the lead agency’s determination. Additional information explaining the choice of alternatives may be included in the administrative record. Among the factors that may be used to eliminate alternatives from detailed consideration in an EIR are: i) failure to meet most of the basic project objectives, (ii) infeasibility, or (iii) inability to avoid significant environmental impacts.”
These requirements were followed in Chapter 7 of the Draft EA, which addresses three alternatives.

The commenter suggests an alternative that includes “a more rapid implementation schedule and more stringent regulations” but does not describe how this would further reduce the noted adverse environmental impacts of the Proposed Regulation. ARB has considered alternatives that could reduce environmental impacts of its regulation. The comment does not elaborate how regulations could be made more stringent or how implementation could feasibly be imposed sooner than in the alternatives discussed in the EA.

A more rapid implementation schedule and more stringent requirements are not feasible. ARB has calibrated schedules to ensure that equipment can be put in place to drive compliance and the regulations implemented (including via the local air districts) in an effective way. A further accelerated schedule would not yield any more environmental benefits because it would not be feasible – indeed, it is possible that it would not reduce the severity of environmental effects by rushing the critical implementation phase. This would be contrary to the purpose of the alternatives analysis, which is to reduce environmental impacts while meeting most of the project objectives as described above.

The commenter cites Cal. Code Regs., tit. 17, §60006, which refers to requirements under ARB’s certified regulatory program. The EA is consistent with ARB’s certified regulatory program, considering “feasible” alternatives that are capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors, and consistent with the state Board’s legislatively mandated responsibilities and duties.

The commenter is correct that an alternative analysis is meant to inform the public and decision-makers, and can also increase project benefits. As discussed in Section 7.B of the EA, ARB made a good faith effort to identify other potentially feasibly project alternatives. This included examining comments received at multiple public workshops and board hearings. No comments revealed an alternative comprehensive approach to meet the State’s long-term goals while reducing any of the Proposed Project’s potentially significant environmental impacts. The EA’s alternatives analysis complies with CEQA, and Cal. Code Regs., tit. 17, §60006 because the EA evaluates a reasonable range of alternatives.

Re: WSPA Comments on draft Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Operations (June 2016)

Dear Jim:

The Western States Petroleum Association (WSPA) is a non-profit trade association representing companies that explore for, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California and four other western states. WSPA appreciates this opportunity to provide comments on the proposed regulatory language published by the California Air Resources Board (ARB) on June 2, 2016 regarding ARB’s draft Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Operations.

WSPA and WSPA member companies, as key stakeholders, have engaged with the ARB in the regulation development and implementation process. As the WSPA member companies each have existing air quality compliance programs, it is important that the final regulation be consistent with current and successful local, state, and federal air quality regulations.

After careful review of the latest draft language, WSPA’s main concerns involve the sections concerning: 1. Gauge Tanks; 2. Circulation Tanks; 3. LDAR; and 4. Definitions.

1. Gauge tanks, which are used to gauge the productivity of a well, have not been in any of the previous versions of the rule. WSPA is concerned with the last minute addition and the lack of feasibility studies and economic analysis of vapor recovery requirements on these tanks.

2. WSPA still believes there is not a full understanding of the circulation tank operations. Some of the requirements are not safe and are technologically or economically infeasible. Although there has been deadline extensions provided, since the technology for 95% control efficiency does not exist, WSPA believes the manufacturers of the control technologies cannot meet even the later deadline.

The rule does not allow the flexibility to perform well stimulations in the future if we cannot find technologically feasible control methods. This section could require us to expend significant time, effort, and money to conduct and report on an investigation that could all be rejected because ARB does not agree with the methods used or if it does not produce desirable results.

cathy@wspa.org • www.wspa.org
Related to that is the infeasibility of not being able to use supplemental gas to support complete combustion of non-combustible gases.

3. Expansion of LDAR program will result in two sets of inspections, two sets of programs and recordkeeping – one for the APCD and one for the ARB – since the programs differ so much in the details that affect implementation. Also, as currently written LDAR will be required for systems that in practical application do not have the potential to emit methane. We expect the cost will be significantly more than estimated by ARB and difficulty in finding enough competent contractors to perform and correctly document inspections.

4. Several definitions need clarity, specifically related to Tank and Separator Systems which may result control requirements on equipment that cannot be controlled, or at least not cost effectively (such as sumps).

The following attachments provide assessments of WSPA and WSPA member company concerns regarding the proposed regulatory language.

Thank you for your consideration of WSPA’s comments. If you have any questions, please contact me at this office, or Jennifer Pitcher of my staff at (661) 321-0884 or email jpitcher@wspa.org.

Sincerely,

cc: Richard Corey, Executive Officer, Air Resources Board

General Comments

Issue 1: WSPA would like to re-iterate comments previously submitted on February 18, 2016 regarding the global warming potential used in the evaluation of this proposed regulation. Over the course of this regulation development process, ARB has changed the Global Warming Potential (GWP) of Methane from 25\(^1\) (100 year average) which was used in the previous economic impact analysis to 72\(^2\) (20 year average). Although ARB has discussed this change in the supporting documentation for the proposed rule, this GWP change is not reflected in either the definition or anywhere else in the regulation itself.

The proposed change is not trivial. Using the 20-yr GWP, which is more than three times the 100-yr GWP, makes the emissions estimates from the regulation appear to be three times the emissions estimates of standard GHG programs like EPA’s Greenhouse Gas Reporting Program (GHGRP), California’s GHG Mandatory Reporting Regulation (MRR), and California’s Cap and Trade Program. It also makes the costs for this regulation appear to be three times smaller when compared to other GHG programs.

A 100-year global warming potential (GWP) value is the current internationally accepted standard used across myriad State and Federal regulatory regimes including the ARB’s statewide emissions inventory, AB 32 Scooping Plan and the Cap-and-Trade regulation. The factor change would defeat the internal consistency of the state’s policy.

ARB notes a concern about climate change consequences in 2050 and 2100 – i.e., the 100 year timeframe. Based on this concern, using the 100 year GWP would be more appropriate. The Intergovernmental Panel on Climate Change (IPCC) Report supports both the 100 year and 20 year factors.\(^3\) These factors were developed to allow comparisons of different GHGs policy making purposes, and ARB’s revised methodologies will deviate from the standards used by EPA and most other international agencies.

If ARB insists on choosing the 20 year horizon for methane, then a 20-year horizon for CO\(_2\) would be a fair comparison. In such a comparison, the effect of CO\(_2\) is very small.\(^4\) As a result California should take the very small radiative forcing of CO\(_2\) into account and reconsider all of its policies with respect to CO\(_2\).

WSPA believes that the lack of a standardized GWP approach between the various AB32 programs is inappropriate, non-transparent and ultimately will cause confusion among stakeholders when comparing the cost-effectiveness and efficiency of the various programs established by ARB and the international community.

WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)

July 10, 2016

Recommendation 1: WSPA recommends ARB revise the regulation and use the 100-yr GWP value of 21 for methane (SAR GWP for 100-yr Time Horizon; Table 2.14, IPCC Fourth Assessment Report: Climate Change 2007) to be consistent with other standard GHG programs.

Issue 2: Currently, Section §95667 does not incorporate a definition of Global Warming Potential of CH₄. This could lead to confusion and several issues during compliance demonstration and enforcement actions. WSPA recommends ARB incorporate the definition of GWP of CH₄ into Section §95667, which will ensure transparency and understanding of compliance requirements for all stakeholders.

Recommendation 2: WSPA requests that ARB add the following term and definition to § 95667.

"Global warming potential" or "GWP" means the ratio of the time-integrated radiative forcing from the instantaneous release of one kilogram of a trace substance relative to that of one kilogram of a reference gas, i.e., CO₂. For the purposes of this regulation, the GWP of methane is 21 (SAR GWP for 100-yr Time Horizon; Table 2.14, IPCC Fourth Assessment Report: Climate Change 2007).

Issue 3: The current cost-effectiveness data provided by ARB in the proposed regulatory package does not include details on impacts for each operator or the assumptions made to determine benefits. Significant variations can exist among operations and/or fields and understanding these variations is important before mandating the proposed requirements on all operations. The same requirement at one location may be cost-effective while another location might be significantly impacted. Therefore, state-wide cost-effectiveness may not represent the actual burden on an operator.

WSPA (letter dated 5/22/15), California Independent Petroleum Association (CIPA letter dated 5/28/15), and Department of Finance (DOF letter dated 5/28/15) have pointed out the need for ARB to conduct operator and unit-level cost-effectiveness analysis in addition to the state-wide cost-effectiveness of the proposed regulation as outlined below:

- CIPA requested “that staff prepare an updated and detailed economic impact document which clearly shows what the individual impact potential would be on entities” due to concerns regarding the macro-scale view of the SRIA.
- WSPA outlined the significant differences in emission reduction estimates included in the SRIA and reported 2013 MRR data.
- WSPA requested that ARB “provide transparent calculations and unit clarifications that result in a revised cost-effectiveness determination or clear demonstration” of how annual benefits were reached.
- DOF requested that ARB “include the direct cost of each alternative in the SRIA rather than just the overall impacts” and that ARB “discuss how an individual facility’s characteristics, such as emission rates and existing control devices, may affect the calculation of direct costs, and thus economic impacts of the proposed regulations”.

WSPA believes that it is critical to understand the economic impacts at the unit level (such as at an operator/system level) in order to clearly determine the impact of the regulation. Significant variations can exist between an operator’s emissions, the cost of control, and direct benefits received by the operator.
Lack of transparency in unit-level cost-effectiveness and practically low/no applicability thresholds in the proposed regulation will lead to significant adverse impact operators. Unit-level analysis can demonstrate operator-level economic burden, where the most impact will be felt. Additionally, without a reasonable threshold for cost-effectiveness at the unit-level, ARB is assuming the same cost and benefit will occur for all operators.

ARB’s response in the staff report to this serious concern is still inadequate. WSPA does not agree with nor support ARB’s calculated cost-effectiveness analysis and the basis for many of the proposed regulatory requirements. This is a critical gap in ARB’s economic analysis as well as the EA, and needs to be addressed before the rule can be adopted. ARB should minimize regulatory burden for operators where the proposed requirements are clearly not cost-effective and could lead to a significant economic burden for the operator(s).

**Recommendation 3.** WSPA strongly recommends ARB clearly demonstrate operator and unit-level economic impacts and cost-effectiveness of the thresholds considered for applicability at operator and unit level.
General Definitions

WSPA requests ARB incorporate the following clarifications regarding certain general definitions included in Section §95677 of the proposed regulatory text. The clarity and correctness of the definitions provided are central to all operators’ understanding and ability to comply with the regulation. Listed below are some general requested corrections. Additional recommendations for definition changes that provide clarity are included in Attachment A.

Issue 4: “Emissions” means the discharge of natural gas into the atmosphere.

- WSPA believes that this definition is inconsistent with the original intent of the rule to control CH₄ emissions.
- ARB’s emissions estimates and cost-effectiveness analyses use “MT CH₄” as the basis of the proposed GHG standards.
- Many sections of the proposed regulatory text require a certain percentage of emissions reductions. This will require an operator to demonstrate compliance in terms of a standard unit of measure such as MT CH₄.
- Additionally, Section §95674(c) describes enforcement in terms of “metric ton of methane.”

However, the definition of emissions states “the discharge of natural gas into the atmosphere.” The inconsistency in the definition and the rest of the regulation will cause issues not only during compliance demonstration but also for the purposes of enforcement.

Recommendation 4: WSPA requests that ARB clarify this language throughout the regulation in order to provide a consistent and measureable standard. WSPA recommends the following changes:

“Emissions” means the discharge of methane natural-gas into the atmosphere.

“Component” means a valve, fitting, flange, threaded-connection, process drain, stuffing box, pressure-vacuum valve, pipes, seal fluid system, diaphragm, hatch, sight-glass, meter, open-ended line, well casing, natural gas-driven pneumatic device, natural gas-driven pneumatic pump, or natural gas reciprocating compressor rod packing or seal in methane service.

“Facility” means any building, structure, or installation to which this subpart applies and which has the potential to emit natural gas by methane. Facilities include all buildings, structures, or installations which:

(A) Are under the same ownership or operation, or which are owned or operated by entities which are under common control;

(B) Belong to the same industrial grouping either by virtue of falling within the same two-digit standard industrial classification code or by virtue of being part of a common industrial process, manufacturing process, or connected process involving a common raw material; and,

(C) Are located on one or more contiguous or adjacent properties.

“Vapor collection system” means equipment and components installed on pressure vessels, separators, tanks, or sumps including piping, connections, and flow-inducing devices used to collect and route emissions methane to a processing, sales gas, or fuel gas system; to a gas disposal well; or to a vapor control device.
WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)

July 18, 2016

Issue 6: WSPA notes that the definition of a sump does not align with other existing regulations.

Recommendation 6: WSPA recommends that ARB align with the definition of a sump as in San Joaquin Valley Air Pollution Control District (SVAPCD) Rule 4402 as below:

“Sump” means a lined or unlined surface impoundment or excavated depression in the ground that which, during normal operations, is in continuous use for separating, storing, or holding emulsion, crude oil, condensate, or produced water, and solids in oil producing fields.

Issue 6: ARB’s definition of separator and tank systems includes “sump” as follows –

(54) “Separator and tank system” means the first separator in a crude oil and natural gas production system and any tank or sump connected directly to the first separator.

WSPA is concerned that ARB is requiring additional controls that cannot be safely achieved. Sumps can introduce oxygen into closed loop vapor recovery systems leading to fire and explosion risks. As already stated in the previous letters (dated March 4, 2016), there is no feasible, cost-effective manner by which to capture emissions from a sump, which is not enclosed.

Recommendation 6: WSPA requests that ARB remove the term “sump” from the definition of “separator and tank system.” WSPA recommends the following definition for “separator and tank system” –

“Separator and tank system” means the first separator in a crude oil and natural gas production system and any tank or sump connected directly to the first separator.

Issue 7: ARB’s definition of terms “Sump” and “Pond” are overlapping –

“Pond” means an excavation or impoundment for the storage and disposal of produced water and which is not used for crude oil separation or processing.

“Sump” means a lined or unlined surface impoundment or depression in the ground that, during normal operations, is used to separate, store, or hold emulsion, crude oil, condensate, or produced water.

ARB’s definitions in Section § 95667 suggest that “Ponds” are subsets of “Sumps” (based on ARB’s proposed definitions both could be an impoundment that store produced water, see yellow highlighted text above). However, the control requirements of § 95669(a)(5) and record-keeping requirements of § 95671(a)(1)(A) and (B) and Appendix A Table A1 apply to sumps and ponds differently. The definitions as currently written will not allow an operator to differentiate between a sump and a pond. In addition, the definition of “pond” needs to exclude containment structures, sand separation equipment, and steam blowdown pits. Containment structures are utilized to contain any releases and minimize impacts to the environment. Steam blowdown pits collect condensed steam which will not contain GHG pollutants.

Recommendation 7: WSPA recommends that ARB clarify the definition of the term “Pond” by basing it on the existing and industry-understood definition of Pond in SVAPCD Rule 4402 as follows –
WSPA Comments  
Draft Regulation for Greenhouse Gas Emission Standards  
for Crude Oil and Natural Gas Operations (June 2016)  

July 18, 2016

(42) “Pond” means any very large excavation that is used for the routine storage and or disposal of clean produced water, is not used for the separation of oil and water, and has no more than five percent visible oil-covered surface area. Steam blowdown pits are not ponds - an excavation or impoundment for the storage and disposal of produced water and is not used for crude oil separation or processing.

WSPA also recommends that ARB add the definition for the term “clean produced water” defined in SJVAPCD Rule 4402 as follows –

Clean Produced Water: produced water containing less than 35 milligrams per liter of VOCs as determined by EPA Test Method 413.2, 418.1 or 1654A and/or, if necessary, EPA Test Method 8260 or 8268. Ethane, provided that the ethane fraction of the hydrocarbon vapors is less than 20 percent by volume, and hydrocarbons heavier than C14 may be excluded from the total concentration. Water samples collected for analysis shall be collected within a five foot radius of the sump inlet. One sample shall be collected near each inlet and the results averaged.

Issue 8: ARB’s definition of term “Pressure Vessel” is inaccurate.

“Pressure vessel” means any hollow container used to hold gas or liquid and rated, as indicated by an ASME pressure rating stamp, and operated to contain normal working pressures of at least 15 psig without vapor loss to the atmosphere.

Based on ARB’s definition in Section § 95667, pressure vessels cannot have vapor loss to the atmosphere. This is not true since all pressure vessels have pressure relief valves for safety purposes. In emergency or upset conditions, pressure relief valves allow release of vapors to balance pressure within the system.

Recommendation 8: WSPA recommends that ARB correct the definition of the term “Pressure Vessel” as follows –

(47) “Pressure vessel” means any hollow container used to hold gas or liquid and rated, as indicated by an ASME pressure rating stamp, and operated to contain normal working pressures of at least 15 psig without continuous vapor loss to the atmosphere.

Issue 9: The proposed regulation has the following definition of vapor control device –

“Vapor control device” means destructive or non-destructive equipment used to control emissions.

The definition of “vapor control device” needs to exclude backup safety devices (e.g. flares) that are used to abate overpressure situations or perform maintenance on equipment.

Recommendation 9: WSPA recommends that ARB correct the definition of the term “Vapor control device” as follows-

(60) “Vapor control device” means destructive or non-destructive equipment with the primary purpose used to control emissions.
WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)
July 18, 2016

Separator and Tank Systems

Issue 10: Section 95668(a)(6) states that "By January 1, 2019, owners or operators of an existing separator or tank system with an annual emission rate greater than 10 metric tons per year of methane shall control the emissions from the separator and tank system and uncontrolled gauge tanks located upstream of the separator and tank system with the use of a vapor collection system as specified in section 95668(c)." (emphasis added).

WSPA is concerned by the inclusion of gauge tanks in section 95668(a)(6) with no notice or discussion of this addition. Section 95668(a)(6) now requires owners or operators of existing separator or tank systems with annual emissions greater than 10 metric tons per year of methane to control emissions from gauge tanks in addition to controlling emission from the separator and tank system. No prior versions of the proposed regulation mentioned gauge tanks nor were gauge tanks discussed with industry prior to this draft being released. In addition, as discussed below, none of the supporting documents provide a compelling reason to include gauge tanks in the regulation and, in fact, most of the supporting documents do not even mention gauge tanks.

WSPA’s understanding was that the vapor collection system would only be required on the primary separator and secondary tank within a separator and tank system. With this understanding, WSPA provided a significant amount of data to assist ARB with estimating and prioritizing emissions from separator and tank systems. ARB’s emissions estimates described in Appendix B of the proposed regulatory package do not include any estimates for gauge tank emissions or costs of control. It appears that this source was added at the last minute without proper cost-effectiveness analysis as required in the Economic Analysis and Standardized Regulatory Impact Assessment (‘SRIA’), and without the required environmental analysis under the California Environmental Quality Act (‘CEQA’).

WSPA is providing the following data, emissions estimates, and costs related to gauge tanks.

1. **Function**: Gauge tanks are used to test the percent oil and water cut from a single well. In most cases, the test is conducted in automated well testers that are closed loop pressure vessels. In certain heavy oil fields (API Gravity < 20), gauge tanks may be used to conduct the tests of remotely located wells.

2. **Location**: Gauge tanks are located close to wells to enable testing and each tank may be used to test one or more wells. Only one well is tested at any given time.

3. **Frequency of Operation**: Gauge tanks do not operate continuously. Most gauge tanks operate once a week or once every few weeks depending on the throughput of the wells they serve. Wells with low throughputs require less frequent testing. Each test may last an average of 2-4 hrs.

4. **Geographical and Operational Separation**: Although the emissions estimates provided in ARB’s economic analysis do not provide any information on gauge tanks, from recent discussions, WSPA understands that ARB has assumed there are approximately 500 uncontrolled gauge tanks in California. However, according to WSPA’s estimates, members have approximately 200 uncontrolled gauge tanks with capacities ranging from 20 bbl to 200 bbl. As stated above, these tanks are located close to remote heavy oil wells and away from centralized tank farms. There is usually significant geographic separation between gauge tanks and
WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)

July 18, 2016

separator and tank systems. In addition, gauge tank operations are separate from the operations of separator and tank systems.

5. Emissions Estimates Not Included in ARB Analysis: ARB’s emissions estimates described in Appendix B and Appendix D do not include any estimates for gauge tank emissions.

6. Emissions Levels Very Low: in order to estimate emissions from gauge tanks, WSPA collected member data of a few random flash test samples of gauge tanks. All samples were taken upstream of the gauge tanks. Using this data, WSPA developed average emission factors for methane emissions from gauge tanks in $\text{MT CH}_4$ per barrel of crude oil and $\text{MT CH}_4$ per barrel of produced water. The results are outlined in Table 1 below.

Table 1: Results of Plan Test Data at station one pumping station of gravel tanks.

1. Actual oil through rate of the tank.
2. Calculated daily average oil through rate (oil through rate × 365 (days/year))
3. Production fraction (CGP) = Oil Throughput (gal/day) / Total Oil Throughput (gal/day)
4. Gas to Oil Ratio = Gas Volume in m³ / Oil Volume in m³
5. Water to Oil Rate = Water Volume in m³ / Oil Volume in m³
6. CH₄ % in water = CH₄ concentration in water / CH₄ concentration in air × 100%
7. Emission Factor CH₄ Dry (ao/mm³) = CH₄ emissions from tank gas, water, and MT CH₄ / Total oil through rate of the tank (gal/day)
8. Emission Factor CH₄ Wet (ao/mm³) = CH₄ emissions from tank gas, water, and MT CH₄ / (Total oil through rate of the tank (gal/day) + Total water through rate of the tank (gal/day))
Based on the above emissions data, the average emissions are 0.14 MT CH₄ per gauge tank per year or 0.000006 MT CH₄ per year/bbl Oil and 0.000004 MT CH₄ per year/bbl Water.

The total emissions from all gauge tanks are expected to be approximately 28 MT CH₄ per year (200 x 0.14 MT CH₄ per gauge tank per year). Compared to ARB’s total estimated emissions from uncontrolled tanks and separators (Economic analysis, Appendix D, Page B-25), our estimates show that emissions from gauge tanks represent less than 0.36% of the expected emissions reductions for the source category (28 MT CH₄ per year ÷ 7,865 MT CH₄ per year).

7. Costs of Control:

a. Economic Analysis: ARB’s Economic Analysis does not take into account the cost to control emissions from gauge tanks with the use of a vapor collection system, as required by section 95668(a)(6). The legal deficiencies of the Economic Analysis are discussed further in issue 53 below.

b. SRIA: ARB’s SRIA also does not consider the impacts of controlling emissions from gauge tanks in its analysis. In fact, the SRIA does not mention gauge tanks and does not consider potential emission reductions from adding vapor collection systems to such tanks or the potential cost of such controls. The legal deficiencies of the SRIA are discussed further in issue 54 below.

8. Draft Environmental Assessment: ARB’s Environmental Assessment (“EA”) for the proposed regulation does not take into account gauge tanks and the potential environmental impacts associated with the proposed regulation’s requirement to control emissions from those tanks with vapor collections systems. The legal deficiencies of the EA are discussed in further detail in issue 55 below.

**Recommendation 10:** WSPA recommends that ARB remove gauge tanks from the proposed regulation. WSPA’s recommended changes to the proposed requirements are detailed in Attachment A.

**Issue 11:** Section 95668(a)(2)(A) of the proposed regulation states that the requirements are not applicable to separator and tank systems that receive less than 50 barrels of crude oil per day and that receive less than 200 barrels of produced water per day. There is no mention of condensate.

In addition, several operators may have large amounts of produced water compared to the amount of oil produced. In several fields, the ratio of oil to produced water can be 1-10% oil to 99-90% water. Furthermore, ARB has not considered low condensate throughputs for this exemption.

**Recommendation 11:** WSPA recommends that ARB recognize the average production ratios in California and make the following changes to Section 95668(a)(2)(A):

Separator and tank systems or any tanks that receive less than 100 50 barrels of crude oil or condensate per day and/or that receive less than 1,000 250 barrels of produced water per day.

WSPA’s recommended changes to the proposed requirements are detailed in Attachment A.
Issue 12: Section 95668(a)(2) does not recognize any exemptions for heavy oil fields where the amount of flash gas is expected to be insignificant. Our understanding is that ARB would like to not impose burdensome requirements on heavy oil fields where the amount of flash gas is expected to be very low.

Recommendation 12: In order to clarify the above understanding, WSPA recommends that ARB add the following to Section 95668(a)(2) –

(B)(C) Separator and tank systems or any tanks that receive production from wells that have an API gravity of 20 or lower.

WSPA's recommended changes to the proposed requirements are detailed in Attachment A.

Issue 13: Section 95668(a)(2) does not recognize any exemptions for small tanks. By design, smaller production wells are served by small tanks and the estimated emissions expected to be insignificant.

Recommendation 13: WSPA recommends that ARB add the following to Section 95668(a)(2) –

(E) Tanks with a capacity of 300 bbls or smaller.

WSPA's recommended changes to the proposed requirements are detailed in Attachment A.

Issue 14: Section 95668(a)(2) provides exemptions for separators or tanks that have not stored liquid for 30 days. WSPA believes that 30 days is a short duration. In several cases, a tank may be used to store liquids for only a few hours during a day.

Recommendation 14: WSPA recommends that ARB modify Section 95668(a)(2) as follows –

Separators, tanks, and sumps that have self-contained crude oil, condensate, or produced water for at least no more than a total of 45 30 calendar days or 1,080 hours during a calendar year.

WSPA's recommended changes to the proposed requirements are detailed in Attachment A.

Issue 15: Section 95668(a)(2) provides exemptions for separators or tanks that recover less than 10 gallons per day of any petroleum product. WSPA believes that 10 gallons is a very small volume.

Recommendation 15: WSPA recommends that ARB modify Section 95668(a)(2) as follows –

(HH) Tanks that recover less than 10 gallons-barrels per day of any petroleum product from equipment provided that the owner or operator maintains, and can make available at the request of the ARB Executive Officer, a record of the amount of liquid recovered.

WSPA's recommended changes to the proposed requirements are detailed in Attachment A.
Issue 16: Sections 95668(a)(2)(D) & (E) outline exemptions for tanks holding or storing liquids from a well less than 90 days unless the liquid is from a well that underwent a well stimulation treatment. Our understanding is that ARB intends to not exempt "circulation tanks used in conjunction with the well stimulation treatments" with this exception. However, as currently written, the statements might be misunderstood to include any tank that receives liquids from any well that may have undergone well stimulation treatment in the past.

In addition, it is our understanding that the exemptions below include general facility maintenance, including spill response. When taking equipment out of service, portable tanks are used to temporarily replace the equipment or to store fluids transferred out of the equipment.

Recommendation 16: WSPA recommends that ARB revise the section to read:

(6)(F) Tanks used for temporarily separating, storing, or holding liquids from any newly constructed well for up to 90 calendar days following initial production from that well, provided that the tank is not used to circulate liquids from a well that has been subject to a well stimulation treatment—This does not include circulation tanks used in conjunction with well stimulation treatments.

(6)(G) Tanks used for temporarily separating, storing, or holding liquids from wells undergoing rework, maintenance, or inspection for up to 90 calendar days, provided they are not used to circulate liquids from a well that has been subject to a well stimulation treatment—This does not include circulation tanks used in conjunction with well stimulation treatments.

Issue 17: WSPA's previously submitted comments on May 22, 2015 address high costs associated with the installation of vapor collection systems. Based on 2013 GHG MRR data, a threshold of 10 MT CH₄/yr would result in a compliance cost of about $200/MT CO₂e (GWP = 21 for CH₄) or $56/MT CO₂e (GWP = 72 for CH₄).

ARB's economic analysis uses very low and outdated 10-yr old costs (EPA 2005) of installing a vapor recovery system (Table B-7, ARB Economic Analysis). The costs today are at least 3-10 times the costs depending on the size of the operations. Furthermore, ARB does not provide the basis for savings that are estimated to be 2,637 MT CH₄ or $498,259 per year or the cost-effectiveness of $7.81 per MT CO₂e. In addition, all gas is assumed to be saleable pipeline quality (high BTU content) with a market value of $3.44 per Mscf. However, most gas collected in vapor recovery systems has low BTU content, does not meet pipeline specifications, and cannot be sold. ARB's cost-effectiveness analysis is inadequate with multiple assumptions.

WSPA's cost effectiveness analysis (submitted March 4, 2016) shows that the threshold of applicability at 100 MT CH₄ will have a 20-yr cost-effectiveness of ~$40/MT CO₂e (GWP = 21 for CH₄) or ~$12/MT CO₂e (GWP = 72 for CH₄) controlled.

ARB has still not provided a unit-level or operator level cost-effectiveness analysis. WSPA re-asserts the importance of conducting unit-level cost effectiveness analysis for objective evaluation of economic impacts on operators.
Recommendation 17: WSPA requests that ARB revise the economic analysis with latest cost data and obtain realistic gas quality data to evaluate the market value to determine the actual savings. WSPA strongly urges that ARB review the data that has been already provided (March 4, 2016) and re-consider the threshold of applicability at 100 MT CH₄.

Issue 18: Certain operators may be willing to voluntarily install vapor recovery systems on separator and tank systems regardless of the emissions by January 1, 2019. The current regulation does not allow a provision for such operators to forgo the flash testing requirements.

Recommendation 18: WSPA requests that ARB allow the following provision to the Section 95668(a)(3) –

(3) By January 1, 2018, owners or operators of existing separator and tank systems that are not controlled for emissions with the use of a vapor collection system shall conduct flash analysis testing of the crude oil, condensate, or produced water processed, stored, or held in the system.

(A) An operator may forego the January 1, 2018 flash analysis testing requirement and instead elect to install vapor recovery system on a separator and tank system as specified in 95668(a)(6). In order to comply, the owner or operator must submit permit applications to the local Air District by January 1, 2018.

Issue 19: Section 95668(a)(5)&(6) of the proposed regulation require addition of a vapor collection system to an existing separator and tank system based on the result of a single annual flash analysis test. A single test result may indicate an annual emission rate very close to 10 metric tons per year of methane which would require an operator to make a large capital investment based on only one data point. Section 95668(a)(5)(F) allows the ARB Executive Officer to request additional testing at their discretion. The operator should be given a similar opportunity to be confident in the result of the testing.

Recommendation 19: WSPA recommends the addition of a Section 95668(a)(5)(G) to allow the operator of a separator and tank system to perform additional flash analysis testing in a year and use the average of the test results to determine the need for addition of a vapor collection system as specified in 95668(a)(6).

(G) Operators of a separator and tank system may perform additional flash analysis testing in a year and use the average of the test results to determine the need for addition of a vapor collection system as specified in 95668(a)(6).

WSPA’s recommended changes to the proposed requirements are detailed in Attachment A.

Issue 20: Section 95668(a)(7) of the proposed regulation states that new separator and tank systems have 180 days from initial flash testing to install vapor collection system. WSPA believes that this does not allow for sufficient time to receive lab analysis and results and for subsequent design, procurement and contracting the construction of the system. Additionally, for a project of this magnitude, budgets must
be presented and approved for most stakeholders at least a year in advance. Furthermore, the permitting process may take longer than expected and dependent on Air District schedules.

Assuming an implementation date of early 2017, the proposed regulation currently allows for up to 2 years for vapor collection system installation on existing systems over the emissions control threshold.

**Recommendation 20**: WSPA recommends that ARB allow for 2 years from initial flash testing, for the installation of vapor collection system on a newly constructed separator and tank system.

WSPA's recommended changes to the proposed requirements are detailed in Attachment A.

**Issue 21**: The proposed regulation does not provide any clarity on requirements for existing systems that exceed the threshold after January 1, 2019.

**Recommendation 21**: WSPA recommends that ARB clarify requirements for existing systems that exceed the threshold after January 1, 2019 allowing for 2 years from the date of flash testing when the emissions threshold is exceeded to install a vapor collection system. WSPA recommends the following addition to the proposed requirements –

(2)(b) Beginning January 1, 2019, owners or operators of existing separator and tank systems that exceed the annual emission rate of 100 metric tons per year of methane shall control the emissions from the separator and tank system with the use of a vapor collection system as specified in section 95668(c) within 24 months of conducting flash analysis testing.
Circulation Tanks for Well Stimulation Treatments

**Issue 22**: WSPA resubmits our previous comment submitted on March 4, 2016 with regards to the definition of a circulation tank as seen below.

Section 95667(a)(6) defines circulation tanks as follows -

“Circulation tank” means a tank or portable tank used to circulate, store, or hold liquids or solids from a crude oil or natural gas well during or following a well stimulation treatment.

It is our understanding that ARB intends to control circulation tanks that are used in conjunction with the well stimulation events. The current definition includes the term “or following” that may be misinterpreted to include any tanks receiving fluids from a well that may have undergone well stimulation in the past.

**Recommendation 22**: WSPA recommends that ARB clarify the definition to accurately reflect ARB’s intent -

“Circulation tank” means a tank or portable tank used to circulate, store, or hold liquids or solids from a crude oil or natural gas well during or following a well stimulation treatment but prior to the well being put on production.

**Issue 23**: Section 95668(b)(1) outlines the requirements of a best practices management plan (BPMP) required to be implemented when circulation tanks are used in conjunction with well stimulation treatments. WSPA understands operators can submit BPMP that are representative for similar groups of wells undergoing a similar process at a facility.

**Recommendation 23**: WSPA recommends the following language to Section 95668(b)(1):

(1) Beginning January 1, 2018, owners or operators of circulation tanks used in conjunction with well stimulation treatments at facilities listed in section 95666 shall implement a best practices management plan that is designed to limit methane emissions from circulation tanks, and shall provide that plan available to ARB upon request. Each plan must contain a list of best practices, identified on the basis of substantial evidence recorded in the plan, to address the following issue areas:

(A) Inspection practices to minimize emissions from circulation tanks.
(B) Practices to reduce venting of emissions from circulation tanks.
(C) Practices to minimize the duration of liquid circulation.
(D) Alternative practices to control vented and fugitive emissions.

**Issue 24**: ARB’s emissions estimates and costs associated with circulation tanks are outlined below –
Emissions from Circulation Tanks are Extremely Small

Based on the emission estimates presented by ARB, the circulation tank source category represents 0.4% of the total statewide emissions that ARB plans to control with the proposed regulation. As seen above, per ARB, this represents 0.12 MT or 264.5 lbs CH₄ per event. WSPA does not agree with these emissions estimates since the 2015 WSPA circulation tank test results demonstrate even fewer emissions.

---

19 Based on Kern County Environmental Impact Assessment Report, approximately 1,025 well stimulation events were conducted over a period of 21 months (1/1/2014 and 9/30/2015). Based on this data, we estimated approximately 566 well stimulation events are conducted annually within the state of California.

20 ARB Presentation February 4, 2016
21 Per ARB’s estimates presented on February 4, 2016, emissions from Circulation tanks are 4,900 MT CO₂e out of a total proposed control of 1.2 million MT CO₂e
with an average of approximately 0.012 or 26 lbs CH₄,²² per event (ten times smaller emissions). This data shows that circulation tanks are an insignificant source of emissions in California, and ARB has not provided the technical basis for proposing a regulation to control emissions from such a small source category.

- **Zero Benefit/Market-Value of Gas**

  WSPA disagrees with ARB's valuation ($17,000) of the gas captured from circulation tanks. These vapors contain very few hydrocarbons. The WSPA testing showed an average higher heating value (HHV) of 7 Btu/scf²³. The estimated average heat content is 1.6 MMBTU for an entire event. There is no market-value for this gas as it does not meet pipeline specifications and cannot be sold.

  When compared to pipeline quality gas (900 – 1,150 Btu/scf) or field waste gas (200 – 900 Btu/scf), the vapors (7 Btu/scf) are extremely low quality and non-combustible without the addition of supplemental higher heating value fuel. There is zero financial benefit in capturing this gas. ARB's proposed benefits of $17,000 are completely baseless.

  WSPA is concerned that a significant amount of effort will be required by ARB and Air Districts to implement and manage the program for minute methane emissions reductions (easily outweighed by emissions from additional criteria pollutants) and virtually no associated benefit. Additionally, operators would have to comply with the proposed unsafe and exceedingly burdensome requirements outlined below.

---

²² Per 2015 WSPA Circulation Tank Test Results, the methane emissions ranged from 0.24 lb CH₄ to 132 lb CH₄ with an average of 26 lb CH₄.

²³ Per 2015 WSPA Circulation Tank Test Results, the calculated HHV ranged from 0.003 Btu/scf to 57 Btu/scf with an average of 7 Btu/scf.
WSPA Comments  
Draft Regulation for Greenhouse Gas Emission Standards  
for Crude Oil and Natural Gas Operations (June 2016)  
July 18, 2016

<table>
<thead>

<tr>
<td>Option 2: Direct vapors to a Vapor Control Device</td>
<td>Installation of Flare (15 ppmv NOx @3% O2)</td>
<td>Increased GHG and criteria pollutant emissions from supplemental fuel for flaring</td>
</tr>
</tbody>
</table>

The above requirements are being proposed for a source with extremely small emissions and used for very limited periods of time leading to capture of emissions less than the 1 MT CH4 (2015 WSPA Recirculation Tank Testing).

**Recommendation 24:** WSPA does not believe that there is a justifiable reason for ARB to propose control requirements for this source category as no benefit can be gained from the potential capture of an insignificant amount of low quality vapors from circulation tanks. Additionally, WSPA believes that the control of this source category cannot be achieved safely or without additional criteria pollutants. WSPA is recommending that ARB allow the continued use of best management practices to achieve emissions reductions beyond 2020.

WSPA’s recommendation for regulatory language is included in Attachment A.
WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)

July 18, 2016

Issue 26: ARB has proposed unsafe mandatory control measures that require operators to install a vapor collection system (Section 93666(b)) on circulation tanks and connect the system to either an existing sales line, existing fuel line or inject the vapors underground. Vapors collected from the circulation tanks contain insignificant and varying concentrations of hydrocarbons (C1 – C6+) ranging from 0 to 5%.24 with high amounts of introduced air from the circulation process (95-100%). Connecting oxygen-rich vapors to an existing sales or fuel line containing hydrocarbons will create an explosive environment.

WSPA has been re-iterating this concern to ARB (WSPA letters dated March 4, 2016) without response. ARB has not included any safety provisions in the regulation. While it appears that ARB is proposing several options, the fact is that the safety concerns eliminate almost all options leaving flaring as the only method of control for this source category, if allowed by Air Districts. In the absence of Air District approval, operators would have to shut down operations (§93666(c)(5)).

Recommendation 25: WSPA recommends that ARB remove unsafe mandatory control measures from the proposed regulation. At a minimum, WSPA urges ARB to incorporate alternative control methods that maintain safe practices.

WSPA’s recommendation for regulatory language is included in Attachment A.

Issue 26: As discussed above, flaring is the only option available for an operator in the absence of safe alternatives for emissions control from circulation tanks. There are significant issues with the flaring option as discussed below:

Restrictions on Flare Use

- **Permitting**: ARB is assuming that Operators will be allowed to install new flares or use existing flares. However, it is extremely difficult, if not impossible, to obtain permits from local Air Districts for new or increased flaring, especially in regions classified as non-attainment, such as within the San Joaquin Valley Air Pollution Control District.

- **Flare use (Emergency only)**: Operators may have existing stationary emergency flares on site. However, these flares can only be used in emergency or upset conditions. Emergency flares are not allowed to be used for flaring of vapors during normal operation of circulation tanks. Further, these flares cannot accommodate the low volume and low BTU content emissions from recirculation events without makeup fuel.

- **Location of Existing Process Flares**: There are few stationary process flares currently permitted in the state for oil and gas operations and most are not located within the vicinity of field operations where well stimulation occurs. If any are located near the fields, the flares are larger and sized for field gas streams with higher flow rates and heat content. These larger flares are

---

24 Per 2015 WSPA Circulation Tank Test Results, total hydrocarbons (C1 to C6+) ranged from 0 to 5% by volume.
not able to adequately combust the extremely low heating value and low volume vapors from circulation tanks unless supplemental fuel is also combusted to meet all regulatory and stoichiometric requirements.

- **Portable Flares**: Small portable flares (usually rented or leased), as described above, are the only option for operators but can only be used at accessible, remote locations where safety and risk are not an overriding issue. In most cases where well stimulation events occur in California (e.g., Beraldine Field), oil fields are congested and portable flares can pose safety issues due to fire risk.

**Control Measures Will Result in Higher Emissions**

Proposed control measures will result in additional GHG and criteria pollutant emissions from both capture and control of vapors from circulation tanks. WSPA has quantified the additional emissions below.

- **Emissions from Capture of Vapors from Circulation Tanks**: Operators are required to capture vapors from circulation tanks by using a portable vapor recovery compressor. Compressors in this service are typically powered by a portable diesel generator. Additional criteria pollutant emissions are expected from the diesel generators and the estimates are provided in the table below.
### WSPA Comments

**Draft Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Operations (June 2016)**

**July 18, 2016**

</tbody>
</table>

As seen above, capture of vapors from circulation tanks using a vapor recovery system alone produces approximately 38 lbs of additional NOx per event mostly within the jurisdiction of SJVAPCD²⁷.

- **Emissions from Flaring of Vapors from Circulation Tanks:** As stated above, the vapors from circulation tanks contain very few hydrocarbons making combustion of the vapors inefficient (i.e., inconsistent burning, low destruction efficiency, and the potential for smoke) or impossible without the addition of supplemental fuel. The average higher heating value (HHV) of the vent gas from circulation tanks is expected to be approximately 7 Btu/scf²⁸ at an average flow rate of 527 scfm with inconsistent and varying concentrations of methane during the circulation process.

  Per 40 CFR 60.18, flares²⁹ are required to maintain an HHV of at least 300 Btu/scf. In order to combust vapors from circulation tanks and meet the requirements of 40 CFR 60.18, operators would be required to add supplemental fuel. The amount of supplemental fuel required would depend on the quality of the vapors collected from circulation tanks and the size of the flare (minimum flow for the available flare).

  The following table shows methane emissions from control of vapors from circulation tanks with natural gas (HHV = 1,020 Btu/scf)³⁰ as supplemental fuel using a low NOx flare as specified in Section 95560(c)(4)(B)(2) –

---

²⁵ Emission Factors from AP-42 Section 3.3-1 (https://www3.epa.gov/ttn/chief/ap42/chp3finalap42c3e03.pdf)
²⁶ Based on Kern County Environmental Impact Assessment Report, approximately 1,025 well stimulation events were conducted over a period of 21 months (1/1/2014 and 9/30/2015). Based on this history, additional emissions were based on an estimated rate of 586 well stimulation events per year.
²⁷ Based on Kern County Environmental Impact Assessment Report, 99.7% percent of well stimulation events occur in Kern and Kings Counties, which are under the jurisdiction of San Joaquin Valley Air Pollution Control District.
²⁸ Per 2015 WSPA Circulation Tank Test Report, the calculated HHV ranged from 0.003 Btu/scf to 57 Btu/scf with an average of 7 Btu/scf.
²⁹ For steam-assisted or air-assisted flares required to meet Best Available Control Technology (BACT).
³⁰ PUC natural gas heating value
As seen above, flaring of vapors from circulation tanks produces approximately 1.8 lbs of additional NOx per event.

- **Total Emissions from Capture and Control of Vapors from Circulation Tanks:**

The following table shows methane emissions from circulation tank vapors (Emissions with No Control) and emissions from capture (diesel generator) and control (Low NOx flare) of vapors from circulation tanks as specified in Section 86688(a)(4)(E)(2) –

The additional and significant amounts of criteria pollutant emissions significantly outweigh the effectiveness of proposed reductions on extremely small amounts of methane emissions (0.4% of the state-wide methane emissions) from circulation tanks. Based on the information provided above, WSPA does not believe the proposed controls are justified.

High Costs of Vapor Control Device

- The costs provided by ARB significantly underestimate the costs of control ($317 per event or $186,000 statewide). Although none of the technologies currently available have demonstrated safe and efficient controls, the estimates for renting potential control equipment are significantly higher than what ARB is assuming. Based on our conversations with equipment suppliers, the equipment to separate gas from a circulation tank (not including piping) rental alone would cost an operator between $3,600 and $7,700 per event or $2.1M and $4.5M statewide for the assumed 586 well stimulation events per year, if operators are allowed to use a temporary flare.

- It is clear that ARB’s cost analysis has not included costs of permitting, engineering and safety analysis, auxiliary equipment rental (such as compressor, flare, piping, and other necessary instrumentation such as meters), costs associated with labor to configure and dismantle the control equipment, training, and other costs.

Proposal Is Not Cost-Effective

- WSPA believes that the proposed cost-effectiveness does not represent the true cost of this control measure.

13 Based on 2014 emissions inventory data from existing permitted flares in San Joaquin Air Pollution Control District.
ARB has not addressed any of these issues. As discussed above, WSPA is concerned that ARB is proposing a significant amount of effort (and costs) to control a very small amount of emissions. WSPA believes that the requirements are ineffective in terms of controlling emissions and not at all cost-effective.

Recommendation 26: For reasons described above, WSPA recommends that ARB consider changes proposed in Section 95668(b) suggested in Attachment A.

Issue 27: Section 95668(b)(2) states that by January 1, 2019, operators must submit an emissions testing report detailing the results of testing emissions control measures on recirculation tanks. There are several issues with this requirement –

- **Lack of Clarity in Testing Requirements:** It is unclear who must conduct the test, how many tests must be conducted, and what is considered an appropriate test.

- **Engineering and Safety Evaluations are Needed prior to Testing:** So far, ARB has only discussed few ideas with equipment/engineering vendors and then shared with WSPA as probable solutions. ARB has yet to actually identify or propose a viable control technology that would achieve the proposed requirements. Engineering and safety evaluations are needed to determine which technologies need to be considered, if any technologies have the potential beyond just preliminary concepts, and if any technologies have the potential to be safely implemented and achieve the desired results. Without this evaluation, ARB is requiring operators to conduct testing and implement controls. WSPA believes that this is a critical gap in the proposed regulation.

- **Concerns about Economic Impacts of Testing:** WSPA is also concerned that the economic impact of this testing has not been taken into account in ARB’s economic analysis. Notwithstanding our concerns expressed above regarding safety and potential increase of additional criteria and methane emissions, ARB’s desire to see new technologies developed for circulation tanks should be researched and funded by ARB and the burden should not be placed on operators. WSPA members understand that WSTs are conducted by operators, and are willing to work with ARB, subject to safety and HES concerns and well stimulation permit approval. ARB should provide the resources for this research activity. WSPA estimates that the cost of this testing and reporting could range from $25,000 to $100,000 per event, dependent on the type of technology that is being tested. Currently, no technology is available in the market that can safely and effectively capture and control emissions from this system.

- **Lack of Results Assessment Step Prior to Control Requirements:** There is an underlying conclusion in the proposed regulation that a 95% control can be achieved for the circulation tanks in a rather short timeline and within the cost estimates assumed by ARB within the economic analysis. However, if such safe, cost-effective technology does not emerge from the testing, operators would have to shut down the WST operations. ARB needs to recognize that this scenario may occur and must prepare to conduct additional economic analysis and environmental assessment using the test results. ARB should also include alternate technically feasible means to comply in such cases. Therefore, in the event no safe and cost-effective control technologies...
emerge from the testing, the operator should be able to continue to implement the BPMPs beyond January 1, 2020.

- **Lack of Clarity in Requirements Beyond 2020:** It is WSPA’s current understanding, from conversations with ARB staff, that it is the intention of the regulation to allow for continued use of BPMPs beyond 2020 if appropriate, safe, and compliant control technology cannot be developed even after best efforts have been made to do so. WSPA is concerned that the current proposed regulation does not reflect this intent.

**Recommendation 27:** WSPA recommends that ARB remove Sections 95668(b)(2)&(3) from the proposed regulation.

If ARB continues to require operators to evaluate technologies proposed to ARB by various vendors, ARB must clarify the requirements of 95668(b). WSPA suggests the following:

(2) **By January 1, 2019:** An owner or operator of circulation tanks used in conjunction with well stimulation treatments beginning January 1, 2018 at the owner or operator’s wells, shall conduct testing of control technologies that are available as of January 1, 2017 and determined by the operator to meet the operator’s environmental and safety standards.

(2)(3) A written report including the detailed results of each test or a group of tests must be provided to the ARB Executive Officer by January 1, 2019, with a written report that details the results of equipment used to control emissions from circulation tanks with at least 95% vapor collection and control efficiency.

(A) The report shall include the results of testing conducted by the owner or operator or equipment manufacturers that demonstrate describe the measured vapor collection and control efficiency of the equipment, including the disposition of collected vapors.

(A)(B) The ARB Executive Officer will evaluate the results of testing to determine control requirements on circulation tanks and will re-evaluate this section beyond 2020.

(4) **By January 1, 2020:** Owners or operators of circulation tanks used in conjunction with well stimulation treatments shall control emissions from the tanks with at least 95% vapor collection and control efficiency.

WSPA’s recommended changes to the proposed requirements are detailed in Attachment A.
Vapor Collection Systems and Vapor Control Devices

**Issue 28:** Section 95668(c) divides separator and tank systems into two “buckets”: 1) a facility with an existing sales gas system, fuel gas system or gas disposal well(s), or 2) a facility currently without one or more of those three options. For facilities in the first bucket, there is no recourse should the existing gas handling option reach capacity or experience a catastrophic failure. For example, what options will be available for a facility that wants to expand and has an existing gas disposal well already operating near its capacity as established by the DOGGR? The facility cannot install a vapor control device as it is not allowed under 95668(c)(2). If that gas disposal well undergoes a catastrophic failure and the facility cannot obtain a new disposal well permit from the DOGGR, what options are available?

This section is entirely too prescriptive to be adapted across the entire suite of production operations in such a large and diverse state. An operator should be able to implement BACT and install the equipment.

**Recommendation 28:** WSPA recommends the following language:

(2) Unless section 95668(c)(3) applies, the vapor collection system shall safely direct the collected vapors to one of the following until system capacity is reached:

(A) Existing sales gas system; or,

(B) Existing fuel gas system; or,

(C)Existing gas disposal well not currently under review by the Division of Oil and Gas and Geothermal Resources;

(3) If no safe existing sales gas system, fuel gas system, or gas disposal well specified in section 95668(c)(2) is available at the facility or the existing system reaches capacity, the owner or operator must control the collected vapors as follows:

(A) For facilities without an existing vapor control device installed at the facility:

1. The owner or operator must install a new vapor control device that achieves at least 95% vapor control efficiency and incorporates Best Available Control Technology as defined and determined by the local air district for NOx; or

(B) For facilities currently operating a vapor control device and which are required to control additional vapors as a result of this subarticle:

1. The owner or operator must demonstrate to the local air district that an existing vapor control device achieves at least 95% vapor control efficiency and incorporates best available control technology as defined and determined by the local air district for NOx; or
WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)

July 18, 2016

(8)(2) The owner or operator must replace the existing vapor control device with a new vapor control device as specified in section 95668(c)(4) to control all of the collected vapors, if the device does not already meet the requirements specified in section 95668(c)(4).

WSPA’s recommended changes to the proposed requirements are detailed in Attachment A.

Issue 29: Section 95668(c)(4)(B)(2) does not allow use of supplemental fuel gas. As stated numerous times in the Staff Report (for example on page E5-1 and page 1) the goal of the proposed regulation is to obtain the maximum GHG emission reductions from the sector in a technically feasible and cost-effective manner. It is not technically feasible to combust collected vapors that have a heating value below the combustible range without the introduction of supplemental fuel gas. The equipment/engineering vendors WSPA member companies have consulted agree that supplemental fuel will be required for these gases.

As stated above, WSPA understands that the use of supplemental fuel will result in additional criteria pollutant emissions in order to dispose of collected vapors from circulation tanks. However, with no supplemental fuel, ARB’s requirements put operators in a catch-22 situation — operators have to install vapor control devices that achieve 95% control while the only potential control technology will require a flare/inocinator that will need supplemental fuel for safe and complete combustion but will also add criteria pollutant emissions. To comply in this situation, the operators will have no other choice but to shut-down operations.

Recommendation 29: WSPA recommends that ARB allow operators to use supplemental fuel where the heating value below the combustible range. WSPA recommends the following change to Section 95668(c)(4)(B)(2) —

2. A vapor control device that achieves at least 95% vapor control efficiency of total emissions and does not generate more than 15 parts per million volume (ppmv) NOx when measured at 3% oxygen, and does not require the use of supplemental fuel gas other than gas required for a pilot burner to operate.

WSPA’s recommended changes to the proposed requirements are detailed in Attachment A.

Issue 30: Section 95668(c)(5) of the proposed regulation states:

If the collected vapors cannot be controlled as specified in section 95668(c)(2) through (4), the equipment subject to the vapor collection and control requirements specified in this subarticle may not be used or installed and must be removed from service by January 1, 2018.

WSPA believes that the January 1, 2018 implementation date of this requirement should be January 1, 2019 to align with current proposed requirements of vapor collection system installation and as written is a carryover from a previous draft of the regulatory language.

Additionally, WSPA believes that in some areas of the State [95668(c)(4)(B)], if the existing system is permitted and offset within the applicable Air District and is operating in compliance with the stated parameters contained in the permit, no further action should be required. Only when the permitted throughput is exceeded should any action be initiated by the operator. Furthermore, if the equipment is
permitted with the APCD, an updated permitting document would be required to address emissions resulting from the increased throughput. It is unreasonable for CARB to assume that because an additional well is brought online that the existing system (permitted, offset and properly designed) would require replacement.

**Recommendation 30:** WSPA recommends that ARB correct the implementation date of Section 95668(c)(5) as follows –

(5) If the collected vapors cannot be controlled as specified in section 95668(c)(2) through (4), the equipment subject to the vapor collection and control requirements specified in this subarticle may not be used or installed and must be removed from service by January 1, 2014 the date the vapor collection system is required.

WSPA’s recommended changes to the proposed requirements are detailed in Attachment A.

**Issue 31:** Section 95668(c)(5) of the proposed regulation allows 30 days for vapor recovery downtime for maintenance. In several cases, 30 days may not be enough especially if vendor delays occur.

**Recommendation 31:** WSPA recommends that ARB allow 60 days for vapor recovery downtime for maintenance.

WSPA’s recommended changes to the proposed requirements are detailed in Attachment A.
Reciprocating and Centrifugal Natural Gas Compressors

**Issue 32:** Sections 95668(d)(4) and (e)(4) require annual testing of rod packing vents from reciprocating natural gas compressors and west seal vents from centrifugal compressors. ARB's GHG MRR already requires annual testing and measurement of rod packing vents and west seal vents. This requirement has been in place since 2012. Operators subject to requirements of both regulations have to conduct duplicate tests to comply with both Section 95668(d)(2) and (e)(8) of the proposed regulation and GHG MRR leading to doubling of costs with no added emissions benefit.

**Recommendation 32:** WSFA recommends that ARB allow operators to use results from the annual testing conducted per the requirements of MRR. WSFA recommends the changes to Section 95668(d)(4) and (e)(4) as follows –

(B) The compressor rod packing or seal emission flow rate through the rod packing or seal vent stack shall be measured annually by direct measurement (high volume sampling, bagging, calibrated flow measuring instrument) while the compressor is running at normal operating temperature using one of the following methods:

1. Flow rates measured annually as per the methods described in Greenhouse Gas Mandatory Reporting Regulation Section 95153(h); or,

2. Vent stacks shall be equipped with a meter or instrumentation to measure the rod packing or seal emissions flow rate, or,

3. Vent stacks shall be equipped with a clearly identified access port installed at a height of no more than six (6) feet above ground level or a permanent support surface for making individual or combined rod packing or seal emission flow rate measurements.

(C) Centrifugal compressor wet seals shall be measured annually by direct measurement (high volume sampling, bagging, calibrated flow measuring instrument) while the compressor is running at normal operating temperature in order to determine the wet seal emission flow rate using one of the following methods:

(A) Flow rates measured annually as per the methods described in Greenhouse Gas Mandatory Reporting Regulation Section 95153(m); or,

(A)(C) Vent stacks shall be equipped with a meter or instrumentation to measure the wet seal emissions flow rate, or,

(B)(C) Vent stacks shall be equipped with a clearly identified access port installed at a height of no more than six (6) feet above ground level or a permanent support surface for making wet seal emission flow rate measurements.
Well Casing Vents

Issue 33: The proposed regulation includes a new source category for well casing vents. This source category was not included in any of the emissions estimates, or pre-draft regulation, or in the cost estimates provided by ARB. The staff report indicates that ARB would like to collect data through this requirement to estimate emissions from this source and potential future control requirements. The current economic analysis does not incorporate costs measuring flow rates. This category appears to include well vents that are normally open to the atmosphere.

WSPA would like to note that the Greenhouse Gas (GHG) Mandatory Reporting Regulation (MRR) requires operators to report GHG emissions from open well casing vents under the source category Associated Gas Venting and Flaring. All operators subject to MRR reporting and operating open well casing vents estimate the emissions data according to the procedure described in GHG MRR. The emissions are reported annually.

WSPA believes that new redundant data collection is unnecessary to estimate emissions from open well casing vents. In addition, WSPA is concerned that ARB has not included an economic analysis associated with measuring well casings.

Recommendation 33: WSPA recommends that ARB should utilize the existing and already available GHG MRR data to quantify emissions from well casing vents instead of creating an unnecessary and redundant dataset through burdensome measurement and reporting requirements. WSPA recommends that ARB remove requirements for this source category from the proposed regulation. If ARB does not remove the source category, WSPA recommends the following changes:

(1) Beginning January 1, 2018, owners or operators of wells located at facilities listed in section 95666 with a well casing vent that is open to the atmosphere shall comply with one of the following requirements:

   (A) Measure the natural gas flow rate from the well casing vent annually by direct measurement (high volume sampling, bagging, calibrated flow measuring instrument).

   (B) Calculate the volume of natural gas vented according to the Air Resources Board Regulation for the Mandatory Reporting of Greenhouse Gas Emissions, Title 17, Division 3, Chapter 1, Subchapter 10, Article 2, Section 95153(k) (February, 2015).
Leak Detection and Repair

**Issue 34**: ARB has stated that the number of components expected to be tested under LDAR are 1,339,185 and the uncontrolled emissions are estimated to be 13,650 MT CH₄ per year using the CAPCOA guidelines (Appendix D Economic Analysis, Pages B35-36). No further detail has been provided.

Most operators have existing and mature leak detection and repair programs under local air district rules. Operators have already shared this data on leakage rates within the existing LDAR programs with ARB very early in the rule-development process (2013 MRR data were provided previously in WSPA’s comment letter dated 9/22/15). Based on this information on, the estimates in the initial Standardized Regulatory Impact Assessment (SRIA) correctly represented the state-wide emissions inventory.

However, for the latest emissions estimates, ARB has used significantly higher emission factors and leak rates than found in California’s existing LDAR programs to estimate the emissions. Considering the actual data previously provided to ARB, the most recent LDAR emissions estimates and cost-effectiveness analysis are significantly skewed and clearly do not represent the actual emissions estimates.

**Recommendation 34**: WSPA recommends that ARB revise the emissions estimates and cost effectiveness of the LDAR requirements using demonstrated leak rates and emission factors that have been already provided to ARB.

**Issue 35**: As explained in our previous comment letters, operators can have streams with very low concentrations of methane (e.g. some produced water streams). Conducting leak detection on these streams will never lead to identification of any leaks above the leak thresholds proposed in the regulation. The costs associated with implementing an LDAR program for such low-methane components would be onerous for operators with no associated emissions benefit.

**Recommendation 35**: WSPA recommends that ARB exempt components that are not expected to exceed the proposed leak thresholds due to very low methane concentrations handled by those components. WSPA recommends that ARB add the following exemption to Section 95669(e) –

Components exclusively handling streams which have methane concentration less than 10 percent by weight (<10 wt%).

**Issue 36**: Section 95669(b)(5) states that “Components that are buried below ground” are exempt from the LDAR requirements of this regulation. This exemption goes on to state that “[t]he portion of well casing that is visible above ground is not considered a buried component”. Repair of leaks associated with a well casing, buried or exposed at the surface could require obtaining and scheduling the services of a workover rig, disconnecting and killing the well, pulling the well, determining the cause, fixing the cause, then putting it all back together and releasing the rig.

In many cases it is not possible for operators to procure that type of equipment in the timeframes listed in the proposed regulation. Shutting in a well for repair requires specialized equipment, skilled labor, and
financial resources to render the necessary repairs. A well shut-in project requires extensive planning to execute. The impromptu shut-in of an operating well subjects the well to potential damage ultimately causing damage to the formation in the general area of the well. Each well shut-in is a planned event, coordinated through both Production and Reservoir engineering to properly identify potential problems associated with the suspension of operation and to identify and execute mitigating actions for limiting potential damage to the well.

Any repair to a leak located at a well casing may also require a blowdown. In most cases, as recognized in EPA’s New Source Performance Standard 0000a, the blowdown would result in greater emissions than would be reduced by repairing the leak. As such, well casing leaks should be allowed more reasonable and realistic repair times, at least 120 days unless the repairs can be completed during the next scheduled workover or well depressurizing event.

**Recommendation 36:** WSPA recommends that leaks associated with well casings be afforded a more realistic repair time of 120 days or by the next scheduled workover or rig servicing activity.

**Issue 37:** Section 95659(b)(6) states that “one-half inch and smaller stainless steel tube fittings used to supply compressed air to equipment or instrumentation” are exempt from the LDAR inspection requirements of this rule. All components associated with air would not be associated with any emissions. WSPA is concerned that no exemptions have been proposed for components that are handling exclusively non-hydrocarbon streams such as compressed air, potable water, or clean produced water. The inspection of non-hydrocarbon service components would be a very costly burden for all stakeholders resulting in zero emissions benefit.

**Recommendation 37:** WSPA recommends that ARB exempt all components that exclusively handle non-hydrocarbon streams. WSPA recommends that ARB add the following exemption to Section 95659(b) –

```
Components exclusively handling non-hydrocarbon streams.
```

**Issue 38:** The proposed regulation has different inspection frequency requirements for manned and unmanned facilities. However, no definition of the terms “manned facility” and “unmanned facility” have been provided. This can cause confusion and inconsistent understanding of requirements among operators. WSPA requests that ARB add definitions for the terms “manned facility” and “unmanned facility.”

**Recommendation 38:** WSPA recommends that ARB add the following definitions from SJVUAPCD Rule 4409 (3.41)

- **Unmanned Facility:** a facility which has no permanent-sited operators. Permanent-sited operators means personnel responsible for the operation of the equipment subject to this rule are in attendance at the facility 24 hours per day.

- **Manned Facility:** a facility that does not meet the definition of an unmanned facility.
WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)

July 18, 2016

Issue 39: Section 95669(a) refers to a number of component types. As currently written, this section is confusing regarding the need to inspect components that are not in operation. Additionally, different requirements for manned and unmanned facilities will lead to confusion on boundaries and frequency requirements especially in large fields.

Recommendation 38: WSPA recommends the following changes to Section 95669(e) –

(a) Except for inaccessible or unsafe to monitor components, Owners or operators shall audio-visually inspect (by hearing and by sight) all operating hatchets, pressure-relief valves, well casings, stuffing boxes, and operating pump seals for leaks or indications of leaks at least once every 24-hours for facilities that are visited daily or at least once per calendar week for unmanned facilities, and,

(1) Owners or operators shall audio-visually inspect all pipes for leaks or indications of leaks at least once every 12 months. Inspections performed pursuant to DOGGR requirements satisfy this requirement.

Issue 40: As ARB noted several times before and explained repeatedly in WSPA’s previous Comment Letters, the majority of facilities are already in a mature LDAR program run by a local air district. With several years of data, these facilities show very low leak rates. Minimal additional methane reduction will be gained by starting with quarterly inspections for operators already in LDAR programs, while costs will quadruple. Beginning with quarterly inspections to demonstrate lower leak rates is extremely onerous without benefit. Operators who can demonstrate a leak rate below the proposed leak rates in the regulation within the first quarter of the first year of compliance or through using data from their existing program should be allowed to continue with annual inspections. This will also encourage operators to proactively comply with the leak detection requirements.

Recommendation 40: WSPA recommends that ARB allow operators to demonstrate lower leak rates than proposed in the regulation during the first quarter of the first year of compliance. Such operators should be allowed to continue with annual inspections unless the operator exceeds the thresholds in subsequent inspections at which time quarterly inspections would be required. WSPA recommends the following changes to the Section 95669(g) –

(g) At least once each calendar quarteryear, all components shall be tested for leaks of total hydrocarbons in units of parts per million volume (ppmv) calibrated as methane in accordance with EPA Reference Method 21 excluding the use of PID instruments.

(1) The annual inspection frequency will be increased to quarterly if the number of allowable leaks for each leak threshold category specified in Table 1 or 3 is exceeded during an inspection period.

(4) The quarterly inspection frequency may be reduced to annually provided that the following conditions are met:

(A) All components have been measured for five (5) consecutive calendar quarters and the number of leaks has been determined to be below the number of allowable leaks for each leak threshold category specified in Table 1 or 3; and,
WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)

July 18, 2016

(B) The change in inspection frequency is substantiated by documentation and approved by the ARB Executive Officer.

(C) The inspection frequency shall revert to quarterly at any time the number of allowable leaks specified in Table 1 or 3 is exceeded during any inspection period.

**Issue 41:** Section 95669(g)(3) states that "[a]ll inaccessible or unsafe to monitor components shall be inspected at least once annually using Method 21." In many cases, these components have been determined to be unsafe to monitor due to the operation of associated equipment. WSPA believes that it is more appropriate, as required in SJVAPCD rule 4409, to require the monitoring of these components during the next regular process shutdown. The current annual timeline may require the shutdown of a process that would result in emissions greater than the emissions measured from the component.

**Recommendation 41:** WSPA recommends that ARB edit the language of Section 95669(g)(3) as below.

(3) All inaccessible or unsafe to monitor components shall be inspected during the next regular process shutdown at least once annually using Method 21.

**Issue 42:** WSPA would like to re-iterate that Section 95669 Tables 1 & 3 allow very low leak rates including no leaks greater than or equal to 50,000 ppmv allowed after the first two years of the LDAR program. As written, just one leak of 50,000 ppmv or greater would require operators to conduct quarterly LDAR.

From Table 5 of the draft Staff Report, the ARB estimates that there will be 393,000 MT CO2e from LDAR programs after implementation of the regulations as proposed. ARB should provide the amount of leaks over 50,000 ppmv that contribute to this annual emissions estimate.

This is important as the ARB is proposing no leaks greater than 50,000 ppmv after 2020. Does the ARB's own analysis demonstrate that by implementing these regulations there will be no leaks greater than 50,000 ppmv?

Stating that there can be no leaks greater than 50,000 ppmv is unreasonable and not justified with current technology. WSPA strongly disagrees that an operator, who has an otherwise very effective LDAR program, should be penalized for one 50,000 ppmv leak. Statistically, it is difficult to have zero leaks that are 50,000 ppmv or greater and this requirement would lead to operators never being able to reduce the inspections to annual. A mature LDAR program will ultimately reduce such leaks. However, a field with 250,000 components will conduct 1,000,000 component inspections each year. The sheer number of components suggests that there is a statistically significant potential for leaks greater than 50,000 ppmv. However, as the program matures, the potential for such leaks will decrease. Providing unrealistic regulatory mandates does nothing to drive the program especially when other aspects of the regulation address this issue.

**Recommendation 42:** WSPA recommends that ARB allow reasonable leak rates for the LDAR program. WSPA recommends the following changes to Section 95669 Tables 1 and 3 —

WSPA also recommends that ARB delete 9569(o)(4). Detailed recommendations are included in Attachment A.

**Issue 43:** Section 9569(i) sets time periods for repairs after January 1, 2020. Heavy equipment or specialty equipment is needed to repair certain leaks. For example, a workover rig may need to be brought in to repair a leak from a component on a wellhead. It is not reasonable to expect that this equipment is ordered, transferred on-site, and fully operating within 2 calendar days or even 6 calendar days in all cases.

**Recommendation 43:** WSPA recommends revising the proposed regulation to incorporate an extended repair period based on the number of components inspected. For example, a 15-day extension to the repair period can be implemented on 1% of the components inspected.
Critical Components

**Issue 44:** WSPA reiterates and expands on a previous comment submitted on March 4, 2016 regarding the identification of critical components—both with regards to leak detection and repair as well as compressors. Section 95670(a) states that “By January 1, 2016 or within 180 days from installation, critical components used in conjunction with a critical process unit at facilities listed in section 95666 must be pre-approved by the ARB Executive Officer.”

WSFA is concerned by this requirement of pre-approval of critical components. In the event that a component that is truly critical to a process is not identified in this administrative timeline, there must be allowances for the repair time of this component.

Additionally, WSPA is concerned that the current regulatory language puts ARB in the position of the decision-maker regarding which components are critical to process operations. WSPA believes that facility engineers and APCD inspectors are knowledgeable of the processes and should be deferred to in the decision of component criticality, especially in the face of safety concerns. If ARB would like additional validation of critical components, operators may obtain a professional engineer’s evaluation.

Reporting of any leaks on critical components that are not repaired in the timeline allotted for leaks to non-critical components would provide ARB the oversight of repairs necessary to assure compliance with the rule without putting ARB in the position of determining which components are necessary for safe operations.

**Recommendation 44:** WSPA recommends that ARB allow knowledgeable operators or a professional engineer to identify and designate the critical components without needing approval from ARB. WSPA recommends that operators include in their annual report a list of any critical component not repaired in the timeline allotted for leaks to non-critical components in lieu of developing a pre-approved list of critical components.

**Issue 45:** Section 95670(e) — Identifying critical components by tags will require a complete component inventory that will require continual updating. Facilities that already have a mature program to tag components do not tag every component. A tag is placed on a larger component and other nearby components are assigned to that tag. Therefore, tagging every component is not a common practice.

**Recommendation 45:** WSPA recommends that ARB allow for a general description of the portion of the system that contains the critical components, which will be more helpful to the operators and the inspectors.

**Issue 46:** Throughout Section 95669 of the proposed regulatory text, ARB has updated the critical component repair time to one year. Table 2 and 4, however, contradict this states a required repair time for critical components of 180 days. WSPA believes this to be an oversight and carry-over from the previous version of the proposed regulation.

Issue 47: Section 95669(m) requires open-ended lines and valves to be sealed. By not including a mitigation response, Section 95669(m) proposes to make any open-ended line or valve a violation of the Regulation. Open-ended lines and valves present an opportunity to leak similar to other components. Not all open-ended lines or valves are leaking; just like not all other components are leaking. However, in the proposed regulation, the ARB allows a repair time for a leak from other components, but no repair time is afforded to an open-ended line or valve that is not leaking. This is not equitable. A repair time for an open-ended line or valve should be developed just like for every other component. If the open-ended line or valve is leaking, then the more stringent leak repair times should be invoked. Also, the regulation should clearly state that process drains are not open-ended lines.

Recommendation 47: WSPA recommends Section 95669(m) be revised to read:

(m) Open-ended lines and valves located at the end of lines shall be sealed with a blind flange, plug, cap or a second closed valve, at all times except during operations requiring liquid or gaseous process fluid flow through the open-ended line. Open-ended lines do not include process drains or vent stacks used to

Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)

July 18, 2016

Reporting Requirements

Issue 48: Section 95672 describes reporting requirements for various source categories. As currently written, the regulation does not provide clear deadlines for reporting.

Recommendation 48: WSPA recommends that ARB add the following deadlines to Section 95672:

(a) Beginning January 1, 2018, owners or operators of facilities listed in section 95666 subject to requirements specified in sections 95668 and 95669 shall report the following information to ARB within the following timeframes specified:

(1) All annual reports described below for a calendar year must be submitted by June 30 of the following year.

(2) All quarterly reports described below must be submitted within 60 days from the end of a quarter.

(a)(3) All other reports must be submitted as specified below.
Implementation

Issue 49: WSPA would like to reiterate this concern that was previously submitted in letter dated March 4, 2016. Section 56673(a)(3) & (4) states the following –

(3) Implementation and enforcement of the requirements of this subarticle by a local air district may in no instance result in a standard, requirement, or prohibition less stringent than provided for by this subarticle, as determined by the Executive Officer. The terms of any local air district permit or rule relating to this subarticle do not alter the terms of this subarticle, which remain as separate requirements for all sources subject to this subarticle.

(4) Implementation and enforcement of the requirements of this subarticle by a local air district, including inclusion or exclusion of any of its terms within any local air district permit, or within a local air district rule, or registration of a facility with a local air district or ARB, does not in any way waive or limit ARB’s authority to implement and enforce upon the requirements of this subarticle. A facility’s permitting or registration status also in no way limits the ability of a local air district to enforce the requirements of this subarticle.

ARB is proposing to implement and enforce the program regardless of Air District efforts. At the same time, several Air Districts are likely to incorporate the proposed regulation by either amending their rules or adopting a separate program. WSPA is very concerned about the duplicative implementation and enforcement of the proposed regulation.

In cases where Air Districts are planning to implement the rule and are required to develop standards, requirements or prohibition that are no less stringent than provided by ARB’s proposed regulation, it is unclear why ARB is proposing duplicative implementation and enforcement. Implementation of two separate programs by both ARB and the Air Districts will lead to doubling of administrative costs for the same emissions control. Additionally, operators will also need to implement two separate programs that will not only lead to confusing compliance requirements but also a doubling of their compliance costs. WSPA strongly believes that this is inefficient both in terms of costs and effectiveness of regulation. Where an Air District is implementing and enforcing the requirements of the proposed regulation, there is no need for duplicative ARB implementation and enforcement of the same requirements.

Recommendation 49: WSPA strongly urges that ARB remove the duplicative implementation and enforcement requirements from the proposed regulation in Section 56673(a)(3) & (4) as follows –

(3) Implementation and enforcement of the requirements of this subarticle by a local air district may in no instance result in a standard, requirement, or prohibition less stringent than provided for by this subarticle, as determined by the Executive Officer. The terms of any local air district permit or rule relating to this subarticle do not alter the terms of this subarticle, which remain as separate requirements for all sources subject to this subarticle.

(4) Implementation and enforcement of the requirements of this subarticle by a local air district, including inclusion or exclusion of any of its terms within any local air district permit, or within a local air district rule, or registration of a facility with a local air district or ARB, does not in any way waive or limit ARB’s authority to implement and enforce upon the requirements of this subarticle. A facility’s permitting
or registration status also in no way limits the ability of a local air district to enforce the requirements of this subarticle.

WSPA's recommendation for regulatory language is also included in Attachment A.

Issue 50: Section 95673(b)(2)(A)(3)(b) requires registration of a list of certain equipment including all pressure vessels. The broad definition of “pressure vessel” would require the registration of air compressors and steam separators. This equipment contains no methane and should not be subject to this requirement. The registration should only apply to equipment with compliance requirements in the regulation.

Recommendation 50: WSPA suggests this paragraph be changed as follows:

b A list identifying all separator and tank systems pressure vessels, tanks, separators, sumps, and vessels at the facility, including the size of each tank and separator in units of barrels comprising the separator and tank system.

Issue 51: Several other changes are necessary in the proposed regulation to provide clarity to operators on the requirements and eliminate any confusion.

Recommendation 51: WSPA's recommendations for additional changes are included in Attachment A.
Legal Comments

**Issue 52:** As stated in issue 10 above, WSPA is concerned that section 95668(a)(6) now includes a requirement that owners or operators of existing separator or tank systems with annual emissions greater than 10 metric tons per year of methane must control emissions from gauge tanks in addition to controlling emission from the separator and tank system. WSPA is concerned by the inclusion of gauge tanks, an insignificant emission source, in section 95668(a)(6) with no notice or discussion. As discussed below, none of the supporting documents provide a compelling reason to include gauge tanks in the regulation and, in fact, most of the supporting documents do not even mention gauge tanks. WSPA believes that adding gauge tanks to the proposed regulation at the last minute, without explanation, is not in accordance with the process as ARB must follow in adopting regulations.

WSPA also believes that there are legal deficiencies with the supporting documents for the proposed regulation due to failure to address gauge tanks, as described below. WSPA is concerned that gauge tanks were included in the proposed regulation without conducting a comprehensive emissions and cost effectiveness analysis. WSPA believes that the minimal additional emissions reductions that could be achieved by requiring gauge tanks to be controlled by a vapor collection system is outweighed by the burdensome cost to implement such controls.

**Recommendation 52:** WSPA recommends that ARB remove gauge tanks from section 95668(a)(6) and section 95667.

**Issue 53:** ARB’s Economic Analysis for the proposed regulation does not take into account the cost to control emissions from gauge tanks with the use of a vapor collection system, as required by section 95668(a)(6). ARB states that the proposed regulation will cost about $23 million dollars per year and is expected to reduce GHG emissions by about 1.5 million MT CO2e per year on a 20 year horizon, for a cost per ton of approximately $15 after savings. State of California Air Resources Board, Staff Report: Initial Statement of Reasons ("ISOR") Appendix A, Economic Analysis, p. B-2, B-7. However, these calculations do not include the cost to install vapor collection systems on all gauge tanks subject to the proposed regulation or the minimal extra emission reductions that will occur from installing such systems, as further explained in issue 10 above. Once the extra cost and minimal benefit is included in the Economic Analysis, the proposed cost per ton of the regulation is much higher than stated in the Economic Analysis.

In addition, the estimated cost to industry summarized in the Economic Analysis is also understated because it does not take into account the cost to add vapor collection systems to the gauge tanks that would be affected by the proposed regulation. See id. at B-12 (stating approximately $26.4 million per year as cost). An operator with one or more upstream remote gauge tanks and a separator and tank system may have to install multiple vapor recovery systems to comply with the proposed control requirements. Therefore, the total cost could be several times the costs estimated by ARB in the Economic Analysis.

ARB must include gauge tanks in the Economic Analysis in order to provide a true and accurate picture of the economic impacts of the proposed regulation. The proposed regulation includes controls on gauge tanks, as explained in the ISOR. See ISOR p. 35, 36, 67. ARB cannot ignore sections of the proposed
regulation in the Economic Analysis merely because they were amended after the Economic Analysis was completed. An accurate analysis which includes the cost to add vapor collection systems to gauge tanks would show that the $15 per ton of reduction figure in the Economic Analysis is vastly understated. The high cost to control all gauge tanks coupled with the very minimal emission reductions that would result from such controls show that the proposed controls on gauge tanks in the proposed regulation are not cost-effective and mean that ARB should remove the gauge tank control requirements from the proposed regulation.

**Recommendation 53:** WSPA recommends that ARB remove gauge tanks from the proposed regulation. If ARB does not remove gauge tanks from the proposed regulation, ARB must complete a new Economic Analysis that adequately considers the cost of the proposed regulation, taking into account the steep cost for installing vapor collection systems on gauge tanks for very minimal additional emission reductions before adopting the proposed regulation.

**Issue 54:** ARB’s Standardized Regulatory Impact Assessment (“SRIA”) also has significant deficiencies as described below.

1. **Gauge Tanks**

The SRIA states that it is “representative of a snapshot of this regulation” and “may differ from the proposed regulation that will be presented to [ARB].” ISOR, Appendix E, Standardized Regulatory Impact Assessment, p. E-2. In fact, the SRIA does not mention gauge tanks and does not consider potential emission reductions from adding vapor collection systems to such tanks or the potential cost of such controls.

The SRIA is required to assess the potential for adverse economic impacts on California businesses and individuals, including avoiding the imposition of unnecessary or unreasonable regulations or reporting. Cal. H&S Code § 11346.3(a). The analysis is intended “to provide agencies and the public with tools to determine whether the regulatory proposal is an efficient and effective means of implementing the policy decisions enacted in statute or by other provisions of law in the least burdensome manner.” Id., subsection (e) (emphasis added). The regulatory impact analysis is required to compare proposed regulatory alternatives to “determine that the proposed action is the most effective, or equally effective and less burdensome, alternative in carrying out the purpose for which the action is proposed, or the most cost-effective alternative to the economy and to affected private persons that would be equally effective in implementing the statutory policy...” Cal. H&S Code § 11346.36(b).

The SRIA cannot accurately determine how to control methane emissions in the “least burdensome manner” or in the most cost-effective way if it does not take into account all of the requirements in the proposed regulation. Looking at a “snapshot” of the regulation, as ARB calls it, in the SRIA does not meet the Health and Safety Code requirements for regulatory analyses. The SRIA must analyze the proposed regulation that will be in effect if the regulation is adopted as drafted, not an earlier version that would not adequately explain the true impacts of the regulation.

2. **Circulation Tanks**
WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Operations (June 2016)

July 18, 2016

The SRIA also does not consider the potential for oil and gas operations to decrease in response to the proposed regulation if it is infeasible to comply with some of the regulation’s requirements. Section 95669(b)(3) requires owners or operators of circulation tanks to control emissions from the tanks with at least 98% vapor collection and control efficiency by January 1, 2020.

It is unclear whether this requirement will be feasible by 2020 as required control technology does not currently exist. The SRIA’s assessment on employment, businesses, output growth, and gross state product do not consider that, if businesses cannot comply with the requirements of the proposed regulation such as section 95669(b)(3), then oil and gas production could move out of state, causing great harm to California’s economy. This is a reasonably foreseeable outcome of the proposed regulation that is not addressed in the SRIA. See SRIA, p. E-19 – E-25.

**Recommendation 54:** WSPA recommends that ARB remove gauge tanks from the proposed regulation. If ARB does not remove gauge tanks from the proposed regulation, it must complete a new SRIA that adequately considers the proposed regulation, taking into account the steep cost for installing vapor collection systems on gauge tanks for very minimal additional emission reductions before it adopts the proposed regulation.

WSPA also recommends that ARB remove control requirements for recirculation tanks from the proposed regulation due to the potential to reduce oil and gas operations in California as the proposed requirements for circulation tanks cannot be met with technology available today. If ARB does not remove circulation tanks from the proposed regulation, it must complete a new SRIA before adopting the proposed regulation which adequately considers the reasonably foreseeable outcome of the controls on recirculation tanks in the proposed regulation.

**Issue 55:** ARB prepared the Environmental Assessment under its CEQA certified regulatory program, which requires public agencies to prepare a “functionally equivalent” or substitute document in lieu of an environmental impact report. ISOR, Appendix C, Draft Environmental Analysis for the Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities (hereafter, “EA”), p. 6.

In compliance with California Public Resources Code § 21159, when ARB adopts a rule or regulation requiring the installation of pollution control equipment, or a performance standard or treatment requirement, the EA must contain “an environmental analysis of the reasonably foreseeable methods by which compliance with that rule or regulation will be achieved.” The analysis must include reasonably foreseeable environmental impacts of the methods of compliance, reasonably foreseeable feasible mitigation measures related to significant impacts, and reasonably foreseeable alternative means of compliance that would avoid or eliminate significant impacts. Id. The EA must also assess the potential for significant adverse and beneficial environmental impacts associated with the proposed action and provide a succinct analysis of those impacts. See generally 14 C.C.R. § 15000 et seq. (“CEQA Guidelines”).

Because the EA does not meet the requirements listed above for numerous reasons, it is inadequate and fails as an informational document.

A. **The EA’s Project Description Is Inadequate and Fails to Inform the Public of the True Scope of the Project**
An environmental document prepared to comply with CEQA must contain a general description of the project's technical, economic, and engineering characteristics, and a statement of the objectives sought by the proposed project. CEQA Guidelines § 15124(b), (c); see Dry Creek Citizens Coalition v. County of Tulare (1999) 70 Cal.App.4th 20. An accurate, stable, and finite project description is the sine qua non of an informative and legally sufficient environmental document. County of Inyo v. City of Los Angeles (1977) 71 Cal.App.3d 165, 192-93.

1. **Gauge Tanks**

Here, the EA's project description does not fully inform the public of the scope of the project. The EA's project description fails to disclose that gauge tanks are part of the proposed regulation and that the regulation will require owners and operators to install vapor collection systems on certain gauge tanks. This omission makes the analysis in the EA incomplete and inadequate. In fact, the EA does not mention gauge tanks once in the entire 100-plus page document. In explaining the proposed requirements for vapor collection on oil and water separators and tanks, the EA states that "only pressure vessels used to separate oil and water would be subject to these vapor collection requirements." EA, p. 17.

An EA is required to disclose and discuss all aspects of the proposed project. Because gauge tanks are not included in the project description, this necessarily means that none of the impact analyses in the EA took gauge tanks, and the proposed controls that will be required on those tanks, into consideration. ARB must not ignore an entire area of regulation that could have potential impacts on the environment in its analysis.

In addition, reasonably foreseeable methods of compliance with the requirements for vapor collection at gauge tanks are not discussed. As described in previous comments, gauge tanks are not necessarily situated near separator and tank systems and thus potential methods of compliance for gauge tanks could differ from potential methods of compliance for separator and tank systems. This is not addressed in the EA.

2. **Circulation Tanks**

Section 05668(b)(3) requires that by January 1, 2020, owners or operators of circulation tanks used in conjunction with well stimulation treatments shall control emissions from the tanks with at least 95% vapor control efficiency of the equipment. The EA states that reasonably foreseeable compliance responses for this requirement would be the same as those discussed for the requirements for uncontrolled oil and water separators, tanks, and sumps. EA, p. 19. However, it is unclear how disposal of vapors from circulation tanks would be conducted, as there are no currently technologies available to meet the requirements of the proposed rule.

The EA states that it is reasonably foreseeable to assume that all replacement devices or newly installed vapor control devices would be low-NOx combustion devices. EA, p. 18. However, it is not clear that the various air districts in which these low-NOx combustion devices would be sited would permit them if they caused an increase in flaring, even if they are low-NOx flares. In fact, some air districts have stated that they do not want any additional flaring to occur in response to the proposed regulation. Because increased flaring and/or new flares would not be allowed without air district permitting, new combustion devices may not be a reasonably foreseeable method of compliance and ARB must address this clear conflict in the EA.

46
WSPA Comments
Draft Regulation for Greenhouse Gas Emission Standards
for Crude Oil and Natural Gas Operations (June 2016)

July 18, 2016

The project description's explanation of reasonably foreseeable compliance responses to the control of vapors from uncontrolled well stimulation circulation tanks does not address the fact that it may be infeasible to meet the control requirements of the proposed regulation.

If the requirements cannot be met, operators may be required to remove equipment from service and stop operations that rely on circulation tanks. See EA, p. 42 (stating that if none of the discussed compliance options is feasible, the proposed regulation requires existing equipment to be taken out of service). For this reason, ARB must consider a reasonably foreseeable compliance response to be shutting down production in California and transferring it to other areas. This could cause numerous environmental impacts, none of which are discussed in the EA.

The Department of Oil, Gas, and Geothermal Resources explained in its 2015 Draft EIR ("DEIR") titled "Analysis of Oil and Gas Well Stimulation Treatments in California" that restricting production in the state could cause numerous indirect environmental impacts. The DEIR states that "[n]ow, California produced almost 230 million barrels of oil from over 52,000 producing wells. That same year, California used over 600 million barrels of oil, importing 15 percent of its oil from Alaska and 45 percent from foreign sources, with Saudi Arabia (25 percent), Iraq (10 percent), Ecuador (17 percent), and Brazil (9 percent) accounting for 70 percent of the imported oil. Since 2008, the percent of foreign oil imports to California has increased to 50 percent of the oil used and imports from domestic sources other than Alaska have also increased. A loss of 25 percent of the California-produced oil would require an additional 57 million barrels per year be purchased from another source." DEIR, p. 8-9 (internal citations omitted).

Because technologies do not currently exist to replace all petroleum-derived products with renewable energy, the largest portion of the lost barrels of oil would be acquired from out-of-state and would require land or sea travel to reach the California market. Thus, reducing oil production in California could cause numerous indirect effects including those from increased well abandonment and increased oil transport. These effects should be considered in the EA when a potential reasonably foreseeable compliance response to the proposed regulation is to remove equipment from service.

B. The EA's Analysis of Potential Environmental Effects is Insufficient

The fundamental purpose of an environmental review document is to inform public agency decision makers and the public of the potentially significant environmental effects of a project and to identify ways to minimize or avoid those effects. CEQA Guidelines § 15121(a), No Oil, Inc. v. City of Los Angeles (1974) 13 Cal.3d 69, 86. Here, the EA does not adequately analyze potential environmental impacts from the proposed regulation.

1. Air Quality

The Air Quality analysis in the EA is deficient for multiple reasons. First, short-term construction-related impacts on Air Quality (Impact 3a) are underreported as more construction will occur than anticipated due to the addition of controls for gauge tanks in the proposed regulation. This will require the installation and replacement of gathering lines and piping, flanges, valves, low-Nox combustion devices, and other similar features associated with adding vapor collection systems to gauge tanks. Emissions from this construction are not addressed in the EA.

The EA states that "ARB has not quantified the potential construction-related emission impacts as these would be too speculative to provide a useful evaluation tool" and "the specific location, type and number
of construction activities is not known.” EA, p. 33. However, as explained elsewhere in the EA, ARB has
counts of the systems found to be uncontrolled with methane emissions exceeding 10 metric tons per
year and do not have access to an existing sales gas system, existing fuel gas system, or existing gas
disposal well from a 2009 Oil and Gas Industry Survey. EA, p. 43. In addition, the Economic Analysis
includes data such as the number of tanks and separator systems, continuous bleed devices, and
centrifugal compressors that would be subject to the proposed regulation, along with other information on
current operations. This data could be extrapolated to estimate potential construction related emissions
from implementation of the proposed regulation. ARB must analyze potential impacts of the regulation in
as much detail as feasible given current knowledge.

In addition, as explained in the EA, one option for compliance with the proposed regulation “requires that
regulated entities operating an existing vapor control device route newly collected vapors into the existing
vapor collection system and then replace the existing vapor control device that would receive increased
vapor throughput with a non-destructive (e.g., non-combustion) or low-NOx vapor control device.” EA, p.
41. This would be in response to proposed section 95668(o)(3) which requires existing vapor collection
devices to meet the requirements of section 95668(o)(4)(B) when in turn requires existing vapor control
devices in non attainment areas to be replaced with a non-destructive device or with a low-NOx device.

ARB is aware of the number of flares currently in existence which may be required to be replaced with
low-NOx vapor control devices or non-destructive devices in order to comply with the proposed
regulation. ARB could reasonably project anticipated construction emissions from replacing those flares
with low-NOx vapor control devices or non-destructive devices. This is a reasonably foreseeable outcome
of the proposed regulation as replacement of some existing vapor control devices will be required by
implementation of the regulation. Thus, construction emissions from retrofitting these flares or replacing
them with non-destructive control devices must be considered in the EA.

The analysis of long-term operational impacts on Air Quality (Impact 3.b) is similarly deficient. As stated
above, the reasonably foreseeable methods of compliance expected by ARB are unclear and / or without
support in the record. ARB notes that new vapor control devices or replacement of these devices are
permitted through local air districts (EA, p. 42), but does not address the distinct possibility that the local
air districts may not permit any additional flaring, causing compliance with the proposed regulation to be
infeasible.

In addition, although “ARB anticipates that [non-combustion devices] will be used in the future” (Id.),
prematurely referring to potential controls for circulation tanks in order to comply with the proposed
regulation, that is not a guarantee that those devices will be available in time for the compliance deadlines
in the regulation. Thus, as stated above, some production may stop due to the inability to comply with the
proposed regulations which would cause indirect impacts that the EA must address and has not.

Finally, ARB assumes that “the use of recovered vapors for on-site equipment fueling would lessen the
amount of conventional fuels that would be combusted on-site and the need to transport those fuels to the
site” (EA, p. 40). However, it is not clear that recovered vapors would be in a form sufficient to use for on-
site equipment fueling. Thus, the assumption that recovered vapors could reduce fuel use and thus
reduce emissions is unwarranted.

There would also likely be an incremental increase in the emissions impacts reported in the EA as more
gas will be routed to flares than was analyzed in the EA due to the addition of gases from the vapor

48
collection systems that will be installed at certain gauge tanks in response to the requirements for controls on gauge tanks. ARB's calculation of potential emission impacts (such as emissions of NOx and other criteria pollutants) from combustion of additional vapors collected and routed to vapor control devices as a response to the proposed regulation does not consider emissions from gauge tanks. See EA, p. 43 – 47. The additional emissions from gauge tanks will cause increased flaring which could cause increased NOx and other criteria pollutant emissions that are not considered in the EA. ARB must correct this deficiency in order to accurately represent potential adverse emission impacts from the project.

Finally, the San Joaquin Valley Air Pollution Control District ("SJVAPCD") separately estimated the change in NOx emissions that might occur as a result of the proposed regulation and came up with ten times higher calculated emissions than ARB. EA, p. 45. It is unclear whether ARB or SJVAPCD's assumptions are correct, but the difference in estimated emissions is large enough to question ARB's calculations. One contrary assumption is that SJVAPCD assumed that captured gas would require an equal amount of supplemental make-up gas before combustion in a flare would be possible. Id. ARB asserts that low NOx incinerators can handle waste gas and likely would not require additional make-up gas, and indeed the proposed regulation does not allow supplemental fuel. WSPA agrees with the SJVAPCD that, in some instances, make-up gas would be required in low NOx incinerators and thus the proposed regulation, as written, may be infeasible in some instances. As stated above, this would result in displaced production, causing reasonably foreseeable indirect impacts that are not addressed in the EA and must be.

2. Biological Resources

As in the Air Quality analysis, ARB has understated the potential construction-related impacts to special status species and habitats (Impact 4.a) due to its failure to include construction of necessary components to add vapor collection systems to gauge tanks. See generally EA, p. 46 – 49. This increased construction would raise the potential for impacts to biological resources and must be addressed in the EA.

3. Greenhouse Gases ("GHGs")

Although the EA reports the long-term operational impacts on GHGs would be beneficial due to the reduction in methane, it also notes that there would be an increase in vehicle emissions associated with the LDAR requirements of the proposed regulation which would increase CO2 emissions by 376 metric tons per year EA, p. 61. This increase should be taken into consideration in Table 4-4 on p. 62, which only summarizes estimated GHG reductions from the project.

4. Transportation and Traffic

The EA's analysis of transportation and traffic is superficial and purely qualitative. ARB estimated numbers of vehicle trips and potential emissions from the additional trips required for compliance with the proposed regulation in the Air Quality analysis (see, e.g., EA, p. 42 – 43) and should complete a more comprehensive, quantitative evaluation of the proposed regulation's potential impacts on transportation and traffic in the EA.

Recommendation 65: WSPA recommends that ARB remove gauge tanks and recirculation tank controls from the proposed regulation. ARB must also revise and recirculate its EA so that the analysis.
adequately considers the potential environmental implications of all of the requirements in the regulation before it can adopt the proposed regulation.

Re: Proposed Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities

To the California Air Resources Board and Staff:

The Center for Biological Diversity submits the following comments on the Proposed Regulation for Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities, and the accompanying the Initial Statement of Reasons ("ISOR") and Draft Environmental Analysis ("Draft EA") prepared by the California Air Resources Board ("ARB").

The Center is a non-profit organization with more than one million members and online activists and offices throughout the United States, including in Oakland, Los Angeles, Sacramento, and Joshua Tree, California. The Center’s mission is to ensure the preservation, protection and restoration of biodiversity, native species, ecosystems, public lands and waters and public health. In furtherance of these goals, the Center’s Climate Law Institute seeks to reduce U.S. greenhouse gas emissions and other air pollution to protect biological diversity, the environment, and human health and welfare. Specific objectives include securing protections for species threatened by global warming, ensuring compliance with applicable law in order to reduce greenhouse gas emissions and other air pollution, and educating and mobilizing the public on global warming and air quality issues.

The Center supports many elements of the proposed regulation, and these comments offer specific recommendations intended to strengthen its goals and enhance its effectiveness.

I. The Regulation Should Eliminate Methane Emissions from the Oil and Gas Sector Entirely, and on the Shortest Possible Timeline

The Center has long supported taking action to address methane emissions from the oil and gas sector. In fact, Californians have been waiting too long for this. Both the 2008 Climate Change Scoping Plan and the subsequent First Update to the Climate Change Scoping Plan identified the regulation of oil and gas operations as an important greenhouse gas ("GHG")...
mitigation measure. Furthermore, the currently proposed regulation was developed largely based upon data that were collected in 2009.

Methane is a substantial component of anthropogenic greenhouse gas emissions, responsible for as much as a quarter of climate forcing, and methane emissions from the oil and gas industry are responsible for approximately 15 percent of methane emissions in the state. Furthermore, methane emissions from the oil and gas sector are strongly associated with copollutants that are known health threats, and many of these emissions are located in close proximity to communities already suffering from poor air quality and associated health impacts.

The staff report points to the recently proposed Short-Lived Climate Pollutant strategy that includes a 40 percent reduction of methane by 2030 with a 40-45 percent reduction from the oil and gas sector as a whole by 2025. The Center agrees with the need for this action, but the goal should be for much greater reductions and on a shorter timeline, and there are numerous ways that the Proposed Regulation could be strengthened to achieve greater reductions.

In many ways methane from the oil and gas sector is among the most ripe and obvious targets for reductions, as the emissions are unintended, accidental, and unnecessary for the underlying activities. The Center strongly supports the goal of achieving substantial reductions in fugitive methane emissions from the oil and gas industry, and urges ARB to consider all options to eliminate methane emissions from the oil and gas sector entirely. The following are specific provisions in the Proposed Regulation that must be strengthened to increase the effectiveness of the

A. Implementation Starting in 2017

Compared with the discussion proposal, the implementation start date for the regulation was pushed back a year, from January 2017 to January 2018. There is no need for this delay, and no reason to allow uncontrolled emissions from the oil and gas industry for any additional time, especially when many of those emissions can be easily reduced through repairs.

B. Quarterly Leak Detection and Repair

The proposed rule requires quarterly LDAR monitoring of facilities initially, but allows facilities to downgrade to annual monitoring if no leaks are found in five consecutive quarters.\footnote{\$ 95689.4(g)(1): "The quarterly inspection frequency may be reduced to annually provided that the following conditions are met: (A) All components have been measured for five (5) consecutive calendar quarters and the number of leaks has been determined to be below the number of allowable leaks for each leak threshold category..." Proposed Regulation at 22.} Not only does this mean that some leaks may occur for up to a year before being detected, but it also creates a perverse incentive for operators to act less effectively to find and report leaks. To maximize compliance and minimize fugitive emissions, LDAR must be required quarterly.
C. Critical Components

The proposed regulation includes special allowances for methane leaks from sources identified as critical components. These special allowances would allow such leaks to continue for up to a year if the repair requires shutting down the operation. While it may make sense not to require the removal of a component for which there is no replacement or possibility of bypass, this option should apply only in those cases where shutdown of the particular operation as a whole would not curtail the leak.

D. Low-Bleed Pneumatics and Heavy Crude Components

The testing of low-bleed pneumatics is required only annually, and heavy crude components are exempt from leak detection and repair requirements entirely because they "emit less total hydrocarbons, and therefore less methane, than other components found in gas or other liquid service." The fact that high-bleed devices generally emit even higher volumes than low-bleed devices is no reason to allow for continued methane emissions from low bleed devices. Low-bleed pneumatics are also exempt from the requirement to be replaced with no-bleed devices. Staff Report at 101. The staff report explains that this allowance is offered in large part because those components were recently replaced in response to recent rule changes. Again, this is no reason to allow for continued methane emissions from low bleed devices.

E. Flaring

While the Proposed Regulation creates a hierarchy that prioritizes gas collection and use over combustion, the potential for increased incidence of flaring should be addressed. Specifically, ARB could set a hard limit on flaring allowed at each type of operation to require collection and use at the larger sources.

II. The Current Requirements for Underground Storage Facilities Must Be Strengthened to Avoid Catastrophic Leaks Not Covered in the Proposed Regulation

The Proposed Regulation at section 95668(i) requires monitoring combined with leak detection and repair at underground storage facilities, but these measures alone will not prevent future disasters like that at Aliso Canyon. By the time that increased ambient methane

---

3 "Critical component" means any component that would require the shutdown of a critical process unit if that component was shutdown or disabled. "Critical process unit" means a process unit that must remain in service because of its importance to the overall process that requires it to continue to operate, and has no equivalent equipment to replace it or cannot be bypassed, and it is technically infeasible to repair leaks from that process unit without shutting it down and opening the process unit to the atmosphere." Proposed regulation at 3.

7 "Critical components are allowed additional time to make repairs, but must be repaired during the next process unit shutdown or within 12 months from the date of the initial leak concentration measurement, whichever is sooner." 95668(d)(3)(F).

4 Section 95669(b)(2)
concentrations are detected, it may be too late to avoid disaster. The largest danger is wells with a single barrier without surrounding cement. Thus, the Proposed Regulation should first identify all single-barrier storage operations. These must be inspected for evidence of corrosion, cracking, or other loss of casing strength. If such evidence is found, the well must be taken out of operation immediately. Furthermore, all storage facilities should be required to have downhole shutoff valves, something that Aliso Canyon storage well SS25 lacked. The presence of a downhole shutoff valve could have avoided the massive leakage at Aliso Canyon and must be required of all storage wells going forward.

III. The Proposed Regulation Must be Expanded to Address Fugitive Emissions from Abandoned Wells

Although the ISOR mentions that “abandoned or idle wells may be located at facilities that were previous oil or natural gas production fields,” no further attempt is made to address these emissions. It is clear that abandoned oil and gas wells can be a significant source of methane emissions, yet current GHG inventories omit this source. One recent study measured methane emission rates from abandoned wells in Pennsylvania and estimated that the emissions accounted for 4 to 7 percent of the state’s total methane emissions.\(^5\) In California, approximately 45 percent of wells in DOGGR’s database are classified as “plugged and abandoned,”\(^6\) raising the distinct possibility that these wells are emitting substantial volumes of methane. These sources must be addressed under the Regulation to achieve the level of reductions necessary to avoid catastrophic climate change.

IV. Leak Detection Devices Must Be Carefully Tested and Calibrated

The requirements of the Proposed Regulation depend on accurate methane measurements; acceptable devices must be thoroughly screened. Recent data suggest that at least one commonly used methane sensor is prone to failures that result in underestimation of methane emissions.\(^7\) ARB should revise the Regulation to ensure that known problematic devices are disallowed and furthermore require evidence that any device used to detect leaks is operating accurately with proper protocol followed to maintain calibration.

---

V. The Regulation is Needed to Fill Critical Gaps in the Current Regulation of Emissions From the Oil and Gas Sector

Although other aspects of the oil and gas sector are subject to a regulation, ARB's Proposed Regulation would be the only state-wide limit on methane from existing oil and gas sources. The federal EPA rules requiring oil and gas operators to check well site facilities for methane leaks on a semi-annual basis and compressor stations on a quarterly basis apply only to new or modified facilities. For these reasons, the proposed regulation is sorely needed to fill critical gaps in the current regulation of emissions from the oil and gas sector. Furthermore, existing regulations of well stimulation do not address methane emissions specifically from these operations, nor do they affect other aspects of oil and gas extraction that are significant sources of fugitive methane.

ARB appears to be interpreting SB 1371 as preemptive of its role in regulating methane emissions from natural gas pipelines. However, the fact that the CPUC is developing regulations as mandated by SB 1371 does not mean that ARB cannot or should not develop emissions requirements for those sources. Nothing in SB 1371 indicates that pipeline emissions cannot also be addressed through regulations developed at ARB to address GHG emissions from the oil and gas sector.

Finally, we note that ARB has indicated the importance of reducing methane from the oil and gas sector as a part of its Strategy to Reduce Short-Lived Climate Pollutants. This is critical not only to achieving the climate goals of the state but to ensuring that our current fuel and supply does not result in unaccounted and unregulated methane leakage. First, as ARB concludes in the Strategy (at 77), meaningful reductions in methane from the oil and gas sector will ultimately depend upon reducing demand does not mean that methane emissions can be permissible in the meantime. To cap this methane source and to begin to move oil and gas toward a standard that allows for meaningful comparison to clean energy sources, fugitive methane should be capped at effectively zero by 2020. Furthermore, it essential that ARB

---

8 "Accordingly, this regulation covers upstream emissions (production, gathering and boosting stations, and processing) as well as natural gas storage and transmission compressor stations (collectively "oil and gas"). This regulation does not cover the petroleum refining sector. Further, GHG emissions from oil and gas pipelines and related facilities are being addressed in a separate regulatory effort in partnership with the California Public Utilities Commission (CPUC)." Staff Report at 1.

9 The Legislative Counsel’s Digest to SB 1371, the 2014 legislation mandating that PUC develop regulations to minimize leaks from natural gas pipelines, describes that bill this way: “[SB 1371] would require the commission, giving priority to safety, reliability, and affordability of service, to adopt rules and procedures governing the operation, maintenance, repair, and replacement of those commission-regulated gas pipeline facilities that are interstate transmission and distribution lines to minimize leaks as a hazard to be mitigated pursuant to the Natural Gas Pipeline Safety Act of 2011, consistent with specified federal regulations, and a specified order of the commission, and to reduce emissions of natural gas from those facilities to the maximum extent feasible in order to advance the state’s goals in reducing emissions of greenhouse gases pursuant to the California Global Warming Solutions Act of 2006.”
continue its efforts (Strategy at 79) to ascertain true levels of methane leakage from the oil and
gas industry such that all fugitive emissions are effectively addressed.

VI. The Global Warming Potential for Methane Must Reflect the Latest Science

The Center strongly supports ARB’s use of a 20-year global warming potential (“GWP”) for methane. The time horizon used to equate methane and CO₂ emissions has significant implications for policy decisions in which the time horizon of the GWP critically influences the cost-benefit analysis of mitigation options. However, the Draft EA and Economic Analysis employ an outdated value for the 20-year GWP of methane, based on the IPCC’s Fourth Assessment Report. Staff Report at 29, Economic Analysis at B-3.

We strongly urge ARB to use GWP values from the most recent IPCC Fifth Assessment Report (“AR5”), as it does for black carbon. The outdated 20-year GWP of 72 omits critical carbon cycle feedbacks. This must be corrected: carbon cycle feedbacks must be included to properly equate methane and CO₂ warming influences. The groundbreaking realization by the contributors to AR5 was that carbon cycle feedbacks are an inherent part of the warming caused by CO₂. Yet, until the most recent Assessment, they were omitted from GWP values for non-CO₂ greenhouse gases. As a result, until AR5, the GWP conversion was actually comparing apples to oranges. The only way to accurately compare among greenhouse gases—the entire purpose of a GWP—is to include carbon cycle feedbacks. According to the AR5, this results in a 100-year methane GWP of 36 and a 20-year GWP of 87.10

VII. The Draft EA Does Not Meet CEQA Requirements

The Draft EA fails to adequately analyze the project under CEQA for several reasons. First, the GHG analysis does not provide data on current and future oil and gas greenhouse gas emissions as context for the expected reductions from this regulation. Second, the alternatives analysis omits any alternatives that would provide greater environmental benefit in the form of deeper emissions cuts. We also note that while ARB considers this a programmatic environmental analysis (Draft EA at 7), this designation in no way excuses faulty or imprecise analysis where data are available. Citizens for a Sustainable Treasure Island v. City and County of San Francisco, 227 Cal. App. 4th 1036, 1052 (Cal. App. 2014). Finally, this Draft EA is prepared for a certified regulatory program. Draft EA at 6. This does not mean, however, that the analysis may short circuit the requirements for a thorough and meaningful analysis under CEQA. Mountain Lion Foundation v. Fish & Game Com., 16 Cal. 4th 105, 115 (1997); Conway v. State Water Resources Control Bd., 235 Cal. App. 4th 671, 680 (2015).

A. The GHG Impacts Analysis Fails to Place Emission Reductions in Context

10G. Myhre et al., Anthropogenic and Natural Radiative Forcing, in CLIMATE CHANGE 2013: THE PHYSICAL SCIENCE BASIS CONTRIBUTION OF WORKING GROUP I TO THE FIFTH ASSESSMENT REPORT OF THE INTERGOVERNMENTAL PANEL ON CLIMATE CHANGE IPCC Table 8.7 at 714 (Cambridge Univ. Press 2013).
The Draft EA reports total GHG emission reductions at Table 4-4, but fails to show how these reductions compare with statewide oil and gas climate pollutants. An adequate description of a project’s baseline, or environmental setting, is essential to allow decisionmakers to fully evaluate the impacts of a project. See CEQA Guidelines § 15125(a), (c). Furthermore, any specific information that would be necessary to evaluate impacts must be included in an environmental analysis document. See Cadiz Land Co. v Rail Cycle, 83 Cal. App. 4th 74, 93-94 (2000). Here, a critical component of the environmental setting for GHG impacts is the baseline emissions from the oil and gas industry as a whole, and from the various categories identified for reduction. The Draft EA must provide a direct comparison between baseline emission levels and targeted reductions in its section on GHG impacts.

Not only are current emissions levels essential, but also estimated future emissions must be disclosed. The Draft EA alludes to a historical decline in GHG emissions from the oil and gas sector (Draft EA at 11), but other data suggest that this trend may change in the future. First, it is well-established that the oil market is highly volatile, making historic trends questionable predictors. Second, Kern County recently issued an environmental impact report (“EIR”) for its ordinance creating a ministerial process for oil and gas permitting in the County. The EIR indicated that there would be approximately 2,697 new producing wells per year in Kern County for the next 20 years and beyond. These data strongly contradict the general evidence provided by the applicant of decreasing oil and gas production. Finally, a recent analysis of well stimulation by the California Council on Science and Technology found that well stimulation may result in expanded oil production in California, especially from the Monterey Formation. Without an estimate of future potential emission trends, it is impossible for decisionmakers to evaluate how this rule may aid efforts to avoid future climate change.

Even though the rule will result in net GHG emission reductions, the public and decisionmakers have been denied the opportunity to assess the significance of those reductions as well as the relative impact of the increases in CO₂ emissions that will result from increased flaring as a result of compliance actions.

B. The Draft EA Fails to Consider Alternatives to Achieve Greater Reductions

The Draft EA considers only three alternatives, none of which represent increased emission reductions over the proposed rule. In so doing, the alternatives analysis denies the public and decisionmakers the opportunity to assess all reasonable options to reduce environmental impacts of the project. The range of alternatives should “include those that could feasibly accomplish most of the basic objectives of the project and could avoid or substantially lessen one or more of the significant effects. CEQA Guidelines 15126.6(c). The Draft EA

considers only three alternatives in addition to the proposed regulation: 1) No Project, 2) No Enhanced Monitoring; and 3) No Vapor Collection. Draft EA at 112. These three alternatives would achieve the same or fewer reductions. Greater climate benefits would be achieved with standards that require greater reductions, yet no such alternative was considered.

An alternative that includes a more rapid implementation schedule and more stringent requirements (See Section XX, supra) is both feasible and would accomplish the majority of the project objectives. In particular, stronger regulations would better meet Objective 7, which is to implement reductions to meet the state’s 2020 GHG reduction goals, and Objective 8, which is to “include those that could feasibly accomplish most of the basic objectives of the project and could avoid or substantially lessen one or more of the significant effects.” Draft EA at 14. In addition, objectives such as developing a regulation to meet goals of the First Update to the Scoping Plan and supporting ARB’s Short Lived Climate Pollutant Plan will be better achieved with earlier, more stringent requirements. Draft EA at 14. Notably, these alternatives are “consistent with the state board’s legislatively mandated responsibilities and duties” as required under ARB’s certified regulatory program. 17 Cal. Code Regs. § 60006.

Although one role of the alternatives analysis is to inform public and decisionmakers of alternate project formulations that will reduce significant impacts, an alternatives analysis can also present alternatives that will increase project benefits, aside from potential environmental costs. See Kostka & Zischke, Practice Under the California Environmental Quality Act §15.7.1.

VIII. Conclusion

Steep and immediate reductions in methane emissions from the oil and gas sector are necessary to achieve the state’s GHG goals, avoid adverse near-term impacts of climate change, and to protect air quality and health of Californians. As discussed above, the Center supports ARB’s proposals to reduce emissions of these “superpollutants” from the oil and gas industry. At the same time we urge ARB to consider all feasible measures to eliminate methane leaks to the greatest extent possible on the shortest possible timeline.

Sincerely,

Anna Moritz
