24 a large proportion of a species' entire population visiting a single site over a few weeks  
25 and requiring a vast quantity of available forage.

26 Waterbirds are typically classified based on habitat and foraging preference. Waterfowl  
27 are those species that depend primarily on open-water habitat for foraging and roosting,  
28 but breed in wetland and/or adjacent upland habitats. Ducks, geese, and grebes are all  
29 waterfowl. Waterfowl are further divided into dabblers and divers. Dabbling ducks, which  
30 feed at or below the surface of shallow water, have increased in the Suisun and San  
31 Pablo Bays, while populations have held steady in the Central and South Bays (Pitkin  
32 and Wood 2011). Diving ducks, which feed in deeper waters, have decreased in San  
33 Pablo Bay, but increased in Suisun Bay, as populations of their primary prey, large  
34 invertebrates, such as clams, have changed. Overall, populations of dabbling ducks  
35 have increased and winter populations of diving ducks have decreased. Seabirds, such  
36 as gulls, terns, and cormorants, forage and nest in many of the habitats found around  
37 the SFBE. Many species make use of human-created habitats such as piers, bridges,  
38 and the structures found at Alcatraz Island (Pitkin and Wood 2011).

1 Shorebirds primarily use beaches, tidal flats, salt ponds, and shallow open-water  
2 habitats for foraging and roosting, and nest on beaches or adjacent upland areas.  
3 Sandpipers, plovers, and dowitchers are all examples of shorebirds. The overall status  
4 of shorebirds in tidal flats is stable. Population declines in the South Bay have been  
5 offset by population increases in San Pablo Bay. The western sandpiper (*Calidris*  
6 *mauri*), one of the most common species, has declined across the SFBE, but  
7 populations of least sandpiper (*Calidris minutilla*) and willet (*Tringa semipalmata*) have  
8 increased greatly (Pitkin and Wood 2011).

9 Marsh birds include species that depend on emergent marshes for foraging, nesting,  
10 and roosting. California black rail (*Laterallus jamaicensis coturniculus*) and song  
11 sparrows are examples of marsh birds. Tidal marsh bird abundance has increased in  
12 San Pablo Bay and Suisun Bay, mainly driven by increases in common yellowthroat  
13 (*Geothlypis trichas*) and California black rail populations, but has decreased in the  
14 Central and South Bays (SFEP 2011). Reproductive success of tidal marsh birds has  
15 increased in Suisun Bay, but is decreasing in San Pablo Bay. In particular, San Pablo  
16 song sparrow (*Melospiza melodia samuelis*) and Suisun song sparrow (*Melospiza*  
17 *melodia maxillaris*) populations are below the level required to sustain their populations,  
18 and are expected to exhibit long-term declines. The decrease in tidal marsh bird  
19 abundance is attributed to predators and nest flooding (Pitkin and Wood 2011).

20 Wading birds use emergent marsh, marsh edge, and shallow open-water habitats to  
21 forage and roost in upland areas. Locally, examples include the great blue heron, cattle  
22 egret, and great egret. Heron and many egret populations are increasing in San Pablo  
23 Bay, but there has been a decline in the nesting success for great egrets (SFEP 2011).

### 24 Mammals

25 Mammals in the SFBE are found on the shore and in the water. The most common  
26 terrestrial species found in coastal marshes include generalists, such as Norway rat  
27 (*Rattus norvegicus*), house mouse (*Mus musculus*), California vole (*Microtus*  
28 *californicus*), and raccoon (*Procyon lotor*), which are adaptable to a wide range of  
29 habitats. Terrestrial mammals that are obligate users of marsh habitat, such as  
30 saltmarsh harvest mouse (*Reithrodontomys raviventris*), have seen drastic population  
31 declines as a result of habitat loss, and many are now listed as threatened or  
32 endangered by the federal and State governments. Populations of beaver (*Castor*  
33 *canadensis*), river otter (*Lontra canadensis*), and sea otter (*Enhydra lutris*) were  
34 extirpated from the SFBE by overharvesting in the 19<sup>th</sup> century. Both river otter and  
35 beaver have recently recolonized the SFBE; river otter have been reported throughout  
36 the San Francisco Bay, including Coyote Creek in the South Bay, the Richmond Marina  
37 in the Central Bay, Martinez Marina on Carquinez Strait, and wetlands in Suisun Bay  
38 (River Otter Ecology Project 2014). Beaver are now found in the marshes in north San  
39 Pablo Bay and on the lower Alhambra Creek in downtown Martinez.

1 The most common aquatic mammals in the SFBE are California sea lion (*Zalophus*  
2 *californianus*) and harbor seal (*Phoca vitulina*) (NOAA 2007). The California sea lions  
3 are mainly males that migrate to the SFBE to forage and establish a dominance  
4 hierarchy; female California sea lions stay south of Santa Barbara. California sea lion  
5 haul outs are found throughout the San Francisco Bay, most prominently on San  
6 Francisco's Pier 39. Harbor seals are resident breeders. Harbor seals will haul out  
7 throughout the San Francisco Bay; major haul out and pupping sites are located in the  
8 Central and South Bays at the Castro Rocks near the Richmond-San Rafael Bridge,  
9 Yerba Buena Island by the San Francisco-Oakland Bay Bridge, Corte Madera, and  
10 Mowry Slough in the South Bay.

### 11 **Nonindigenous Aquatic Species**

12 The SFBE has been described as one of the most invaded ecosystems in North  
13 America (Cohen and Carlton 1995). Nonindigenous aquatic species (NAS) dominate  
14 many parts of the SFBE, to the extent that in some locations it can be difficult to find any  
15 native species (Cohen and Carlton 1995). In 2010, a field survey funded by the  
16 California Department of Fish and Wildlife (CDFW) reported 497 species from SFBE, of  
17 which 98 species were classified as introduced, including three newly detected species  
18 to SFBE that had likely been spread from other locations in California (CDFW Office of  
19 Spill Prevention and Response [OSPR] 2011). The results indicate high numbers of  
20 introduced species are found in the South Bay, San Pablo Bay, and Central Bay. Suisun  
21 Bay had the lowest number of introduced species.

22 Nonindigenous aquatic species have been introduced to the SFBE via a number of  
23 vectors, including the deliberate introduction of species for recreational or commercial  
24 purposes. The shipping industry has been identified as one of the major vectors of NAS,  
25 and vessel biofouling and ballast water are considered the largest contributors of NAS  
26 to the SFBE (California State Lands Commission [CSLC] 2013c). Eighteen percent of  
27 established nonindigenous aquatic species are tied to vessel biofouling as the primary  
28 likely vector and 9 percent to ballast water; however, when considering established  
29 species with multiple possible vectors, 60 percent could have been introduced via  
30 vessel biofouling as one of several possible vectors, and 53 percent could have been  
31 introduced via ballast water as one of several possible vectors (OSPR 2011). Non-  
32 native jellyfish are found throughout the estuary, including three hydrozoan species  
33 thought to be native to the Black Sea and one scyphozoan species thought to be  
34 introduced from Tokyo Bay. The hydrozoan species are present among the plankton  
35 from May through November, with peak abundances coinciding with warmer summer  
36 and fall temperatures. Jellyfish may be passively spread through all low-salinity areas of  
37 SFBE via attachment to boat bottoms (NOAA 2007).

38 Nonindigenous aquatic species may compete directly with native species for food or  
39 space, or prey upon native species. They can also change the food chain or physical

1 environment to the detriment of native species. Approximately 42 percent of the species  
2 on the federal threatened or endangered species list are at risk, primarily because of  
3 predation, parasitism, and competition from NAS (OSPR 2011). One such currently  
4 pernicious NAS is the overbite clam (*Corbula amurensis*), first found in the SFBE in  
5 1986. Thought to have been introduced into the SFBE by ballast water discharge from a  
6 vessel, this filter feeder is now so abundant that the current population is capable of  
7 filtering the water column over the SFBE shallows almost 13 times per day (SFEP  
8 2004). In some portions of the Suisun Bay floor, the clam accounts for the vast majority  
9 of biomass, and it has been implicated in the pelagic organism decline by severely  
10 reducing the availability of phytoplankton in Suisun Bay (SFEP 2004).

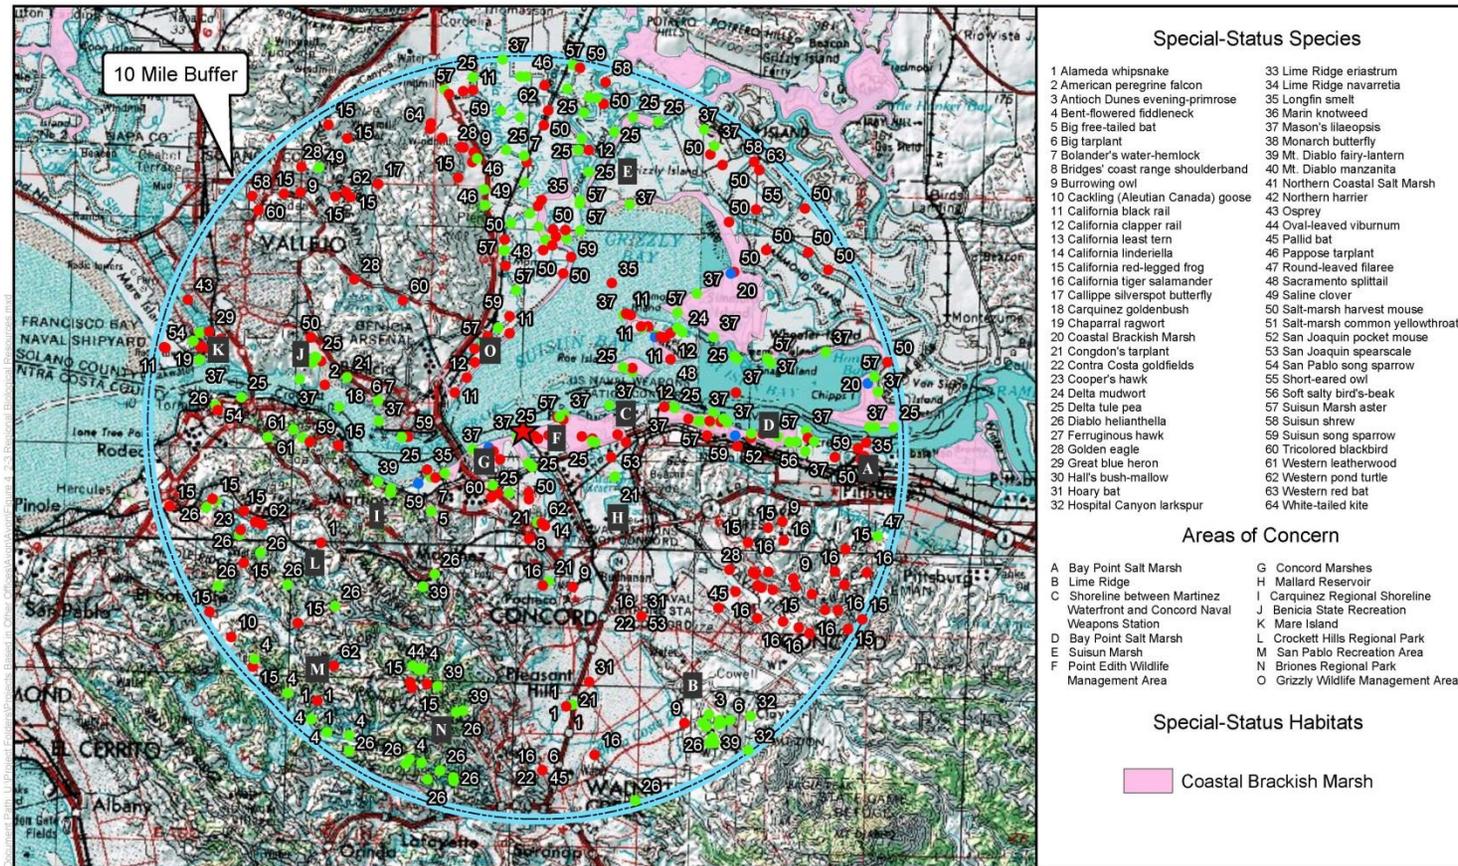

### 11 **Rare, Threatened, and Endangered Species**

12 The distribution and abundance of rare and sensitive species that depend on the  
13 estuarine habitat for some or all of their life cycle vary throughout the region due to the  
14 diversity of habitat between embayments. Each habitat supports a distinct community of  
15 sensitive species. To aid in impact assessment, each category of sensitive species is  
16 summarized by embayment (see Appendix C, Tables C-1 through C-5, for information  
17 about each species, and their potential to be present near the Project site and impacted  
18 by the Project). Figure 4.2-3 depicts the special-status species that have been recorded  
19 by the California Natural Diversity Database within a 10-mile radius of the Project.

### 20 Sensitive Plants

21 Tidal habitats in the SFBE support 12 plant species that are identified by federal and/or  
22 State agencies as endangered, threatened, or rare, or are listed by the California Native  
23 Plant Society as status 1B or higher (California Native Plant Society 2014). The  
24 distribution of sensitive plant species varies geographically within the SFBE. In general,  
25 the less urbanized the bay, the more likely it is to retain a proportion of its historical  
26 marshland and to support rare or sensitive plants (see Appendix C, Table C-1).

27 The Central Bay has not retained any historical tidal marsh remnants, which limits the  
28 potential for rare plants, with few exceptions. Naturally occurring populations of Point  
29 Reyes bird's-beak (*Cordylanthus maritimus* ssp. *palustris*) are found along the shores of  
30 Richardson Bay, and a population was reintroduced to the Crissy Field wetlands in the  
31 Presidio. This species inhabits the high marsh or upper middle marsh zone. It is a  
32 hemiparasitic plant, meaning that although it possesses chlorophyll and is capable of  
33 limited photosynthesis, it must attach its root system to a host plant to extract water and  
34 nutrients, and to reproduce. Point Reye's bird's-beak is dependent upon plants that are  
35 active in summer such as pickleweed (*Salicornia* sp.), saltgrass (*Distichlis* sp.), and  
36 fleshy jaumea (*Jaumea carnosa*), all of which are abundant in Richardson Bay.

1 One other sensitive species found in the Central Bay, California sea blite (*Suaeda*  
2 *californica*), is restricted to the intertidal zone of salt marshes, and was extirpated from  
3 the SFBE in the 1960s. Since 2000, it has been successfully reintroduced at four sites  
4 in the Central Bay: Heron's Head Park at Pier 98, Pier 94, Eastshore State Park north of  
5 Oakland, and Roberts Landing near San Leandro in the South Bay.

6 The South Bay retains fragments of historical tidal marshes at upper Newark Slough,  
7 Dumbarton Marsh, and along the Palo Alto shoreline. However, no sensitive tidal marsh  
8 or estuarine beach plants are known to remain in the South Bay. As mentioned  
9 previously, one population of California sea blite was re-introduced at Roberts Landing.

10 San Pablo Bay, which has retained more of its historic tidal marshes than any other bay,  
11 supports naturally occurring populations of six rare plant species. Historical tidal  
12 marshes are found along the north edge of San Pablo Bay, including China Camp in  
13 San Rafael, Heerdt Marsh by Corte Madera, most of Petaluma Marsh, George Whittell  
14 Marsh by Point Pinole, and areas of Napa marsh, including Fagan's Slough. The richest  
15 diversity of sensitive plants is found in the marshes at the mouths of the Petaluma and  
16 Napa Rivers. San Joaquin spearscale (*Atriplex joaquinana*) is a tall annual herb known  
17 mainly from alkali grasslands and is only rarely known from tidal marsh edges where it  
18 may opportunistically colonize high-tide shorelines. Recent populations are reported  
19 from along the lower Napa River. Saline marsh clover (*Trifolium hydrophilum*) occurs in  
20 marshes and alkaline grasslands and is present in the Viansa wetlands in northwest  
21 San Pablo Bay. The upper marsh zone of San Pablo Bay's brackish and freshwater  
22 marshes supports populations of endemic species known only to SFBE: Suisun marsh  
23 aster (*Symphyotrichum lentum*), delta tule pea (*Lathyrus jepsonii* var. *jepsonii*), and  
24 Mason's lilaeopsis (*Lilaeopsis masonii*). Suisun marsh aster was once widely distributed  
25 in San Pablo Bay, but is now reported only near Fagan Slough. The delta tule pea, a  
26 climbing species, is present in marshes along the Napa River. Mason's lilaeopsis is also  
27 known from the Napa River corridor; it is a shade-sensitive, early successional colonizer  
28 of newly deposited or exposed sediments. Two species of bird's-beak are found in the  
29 upper marsh zone in San Pablo Bay: one population of Point Reyes bird's-beak is  
30 known from the Petaluma River; and extant populations of the federally endangered soft  
31 bird's-beak (*Cordylanthus mollis* ssp. *mollis*) are found in the marshes along the mouth  
32 of the Napa River.

33 Most sensitive plants found in San Pablo Bay are also found in Suisun Bay, where they  
34 are more widely distributed and abundant, particularly in the brackish waters of Suisun  
35 Marsh. In addition to the plants described previously, Suisun Bay contains populations  
36 of the federally endangered Suisun thistle (*Cirsium hydrophilum* var. *hydrophilum*) in the  
37 northern reaches of Suisun Marsh in the vicinity of Rush Ranch. Bolander's water-  
38 hemlock (*Cicuta maculata* var. *bolanderi*) was once common in Suisun Marsh.

## 1 Sensitive Fishes

2 The SFBE provides habitat to seven species of sensitive fish. Most sensitive fish  
3 species in the SFBE rely on brackish water habitat for their adult habitat and/or travel  
4 upstream to spawn in freshwaters, and have thus been affected by degradation or  
5 removal of spawning habitats, entrainment, drought, pollution, predation, disruption of  
6 the food web, and direct competition for space with and predation by nonindigenous  
7 aquatic species. The following discussion summarizes the distribution of sensitive  
8 species in the estuary; Table C-2 in Appendix C provides more detailed information for  
9 each species. Sensitive fish species are found mainly in the north bays. Suisun Bay is  
10 home to two native species of “true” estuarine fish (i.e., fish that spend all their lives in  
11 estuaries): delta smelt and Sacramento splittail (*Pogonichthys macrolepidotus*). Both  
12 species are endemic to the Delta, and both travel into fresh water to spawn. Delta smelt  
13 are found in greatest abundance in shallow, turbid waters at the freshwater edge of the  
14 entrainment zone, where they feed on plankton; Sacramento splittail are found mainly  
15 along the benthos of small, shallow, turbid sloughs lined with emergent vegetation,  
16 where they feed on macroinvertebrates and detritus. The delta smelt population is listed  
17 as threatened at the federal level and endangered by the State. As of 2010, populations  
18 of the splittail were considered stable by the USFWS, which found its listing was not  
19 warranted, but the species remains a CDFW species of special concern, and it is a  
20 targeted species of the Delta Stewardship Council.

21 Four anadromous species are found in the SFBE: longfin smelt, chinook salmon  
22 (*Oncorhynchus tshawytscha*), steelhead trout (*Oncorhynchus mykiss*), and the  
23 Southern Distinct Population of green sturgeon (*Acipenser medirostris*). Longfin smelt  
24 are primarily estuarine, though they are found in small numbers in the coastal waters  
25 beyond the Golden Gate Bridge. In summer, adults congregate in the cooler waters and  
26 deep-water habitats of the Central Bay, where they feed on zooplankton such as the  
27 opossum shrimp, *Acanthomysis* sp., and *Neomysis mercedis*, when available, and on  
28 copepods otherwise (Hobbs 2006). They migrate upstream in fall to spawn in the  
29 limnetic and oligohaline waters of the Delta. Populations have declined steadily over the  
30 past two decades (Rosenfield and Baxter 2007).

31 Chinook salmon are born in fresh water and migrate into the Pacific Ocean to mature,  
32 reaching maturity between 2 and 5 years of age. They migrate into freshwater streams  
33 to spawn, after which they die. Their eggs incubate for several months. Upon hatching,  
34 fry undergo physiological changes in preparation for migration, and enter the smolt  
35 stage. Most chinook smolt migrate to the ocean within a few months of hatching, though  
36 some may remain in fresh water for a year. Peak out-migrations are between April and  
37 June. The Sacramento-San Joaquin River basin runs of chinook salmon are  
38 differentiated into four runs by their time-of-spawning migrations: fall-run, late fall-run,  
39 winter-run, and spring-run. Fall-run chinook migrate upstream from July to November,  
40 late fall-run migrate October to February, winter-run migrate December to April, and

1 spring-run migrate April to July. The Delta is a nursery area for all runs of chinook  
2 salmon. Winter-run chinook, the young of which out-migrate during the driest times of  
3 the year, are listed as critically endangered at both the federal level and by the State.  
4 Spring-run salmon are listed as threatened at both the federal and State levels.

5 An ally to salmon, the steelhead, is an anadromous type of rainbow trout. They migrate  
6 into the estuarine river basins from October to April and spawn from December to May.  
7 Central California Coast steelhead populations in the SFBE are aggregated into two  
8 geographically based diversity strata, both of which are listed as threatened at the  
9 federal level. The Coastal SFBE strata includes populations that spawn in Corte Madera  
10 Creek, Guadalupe River, Miller Creek, Novato Creek, and San Francisquito Creek. The  
11 Interior SFBE strata includes populations that spawn in Alameda Creek, Coyote Creek,  
12 Napa River, Petaluma River, San Leandro Creek, and San Lorenzo Creek (National  
13 Marine Fisheries Service [NMFS] 2011a). Central Valley steelhead, which are also  
14 listed as threatened at the federal level, migrate through the SFBE en route to spawning  
15 sites in tributaries to the Sacramento and San Joaquin Rivers (NMFS 2011b).

16 Green sturgeon may be found throughout the Central, San Pablo, and Suisun Bays.  
17 Adults are primarily marine, but enter the estuary to feed or migrate to spawning  
18 grounds. Juveniles rear in the northern bays for 1 to 4 years before joining the more  
19 marine adults. Sturgeon are benthic feeders, feeding mainly on shrimp and crabs.

#### 20 Sensitive Birds

21 Sensitive birds in the SFBE are generally obligate inhabitants of tidal marshes, and  
22 have experienced population declines as a result of the removal and degradation of  
23 marsh habitat (see Appendix C, Table C-3 for species list). Thus, the Central Bay, which  
24 possesses few tidal marshes, has few populations of sensitive birds. Many sensitive  
25 species, such as California clapper rail (*Rallus longirostris obsoletus*) and California  
26 black rail, are widely distributed throughout the SFBE. Others are subspecies known  
27 from single embayments: the Suisun song sparrow is found in Suisun Bay, the San  
28 Pablo song sparrow in San Pablo Bay, and the Alameda song sparrow (*Melospiza*  
29 *melodia pusillula*) in the South Bay. California least tern (*Sterna antillarum browni*) is  
30 known to nest in the South Bay and along the southern shore of Suisun Bay. Western  
31 snowy plover also nests in the South Bay, as well as in the San Pablo Bay marshes.  
32 Colonial nesters found in the SFBE include double-crested cormorant (*Phalacrocorax*  
33 *auritus*), great blue heron (*Ardea herodias*), great egret (*Ardea alba*), black-crowned  
34 night-heron (*Nycticorax nycticorax*), and snowy egret (*Egretta thula*). Double-crested  
35 cormorant colony nest sites are found under the bridges that divide the bays and on  
36 large electric transmission structures in the South Bay. Heron rookeries, which may  
37 consist of several heron and egret species, are found throughout the Bay Area.

## 1 Sensitive Mammals

2 Tidal marshes in the SFBE support four sensitive mammalian species, while seven  
3 mammalian species use the aquatic habitats of the estuary. Additionally, three species  
4 of bats forage over tidal marsh and estuarine waters (see Appendix C, Table C-4). The  
5 sensitive mammals of the tidal marsh habitats are small rodents: Suisun ornate shrew  
6 (*Sorex ornatus sinuosus*), saltmarsh wandering shrew (*Sorex vagrans halicoetes*), the  
7 federally endangered saltmarsh harvest mouse, and San Pablo vole (*Microtus*  
8 *californicus sanpabloensis*), all weighing less than an ounce at adult size. Where  
9 present, they are prey species for higher-order predators. Both shrews are  
10 insectivorous, while the mouse and vole are vegetarian. The endemic saltmarsh harvest  
11 mouse is generally restricted to tidal marsh habitats. It is found throughout the SFBE,  
12 albeit in low numbers due to habitat destruction and degradation. The saltmarsh  
13 wandering shrew is found in the South Bay, while the Suisun ornate shrew is found in  
14 Suisun Bay. The San Pablo vole is known only from a small region in the vicinity of  
15 Wildcat Creek, on the southeast shore of San Pablo Bay.

16 Seven marine mammal species are known to migrate, forage, and rest in the SFBE.  
17 Gray whale (*Eschrichtius robustus*) and humpback whale (*Megaptera novaeangliae*)  
18 occasionally enter the Central Bay to feed during seasonal migrations. The harbor  
19 porpoise (*Phocoena phocoena*) is another visitor to the Central Bay. Harbor seal and  
20 California sea lion both venture as far upstream as Suisun Bay, but in general, marine  
21 mammals prefer the deep, cold waters of the Central Bay.

22 The distribution of bat species and their use of estuarine habitats has not been well  
23 described. The big free-tailed bat (*Nyctinomops macrotis*) has been collected in  
24 Martinez. Hoary bat (*Lasiurus cinereus*) has been observed in Suisun Marsh, but is  
25 more widely distributed in the South Bay. The pallid bat (*Antrozous pallidus*) has been  
26 collected in the Central, South, and San Pablo Bays.

## 27 Sensitive Amphibians and Reptiles

28 The SFBE supports a few sensitive amphibians and reptiles (see Appendix C, Table C-  
29 5). California red-legged frog (*Rana draytonii*) and western pond turtle (*Actinemys*  
30 *marmorata*), which prefer freshwater ponds and streams but are tolerant of limited  
31 saltwater intrusion, are distributed in low numbers throughout the SFBE (CDFW 2013c)  
32 and are documented from brackish marshes in the San Pablo and Suisun Bays.  
33 California red-legged frogs appear to be eliminated from the western lowland portions of  
34 Contra Costa and Alameda Counties, particularly in urban areas. California tiger  
35 salamanders (*Ambystoma californiense*), which are found in grasslands and vernal  
36 pools, are known only from the Don Edwards National Wildlife Refuge in the South Bay  
37 (CDFW 2013c).

1 **4.2.1.2 Project Study Area**

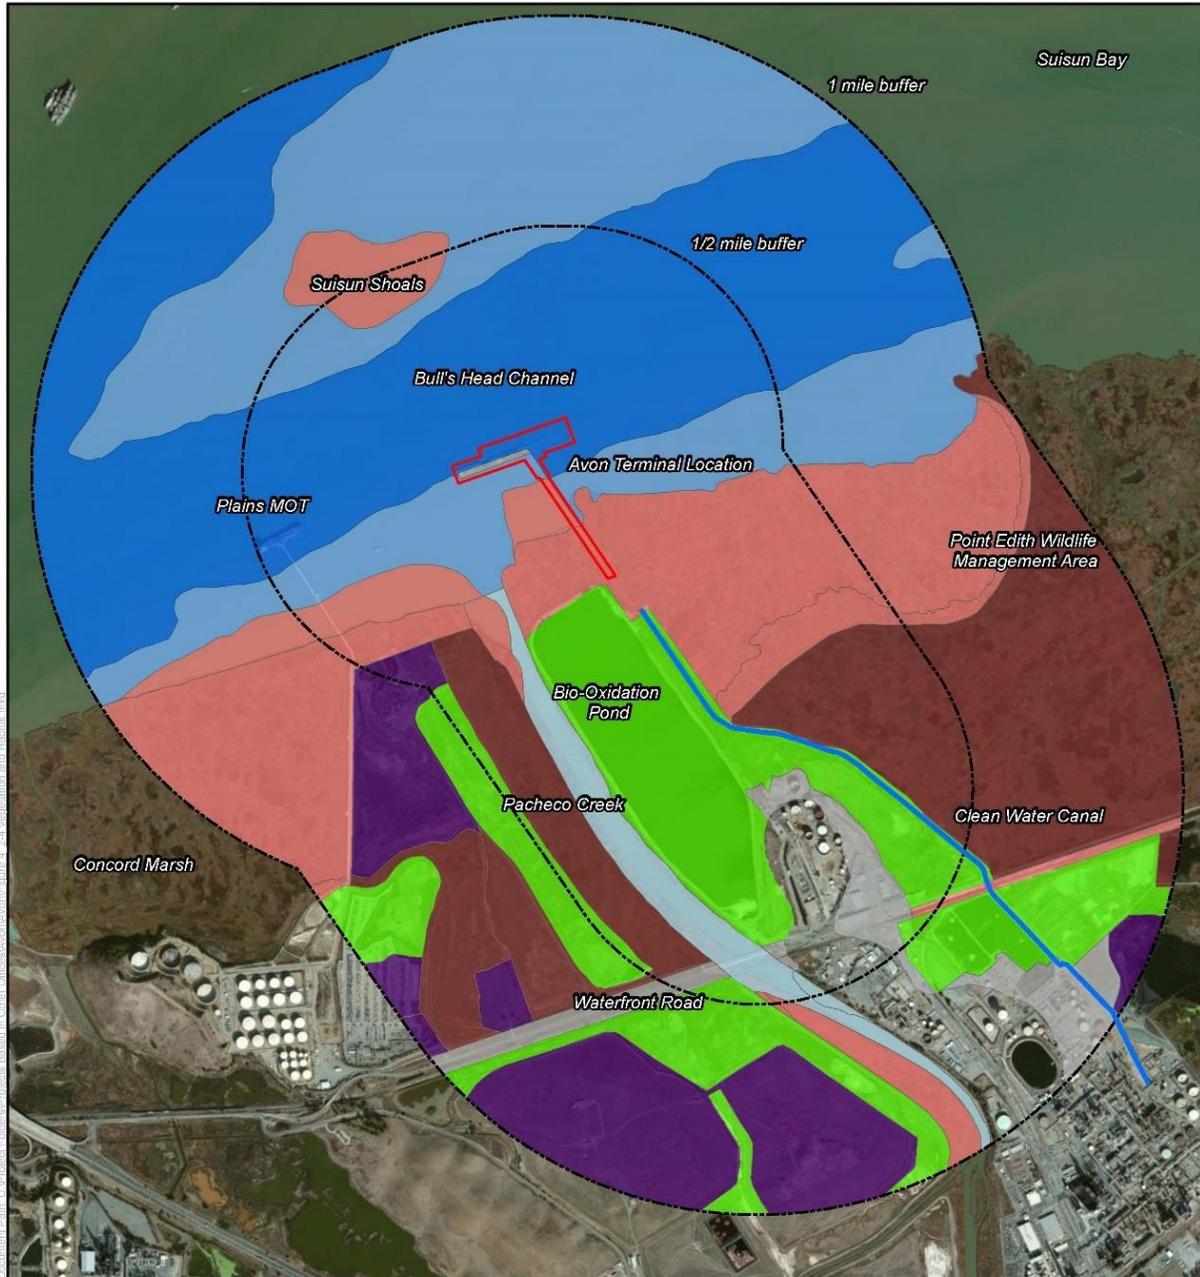

2 The Project study area includes lower Suisun Bay and upper Carquinez Strait, including  
3 vegetation at, and along the shoreline within a 0.5-mile radius of, the Avon Terminal.  
4 Known habitats of rare, threatened, or endangered plant or animal species are present  
5 within a 1-mile radius of the Avon Terminal (see Figure 4.2-4). Table C-6 in Appendix C  
6 includes a matrix depicting habitat use by wildlife found in the Project study area.

7 **Characteristics of the Project Study Area**

8 The Project is located on the south shore of Suisun Bay, approximately 1.75 miles east  
9 of the Benicia-Martinez Bridge. The existing lease extends approximately 1,200 feet into  
10 the bay. Water depths in the lease area range from 13 meters at the lease edge to 3  
11 meters along the dock. Maintenance dredging at the Avon Terminal maintains the  
12 overall sediment elevation at approximately 44 feet below MLLW. The benthic substrate  
13 consists of soft bay sediments over bedrock, also known as mudstone. The Avon  
14 Terminal is located in a slightly depositional environment, where water moving into the  
15 Carquinez Strait slows as it passes through Berth 1, allowing sediment in the water to  
16 settle out. Local scour occurs east of the Avon Terminal.

17 Land uses near the Avon Terminal include industrial and open space. North of the Avon  
18 Terminal, Carquinez Strait and Suisun Bay provide wildlife habitat, commercial and  
19 recreational water use, and industrial transport access. The channel north of the Avon  
20 Terminal is about 9,000 feet wide; the north shore is home to the Suisun Bay Reserve  
21 Fleet and Grizzly Island Wildlife Area. The shoreline east and west of the Avon Terminal  
22 is composed of coastal brackish marsh, and areas of tidal flats lie to the south and west.  
23 Point Edith Wildlife Area lies east of the Avon Terminal and approachway. West of the  
24 Avon Terminal are the Point Edith Wetlands (also known as Concord Marsh) and the  
25 Plains All American Marine Oil Terminal.

26 Carquinez Strait is a narrow gap in the Coast Range that connects San Pablo Bay to  
27 Suisun Bay and the Sacramento-San Joaquin River Delta. The Strait's narrow channel  
28 restricts the outflow of flood waters and sediment from the Central Valley to the ocean,  
29 causing waters to pool and sediment to slow and settle in Suisun Bay, resulting in a  
30 geological feature known as an inverted river delta. Upstream, channel depths transition  
31 rapidly from the deep channel of Carquinez Strait into the shallows of Suisun Bay. This  
32 area of bathymetric change, known as the Garnet Sill, is the upstream endpoint of a  
33 gravitational circulation cell that forms in response to strong tidal currents that carry salt  
34 water upstream along the bottom of the channel, while fresh water flows seaward along  
35 the top of the channel. Salinity in the water column in Suisun Bay is stratified by depth,  
36 with fresh water along the surface and saline water along the bottom (see Figure 4.2-5).  
37 Salinity stratification is greatest during neap tides. Following winter storms, surface  
38 waters reach their lowest levels of salinity, and for a brief time, the channel becomes  
39 oligohaline. Once winter floods have stopped, channel waters return to mesohaline.

**Figure 4.2-5: Salinity Stratification at Avon Terminal**  
 California State Lands Commission  
*Avon Marine Oil Terminal Lease Consideration Project*

- 1 The area where upstream and downstream currents meet and cancel each other out is
- 2 known as the null zone; in Carquinez Strait, this zone typically forms near the strait's
- 3 upper end, downstream of the Garnet Sill. During spring tide, the strait is the site of the
- 4 SFBE turbidity maxima; during neap tide, the estuarine turbidity maximum is found
- 5 upstream at Middle Ground (Schoellhamer 2002). Suspended sediment concentration
- 6 (SSC) is greater near the bottom of the channel than higher in the water column. SSCs
- 7 are seasonally dependent and are at their highest in the winter and spring, and
- 8 decrease through summer to fall lows (see Figure 4.2-6).

California State Lands Commission

*Avon Marine Oil Terminal Lease Consideration Project*

### 1 Avon Terminal Structures

2 The Avon Terminal consists of an existing 1,520-foot-long docking facility connected to  
 3 the shore by an approximately 1-mile-long approachway. The Avon Terminal is  
 4 constructed of wood, concrete, and metal. Several buildings are located on the Avon  
 5 Terminal, including buildings for personnel, a pump house, and a tool shed. Lights are  
 6 placed regularly along the Avon Terminal and approachway, and there is a large light  
 7 bank under the main loading arm.

8 The Avon Terminal provides shade and refuge areas for fish, and resting spots and  
 9 foraging opportunities for fish, birds, and marine mammals. Avon Terminal structures  
 10 also provide nesting habitat for birds, including a pair of osprey nesting on Berth 5.  
 11 Support pilings provide attachment areas for sessile invertebrates and a place for fish to  
 12 spawn. The barren roads, road margins, and dirt parking lots within the Project area

1 provide nesting habitat for killdeer (*Charadrius vociferous*). The various structures and  
2 infrastructure (e.g., light poles, wires, pipelines) provide perch and nest sites for  
3 common birds such as black phoebe (*Sayornis nigricans*) and house finch  
4 (*Haemorhous mexicanus*). Western fence lizards (*Sceloporus occidentalis*) likely use  
5 exposed road beds, metal ladders, and other human-constructed hard surfaces. Most of  
6 the mammal species mentioned below under coyote brush scrub also forage and move  
7 through developed portions of the study area.

### 8 Open Water

9 Open-water habitat within the study area includes open estuarine waters of Suisun Bay  
10 (discussed further below) and associated tidal channels extending into the marsh, the  
11 eastern edge of the bio-oxidation pond, and freshwater wastewater treatment features  
12 (i.e., bio-oxidation pond and Clean Water Canal). Suisun Bay supports numerous native  
13 fish species, and provides foraging and loafing habitat for various species of ducks,  
14 gulls, terns, cormorants, and other waterbirds. Diving ducks, such as greater scaup  
15 (*Aythya marila*) and ruddy duck (*Oxyura jamaicensis*), are more likely to forage in the  
16 waters adjacent to the Avon Terminal, while dabbling ducks, such as mallard (*Anas*  
17 *platyrhynchos*), American wigeon (*Anas Americana*), and green-winged teal (*Anas*  
18 *crecca*), are more likely to forage within the marsh and water treatment features.

### 19 Subtidal Estuarine

20 The estuarine water column consists of the area between the benthos and the water  
21 surface. The water column contains both channels, which are areas with strong currents  
22 and a deep, rounded bottom, and shoals, or shallow, weak-current areas. Channels  
23 provide a connection between marine and freshwater ecosystems, while shoals function  
24 as collection areas for sediment and detritus. In the SFBE, areas of the water column  
25 less than 18 feet deep are considered shallow bay, and areas deeper than 18 feet are  
26 considered deep bay. Approximately 640 acres of shallow bay and 740 acres of deep  
27 bay are found within 1 mile of the Avon Terminal. These habitats provide foraging areas  
28 for invertebrates, fish, diving birds, and marine mammals, as well as nursery and  
29 spawning habitat for invertebrates and fish.

30 Compared to other parts of the SFBE, Suisun Bay is not especially rich in  
31 phytoplankton. Phytoplankton productivity is generally calculated from measurements of  
32 chlorophyll  $\alpha$ . Chlorophyll  $\alpha$  concentrations below about 10 micrograms per liter are  
33 known to cause food-limited declines in zooplankton reproduction. Measurements of  
34 water quality in west Suisun Bay from 2003 to 2013 show that chlorophyll  $\alpha$  levels in the  
35 Carquinez Strait rarely exceed this threshold in either spring or fall (USGS 2013a).

36 The benthic substrate at the Project site consists of soft bay sediments over bedrock,  
37 also known as mudstone. Due to the lack of hard surfaces for rooting, few plants are  
38 associated with soft-bottom habitats. However, although mobile, the fine-grained

1 sediment is stable and compact enough to support a diverse benthic assemblage. The  
2 biotic assemblage associated with this habitat is known as the benthos. Due to the  
3 variability in salinity, the benthic habitat and community composition fluctuates  
4 seasonally. The overbite clam (*Corbula amurensis*), a NAS, is the most common  
5 benthic species observed near the Avon Terminal.

#### 6 Tidal Flat

7 Three areas of tidal flat comprising an area of approximately 107 acres are located  
8 within 1 mile of the Avon Terminal lease. A 12-acre tidal flat is located between the  
9 Avon Terminal and the shoreline, and a band of tidal flat, approximately 54 acres,  
10 stretches along the west bank of Pacheco Creek and the southern shoreline of Suisun  
11 Bay. Tidal flats are also found at Suisun Shoal, approximately 0.5 mile north of the Avon  
12 Terminal. The Project area tidal flats are comprised of mudflats, which are formed of  
13 fine-grained silts and clays, and typically support a diverse community of diatoms,  
14 worms, shellfish, and algal flora. These creatures are prey for a wide variety of birds  
15 and fish. Wading birds known to use the tidal flats for forage during low tide include  
16 western sandpiper, least sandpiper, willet, and dunlin (*Calidris alpina*) (eBird 2012).  
17 Harbor seals are also known to frequent tidal flats. Other species, such as white pelican  
18 (*Pelecanus erythrorhynchos*), rest on the tidal flats between fishing expeditions. During  
19 high tide, the tidal flats provide foraging areas for fish, including longfin smelt.

#### 20 Tidal Marsh

21 Approximately 624 acres of fully tidal or muted tidal marsh are found along the southern  
22 shore of Suisun Bay within 1 mile of the Avon Terminal. West of the Avon Terminal, the  
23 predominantly low/middle marsh plain extends up to 3,500 feet from the edge of the  
24 tidal flat; east of the Avon Terminal, the marsh plain is approximately 2,500 feet wide.  
25 Both marsh plains contain a fringe of high tidal marsh and abut areas of muted tidal  
26 brackish marsh. The plains are fairly level. Their tidal channels are a combination of  
27 straight channels superimposed on the marsh for drainage or mosquito control and  
28 linear dendritic channels in areas closest to shore. The dominant species present are  
29 common reed (*Phragmites australis*), cattails, California tule (*Schoenoplectus*  
30 *californicus*), broad-leaf pepperweed (*Lepidium latifolium*), pickleweed (*Salicornia*  
31 *pacifica*), Baltic rush (*Juncus balticus*), and gumplant.

32 Tidal brackish marsh within the study area provides high-quality habitat for a variety of  
33 bird species, including great egret, snowy egret, northern harrier (*Circus cyaneus*),  
34 Virginia rail (*Rallus limicola*), sora (*Porzana carolina*), marsh wren (*Cistothorus*  
35 *palustris*), salt marsh common yellowthroat (*Geothlypis trichas sinuosa*), Suisun song  
36 sparrow, and red-winged blackbird (*Agelaius phoeniceus*). The high saline content and  
37 regular inundation of brackish marsh precludes regular use by amphibians, reptiles, and  
38 most mammals, but species from these taxa that use adjacent uplands and developed  
39 areas likely forage in the marsh on an incidental basis. Common bat species, such as

1 big brown bat (*Eptesicus fuscus*) and Brazilian free-tailed bat (*Tadarida brasiliensis*),  
2 likely forage over the marsh at night.

3 Muted tidal marsh adjacent to the Avon Terminal provides habitat for a variety of rare,  
4 threatened, and endangered species, including California clapper rail and California  
5 black rail. Saltmarsh harvest mouse inhabit marshes in the Project area. Several rare  
6 plants have potential to be found in the marshes, including soft bird's-beak, delta tule  
7 pea, Mason's lilaepsis, and Suisun thistle.

8 An additional 104 acres of diked brackish marsh is found within 1 mile of the lease,  
9 including the marshlands under the approachway. Diked marshes provide important  
10 habitat for waterfowl, shorebirds, and small mammals, and may provide high-tide  
11 refugia for small mammals and roosting habitat for shorebirds.

## 12 Coyote Brush Scrub

13 The dense shrub cover and scattered trees growing on the levees and berms within the  
14 study area provide nesting and foraging habitat for bird species such as white-tailed kite  
15 (*Elanus leucurus*), red-tailed hawk (*Buteo jamaicensis*), great horned owl (*Bubo*  
16 *virginianus*), mourning dove (*Zenaida macroura*), Anna's hummingbird (*Calypte anna*),  
17 western scrub-jay (*Aphelocoma californica*), and northern mockingbird (*Mimus*  
18 *polyglottos*). Exposed concrete rubble, or other hard surfaces, provide basking habitat  
19 for western fence lizards, and the dense shrub cover may support common amphibians  
20 and reptiles such as Sierran treefrog (*Pseudacris sierra*), common garter snake  
21 (*Thamnophis sirtalis*), and gopher snake (*Thamnophis sirtalis*). Mammal species  
22 expected to occur in scrub and levee slopes include California ground squirrel  
23 (*Spermophilus beecheyi*), Botta's pocket gopher (*Thomomys bottae*), California vole  
24 (*Microtus californicus*), black-tailed jackrabbit (*Lepus californicus*), coyote (*Canis*  
25 *latrans*), northern raccoon (*Procyon lotor*), and striped skunk (*Mephitis mephitis*), along  
26 with the non-native Norway rat (*Rattus norvegicus*) and house mouse (*Mus musculus*).

## 27 **Special-status Species**

### 28 Plants

29 Of the 12 special-status plant species that occur in the tidal marshes of SFBE, seven  
30 species have potential to occur at the Project site:

- 31 • Salty soft bird's-beak (*Cordylanthus mollis* ssp. *mollis*)
- 32 • Mason's lilaepsis (*Lilaeopsis masonii*)
- 33 • Suisun marsh aster (*Symphytrichum lentum*)
- 34 • Saline clover (*Trifolium depauperatum* var. *hydrophilum*)
- 35 • Delta tule pea (*Lathyrus jepsonii* var. *jepsonii*)
- 36 • San Joaquin spearscale (*Atriplex joaquinana*)
- 37 • Delta mudwort (*Limosella australis*)

1 Fish

2 All special-status fish species of the SFBE with extant populations have potential to  
3 occur within the Project site:

- 4 • Green sturgeon, Southern Distinct Population Segment (*Acipenser medirostris*)
- 5 • Delta smelt (*Hypomesus transpacificus*)
- 6 • Longfin smelt (*Spirinchus thaleichthys*)
- 7 • Central Valley steelhead (*Oncorhynchus mykiss*)
- 8 • Central California Coast steelhead (*Oncorhynchus mykiss*)
- 9 • Central Valley spring-run Chinook salmon (*Oncorhynchus tshawytscha*)
- 10 • Sacramento River winter-run Chinook salmon (*Oncorhynchus tshawytscha*)

11 Terrestrial Wildlife

12 Suitable habitat for 20 special-status wildlife species occurs within the Project site:

- 13 • Western pond turtle (*Emys marmorata*)
- 14 • Cooper's hawk (*Accipiter cooperii*)
- 15 • Tricolored blackbird (*Agelaius tricolor*)
- 16 • Great blue heron (*Ardea herodias*)
- 17 • Northern harrier (*Circus cyaneus*)
- 18 • Short-eared owl (*Asio flammeus*)
- 19 • Cackling (=Aleutian Canada) goose (*Branta hutchinsii leucopareia*)
- 20 • White-tailed kite (*Elanus leucurus*)
- 21 • American peregrine falcon (*Falco peregrinus anatum*)
- 22 • Salt marsh common yellowthroat (*Geothlypis trichas sinuosa*)
- 23 • Bald eagle (*Haliaeetus leucocephalus*)
- 24 • California black rail (*Laterallus jamaicensis coturniculus*)
- 25 • California clapper rail (*Rallus longirostris obsoletus*)
- 26 • Suisun song sparrow (*Melospiza melodia maxillaris*)
- 27 • San Pablo song sparrow (*Melospiza melodia samuelis*)
- 28 • Osprey (*Pandion haliaetus*)
- 29 • Double-crested cormorant (*Phalacrocorax auritis*)
- 30 • Salt marsh harvest mouse (*Reithrodontomys raviventris*)
- 31 • Suisun shrew (*Sorex ornatus sinuosus*)
- 32 • Big free-tailed bat (*Nyctinomops macrotis*)

33 Marine Mammals

34 Marine mammals with potential to occur within the Project site include:

- 35 • California sea lion (*Zalophus californianus*)
- 36 • Harbor seal (*Phoca vitulina richardii*)

1 **Special-status Habitats**

2 Jurisdictional Waters

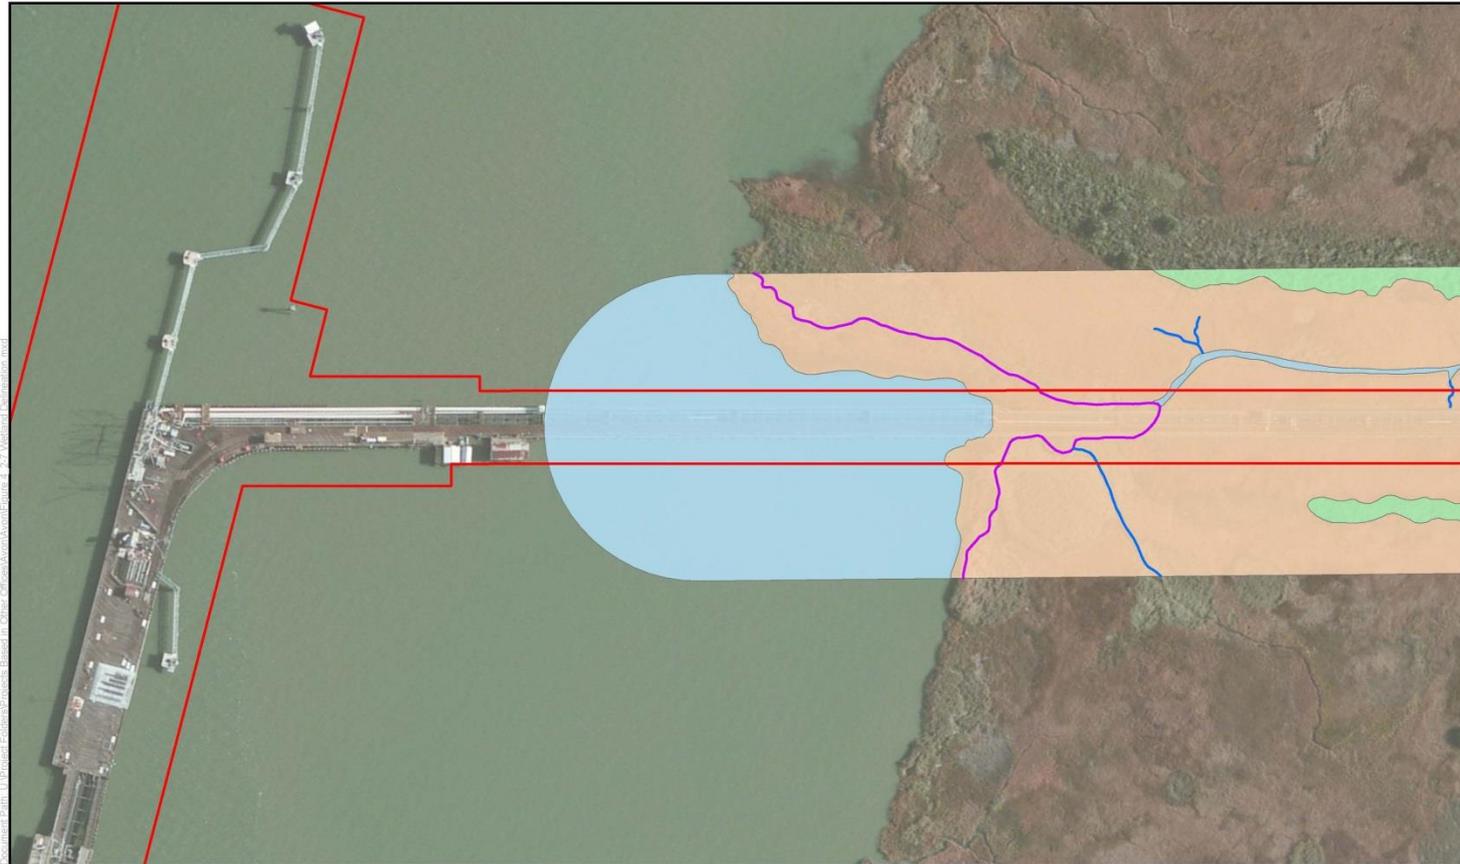

3 LSA Associates (2013) conducted a Preliminary Wetland Delineation within a 47-acre  
4 study area, and concluded that potential Clean Water Act (CWA) Section 404  
5 jurisdictional features consist of 22.78 acres of tidal/non-tidal marsh wetlands and 4.79  
6 acres of non-wetland waters (see Figure 4.2-7). Suisun Bay and a single tributary  
7 slough that parallels the approachway north of Land's End (located at Bent 168,  
8 between Areas B and C, on the approachway; refer to Figure 2-4) are also subject to  
9 U.S. Army Corps of Engineers (USACE) jurisdiction, pursuant to Section 10 of the  
10 Rivers and Harbors Act. The bio-oxidation pond and the Clean Water Canal are covered  
11 under a National Pollutant Discharge Elimination System permit, as part of the Golden  
12 Eagle Refinery's wastewater treatment system.

13 Critical Habitat

14 The open waters of Suisun Bay within the Project area have been designated as critical  
15 habitat for Sacramento River winter-run Chinook salmon (58 Code of Federal  
16 Regulations [CFR] 33212), delta smelt (59 CFR 65278), and green sturgeon (74 CFR  
17 52300). Primary constituent elements (PCEs) of designated critical habitat for salmon  
18 and sturgeon include the estuarine water column, which includes suitable depth,  
19 sediment, and water quality; and adequate food resources and foraging habitat. PCEs  
20 for the delta smelt that are located within the vicinity of the Project include the physical  
21 habitat, water, river flow, and salinity concentrations required to maintain delta smelt  
22 habitat for: (1) larval and juvenile transport, (2) rearing habitat, and (3) adult migration.  
23 Due to the fluid nature of the Delta's hydrology, the quality of the PCEs for the delta  
24 smelt fluctuate within the designated area.

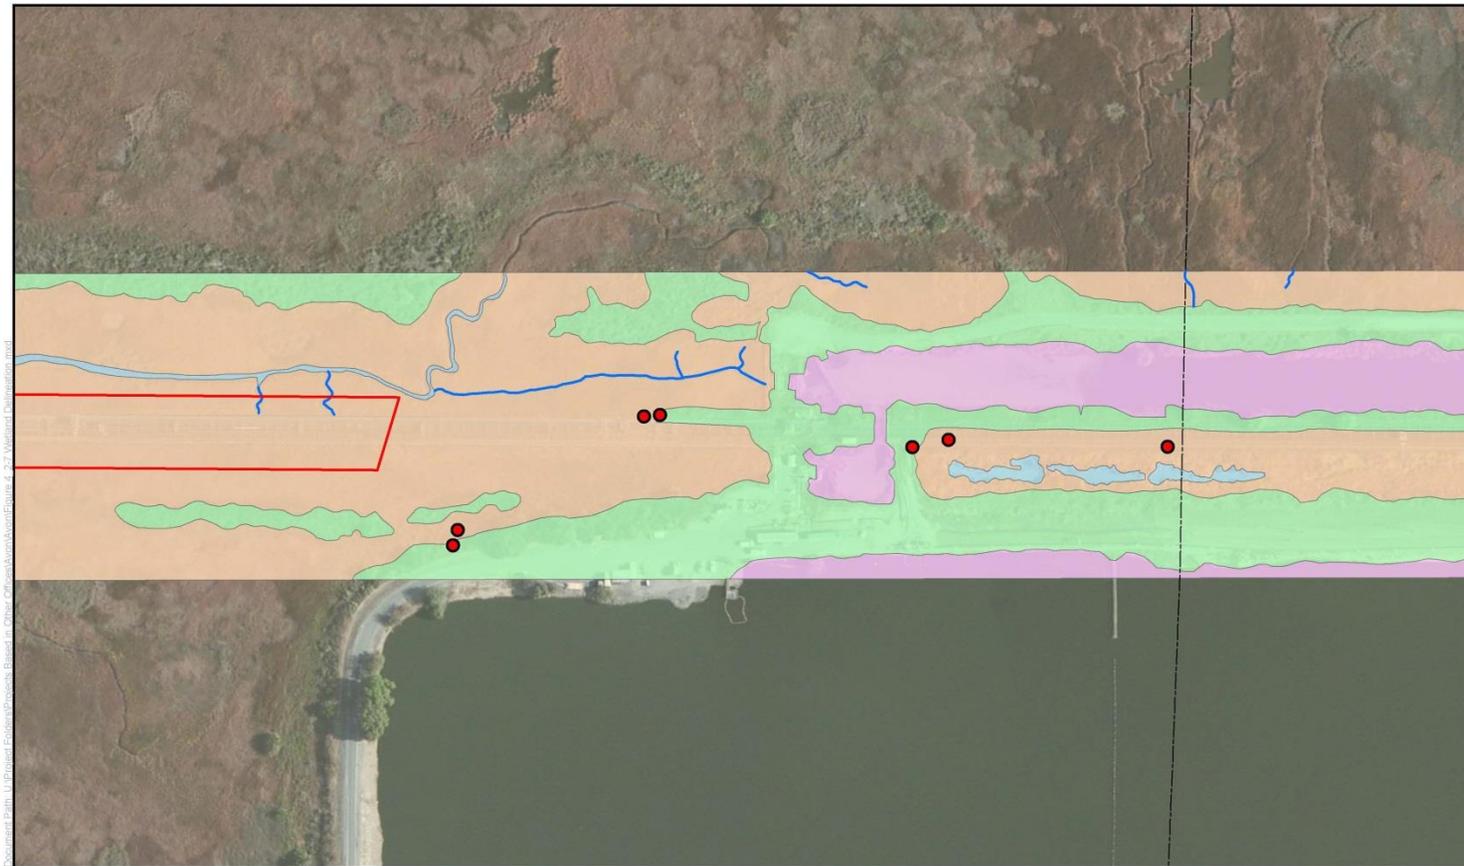

25 California Department of Fish and Wildlife Natural Communities

26 Coastal brackish marsh is found along the shoreline at the Avon Terminal. The coastal  
27 brackish marsh is dominated by perennial, emergent, herbaceous monocots that create  
28 a dense cover up to 2 meters tall. Due to the saline and semi-aquatic environment, plant  
29 species diversity in coastal brackish marshes is typically low. Plant species are stratified  
30 by salinity levels. Both marsh types support a diverse biotic assemblage and provide  
31 nursery grounds for numerous organisms, including fish, mammals, and birds (CERES  
32 1996).

SACRAMENTO, CALIFORNIA 95825-8202

FEBRUARY 2014

## 4.2 BIOLOGICAL RESOURCES

---

1  
2 Section 4.2 presents the existing environment and impacts analysis of biological resource  
3 issues associated with the granting of a new lease to the Amorco Marine Oil Terminal  
4 (Amorco Terminal) to continue to operate in the southeastern Carquinez Strait. The  
5 existing biological resources in the San Francisco Bay Estuary and in the Amorco Marine  
6 Oil Terminal Lease Consideration Project (Project) study area (lower Suisun Bay and  
7 upper Carquinez Strait) are described, as well as in the immediate vicinity of the Amorco  
8 Terminal. Also included is a summary of laws and regulations that may affect biological  
9 resources. This is followed by an analysis of the potential Project impacts. Routine  
10 operations at the Amorco Terminal, or an accidental release of oil, present the potential  
11 to impact nearby biological resources. An oil spill could have wide-ranging effects on  
12 biological resources in the San Francisco Bay Estuary.

### 13 4.2.1 ENVIRONMENTAL SETTING

#### 14 4.2.1.1 San Francisco Bay Estuary

##### 15 *Geographic and Hydrologic Characteristics of the San Francisco Bay Estuary*

16 The San Francisco Bay Estuary is typically divided into five segments: The Sacramento-  
17 San Joaquin River Delta (Delta), Suisun Bay, San Pablo Bay, Central Bay, and South  
18 Bay (see Figure 4.2-1).

19 The Delta is the easternmost, or most upstream, segment. The Delta is a 1,150-square-  
20 mile triangle-shaped region roughly bounded on the north by the city of Sacramento, on  
21 the south by the city of Tracy, and on the west by Chipps Island. The Sacramento and  
22 San Joaquin Rivers and their tributaries flowing into the Delta drain about half of the  
23 surface area of California and establish the extent of brackish water habitat in Suisun  
24 Bay.

25 Suisun Bay is a shallow estuarine bay bounded by Chipps Island on the east and the  
26 Benicia-Martinez Bridge on the west. Suisun Marsh, the largest brackish water marsh in  
27 the United States and the largest wetland in California, forms its northern boundary.  
28 Suisun Bay has the lowest salinity levels in the San Francisco Bay system, with values  
29 ranging from oligohaline (0.5 to 5.0 parts per thousand [ppt]) to mesohaline (5.0 to 18.0  
30 ppt) depending on seasonal variations in tides, evaporation, and freshwater inflows from  
31 the Delta. The southern shore of Suisun Bay is home to the Concord Naval Weapons  
32 Station and the cities of Pittsburg, West Pittsburg, Avon, and Martinez. Suisun Bay is  
33 connected to San Pablo Bay via the Carquinez Strait, a narrow, 12-mile-long band of  
34 water that extends from between the Benicia-Martinez Bridge to Mare Island.

1 San Pablo Bay is the second largest bay in the estuary; it extends from the Carquinez  
2 Strait to the San Pablo Strait near the Richmond-San Rafael Bridge, where it forms the  
3 upstream boundary of the Central Bay. San Pablo Bay is moderately saline, or polyhaline,  
4 with salinity levels ranging from 18.0 – 30.0 ppt. Much of the north shore of San Pablo  
5 Bay is protected as part of the San Pablo Bay National Wildlife Refuge.

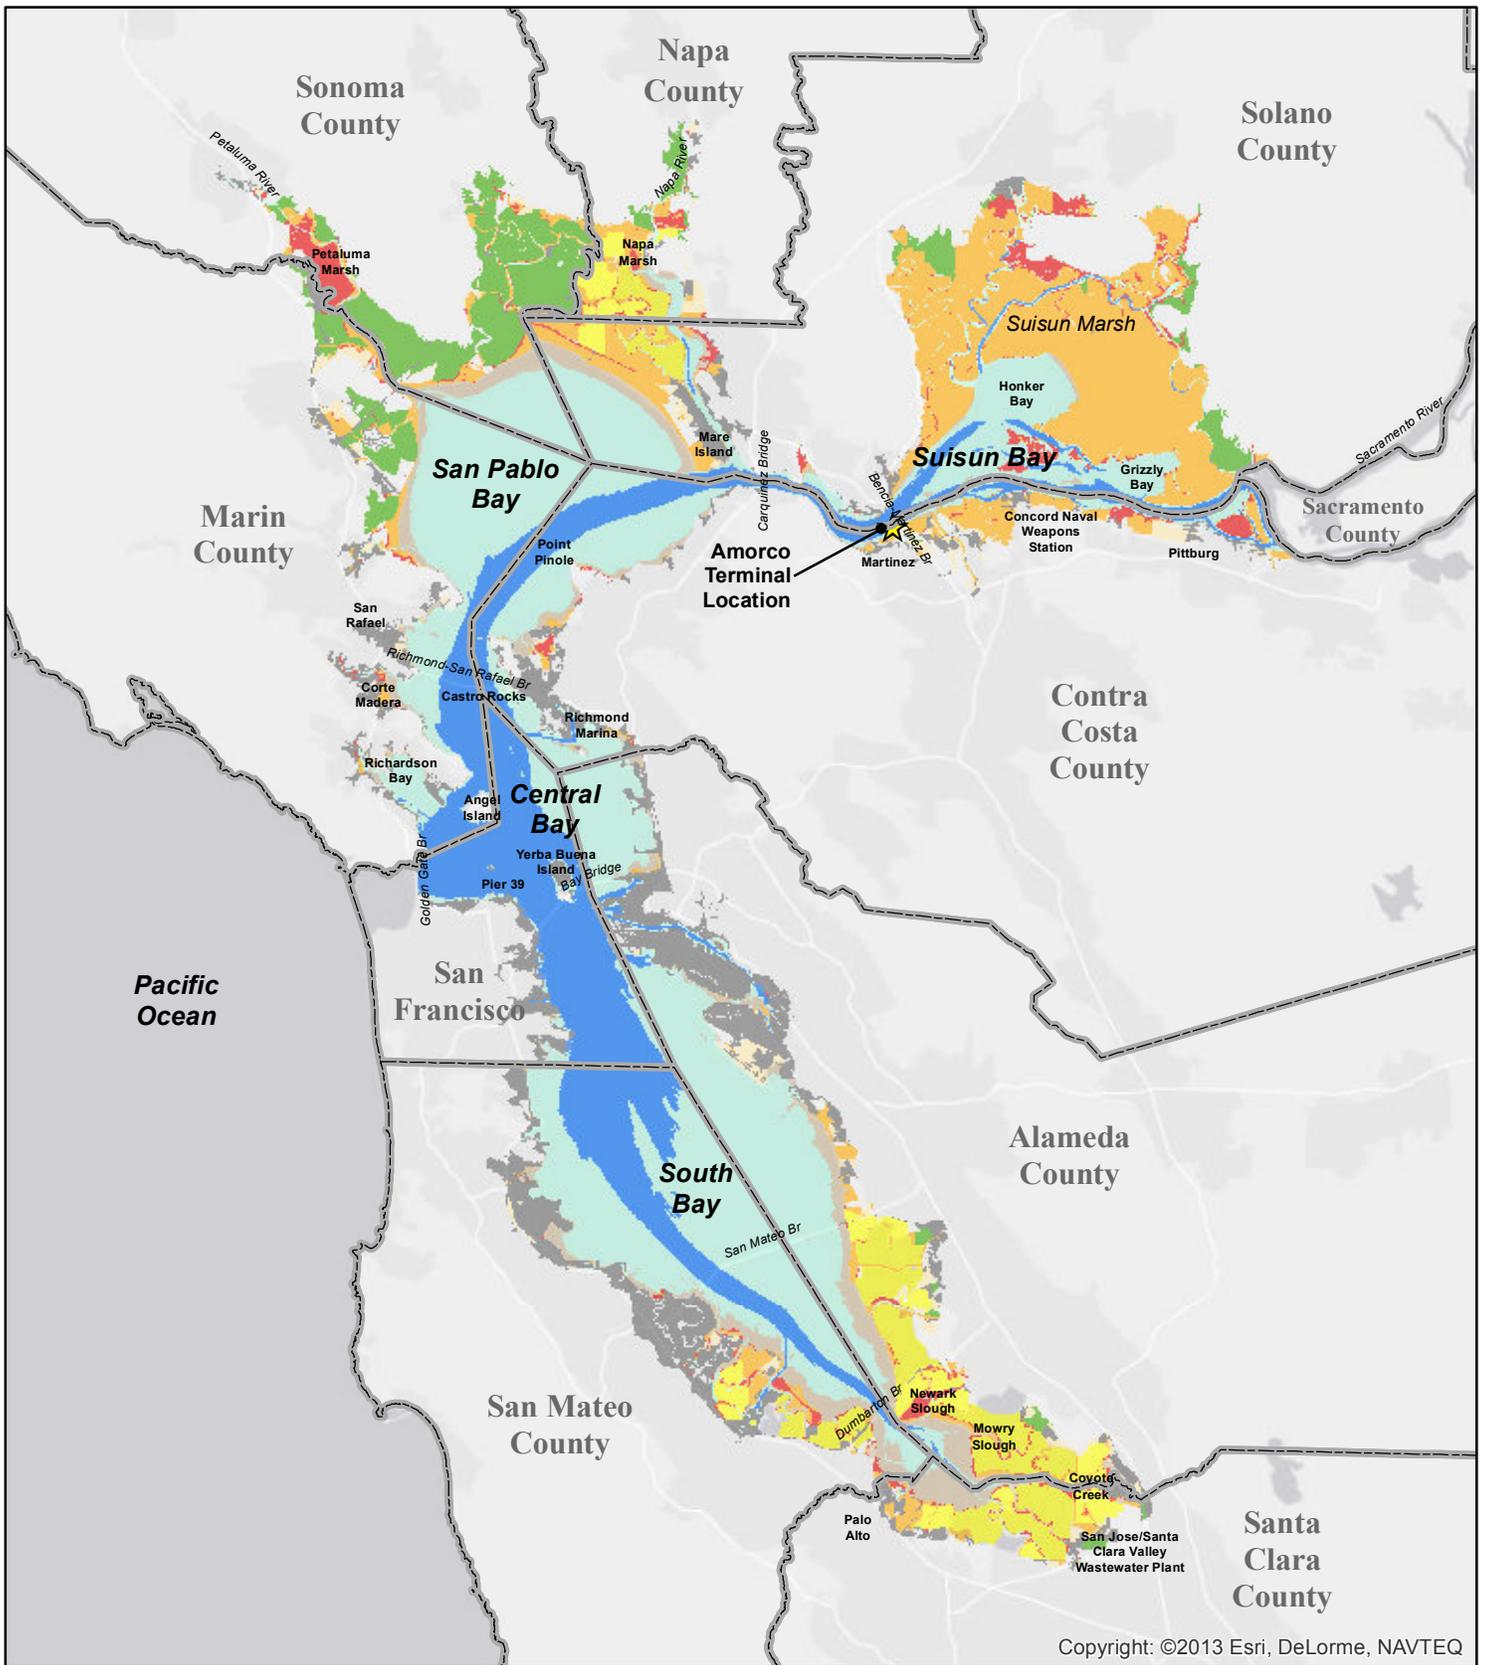

6 The Central Bay is defined as an area bounded by three bridges: The Richmond-San  
7 Rafael Bridge, Golden Gate Bridge, and San Francisco-Oakland Bay Bridge. Central Bay  
8 is the coldest, deepest, and most saline of the bays; it is considered euhaline, with salinity  
9 levels between 30.0 – 35.0 ppt. Because of its proximity to the Pacific Ocean, its water  
10 quality parameters are more stable than its neighboring bays. Ecological conditions in the  
11 Central Bay are also more stable than in neighboring bays (SFEP 2011).

12 The waters south of the San Francisco-Oakland Bay Bridge form the largest embayment,  
13 known as the South Bay. The waters here are shallow and polyhaline. Freshwater flows  
14 to the South Bay are limited to seasonal flows from Guadalupe River and other streams.  
15 Throughout the year, the largest flows into South Bay are treated waters from the San  
16 Jose/Santa Clara County Water Pollution Control Plant (Okamoto and Wong 2011).  
17 Water circulation and fresh inflows are so limited that this bay is considered a lagoon-like,  
18 estuarine backwater.

19 The estuary's tidal cycle is mixed semidiurnal, resulting in two cycles each day. The  
20 average height of the higher tide is called extreme high tide, or local mean higher high  
21 water (MHHW), while the average of the high tides is called high tide, or local mean high  
22 water (MHW). Extreme low tide or mean lower low water (MLLW) and low tide or mean  
23 low water (MLW) refer to the average height of the lowest tide and the average of all low  
24 tides, respectively. Mean tide level (MTL) lies midway between MHW and MLW. Tidal  
25 highs and lows in the bay vary with time of day, the position of the moon, season, and  
26 distance from the Pacific Ocean. The relative height covered by these tidal datums have  
27 important implications for shoreline habitat.

### 28 ***Habitats of the San Francisco Bay Estuary***

29 The habitats in the estuary are dynamic and can be influenced by seasonal flooding,  
30 extreme tides, drought, and human activity. Characteristics of the biotic communities at  
31 each habitat are found in Table 4.2-1. Figure 4.2-2 depicts habitat distribution in the  
32 estuary.

Table 4.2-1: Biotic Communities of the San Francisco Bay Estuary<sup>1</sup>

Community	Locations & Examples	Characteristic Plants	Characteristic Animals
Diadromous	Open waters of the San Francisco Bay Estuary, Sacramento and San Joaquin Rivers, Napa River	N/A	Chinook salmon ( <i>Oncorhynchus tshawytscha</i> ), steelhead ( <i>Oncorhynchus mykiss</i> ), delta smelt ( <i>Hypomesus transpacificus</i> ), longfin smelt ( <i>Spirinchus thaleichthys</i> ), striped bass ( <i>Morone saxatilis</i> )
Limnetic	0 – 0.5 ppt <sup>2</sup> salinity. Sacramento River, San Joaquin River	Sago pondweed ( <i>Potamogeton pectinatus</i> )	Asian clam ( <i>Corbicula fluminea</i> )
Oligohaline	0.5 – 5.0 ppt salinity. Suisun Bay	Widgeon grass ( <i>Ruppia maritima</i> )	California bay shrimp ( <i>Crangon franciscorum</i> )
Mesohaline	5.0 – 18.0 ppt salinity. Suisun Bay, Carquinez Strait	Widgeon grass ( <i>Ruppia maritima</i> )	Overbite clam ( <i>Corbula amurensis</i> ), Oriental shrimp ( <i>Palaemon macrodactylus</i> ), starry flounder ( <i>Platichthys stellatus</i> )
Polyhaline	18.0 – 30.0 ppt salinity. Carquinez Strait, San Pablo Bay, South Bay	<i>Ulva</i> , <i>Gracilaria pacifica</i> , <i>Fucus</i> , <i>Sargassum muticum</i> , eelgrass ( <i>Zostera marina</i> )	Blacktail bay shrimp ( <i>Crangon nigricauda</i> ), Dungeness crab ( <i>Metacarcinus magister</i> ), Pacific herring ( <i>Clupea pallasii</i> ), Pacific staghorn sculpin ( <i>Leptocottus armatus</i> ), English sole ( <i>Parophrys vetulus</i> )
Euhaline	30.0 – 35.0 ppt salinity. Central Bay	<i>Ulva</i> , <i>Gracilaria pacifica</i> , <i>Fucus</i> , <i>Sargassum muticum</i> , eelgrass ( <i>Zostera marina</i> )	Blackspotted bay shrimp ( <i>Crangon nigromaculata</i> ), leopard shark ( <i>Triakis semifasciata</i> ), bat ray ( <i>Myliobatis californica</i> ), Pacific sardine ( <i>Sardinops sagax</i> ), northern anchovy ( <i>Engraulis mordax</i> ), California halibut ( <i>Paralichthys californicus</i> )

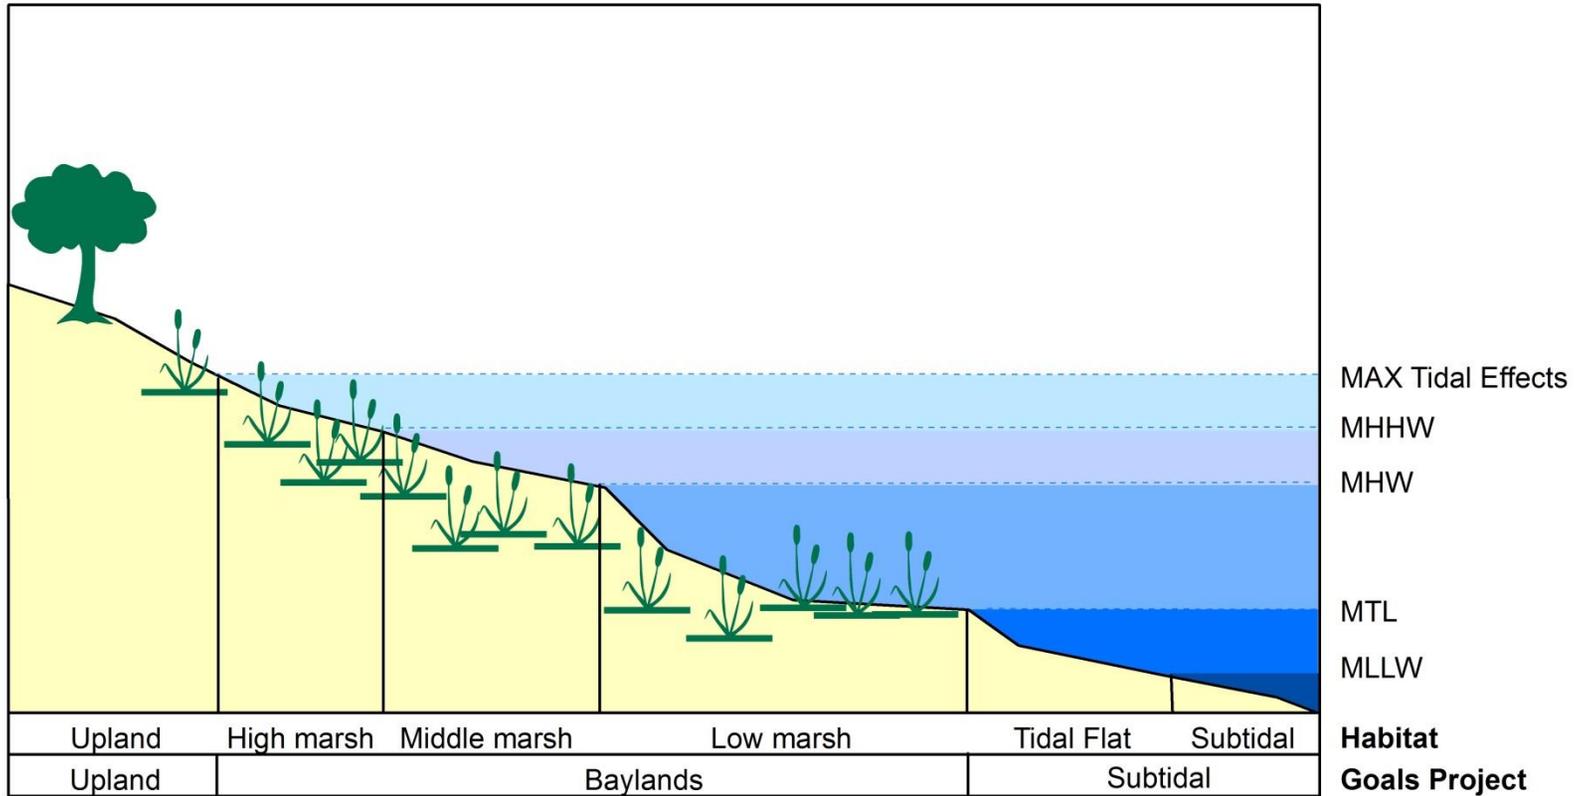

## 4.2 Biological Resources

Community	Locations & Examples	Characteristic Plants	Characteristic Animals
Tidal flat	Along bay shore in San Mateo, Santa Clara, Alameda, Marin, Napa, Contra Costa, Solano counties	<i>Ulva spp.</i> , <i>Gracilaria pacifica</i> , <i>Fucus spp.</i> , <i>Sargassum muticum</i> , eelgrass ( <i>Zostera marina</i> )	California bay shrimp ( <i>Crangon franciscorum</i> ), least sandpiper ( <i>Calidris minutilla</i> ), western sandpiper ( <i>Calidris mauri</i> ), willet ( <i>Tringa semipalmata</i> )
Tidal marsh	Along bay shore in San Mateo, Santa Clara, Alameda, Marin, Napa, Contra Costa, Solano counties (e.g., Martinez marshes, Peyton Slough)	Pickleweed ( <i>Salicornia virginica</i> ), sea blite ( <i>Suaeda californica</i> ), marsh rosemary ( <i>Limonium commune</i> ), marsh grindelia ( <i>Grindelia hirsutula</i> ), California cord grass ( <i>Spartina foliosa</i> )	Clapper rail ( <i>Rallus longirostris</i> ), marsh hawk ( <i>Circus cyaneus</i> ), short-eared owl, ( <i>Asio flammeus</i> ), salt-marsh harvest mouse ( <i>Reithrodontomys raviventris</i> ), vagrant shrew ( <i>Sorex vagrans</i> ), salt marsh fly ( <i>Ephydra riparia</i> ), salt marsh mosquitoes ( <i>Aedes sqamiger</i> , <i>A. dorsalis</i> ).
Coastal scrub	Dry rocky or gravelly slopes below 3,000 feet (e.g., steep slopes at the Amorco Terminal)	California sage brush ( <i>Artemesia californica</i> ), black sage ( <i>Salvia mellifera</i> ), coyote brush ( <i>Baccharis pilularis</i> ), bush monkey-flower ( <i>Mimulus aurantiacus</i> ).	Rufous-crowned sparrow ( <i>Aimophila rucifeps</i> ), rock wren ( <i>Salpinctes obsoletus</i> ), wrentit ( <i>Chamaea fasciata</i> ), brush rabbit ( <i>Sylvilagus bachmani</i> ), western fence lizard ( <i>Sceloporus occidentalis</i> ).
Urban shoreline	Manmade shorelines in all San Francisco Bay Area counties, San Francisco shoreline, Oakland shoreline	Himalayan blackberry ( <i>Rubus armeniacus</i> ), pampas grass ( <i>Cortaderia spp.</i> ), Bermuda grass ( <i>Cynodon dactylon</i> )	House sparrow ( <i>Passer domesticus</i> ), rock dove ( <i>Columba livia</i> ), western scrub jay ( <i>Aphelocoma californica</i> ), domestic cat ( <i>Felis catus</i> ), domestic dog ( <i>Canis lupus familiaris</i> ), raccoon ( <i>Procyon lotor</i> )

Note: <sup>1</sup> Many aquatic plant and animal species may be found in more than one biotic community and inclusion as a characteristic species does not mean a species can only be found in a single habitat.

1 Subtidal

2 Open-water habitats are divided into two categories: Shallow bay and deep bay. Shallow  
3 bays are subtidal areas less than 18 feet deep below extreme low tide; deep bay habitats  
4 are deeper. The bay contains approximately 164,000 acres of shallow bay habitat and  
5 81,000 acres of deep bay habitat (Monroe et al. 1999). Deep bay areas are found in the  
6 Central Bay and South Bay, and along the main deep-water channel in the San Pablo  
7 and Suisun Bays. All bays contain extensive areas of shallow bay habitat.

8 The open waters of the bay are primarily underlain by soft-bottom bay sediments,  
9 although there are small and important areas where the substrate is either vegetated or  
10 supports shellfish beds. Areas of eelgrass habitat are found along the urban coastlines  
11 west of Richmond and Oakland. The southern shoreline of San Pablo Bay contains the  
12 most extensive areas of eelgrass beds in the San Francisco Bay Estuary. Native oyster  
13 beds are found in the same general areas as eelgrass habitats. Crushed shell substrate  
14 is found in the South Bay (SFEP 2011).

15 Soft-bottom substrate consists of sedimentary particles such as clay, silt, and sand that  
16 can be readily mobilized by tidal currents. This widespread substrate covers 90 percent  
17 of the San Francisco Bay Estuary (SFEP 2011). The primary sources of sediment into the  
18 San Francisco Estuary are the watersheds of the Sacramento and San Joaquin Rivers.  
19 River currents carry sediment into the estuary and deposit it onto the channel bottom,  
20 while tidal currents resuspend the fine sediment into the water column. The cyclical  
21 deposition and resuspension of fine sediments leads to sorting by grain size, where larger  
22 grain sediments are found in the channels and mud/silt/clay accretes into consolidated  
23 mudflats near shore. Soft-bottom substrates are characterized by a lack of large, stable  
24 surfaces for plant and animal attachment (National Oceanic and Atmospheric  
25 Administration [NOAA] 2007). Because of the lack of hard surfaces for rooting, few plants  
26 are associated with soft-bottom habitats. However, though mobile, the fine-grained  
27 sediment is both stable and compact enough to support a diverse benthic assemblage.

28 The biotic assemblages in the subtidal habitats of the San Francisco Bay Estuary vary  
29 with salinity. Species tolerant of high levels of salinity but less adaptable to variable  
30 changes in salinity are found in Central and South Bays. San Pablo Bay and Suisun Bay  
31 support brackish water and freshwater species that are more tolerant of the shifting  
32 salinity levels.

33 Suisun Bay is also the site of the entrapment zone, an area where suspended materials  
34 concentrate as a result of mixing by the outgoing freshwater flow from the Delta above  
35 the heavier saltwater flow from San Francisco Bay. The entrapment zone contains  
36 concentrations of suspended materials such as nutrients, plankton, and fine sediments  
37 that are often many times higher than in areas upstream or downstream of the entrapment  
38 zone (Levine-Fricke 2004). This trophically rich habitat is thought to be important for the

1 rearing of many fish species. Its precise location between the lower Delta and Suisun Bay  
2 varies according to the strength and phase of the tides, and the level of freshwater inflow  
3 from the Sacramento and San Joaquin Rivers. High freshwater flows from the Delta push  
4 the entrapment zone west toward Carquinez Strait; low flows put it closer to the mouth of  
5 the Delta.

#### 6 Tidal Flats

7 Tidal flat habitat is the strip of intertidal habitat located between MLLW and MTL. It is  
8 exposed twice a day during low tide. During high tide, inundated tidal flats provide foraging  
9 habitat for fish such as longfin smelt, starry flounder (*Platichthys stellatus*), and several  
10 species of sculpin. During low tide, shorebirds feed on clams, shrimp, and worms found  
11 in the exposed tidal flats. Extreme high and low tides occur between May and June and  
12 in November and December, the latter period coinciding with the time that high numbers  
13 of waterbirds migrate through the San Francisco Bay Area (Bay Area).

14 The most extensive areas of tidal flat are found in the South Bay and along the north  
15 shore of San Pablo Bay. About half of the bay's tidal flats are found in the South Bay,  
16 making it the region's most important area for shorebirds (Monroe et al. 1999). Tidal flats  
17 in the Central Bay are limited by shoreline development. Suisun Bay has a more narrow  
18 tidal range than the other bays and has correspondingly less tidal flat.

#### 19 Tidal Marsh

20 Tidal marshes are defined as the vegetated habitat between MLW and extreme high  
21 water (Josselyn 1983). Though not all tidal marshes are saline, they are sometimes also  
22 called salt marshes or saline wetlands. These marshes intergrade on their bay side with  
23 tidal flats and on their inland side with freshwater marshes. Tidal marshes are highly  
24 productive biological systems. Though only a small number of vascular plant species are  
25 capable of living in these areas, they support unique and diverse communities of plants  
26 and animals. Vegetation in tidal marshes are nurseries for commercially important  
27 species and endangered species; the tidal marshes are feeding and nesting areas for  
28 birds. In recognition of the importance of the San Francisco Bay Estuary, the United  
29 States named it as its 35<sup>th</sup> Wetland of International Importance (Ramsar Convention on  
30 Wetlands 2013).

31 Birds that feed or roost in tidal marshes include herons, egrets, ducks, coots, rails,  
32 swallows, wrens, and hawks. The majority of birds that use the tidal marshes of San  
33 Francisco Bay are migratory. Shorebirds that breed in the marshes include American  
34 avocet (*Recurvirostra Americana*), black-necked stilt (*Himantopus mexicanus*), and  
35 snowy plover (*Charadrius alexandrinus*). Mammals found in these areas include mice,  
36 shrews, bats, and raccoons. Lizards and snakes are commonly found here, as are frogs  
37 and toads. Tidal marshes provide nursery habitat for fish, offering protection, food, and  
38 reduced osmoregulatory stress (Josselyn 1983).

1 Tidal marshes can be qualitatively divided into low, middle, and high marsh based on tidal  
2 inundation (see Figure 4.2-2). Low marsh consists of the area between MTL and MHW  
3 (Monroe et al. 1999). In salt marshes, these areas are characterized by saline-tolerant  
4 plants, usually grasses, which are adapted to regular inundation. In brackish and  
5 freshwater tidal marshes, cattails (*Typha* sp.), California bulrush (*Scirpus* sp.), and alkali  
6 bulrush (*Bolboschoenus maritimus*) dominate the low marsh. Waterfowl and rails make  
7 extensive use of low marshes. Middle marsh consists of the area between MHW and  
8 MHHW. Plant species typically found in the middle marsh include bulrushes (*Scirpus* sp.),  
9 spike rush (*Eleocharis* sp.), silverweed (*Potentilla anserine*), and salt grass (*Atriplex* sp.).  
10 High marsh consists of the area between MHHW and the highest margin of the marsh.  
11 Plants found in the high marsh include pickleweed (*Salicornia* sp.), saltgrass, gumplant  
12 (*Grindelia* sp.), and alkali heath (*Frankenia salina*).

13 Extensive areas of tidal marsh are found in all bays except the Central Bay. Suisun Marsh,  
14 found north of Suisun Bay, is the State's largest brackish-water marsh. Most of northern  
15 San Pablo Bay is marshland, and the extent of marshland in the South Bay is rising with  
16 ongoing restoration of the area's salt ponds.

### 17 Urban Shoreline

18 Much of the historical shoreline of Central Bay has been replaced with artificial fill or  
19 structures armored with revetments, seawalls, or rip-rap. Urban land uses tend to  
20 encroach on the shoreline in urbanized areas. These areas of shoreline may be fringed  
21 with narrow bands of recently formed tidal marshes dominated by common, widespread  
22 marsh species, including a high proportion of non-native species. The shorelines of the  
23 Central Bay and the northeast and northwest shorelines of the South Bay are heavily  
24 urbanized; the south shorelines of San Pablo Bay and Suisun Bay are less intensely  
25 urbanized.

### 26 Coastal Scrub

27 California's coastal scrub communities are dominated by low-growing shrubs such as  
28 coyote brush (*Baccharis pilularis*), California blackberry (*Rubus ursinus*), and poison oak  
29 (*Toxicodendron diversilobum*). Coastal scrub provides habitat for a variety of small-  
30 mammal species such as Botta's pocket gopher (*Thomomys bottae*), California mouse  
31 (*Peromyscus californicus*), and western harvest mouse (*Reithrodontomys megalotis*).  
32 Larger mammals such as bobcat (*Lynx rufus*), coyote (*Canis latrans*), and mule deer  
33 (*Odocoileus hemionus*) may occur in or near frequent larger areas of coastal scrub  
34 communities. Bird species that frequent coastal scrub habitat include California towhee  
35 (*Melospiza crissalis*), spotted towhee (*Pipilo maculatus*), white-crowned sparrow  
36 (*Zonotrichia leucophrys*), wrentit (*Chamaea fasciata*), California thrasher (*Toxostoma*  
37 *redivivum*), and western scrub jay (*Aphelocoma californica*). Lizards such as western  
38 fence lizard (*Sceloporus occidentalis*) and northern alligator lizard (*Elgaria coerulea*) may  
39 also occur within coastal scrub and adjacent grassland habitats.

## 1 **Biological Characteristics of the San Francisco Estuary**

### 2 Plankton

3 Phytoplankton (e.g., diatoms, cyanobacteria, dinoflagellates) are photosynthesizing  
4 microorganisms that inhabit water. Phytoplankton provide a source of organic carbon and  
5 energy at the base of the food chain (Cloern 1979). Compared to other estuaries,  
6 phytoplankton primary productivity in the San Francisco Bay Estuary is relatively low. The  
7 population density of phytoplankton in the bay cycles throughout the year, with levels  
8 higher during spring in San Pablo, Central, and South Bays, and during the summer in  
9 Suisun Bay (Cloern 1979). In the northern bays, phytoplankton growth can be separated  
10 into three seasons: A spring bloom period during which water-borne nitrates are available  
11 to phytoplankton; a low-productivity period in the summer when turbidity limits light  
12 penetration into the water; and a second, smaller fall bloom based on ammonium uptake  
13 (Wilkerson et al. 2006). High levels of phytoplankton (algal blooms) can cause  
14 environmental stress, affecting concentrations of dissolved oxygen and carbon dioxide,  
15 dissolved organic and inorganic substances, and pH.

16 Zooplankton are a diverse group that can range in size from microscopic (microplankton)  
17 to those that can be seen by the naked eye (macroplankton). This heterogeneous group  
18 includes mysid shrimp, clams, jellyfish, copepods, and crustaceans. They feed upon  
19 phytoplankton, bacteria, organic detritus, and each other.

20 Nonnative jellyfish are found throughout the estuary, including three hydrozoan species  
21 thought to be native to the Black Sea and one scyphozoan species thought to be  
22 introduced from Tokyo Bay. The hydrozoan species are present among the plankton from  
23 May through November, with peak abundances coinciding with warmer summer and fall  
24 temperatures. It has been suggested that jellyfish are passively spread through all low-  
25 salinity areas of San Francisco Bay via attachment to boat bottoms (NOAA 2007).

26 Ichthyoplankton consists of fish eggs and larvae found in near-surface waters, where they  
27 float passively on water currents. Ichthyoplankton feed on microplankton and are in turn  
28 fed on by larger animals.

### 29 Invertebrates

30 California bay shrimp (*Crangon franciscorum*) is the most common shrimp in San  
31 Francisco Bay most years and supports a small commercial fishery. The blackspotted  
32 shrimp (*Crangon nigromaculata*) is the second most common shrimp in the San Francisco  
33 Bay overall and the most common shrimp in some years.

34 The San Francisco Bay Estuary is a nursery area for shrimp and crabs, and fish. The  
35 highest densities of bay shrimp are found in Suisun Bay, where juveniles rear in shallow,  
36 low saline waters (NOAA 2007). Dungeness crab (*Metacarcinus magister*) reproduce in  
37 the ocean, and the small juvenile stages settle to the bottom of the ocean where they are

1 carried into the bay on tidal currents and spend the first year or two of their lives rearing  
2 in San Pablo and South Bays (NOAA 2007).

3 Different species of shrimp tend to inhabit different regions of the bay, though species do  
4 overlap in distribution. Shrimp species that live in the more saline environment of the bay  
5 have grown in abundance over the past 15 years and expanded in range into the  
6 upstream regions of the bay, particularly in dry years when saline levels increase  
7 upstream. Low-salinity species such as the bay shrimp show no increase in abundance  
8 over the past 15 years. Regionally, shrimp abundance increased in all parts of the bay  
9 except in Suisun Bay (SFEP 2011).

10 The abundance of shrimp and crab in the South Bay during the last 15 years is largely in  
11 response to increased nutrient availability in coastal waters. Because shrimp and crab  
12 prey on large benthic invertebrates, particularly clams, the increased numbers have led  
13 to a decline in the abundance of clams in the South Bay (Cloern 2011).

### 14 Fish

15 The health of the San Francisco Bay Estuary's fish communities varies geographically.  
16 The Central Bay fish population has been stable for 30 years, but the populations in the  
17 other bays have seen declines in health over the same period. This decline has been  
18 most dramatic for Suisun Bay, but is also apparent in San Pablo Bay and, increasingly,  
19 in the South Bay. Fish abundance, diversity, and percentage of native species have  
20 declined in all bays except the Central Bay (SFEP 2011).

21 Beginning in 2002, abundance indices of four pelagic fishes in the upper San Francisco  
22 Estuary declined rapidly to record low levels from which they have not recovered. Since  
23 2004, a consortium of federal and State agencies formed the Pelagic Organisms Decline  
24 Management Team to focus attention on the causes of the decline for delta smelt, longfin  
25 smelt, threadfin shad (*Dorosoma petenense*), and juvenile striped bass (*Morone*  
26 *saxatilis*). The emerging conclusion from nearly a decade of research is that the decline  
27 has its roots in multiple, interacting causes, including low original population abundance,  
28 a decrease in suitable habitat, mortality from predation and entrainment into water  
29 diversions, and a fundamental shift in the food web in the upper Delta from a  
30 phytoplankton-based food web to a detritus-based food web (IEP 2010).

### 31 Birds

32 San Francisco Bay Estuary is a major stopover for birds migrating along the Pacific  
33 Flyway, and many birds also nest along the San Francisco Bay. Nearly half of Pacific  
34 Coast waterfowl and shorebirds depend upon the San Francisco Bay and its mudflats for  
35 foraging during migration, with peak abundance occurring November through mid-March  
36 (SFEP 2011). In recognition of its critical conservation importance for shorebirds, San  
37 Francisco Bay Estuary is listed as an important shorebird migratory stopover in the  
38 Western Hemisphere Shorebird Reserve Network (USFWS 2002). Migratory stopovers

1 are wetlands and associated habitats that have high densities of food available at critical  
2 times during waterfowl and shorebird migration. These migrations are energy intensive  
3 and may include long-distance, non-stop flights of over 1,000 miles between stopover  
4 areas. Migrating flocks are large and migrations may occur in a very tight window,  
5 resulting in a large proportion of a species' entire population visiting a single site over a  
6 few weeks and requiring a vast quantity of available forage.

7 Waterbirds are typically classified based on habitat and foraging preference. Waterfowl  
8 are those species that depend primarily on open-water habitat for foraging and roosting,  
9 but breed in wetland and/or adjacent upland habitats. Ducks, geese, and grebes are all  
10 waterfowl. Waterfowl are further divided into dabblers and divers. Dabbling ducks, which  
11 feed at or below the surface of shallow water, have increased in Suisun and San Pablo  
12 Bays, while populations have held steady in the Central and South Bays (Pitkin and Wood  
13 2011). Diving ducks, which feed in deeper waters, have decreased in San Pablo Bay but  
14 increased in Suisun Bay as populations of their primary prey, large invertebrates such as  
15 clams, have changed. Overall, populations of dabbling ducks have increased and winter  
16 populations of diving ducks have decreased. Seabirds such as gulls, terns, and  
17 cormorants forage and nest in many of the habitats found around the San Francisco Bay.  
18 Many species make use of human-created habitats such as piers, bridges, and the  
19 structures found at Alcatraz Island (Pitkin and Wood 2011).

20 Shorebirds primarily use beach, tidal flats, salt ponds, and shallow open-water habitats  
21 for foraging and roosting, and nest on beaches or adjacent upland areas. Sandpipers,  
22 plovers, and dowitchers are all examples of shorebirds. The overall status of shorebirds  
23 in tidal flats is stable. Population declines in the South Bay have been offset by population  
24 increases in San Pablo Bay. The western sandpiper (*Calidris mauri*), one of the most  
25 common species, has declined across the San Francisco Estuary, but populations of two  
26 other common species, least sandpiper (*Calidris minutilla*) and willet (*Tringa*  
27 *semipalmata*), have increased greatly (Pitkin and Wood 2011).

28 Marsh birds include species that depend on emergent marshes for foraging, nesting, and  
29 roosting. California black rail (*Laterallus jamaicensis coturniculus*) and song sparrows are  
30 examples of marsh birds. Tidal marsh bird abundance has increased in San Pablo Bay  
31 and Suisun Bay, mainly driven by increases in common yellowthroat (*Geothlypis trichas*)  
32 and California black rail populations, but has decreased in the Central and South Bays  
33 (SFEP 2011). Reproductive success of tidal marsh birds has increased in Suisun Bay but  
34 is decreasing in San Pablo Bay. In particular, San Pablo song sparrow and Suisun song  
35 sparrow populations are below the level required to sustain their populations, and are  
36 expected to exhibit long-term declines. The decrease in tidal marsh bird abundance is  
37 attributed to predators and nest flooding (Pitkin and Wood 2011).

38 Wading birds use emergent marsh, marsh edge, and shallow open-water habitats to  
39 forage and roost in upland areas. Locally, examples include the great blue heron, cattle

1 egret, and great egret. Heron and many egret populations are increasing in San Pablo  
2 Bay, but there has been a decline in the nesting success for great egrets (SFEP 2011).

### 3 Mammals

4 San Francisco Bay Estuary's mammals are found on the shore and in the water. The most  
5 common terrestrial species found in coastal marshes include generalists such as Norway  
6 rat (*Rattus norvegicus*), house mouse (*Mus musculus*), California vole (*Microtus*  
7 *californicus*), and raccoon (*Procyon lotor*), which are adaptable to a wide range of  
8 habitats. Terrestrial mammals that are obligate users of marsh habitat, such as saltmarsh  
9 harvest mouse (*Reithrodontomys raviventris*), have seen drastic population declines as a  
10 result of habitat loss, and many are now listed as Threatened or Endangered by the  
11 federal and State governments.

12 Populations of beaver (*Castor canadensis*), river otter (*Lontra canadensis*), and sea otter  
13 (*Enhydra lutris*) were extirpated from the San Francisco Estuary by over harvesting in the  
14 19<sup>th</sup> century. Both river otter and beaver have recently recolonized the San Francisco  
15 Estuary; river otter have been reported throughout the San Francisco Bay, including  
16 Coyote Creek in the South Bay, the Richmond Marina in the Central Bay, Martinez Marina  
17 on Carquinez Strait, and from wetlands in Suisun Bay (ROEP 2013). Beaver are now  
18 found in the marshes in north San Pablo Bay and on the lower Alhambra Creek in  
19 downtown Martinez.

20 The most common aquatic mammals in the San Francisco Estuary are California sea lion  
21 (*Zalophus californianus*) and harbor seal (*Phoca vitulina*) (NOAA 2007). The California  
22 sea lions are mainly males that migrate to the San Francisco Estuary to forage and  
23 establish a dominance hierarchy; female California sea lions stay south of Santa Barbara.  
24 California sea lion haul outs are found throughout the San Francisco Bay, most  
25 prominently on San Francisco's Pier 39. Harbor seals are resident breeders. Harbor seals  
26 will haul out throughout the San Francisco Bay; major haul out and pupping sites are  
27 located in the Central and South Bays at the Castro Rocks near the Richmond-San Rafael  
28 Bridge, Yerba Buena Island by the San Francisco-Oakland Bay Bridge, Corte Madera,  
29 and Mowry Slough in the South Bay.

### 30 **Nonindigenous Aquatic Species**

31 San Francisco Bay Estuary has been described as one of the most invaded ecosystems  
32 in North America (Cohen and Carlton 1995). Nonindigenous aquatic species dominate  
33 many parts of the San Francisco Bay, to the extent that in some locations only introduced  
34 species can be found. In 2010, the California Department of Fish and Wildlife (CDFW)  
35 collected 497 species from San Francisco Bay Estuary, of which 98 species were  
36 classified as introduced, including three newly detected species to San Francisco Bay  
37 Estuary that had likely been spread from other locations in California (OSPR 2011). The

1 results indicate high numbers of introduced species are found in the South Bay, San  
2 Pablo Bay, and Central Bay. Suisun Bay had the lowest number of introduced species.

3 Nonindigenous aquatic species have been introduced to the San Francisco Bay via a  
4 number of vectors, including the deliberate introduction of species for recreational or  
5 commercial purposes. The shipping industry has been identified as one of the major  
6 vectors of nonindigenous aquatic species, and vessel biofouling and ballast water are  
7 considered the largest contributors of nonindigenous species to the San Francisco Bay  
8 (California State Lands Commission [CSLC] 2013e). Eighteen percent of established  
9 nonindigenous aquatic species are tied to vessel biofouling as the primary likely vector  
10 and 9 percent for ballast water; however, when considering established species with  
11 multiple possible vectors, 60 percent could have been introduced via vessel biofouling as  
12 one of several possible vectors, and 53 percent could have been introduced via ballast  
13 water as one of several possible vectors (OSPR 2011).

14 Invasive species may compete directly with native species for food or space, or prey upon  
15 native species. They can also change the food chain or physical environment to the  
16 detriment of native species. Approximately 42 percent of the species on the federal  
17 Threatened or Endangered species list are at risk primarily because of predation,  
18 parasitism, and competition from nonindigenous invasive species (OSPR 2011). One  
19 such currently pernicious invasive species is the overbite clam (*Corbula amurensis*), first  
20 found in the San Francisco Bay Estuary in 1986. Thought to have been introduced into  
21 the San Francisco Bay Estuary by ballast water discharge from a vessel, this planktivore  
22 is now so abundant that the current population is capable of filtering the estuary's water  
23 column several times a day. In some portions of the Suisun Bay floor, the clam accounts  
24 for the vast majority of biomass, and it has been implicated in the pelagic organism decline  
25 by severely reducing the availability of phytoplankton in Suisun Bay (SFEP 2004, Greene  
26 2011).

### 27 ***Rare, Threatened, and Endangered Species***

28 Owing to the diversity of habitat between embayments, the distribution and abundance of  
29 rare and sensitive species that depend on the estuarine habitat for some or all of their life  
30 cycle vary throughout the region. Each habitat supports a distinct community of sensitive  
31 species. To aid in the assessment of impacts, each category of sensitive species is  
32 summarized by embayment. Appendix D includes Tables D-1 through D-5, which provide  
33 further detailed information about each species that was considered under this  
34 assessment and their potential to be present near the Project site and impacted by the  
35 Project.

### 36 Sensitive Plants

37 Tidal habitats in the San Francisco Estuary support 12 plant species that are identified by  
38 federal and/or State agencies as endangered, threatened, or rare, or are listed by the

1 California Native Plant Society as status 1B or higher. The distribution of sensitive plant  
2 species varies geographically within the estuary. In general, the less urbanized the bay,  
3 the more likely it is to retain a proportion of its historical marshland and to support rare or  
4 sensitive plants (see Appendix D, Table D-1).

5 The Central Bay has not retained any historical tidal marsh remnants, which limits the  
6 potential for rare plants with few exceptions. Naturally occurring populations of Point  
7 Reye's bird's-beak (*Cordylanthus maritimus* ssp. *palustris*) are found along the shores of  
8 Richardson Bay, and a population was reintroduced to the Crissy Field wetlands in the  
9 Presidio. This species inhabits the high marsh or upper middle marsh zone. It is a  
10 hemiparasitic plant, meaning that although it possesses chlorophyll and is capable of  
11 limited photosynthesis, it must attach its root system to a host plant to extract water and  
12 nutrients and to reproduce. Point Reye's bird's-beak is dependent upon plants that are  
13 active in summer such as pickleweed (*Salicornia* sp.), saltgrass (*Distichlis* sp.), and fleshy  
14 jaumea (*Jaumea carnosa*), all of which are abundant in Richardson Bay. One other  
15 sensitive species is found in the Central Bay: California sea blite (*Suaeda californica*).  
16 This species is restricted to the intertidal zone of salt marshes, and was extirpated from  
17 the San Francisco Bay region in the 1960s. Since 2000, it has been successfully  
18 reintroduced at four sites in the Central Bay: Heron's Head Park at Pier 98, Pier 94,  
19 Eastshore State Park north of Oakland, and Roberts Landing near San Leandro in South  
20 Bay.

21 The South Bay retains fragments of historical tidal marshes at upper Newark Slough,  
22 Dumbarton Marsh, and along the Palo Alto shoreline. However, no sensitive tidal marsh  
23 or estuarine beach plants are known to remain in the South Bay. As mentioned above,  
24 one population of California sea blite was re-introduced at Roberts Landing.

25 San Pablo Bay has retained more of its historic tidal marshes than any other bay, and as  
26 a result supports naturally occurring populations of six rare species. Historical tidal  
27 marshes are found along the north edge of San Pablo Bay, including China Camp in San  
28 Rafael, Heerdt Marsh by Corte Madera, most of Petaluma Marsh, Whittell Marsh by Point  
29 Pinole, and areas of Napa marsh, including Fagan's Slough. The richest diversity of  
30 sensitive plants is found in the marshes at the mouths of the Petaluma and Napa Rivers.

31 San Joaquin spearscale (*Atriplex joaquinana*) is a tall annual herb known mainly from  
32 alkali grasslands and is only rarely known from tidal marsh edges where it may  
33 opportunistically colonize the high-tide shorelines. Recent populations are reported from  
34 along the lower Napa River. Saline marsh clover (*Trifolium hydrophilum*) is known to  
35 occur in marshes as well as alkaline grasslands. One population is known from the Viansa  
36 wetlands in northwest San Pablo Bay. The upper marsh zone of San Pablo Bay's brackish  
37 and freshwater marshes supports populations of endemic species known only to San  
38 Francisco Bay Estuary: Suisun marsh aster (*Symphotrichum lentum*), delta tule pea  
39 (*Lathyrus jepsonii* var. *jepsonii*), and Mason's lillaeopsis (*Lillaeopsis masonii*). Suisun

1 marsh aster was once widely distributed in San Pablo Bay, but is reported now only from  
2 the vicinity of Fagan Slough. The delta tule pea is a climbing species; individuals are  
3 present in marshes along the Napa River. Mason's lilaepsis (*Lilaeopsis masonii*) is also  
4 known from the Napa River corridor; it is a shade-sensitive, early successional colonizer  
5 of newly deposited or exposed sediments. Two species of bird's-beak are found in the  
6 upper marsh zone in San Pablo Bay: Point Reye's bird's beak and the federally  
7 endangered soft-bird's beak (*Cordylanthus mollis* ssp. *mollis*). One population of Point  
8 Reye's bird's-beak is known from the Petaluma River. Extant populations of soft bird's-  
9 beak are found in the marshes along the mouth of the Napa River.

10 Most of the sensitive plants found in San Pablo Bay are also found in Suisun Bay, where  
11 they are more widely distributed and abundant, particularly in the extensive brackish  
12 waters of Suisun Marsh. In addition to the plants described above, Suisun Bay contains  
13 populations of the federally endangered Suisun thistle (*Cirsium hydrophilum* var.  
14 *hydrophilum*) in the northern reaches of Suisun Marsh in the vicinity of Rush Ranch.  
15 Bolander's water-hemlock (*Cicuta maculata* var. *bolanderi*) was once common in Suisun  
16 Marsh.

#### 17 Sensitive Fishes

18 The San Francisco Estuary provides habitat to seven species of sensitive fish. Most of  
19 the sensitive fish species in the estuary either rely on brackish water habitat for their adult  
20 habitat and/or travel upstream to spawn in freshwaters and have thus been affected by  
21 degradation or removal of spawning habitats, entrainment by the State water projects,  
22 drought, pollution, predation, disruption of the food web and direct competition for space  
23 with and predation by non-indigenous aquatic species. The discussion below summarizes  
24 the distribution of sensitive species in the estuary; Table D-2 in Appendix D provides more  
25 detailed information for each species. Sensitive fish species are found mainly in the north  
26 bays. All sensitive fish species of the San Francisco Estuary have the potential to be  
27 impacted by a crude oil spill. Suisun Bay is home to two native species of "true" estuarine  
28 fish, i.e. fish that spend all their lives in estuaries: delta smelt and Sacramento splittail  
29 (*Pogonichthys macrolepidotus*). Both species are endemic to the Delta, and both travel  
30 into fresh water to spawn. Delta smelt are found in greatest abundance in shallow, turbid  
31 waters at the freshwater edge of the entrapment zone where they feed on plankton;  
32 Sacramento splittail are found mainly along the benthos of small, shallow, turbid sloughs  
33 lined with emergent vegetation, where they feed on macroinvertebrates and detritus. The  
34 delta smelt population is listed as threatened at the federal level and endangered by the  
35 State. As of 2010, populations of the splittail were considered stable by the United States  
36 Fish and Wildlife Service (USFWS), which found its listing was not warranted, but the  
37 species remains a CDFW species of special concern, and it is a targeted species of the  
38 Delta Stewardship Council (USFWS 2010).

1 Four anadromous species are found in the San Francisco Bay: longfin smelt, chinook  
2 salmon (*Oncorhynchus tshawytscha*), steelhead trout (*Oncorhynchus mykiss*), and the  
3 Southern Distinct Population of green sturgeon (*Acipenser medirostris*). Longfin smelt are  
4 primarily estuarine, though they are found in small numbers in the coastal waters beyond  
5 the Golden Gate Bridge. In summer, adults congregate in the cooler waters and deep-  
6 water habitats of the Central Bay, where they feed on zooplankton such as the opossum  
7 shrimp, *Acanthomysis* sp., and *Neomysis mercedis* when available and on copepods  
8 otherwise (Hobbs 2006). They migrate upstream in fall to spawn in the limnetic and  
9 oligohaline waters of the Delta. Populations have declined steadily over the past two  
10 decades (Rosenfeld and Baxter 2007).

11 Chinook salmon are born in fresh water and migrate into the Pacific Ocean to mature,  
12 reaching maturity between 2 and 5 years of age. They migrate into freshwater streams to  
13 spawn, after which they die. Their eggs incubate for several months. Upon hatching, fry  
14 undergo physiological changes in preparation for migration and enter the smolt stage.  
15 Most chinook smolt migrate to the ocean within a few months of hatching, though some  
16 may remain in fresh water for a year. Peak out-migrations are between April and June.

17 The Sacramento-San Joaquin River basin runs of chinook salmon are differentiated into  
18 four runs by their time-of-spawning migrations: Fall-run, late fall-run, winter-run, and  
19 spring-run. Fall-run chinook migrate upstream from July to November, late fall-run migrate  
20 October to February, winter-run migrate December to April, and spring-run migrate April  
21 to July. The Delta is a nursery area for all runs of chinook salmon. Winter-run chinook,  
22 the young of which out-migrate during the driest times of the year, are listed as critically  
23 endangered at both the federal level and by the State. Spring-run salmon are listed as  
24 threatened at both federal and state levels.

25 A close ally to salmon, the steelhead is an anadromous kind of rainbow trout. They  
26 migrate into the estuarine river basins from October to April and spawn from December  
27 to May. Populations that spawn eastward to the Napa River are listed as threatened at  
28 the federal level. This includes runs in San Pablo Bay's Napa River, Petaluma River, and  
29 Sonoma Creek, and the South Bay's Guadalupe River.

30 Green sturgeon may be found throughout the Central, San Pablo, and Suisun Bays.  
31 Adults are primarily marine, but enter the estuary to feed or migrate to spawning grounds.  
32 Juveniles rear in the northern bays for 1 to 4 years before joining the more marine adults.  
33 Sturgeon are benthic feeders, feeding mainly on shrimp and crabs.

### 34 Sensitive Birds

35 San Francisco Bay Estuary's sensitive birds are generally obligate inhabitants of tidal  
36 marshes, and have experienced population declines as a result of the removal and  
37 degradation of marsh habitat. Thus, the Central Bay, which possesses few tidal marshes,  
38 has few populations of sensitive birds (see Appendix D, Table D-3).

1 Many sensitive species such as California clapper rail (*Rallus longirostris obsoletus*) and  
2 California black rail are widely distributed throughout the bays. Others are subspecies  
3 known from single embayments: The Suisun song sparrow (*Melospiza melodia maxillaris*)  
4 is found in Suisun Bay, the San Pablo song sparrow (*Melospiza melodia samuelis*) in San  
5 Pablo Bay, and the Alameda song sparrow (*Melospiza melodia pusillula*) in the South  
6 Bay. California least tern (*Sterna antillarum browni*) is known to nest in the South Bay and  
7 along the southern shore of Suisun Bay. Western snowy plover (*Charadrius nivosus* ssp.  
8 *nivosus*) also nests in the South Bay, as well as in the San Pablo Bay marshes.

9 Colonial nesters found in the estuary include double-crested cormorant (*Phalacrocorax*  
10 *auritus*), great blue heron (*Ardea herodias*), great egret (*Ardea alba*), black-crowned  
11 night-heron (*Nycticorax nycticorax*), and snowy egret (*Egretta thula*). Double-crested  
12 cormorant colony nest sites are found under the bridges that divide the bays and on large  
13 electric transmission structures in the South Bay. Heron rookeries, which may consist of  
14 several heron and egret species, are found throughout the Bay Area.

#### 15 Sensitive Mammals

16 Tidal marshes in the San Francisco Estuary support four sensitive mammalian species,  
17 while seven mammalian species use the aquatic habitats of the estuary. Additionally,  
18 three species of bats forage over tidal marsh and estuarine waters (see Appendix D,  
19 Table D-4).

20 Many of the sensitive mammals of the tidal marsh habitats are small rodents: Suisun  
21 ornate shrew (*Sorex ornatus sinuosus*), saltmarsh wandering shrew (*Sorex vagrans*  
22 *halicoetes*), the federally endangered saltmarsh harvest mouse, and the San Pablo vole  
23 (*Microtus californicus sanpabloensis*) all weigh less than an ounce at adult size. Where  
24 present, they are prey species for higher order predators. Both shrews are insectivorous,  
25 while the mouse and vole are vegetarian. The endemic saltmarsh harvest mouse is  
26 generally restricted to tidal marsh habitats. It is found throughout the estuary, albeit in low  
27 numbers due to habitat destruction and degradation. The saltmarsh wandering shrew is  
28 found in the South Bay, while the Suisun ornate shrew is found in Suisun Bay. The San  
29 Pablo vole is known only from a small region in the vicinity of Wildcat Creek, on the  
30 southeast shore of San Pablo Bay.

31 Seven marine mammal species are known to migrate, forage, and rest in the San  
32 Francisco Bay. Gray whale (*Eschrichtius robustus*) and humpback whale (*Megaptera*  
33 *novaeangliae*) occasionally enter the Central Bay to feed during seasonal migrations. The  
34 harbor porpoise (*Phocoena phocoena*) is another visitor to the Central Bay. Harbor seal  
35 and California sea lion both venture as far upstream as Suisun Bay, but in general marine  
36 mammals prefer the deep, cold waters of the Central Bay.

37 The big free-tailed bat (*Nyctinomops macrotis*) has been collected in Martinez. Hoary bat  
38 (*Lasiurus cinereus*) has been observed in Suisun Marsh, but is more widely distributed in

1 the South Bay. The pallid bat (*Antrozous pallidus*) has been collected in the Central,  
2 South, and San Pablo Bays. The distribution of these species and their use of estuarine  
3 habitats has not been well described.

#### 4 Sensitive Amphibians and Reptiles

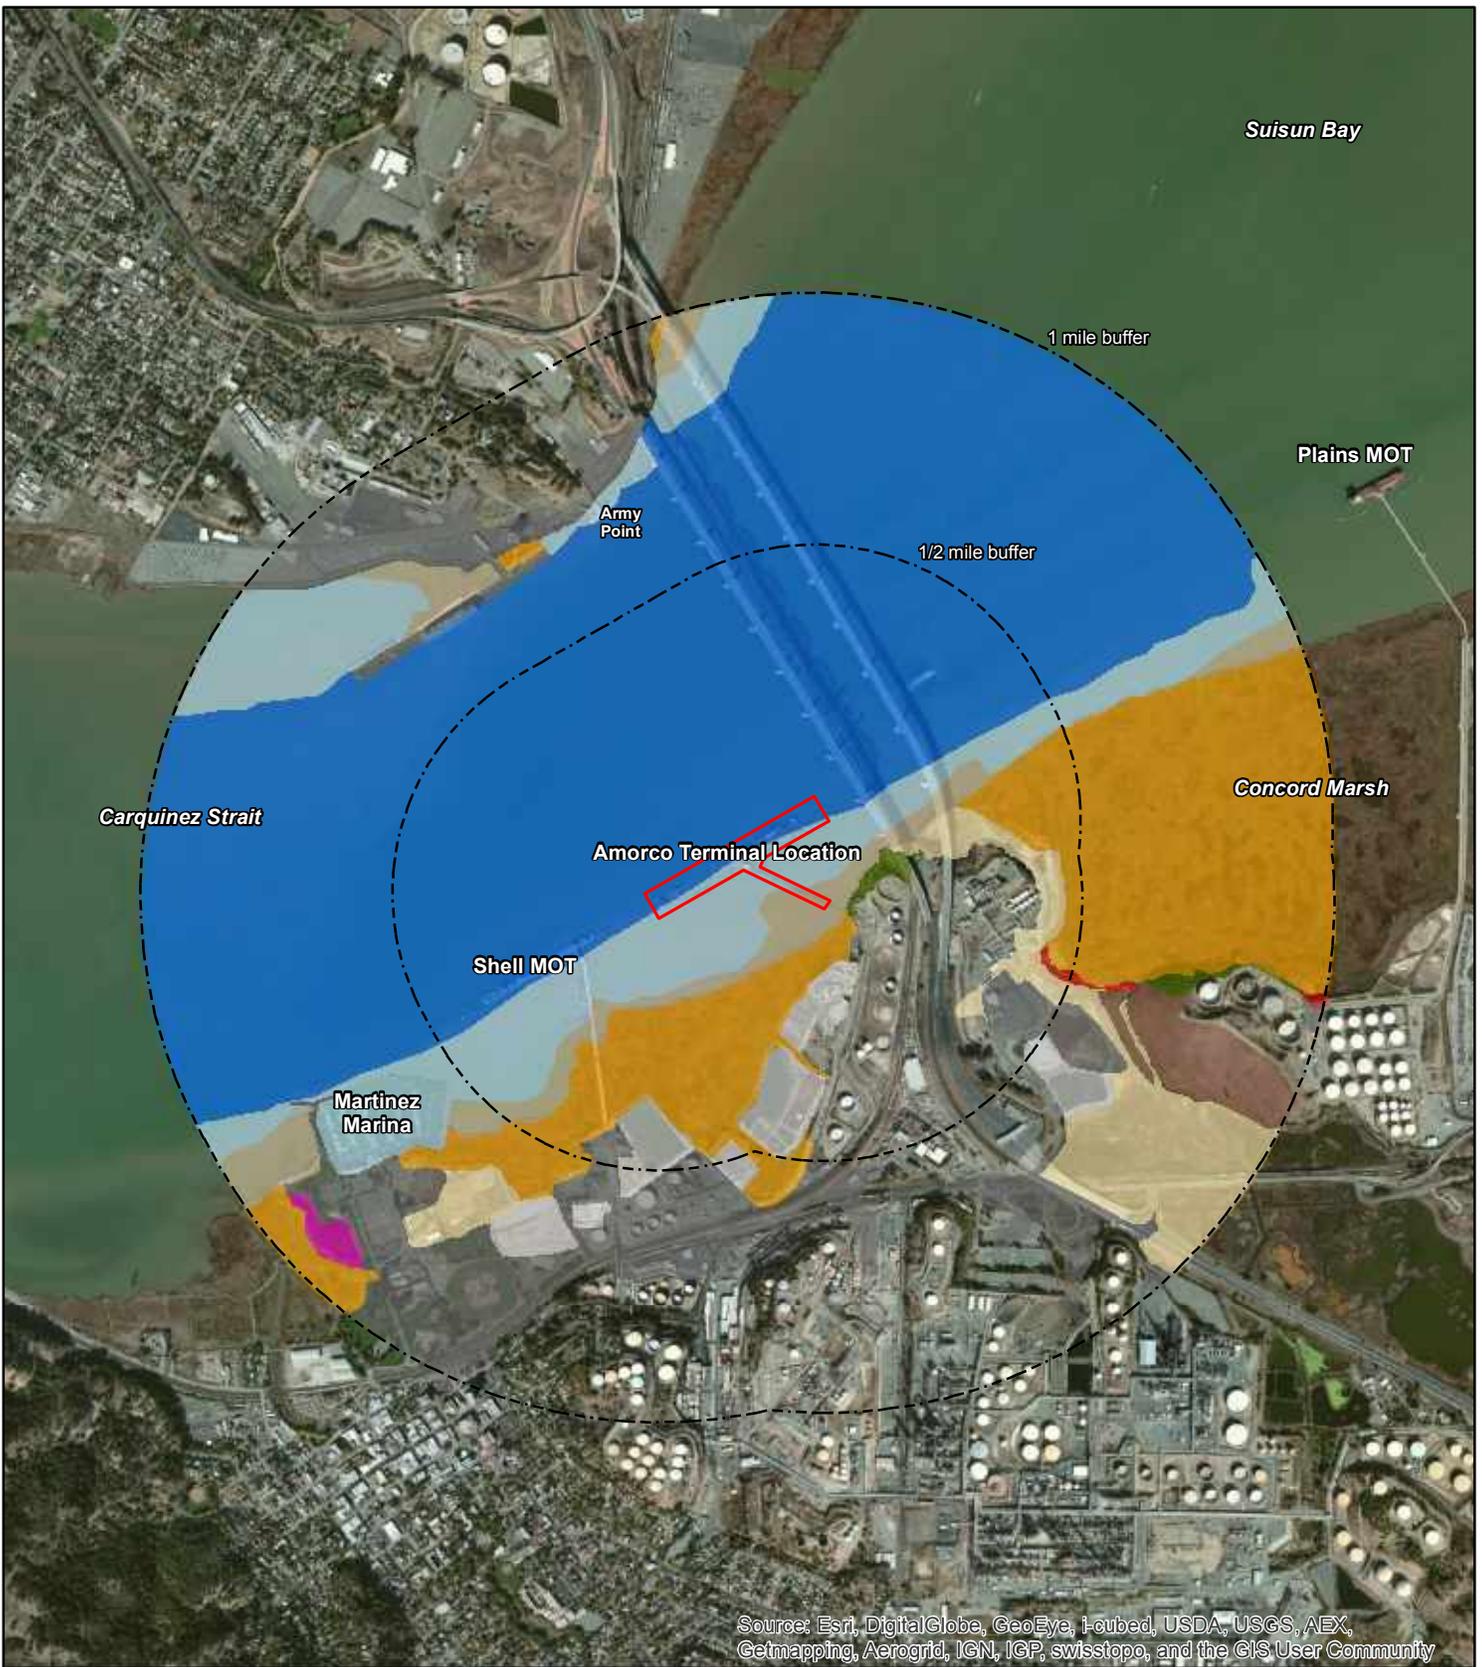

5 The San Francisco Bay Estuary supports only a handful of sensitive amphibians and  
6 reptiles (see Appendix D, Table D-5). Both California red-legged frog (*Rana draytonii*) and  
7 western pond turtle (*Actinemys marmorata*) are distributed in low numbers throughout the  
8 San Francisco Bay (CDFW 2013c). These species prefer freshwater ponds and streams,  
9 but are tolerant of limited saltwater intrusion and are documented from brackish marshes  
10 in San Pablo and Suisun Bays. California red-legged frogs appear to be eliminated from  
11 the western lowland portions of Contra Costa and Alameda counties (west of Highway 80  
12 and 880, particularly in urban areas). California tiger salamanders, which are found in  
13 grasslands and vernal pools, are known only from the Don Edwards National Wildlife  
14 Refuge in the South Bay (CDFW 2013c).

#### 15 **4.2.1.2 Project Study Area**

16 The Project study area includes lower Suisun Bay and upper Carquinez Strait, including  
17 vegetation at the Amorco Terminal lease area and along the shoreline within a 0.5-mile  
18 radius of the Amorco Terminal, as well as known habitats of rare, threatened, or  
19 endangered plant or animal species within a 1-mile radius of the Amorco Terminal (see  
20 Figure 4.2-3). Table D-6 in Appendix D includes a matrix depicting habitat use by wildlife  
21 found in the Project study area.

#### 22 ***Characteristics of the Project Study Area***

23 The Project is located on the eastern end of the Carquinez Strait in northern Contra Costa  
24 County on 16.6 acres of public land leased from the CSLC (proposed to be 14.9 acres as  
25 part of a new lease), approximately 300 feet west of the Benicia-Martinez Bridge. The  
26 lease extends approximately 1,300 feet into the Strait.

THIS PAGE IS INTENDED TO BE LEFT BLANK

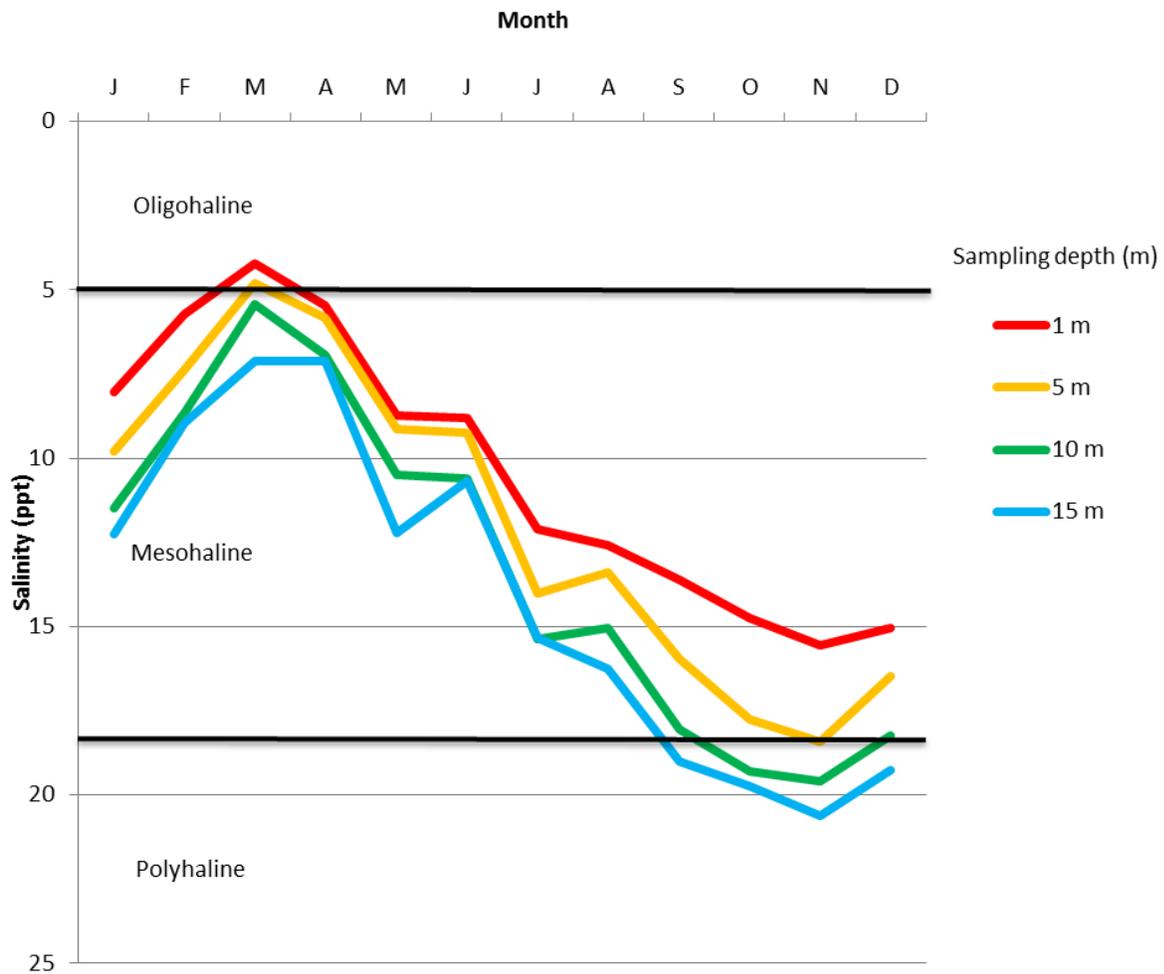

1 Water depths in the lease area range from 15 meters at the lease edge to 3 meters along  
2 the dock. The benthic substrate consists of soft bay sediments over bedrock, also known  
3 as mudstone.

4 Land use in the vicinity of the Amorco Terminal is a mosaic of industrial and open space.  
5 Coastal brackish marsh is present along the shoreline between Bulls Head Point to the  
6 east and the Martinez Marina to the west of the Amorco Terminal. Upland areas  
7 associated with the marshlands are given over to industrial use with the exception of a  
8 small patch of coastal scrub/ruderal vegetation found on the hillside leading up to the  
9 Amorco Tank Farm. Directly west of the Amorco Terminal, Hanson Sand Mining has a  
10 floating pipeline used to transfer sand slurry from vessels to the shore. The Shell Martinez  
11 Marine Terminal is approximately 500 feet west of the Amorco Terminal. The channel  
12 north of the Amorco Terminal is about 4,000 feet wide and is bordered by the Port of  
13 Benicia and Valero's Benicia Refinery.

14 Carquinez Strait is a narrow gap in the Coast Range that connects the San Pablo Bay to  
15 Suisun Bay and the Sacramento-San Joaquin River Delta. Typical river deltas widen from  
16 their source into a fan-shaped, sediment-heavy region. The narrow channel in the  
17 Carquinez Strait, however, restricts the outflow of flood waters and sediment from the  
18 Central Valley to the ocean, causing waters to pool and sediment to slow and settle in  
19 Suisun Bay, and resulting in a rare geological feature known as an inverted river delta.  
20 Upstream of the strait, the channel depth transitions rapidly from the deep channel of  
21 Carquinez Strait into the shallows of Suisun Bay. This area of bathymetric change is  
22 known as the Garnet Sill.

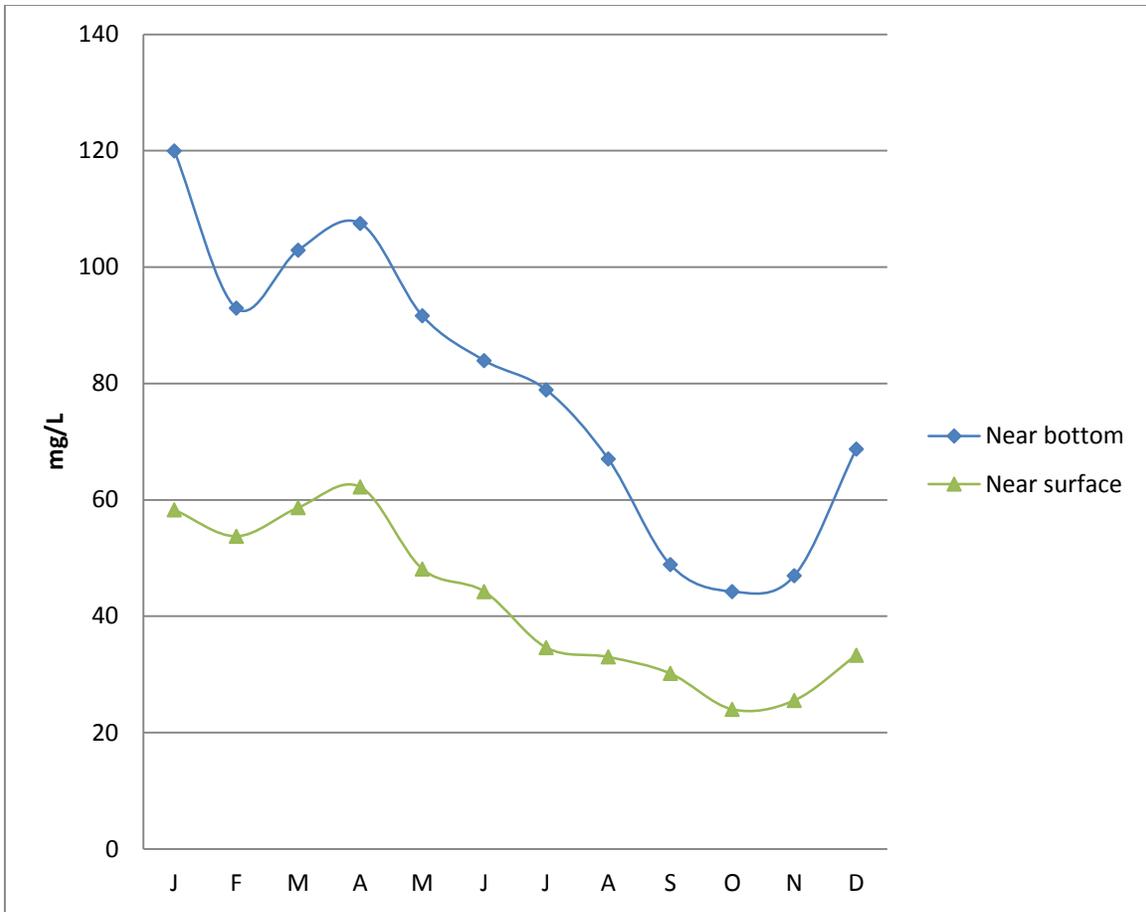

23 The Garnet Sill is the upstream endpoint of a gravitational circulation cell that forms in  
24 response to strong tidal currents that carry salt water upstream along the bottom of the  
25 channel while fresh water flows seaward along the top of the channel. Salinity in the water  
26 column in Carquinez Strait is stratified by depth, with fresh water along the surface and  
27 saline waters along the bottom (see Figure 4.2-4). Salinity stratification is greatest during  
28 neap tides. Following winter storms, the surface waters reach their lowest levels of  
29 salinity, and for a brief time, the upper five meters of the channel become oligohaline.  
30 Once the winter floods have stopped, the channel waters quickly become mesohaline  
31 and then slowly polyhaline.

32 The area where upstream and downstream currents meet and cancel each other out is  
33 known as the null zone; in Carquinez Strait, this zone typically forms near the strait's  
34 upper end, downstream of the Garnet Sill. During spring tide, the strait is the site of the  
35 San Francisco Bay estuarine turbidity maxima; during neap tide, the estuarine turbidity  
36 maximum is found upstream at Middle Ground (Schoellhamer 2002). Suspended  
37 sediment concentration (SSC) is greater near the bottom of the channel than higher in  
38 the water column. SSCs are seasonally dependent and are at their highest in the winter  
39 and spring, and decrease through summer to fall lows (see Figure 4.2-5).

**Figure 4.2-5: Average Suspended Sediment Concentration at Benicia Bridge, 2003-2007**

California State Lands Commission  
*Amorco Marine Oil Terminal Lease Consideration Project*

Note: Benicia Station is located approximately 0.6 mile north of the Amorco Marine Oil Terminal. Data from this site are considered representative of suspended-solids concentration in the strait.

1 **Terminal Structures**

2 The Amorco Terminal consists of a 1,130-foot-long wharf arm connected to the shore by  
3 1,500 feet of approach trestle. The Amorco Terminal is constructed of wood, concrete,  
4 and metal. The wharf has four small buildings on-site, including two buildings for  
5 personnel, a pump house, and a tool shed. Lights are placed regularly along the wharf  
6 arm and approach trestle, and there is one large light bank under the main loading arm.

7 The Amorco Terminal provides shade and refuge areas for fish, and resting spots and  
8 foraging opportunities for fish, birds, and marine mammals. The Amorco Terminal also  
9 provides nesting habitat for some bird species, including a pair of osprey (*Pandion*  
10 *haliaetus*) that have successfully fledged offspring from a nest atop the main loading arm  
11 since 2009 (Jim Herron pers. comm.). Support pilings provide attachment areas for  
12 sessile invertebrates and a place for fish to spawn.

13 **Subtidal**

14 The water column consists of the area between the benthos and the water surface. The  
15 water column contains both channels, which are areas with strong currents and a deep  
16 rounded bottom, and shoals, or shallow weak-current areas. Channels provide a  
17 connection between marine and freshwater ecosystems, while shoals function as  
18 collection areas for sediment and detritus. In San Francisco Bay Estuary, areas of the  
19 water column less than 18 feet deep are considered shallow bay; areas deeper than 18  
20 feet are considered deep bay. Approximately 238 acres of shallow bay and 1,097 acres  
21 of deep bay are found within 1 mile of the Amorco Terminal. The lease area includes 5.00  
22 acres of shallow bay and 8.93 acres of deep bay. These habitats provide foraging areas  
23 for invertebrates, fish, diving birds, and marine mammals, and nursery and spawning  
24 habitat for invertebrates and fish.

25 Compared to other parts of the San Francisco Bay, the Carquinez Strait is not particularly  
26 rich in phytoplankton (USGS 2013a). Phytoplankton productivity is generally calculated  
27 from measurements of chlorophyll  $\alpha$ . Chlorophyll  $\alpha$  concentrations below about 10  
28 micrograms per liter are known to cause food-limited declines in zooplankton  
29 reproduction. Measurements of water quality in the Carquinez Strait from 2003 to 2013  
30 show that chlorophyll  $\alpha$  levels in the strait rarely exceed this threshold in either spring or  
31 fall (USGS 2013).

32 The benthic substrate at the Project site consists of soft bay sediments over bedrock, also  
33 known as mudstone. Because of the lack of hard surfaces for rooting, few plants are  
34 associated with soft-bottom habitats. However, though mobile, the fine-grained sediment  
35 is both stable and compact enough to support a diverse benthic assemblage. The biotic  
36 assemblage associated with this habitat is known as the benthos. The benthos consists  
37 of bacteria and animals that live in (infauna), on (epifauna), or near (demersal) the bottom  
38 of the water channel.

1 Salinity levels along the substrate are generally polyhaline in summer and fall and  
 2 mesohaline in the winter and spring, leading to fluxation on the benthic habitat and  
 3 community composition.

4 The most common benthic species observed at the Amorco Terminal is *Corbula*  
 5 *amerensis* (see Table 4.2-2).

6 **Table 4.2-2: Common Benthic Invertebrates in Carquinez Strait**

Species	Status	Group	Salinity	Habitat	Relative Frequency
<i>Ampelisca abdita</i>	I	amphipod	polyhaline	channel, shallow subtidal	common, persistent
<i>Ascidia zara</i>	I	tunicate	polyhaline	hard bottom substrate	common, persistent
<i>Corbula amurensis</i>	I	bivalve	oligohaline, mesohaline, polyhaline	channel, channel edge, shallow subtidal	common, persistent
<i>Gemma gemma</i>	I	bivalve	polyhaline	shallow subtidal	common, persistent
<i>Grandidierella japonica</i>	I	amphipod	mesohaline	channel edge	persistent in low numbers
<i>Heteromastus spp.</i>	U	polychaete	mesohaline, polyhaline	channel, shallow subtidal	persistent in low numbers
<i>Macoma petalum</i>	I	bivalve	polyhaline	shallow subtidal	low numbers, persistent
<i>Monocorophium acherusicum</i>	I	amphipod	polyhaline	shallow subtidal	sporadic
<i>Arcuatula senhousia</i>	I	bivalve	polyhaline	channel, shallow subtidal	low numbers, persistent
<i>Mya arenaria</i>	I	bivalve	polyhaline	channel, shallow subtidal	common, persistent
<i>Alitta succinea</i>	I	polychaete	polyhaline	channel	low numbers, persistent
<i>Nippoleucon hinumensis</i>	I	cumacean	mesohaline, polyhaline	channel, channel edge, shallow subtidal	persistent in low numbers in the channel, and peaks in spring/summer at channel edge
<i>Polydora cornuta</i>	C	polychaete	polyhaline	channel	low numbers, persistent
<i>Streblospio benedicti</i>	I	polychaete	polyhaline	channel	low numbers, persistent

## 7 **Tidal Flat**

8 A narrow band of tidal flat habitat is located between the shallow waters of the San  
 9 Francisco Bay and shoreline marsh areas. The Amorco Terminal lease includes  
 10 approximately 0.96 acre of this habitat; approximately 77 acres are found within 1 mile of  
 11 the Amorco Terminal. The tidal flats at the Amorco Terminal are comprised of mudflats,

1 which are formed of fine-grained silts and clays, and typically support a diverse  
2 community of diatoms, worms, shellfish, and algal flora. These creatures are prey for a  
3 wide variety of birds and fish. Wading birds known to use the tidal flats for forage during  
4 low tide include western sandpiper, least sandpiper, willet, and dunlin (*Calidris alpina*)  
5 (eBird 2012). Harbor seals are also known to frequent tidal flats. Other species such as  
6 white pelican (*Pelecanus erythrorhynchos*) rest on the tidal flats between fishing  
7 expeditions. During high tide, the flats provide foraging areas for fish, including longfin  
8 smelt.

### 9 **Tidal Marsh**

10 Approximately 432 acres of tidal marsh are found within 1 mile of the Amorco Terminal,  
11 mainly along the southern shore of the Carquinez Strait where they are surrounded by  
12 heavy industry. The marshes are composed primarily of low/middle tidal brackish marsh,  
13 muted tidal brackish marsh, and diked brackish marsh. Small, discrete areas of high tidal  
14 marsh occur along the north shore of Carquinez Strait and at the southern edge of the  
15 Concord Marshes.

16 Tidal brackish marsh is found along the southern edge of the Carquinez Strait east of the  
17 Benicia-Martinez Bridge and west of the Martinez Marina. East of the bridge, the  
18 predominantly low/middle marsh plain extends up to 3,000 feet from the edge of the tidal  
19 flat; west of Martinez Marina, the marsh plain is approximately 1,000 feet wide and abuts  
20 an area of muted tidal brackish marsh. A narrow band of high marsh is found at its  
21 southern edge. Muted tidal brackish marsh is found west of the Carquinez Bridge, where  
22 the marsh plain varies in width between 300 and 1,500 feet. Both marsh plains are fairly  
23 level. Their tidal channels are a combination of straight channels superimposed on the  
24 marsh for drainage or mosquito control and linear dendritic in areas closest to shore. The  
25 dominant species present are common reed (*Phragmites australis*), cattails, California  
26 tule (*Schoenoplectus californicus*), broad-leaf pepperweed (*Lepidium latifolium*),  
27 pickleweed (*Salicornia pacifica*), Baltic rush (*Juncus balticus*) and gumplant.

28 The muted tidal marsh adjacent to the Amorco Terminal provides habitat for a variety of  
29 rare, threatened, and endangered species. California clapper rail was detected during a  
30 2008 survey of the marsh but appeared to be foraging rather than breeding; California  
31 black rail forage and breed in the marsh (WRA 2011). Based on habitat quality and survey  
32 results from adjacent marshes, saltmarsh harvest mouse are presumed to inhabit this  
33 marsh. Several rare plants have potential to be found in the marshes, including soft bird's-  
34 beak, delta tule pea, Mason's lilaepsis (*Lilaepsis masonii*), and Suisun thistle.

35 Diked brackish marsh is found adjacent to both the tidal brackish marsh and the muted  
36 tidal marsh. Diked marshes may provide important habitat for a variety of wildlife,  
37 especially waterfowl, shorebirds, and small mammals. They may provide high-tide refugia  
38 for small mammals and roosting habitat for shorebirds.

## 1 **Lagoon**

2 A 6-acre lagoon is located at the Martinez Marina approximately 0.75 mile from the  
3 Amorco Terminal. Lagoons support the same species of aquatic invertebrates and fish  
4 found in shallow bays and tidal channels, and provide feeding and resting areas for water  
5 birds. They may also provide protected areas that facilitate early colonization by  
6 nonindigenous aquatic species (Monroe et al. 1999).

## 7 **Special-status Habitats**

### 8 Critical Habitat

9 The Project is located within critical habitat for delta smelt (59 Federal Register 242), the  
10 southern Distinct Population Segment (DPS) of green sturgeon (74 Federal Register  
11 195), winter-run chinook salmon, Central Valley steelhead, and Central California coastal  
12 steelhead (70 Federal Register 170).

13 Primary constituent elements (PCEs) for the delta smelt that are located within the vicinity  
14 of the Project include the physical habitat, water, river flow, and salinity concentrations  
15 required to maintain delta smelt habitat for (1) larval and juvenile transport, (2) rearing  
16 habitat, and (3) adult migration. Because of the fluid nature of the Delta's hydrology, the  
17 quality of the PCEs for the delta smelt fluctuate within the designated area. The final ruling  
18 on the critical habitat identifies marina construction as activities that, depending on the  
19 season of construction and scale of the Project, might result in destruction or adverse  
20 modification of critical habitat that could jeopardize the continuing existence of the delta  
21 smelt and that would require consultation with the USFWS.

22 PCEs for the southern DPS of the green sturgeon in the estuary include food resources  
23 for all life stages, water flows, water quality, migratory corridors, channel depths, and  
24 sediment quality. Dredging, in-water construction, National Pollutant Discharge  
25 Elimination System activities, commercial shipping, and habitat restoration are identified  
26 in the final critical habitat rule as activities that may affect one or more PCEs through  
27 alteration of the physical parameters of the estuary.

28 The Amorco Terminal is located in critical habitat for steelhead. Critical habitat for  
29 steelhead includes the Sacramento River from Keswick Dam in Shasta County to Chipps  
30 Island, and all waters downstream of Chipps Island and north of the San Francisco-  
31 Oakland Bay Bridge.

### 32 California Department of Fish and Wildlife Natural Communities

33 The California Natural Diversity Database shows two natural communities within and  
34 adjacent to the lease area: Coastal Brackish Marsh and Northern Coastal Salt Marsh  
35 (CDFW 2013c). Coastal Brackish Marsh is found along the shoreline at the Amorco  
36 Terminal. The Coastal Brackish Marsh is dominated by perennial, emergent, herbaceous

1 monocots that create a dense cover up to 2 meters tall. The Amorco Terminal is located  
2 approximately 0.3 mile east of Northern Coastal Salt Marsh. Due to the saline and semi-  
3 aquatic environment, plant species diversity in these types of marshes is typically low.  
4 Plant species are stratified by salinity levels. Both marsh types support a diverse biotic  
5 assemblage and provide nursery grounds for numerous organisms, including fish,  
6 mammals, and birds (CERES 1996).

#### 7 **4.2.2 REGULATORY SETTING**

8 Federal and State laws that may be relevant to the Project are identified in Table 4-1.  
9 Regional and local laws, regulations, and policies are discussed below.

#### 10 ***National Estuary Program, Comprehensive Conservation and Management Plan***

11 The San Francisco Estuary Project is a federal-state-local partnership established in 1987  
12 under the CWA Section 320: National Estuary Program. The 1993 plan was mandated  
13 under a reauthorization of the CWA in 1987, and revised in 2007. This plan is  
14 administered by the San Francisco Estuary Project Implementation Committee.

#### 15 ***Contra Costa County***

16 The Amorco Terminal abuts marshes along the shoreline between the Martinez waterfront  
17 and the Concord Naval Weapons Station, an area that has been identified in the *Contra*  
18 *Costa County General Plan* (2005) as a Significant Ecological Resource Area. The  
19 general plan contains goals and policies to recognize and protect sensitive and significant  
20 ecological resources.

#### 21 **4.2.3 IMPACT ANALYSIS**

##### 22 **4.2.3.1 Significance Criteria**

23 For the purposes of this analysis, an impact was considered to be significant and to  
24 require mitigation if it would result in any of the following:

- 25 • Substantially affect threatened or endangered species, or protected species  
26 (including candidate, sensitive, or special-status species)
- 27 • Alter or diminish critical habitat or a special biological habitat, including saltwater,  
28 freshwater, or brackish marsh; major marine mammal haul out or breeding area;  
29 eelgrass; major seabird rookery; or any Area of Special Biological Significance
- 30 • Violate any environmental law or regulation designed to protect wildlife, plants, or  
31 habitat areas
- 32 • Isolate wildlife populations and/or disrupt wildlife migratory or movement corridors,  
33 or use native wildlife nursery sites

## EXECUTIVE SUMMARY

### INTRODUCTION

The United States Army Corps of Engineers (USACE) proposes to continue maintenance dredging of the federal navigation channels in San Francisco Bay to maintain the navigability of the channels. The San Francisco Bay Regional Water Quality Control Board (Regional Water Board) proposes to issue a Clean Water Act (CWA) Section 401 water quality certification (WQC), and may also issue waste discharge requirements (WDRs) pursuant to the state Porter-Cologne Water Quality Control Act, for USACE's continued maintenance dredging operations in San Francisco Bay. This authorization is referenced throughout as "WQC."

The USACE and Regional Water Board have prepared this Environmental Assessment (EA)/Environmental Impact Report (EIR) to address the environmental effects of the maintenance dredging of federal navigation channels in San Francisco Bay and the associated placement of dredged materials for a period of 10 years. This EA/EIR is prepared in accordance with the National Environmental Policy Act (NEPA) of 1969, 42 U.S.C. § 4321 et seq.; the Council on Environmental Quality regulations for implementing NEPA, 40 C.F.R. pt. 1500-1508; USACE Procedures for Implementing NEPA (Engineer Regulation 200-2-2); USACE regulations for operation and maintenance of civil works projects (33 C.F.R. pt. 335-338); Section 404 of the CWA (33 U.S.C. § 1344 and 33 C.F.R. pt. 320-330); the California Environmental Quality Act (CEQA) of 1970, California Public Resources Code, Section 21000 et seq., as amended, and the Guidelines for Implementation of CEQA, Title 14, California Code of Regulations, Section 15000 et seq. The USACE is the NEPA lead agency, and the Regional Water Board is the CEQA lead agency.

The dredging process involves the excavation of accumulated sediment from the channel bed, and the subsequent transportation and placement of the sediment at a permitted facility or location in a manner consistent with the permit conditions established by applicable regulatory agencies, after determination of suitability for placement at that site. The environmental impacts of maintenance dredging of the federal navigation channels were initially described in USACE's *Final Composite Environmental Impact Statement for Maintenance Dredging of Existing Navigation Projects, San Francisco Bay Region* in December 1975. The environmental effects of dredged material placement activities associated with dredging the federal navigation channels in San Francisco Bay were analyzed in the *Long-Term Management Strategy for Placement of Dredged Material in the San Francisco Bay Region, Final Policy Environmental Impact Statement/Programmatic Environmental Impact Report* in 1998. Subsequent to the publication of these documents, USACE has conducted NEPA compliance review, and the Regional Water Board has conducted CEQA compliance review, for maintenance dredging activities on an individual channel basis; this NEPA and CEQA<sup>1</sup> compliance has been conducted periodically as warranted by operation and dredging maintenance needs. This document is intended to fulfill USACE's NEPA compliance requirements for maintenance dredging of federal navigation channels it maintains in San Francisco Bay for the federal fiscal years<sup>2</sup> 2015 through 2024. This document is also intended to fulfill the Regional Water Board's CEQA compliance requirements for issuance of a 10-year WQC to USACE. Additionally, for those maintenance dredging projects that involve discharge of dredged or fill material into waters of the United States, this document is intended to serve as the Section 404(b)(1) analysis for maintenance dredging in compliance with the CWA.

---

<sup>1</sup> "Maintenance dredging where the spoil is deposited in a spoil area authorized by all applicable state and federal regulatory agencies" is a Class 4 Categorical Exemption under CEQA (CEQA Guidelines, Section 15304). Past WDRs were issued under this Categorical Exemption. The listings of longfin smelt and green sturgeon, noted in the following paragraph, warranted the preparation of an EIR under CEQA.

<sup>2</sup> The federal fiscal year begins October 1 and ends September 30.

Longfin smelt and green sturgeon were not protected under the federal or state Endangered Species Acts at the time the Long-Term Management Strategy (LTMS) Environmental Impact Statement (EIS)/EIR was completed. Longfin smelt is a state-listed threatened species, and the green sturgeon southern distinct population segment is a federally listed threatened species. Delta smelt was addressed in the LTMS Final EIS/EIR as a federally listed and state-listed threatened species; however, the state elevated its listing status from threatened to endangered in 2010. Listed salmonids were addressed in the LTMS EIS/EIR. Subsequent to the completion of the LTMS EIS/EIR and to the listing of longfin smelt, USACE implemented monitoring to determine whether dredging operations were resulting in take of listed fish species. In 2011, there were occurrences of delta smelt and longfin smelt becoming entrained in hopper dredging equipment during USACE maintenance dredging at certain locations. To minimize the potential for future impacts to listed fish species, the proposed project would address aspects of USACE's maintenance dredging and dredged materials placement program that could result in injury or mortality of these species.

The federal navigation channels and associated placement sites are in the San Francisco Bay LTMS Program Planning Area, which spans 11 counties, including Alameda, Contra Costa, Marin, Napa, Sacramento, San Joaquin, Santa Clara, San Francisco, San Mateo, Solano, and Sonoma.<sup>3</sup> However, the geographic scope of potential impacts of the proposed project are limited to 10 federally authorized navigation channels and associated placement sites in San Francisco Bay (Figure ES-1).

## PROJECT PURPOSE, NEED, AND OBJECTIVES

The USACE, as mandated by Congress, is responsible for maintaining navigability of federal navigation channels to authorized depth or lesser regulatory depth.<sup>4</sup> Accumulation of sediment that settles in these channels can impede navigability. Maintenance dredging removes this sediment and returns the channels to regulatory depths to provide safe, reliable, and efficient waterborne transportation systems (channels, harbors, and waterways) for the movement of commerce, national security needs, and recreation. Therefore, USACE's purpose of the project is to continue maintenance dredging of the federal navigation channels in San Francisco Bay consistent with the goals and adopted plans of the LTMS, while adequately protecting the environment, including listed species. The Regional Water Board's overall project objective is to ensure USACE's consistency with the water quality objectives and beneficial uses adopted in the Water Quality Control Plan for the San Francisco Bay Basin, as will be addressed through the Section 401 WQC process.

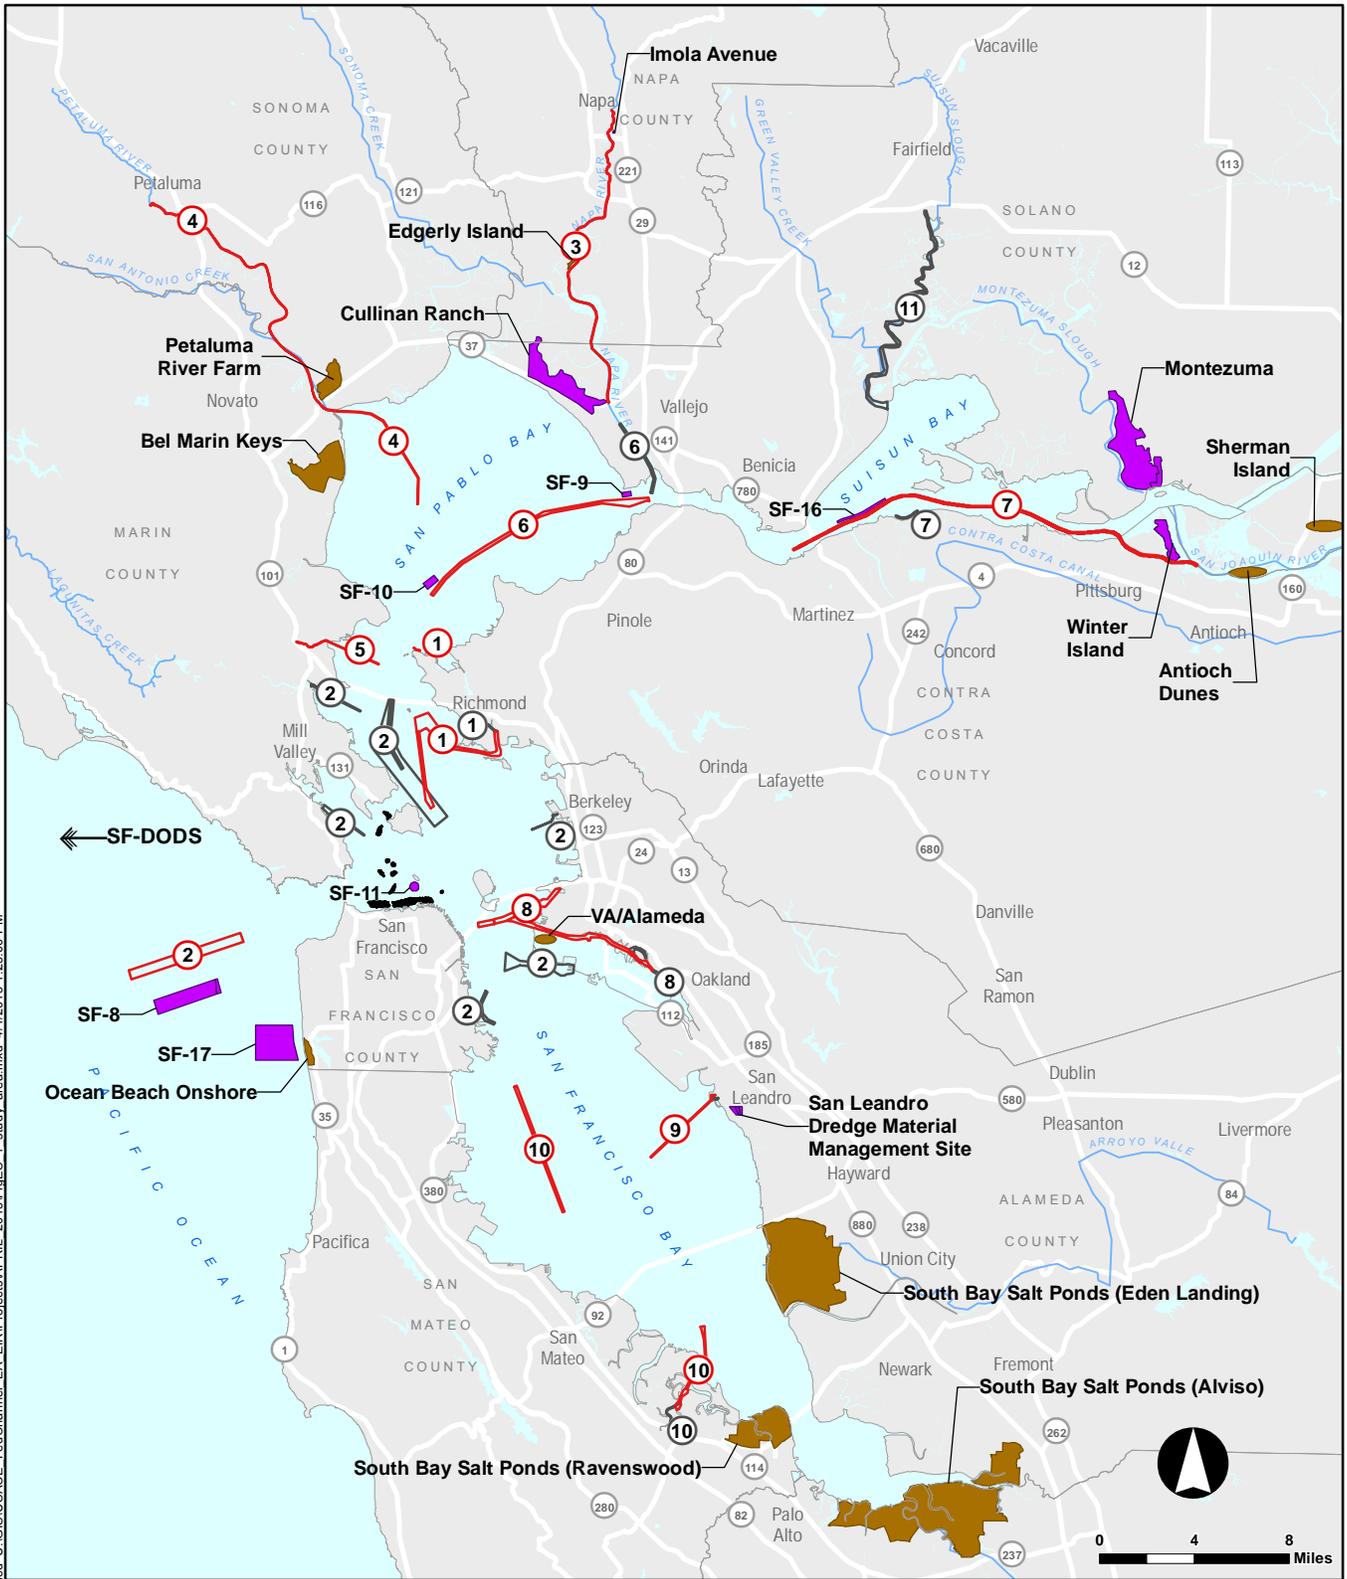

The USACE's specific project objectives are to:

- Provide safe, reliable, and efficient navigation through federal channels in San Francisco Bay in a feasible manner. This objective is considered the underlying fundamental purpose of the proposed project;
- Ensure consistency, to the maximum extent practicable, with the goals of the LTMS program as described in the 1998 LTMS Final EIS/EIR and the 2001 LTMS Management Plan; and
- Conduct dredging in a manner that adequately protects the environment, including listed species.

The Regional Water Board has authority under CWA Section 401 and the Porter-Cologne Act to issue permits governing dredge and fill activities. The Regional Water Board will consider USACE's application for a multi-year WQC for continued maintenance dredging of San Francisco Bay federal channels and associated dredged materials placement. To issue a WQC to USACE, the Regional Water Board, in compliance with CEQA, must analyze and disclose potential water quality and other environmental impacts of the project; consider alternatives that would avoid or substantially reduce

<sup>3</sup> Although portions of Sacramento and San Joaquin counties were part of the Planning Area for the LTMS EIS/EIR, they are not part of the LTMS Program.

<sup>4</sup> Regulatory depth is the depth to which federal environmental compliance has been completed.

potentially significant impacts of the project as approved; adopt or make a condition of approval all feasible mitigation for potentially significant impacts; and demonstrate that all applicable state water quality requirements are met.

## ALTERNATIVES

Typical methods of maintenance dredging include hydraulic or mechanical dredging. Hydraulic dredging usually involves hopper dredges (a ship with a hopper bin to store and transport material dredged) or suction/cutterheads attached to hydraulic pipelines that convey the dredged material to a scow or directly to a placement site. Mechanical dredging usually involves bucket or clamshell dredges, which scoop material directly into a scow for transport to a placement site. Once the material is dredged, it is transported to, and placed at, a designated dredged material placement site.

This EA/EIR evaluates in detail four alternatives for USACE's maintenance dredging of the federal navigation channels in San Francisco Bay: the No Action/No Project Alternative, the Proposed Action/Project, and two action alternatives involving reduced use of hopper dredge equipment (Reduced Hopper Dredge Use Alternatives 1 and 2).

### No Action/No Project Alternative

Under NEPA, in cases where the project involves modification of an existing program or management plan, No Action may be defined as no change from current program implementation, or no change in management direction or intensity. Therefore, the No Action Alternative may be thought of in terms of continuing with the present course of action until that action is changed. Similarly, Section 15126.6 (e)(3)(A) of the CEQA Guidelines states that "when the project is the revision of an existing land use or regulatory plan, policy or ongoing operation, the no project alternative will be the continuation of the existing plan, policy or operation into the future." Therefore, under the No Action/No Project Alternative, USACE would continue current maintenance dredging practices for the projects it maintains in San Francisco Bay, and the Regional Water Board would consider issuing a WQC based on USACE's current dredging practices. Current maintenance dredging practices were determined through a review of maintenance dredging activities for fiscal year 2000 through fiscal year 2012 to determine the typical dredge equipment type, frequency of dredging, volumes dredged, and placement site(s) for each specific maintenance dredging project. Table ES-1 describes maintenance dredging and placement activities that would occur under the No Action/No Project Alternative, based on these current practices.<sup>5</sup>

Under the No Action/No Project Alternative, dredging and placement would be conducted in accordance with previously established permit conditions and minimization measures, as detailed in Chapter 2. Dredging and disposal activities would continue to be limited to the LTMS Program work windows (USFWS, 1999; USFWS, 2004a; NMFS, 1998)<sup>6</sup>, unless through an additional consultation process, the appropriate agencies provide written authorization to work outside these windows.

---

<sup>5</sup> Under any alternative, the channels proposed for dredging with a hydraulic dredge could also be dredged with a mechanical dredge, with the exception of the San Francisco Bay Main Ship Channel; however, for the purpose of the analysis in the EA/EIR, use of a hydraulic dredge was assumed because that is the equipment typically used.

<sup>6</sup> NMFS is revising the 1998 LTMS programmatic biological opinion; the updated biological opinion (expected 2015) will supersede the 1998 document. The USACE will comply with the terms and conditions of the updated biological opinion. The revised biological opinion may expand the salmonid work windows to year-round if dredging is conducted with a clamshell dredge and dredged material is placed at a beneficial reuse site that NMFS agrees will provide aquatic habitat benefits, such as a tidal wetlands restoration. Should the updated biological opinion allow for this, USACE may opt to dredge certain federal navigation channels with a clamshell dredge outside the work windows and place sediment at a beneficial reuse site. All other dredging outside the work window (i.e., hydraulic dredging or clamshell dredging with placement at a non-beneficial reuse site) would require consultation with NMFS.

**Table ES-1  
No Action/No Project Alternative Summary**

Channel	Dredge Type	Typical Dredging Frequency (years)	Range of Volume Dredged per Episode (CY) <sup>1</sup>	Median Volume Dredged Per Episode (CY) <sup>2</sup>	Placement Site
Richmond – Inner Harbor Outer Harbor	Clamshell-Bucket	1	11,000 – 631,000	390,000	SF-DODS, SF-11 <sup>3</sup>
	Hopper	1	78,000 – 318,000	190,000	SF-11
San Francisco Harbor – Main Ship Channel	Hopper	1	78,000 – 613,000	306,000	SF-8, SF-17
Napa River Channel*	Cutterhead-Pipeline	6-10	140,000 <sup>4</sup>	140,000 <sup>4</sup>	Upland (Sponsor Provided)
Petaluma River Channel (and Across the Flats*)	Cutterhead-Pipeline (River Channel) Clamshell-Bucket (Across the Flats)	4-7	250,000 <sup>4</sup>	250,000 <sup>4</sup>	Upland (Sponsor Provided) for the River Channel SF-10 for Across the Flats
San Rafael Creek Channel	Clamshell-Bucket	4-7	78,000 – 87,000 <sup>4</sup>	83,000 <sup>4</sup>	SF-11
Pinole Shoal	Hopper	1	80,000 – 487,000	146,000	SF-10
Suisun Bay Channel and New York Slough	Hopper	1	21,000 – 423,000	159,000	SF-16
Oakland Inner and Outer Harbor	Clamshell-Bucket	1	122,000 – 1,055,000 <sup>5</sup>	330,000	SF-DODS, MWRP
San Leandro Marina (Jack D. Maltester Channel)	Cutterhead-Pipeline	4-6	121,000 – 187,000 <sup>4</sup>	154,000 <sup>4</sup>	Upland (Sponsor Provided)
Redwood City Harbor	Clamshell-Bucket (Harbor Channels) Hopper (San Bruno Channel)	1-2	10,000 – 560,000	179,000	SF-11

## Notes:

\* For areas not dredged since 2000, the last dredging event is reported.

<sup>1</sup> Range of volume dredged per fiscal year since 2000 (USACE, 2014). For areas not dredged since 2000, the last dredging event is reported.

<sup>2</sup> Median volume dredged per fiscal year since 2000. For areas not dredged since 2000, the last dredging event is reported.

<sup>3</sup> SF-11 was used for Richmond Inner Harbor during the 2000 to 2012 baseline period but is no longer approved as a placement option for Richmond Inner Harbor.

<sup>4</sup> Due to the lower frequency at which these channels are dredged, future dredge volumes could be greater.

<sup>5</sup> Due to the deepening of Oakland Harbor completed in 2010, future dredge volumes could be greater.

CY = cubic yards

MWRP = Montezuma Wetlands Restoration Project (in Solano County)

SF-8 = San Francisco Bar Channel Disposal Site (ocean site)

SF-10 = San Pablo Bay placement site (in-Bay site)

SF-11 = Alcatraz Island placement site (in-Bay site)

SF-16 = Suisun Bay placement site (in-Bay site)

SF-17 = Ocean Beach placement site (nearshore site, includes the Ocean Beach demonstration site)

SF-DODS = San Francisco Deep Ocean Disposal Site (approximately 55 miles [48 nautical miles] west of Golden Gate)

The USACE would meet all federal environmental compliance requirements (e.g., CWA Section 404, Endangered Species Act), including those federal requirements implemented by state agencies (e.g., Clean Water Act Section 401, Coastal Zone Management Act). The USACE would undertake mitigation, as appropriate, in meeting its compliance requirements.

### Proposed Action/Project

Under USACE's Proposed Action/Project, USACE would perform dredging practices for the projects it maintains in San Francisco Bay. The dredge equipment type, frequency of dredging, and volumes dredged would be the same as under the No Action/No Project Alternative. Table ES-2 identifies the federal standard placement site and proposed alternate placement sites that would be used for each location as well as expected dredge volumes. The USACE would beneficially reuse dredged material to the maximum extent its authorities allow. Although it is assumed, for the purpose of this EA/EIR, that placement would occur at the identified federal standard<sup>7</sup> sites.<sup>8</sup> USACE would place dredged material at beneficial reuse sites when costs are equivalent to the federal standard or a cost-sharing partner is supporting beneficial reuse.

Dredging and placement would be conducted in accordance with the conditions described under the No Action/Project Alternative. In addition, USACE would implement the following best management practices (BMPs) to minimize impacts to longfin smelt and delta smelt:

- Completing hydraulic dredging in the Central Bay later in the year (from August 1 to November 30) during the June-to-November environmental dredging window, to the extent feasible,<sup>9</sup> to allow young-of-the-year longfin smelt to grow large, and spawning adults to return upstream;
- Completing hydraulic dredging in Suisun Bay between August 1 and September 30, to the extent feasible, to avoid impacts to spawning adult longfin and delta smelt;
- Maintaining contact of drag head, cutterheads, and pipeline intakes with the seafloor during suction dredging;<sup>10</sup> and
- Closing the drag head water intake doors in locations most vulnerable to entraining or entrapping smelt. In circumstances when the doors need to be opened to alleviate clogging, the doors would be opened incrementally (i.e., the doors would be opened in small increments and tested to see if the clog is removed) to ensure that doors are not fully opened unnecessarily. It may take multiple iterations to fine tune the exact intake door opening necessary to prevent clogging. For each project, the intake door opening will be different because the sediment in each location is different. The sediment physical characteristics (e.g., sand versus mud) determine how much water is needed to slurry the sediment adequately. Typically, the drag arms do not clog when dredging areas composed mostly of sand.

---

<sup>7</sup> The federal standard is defined as the least-costly dredged material disposal or placement alternative consistent with sound engineering practices, and meeting the environmental standards established by the Section 404(b)(1) evaluation process or ocean dumping criteria (33 C.F.R. § 335.7).

<sup>8</sup> The USACE may be forced by logistical constraints to use the alternate placement sites. Examples of logistical constraints include: 1) unsafe condition at the placement site (e.g., weather/wave conditions); 2) an event blocking access to a placement site (this occurred during America's Cup 34); and 3) the federal standard site reaching its monthly disposal limit (as established by the Bay Plan and Basin Plan).

<sup>9</sup> Feasibility is contingent upon the availability of federal funds (e.g., timing of Congressional appropriations) to execute the dredging work, as well as the availability of dredging equipment to perform the dredging work at the referenced time and locations.

<sup>10</sup> The seafloor surface is not uniform and is undulating, which could cause the drag head to temporarily lose contact with the seafloor. The hopper dredge also has to contend with sea state (i.e., swells and wave action) in the bay which also affects the drag head's contact with the channel bottom. The dredge's swell compensator provides an opposing force to maintain contact with the seafloor when the bottom is uneven or there is wave/swell action.

SF-11 = Alcatraz Island placement site (in-Bay site)

SF-16 = Suisun Bay placement site (in-Bay site)

SF-17 = Ocean Beach placement site (nearshore site, includes the Ocean Beach demonstration site)

SF-DODS = San Francisco Deep Ocean Disposal Site (approximately 55 miles [48 nautical miles] west of Golden Gate)

USACE = United States Army Corps of Engineers

The USACE would purchase 0.92 acre mitigation credit at the Liberty Island Conservation Bank, or other approved site, annually for potential impacts to listed species. The 0.92 acre mitigation credit was calculated from an equation (3.0 million acre-feet/800 acres = volume dredged/X acres of mitigation habitat) that was developed by resource agencies to determine mitigation requirements for other projects with entrainment impacts as a result of pumping water, including the State Water Project. For volume dredged, available government-hopper-dredge-pumped total sediment and water volumes for 2006 through 2012 were reviewed. The highest volume for each of the in-Bay channels (Pinole Shoal, Richmond Outer Harbor, and Suisun Bay Channel/New York Slough) from this period was used in the calculation. Of the 0.92 acre mitigation credit, 0.19 acre mitigation credit would be for Pinole Shoal, 0.34 acre mitigation credit would be for Richmond Outer Harbor, and 0.39 acre mitigation credit would be for Suisun Bay Channel and New York Slough.

To the extent feasible, hydraulic dredging in the Napa and Petaluma rivers and San Leandro Marina would occur when water temperatures are above 22 degrees Celsius. If hydraulic maintenance dredging occurs when water temperatures are less than 22 degrees Celsius, USACE would coordinate mitigation, as appropriate, with USFWS, NMFS, and CDFW at the times such dredging episodes occur. For hydraulic dredging of San Bruno Shoal, USACE would conduct compensatory mitigation using the equation above; however, because this channel is so rarely dredged and volumes are not known, USACE would determine the amount of mitigation when/if this channel is dredged.

In addition, an approximate ½-mile portion of Bulls Head Reach, just east of the Benicia-Martinez Bridge in Suisun Bay Channel, shoals rapidly and becomes a navigation hazard that requires urgent action by USACE to maintain navigational safety in a critical maneuvering area. In the past, USACE has been requested by the United States Coast Guard to make an emergency<sup>11</sup> declaration to conduct maintenance dredging of this area outside of the LTMS work window, and completed NEPA and other environmental compliance requirements pursuant to the CWA, federal Endangered Species Act, and the Coastal Zone Management Act after the maintenance dredging occurred. Under the Proposed Action, USACE would take urgent<sup>12</sup> action outside the LTMS work window, as needed, to remove the hazardous shoal. Removal of the shoal would likely involve 1 to 5 days of dredging to clear the hazard area. Past critical dredging episodes<sup>13</sup> have not occurred at a regular or predictable frequency; therefore, USACE estimates urgent removal of this shoal may be required in any given year within the 10-year planning horizon. Analysis of impacts related to the removal of this shoal in this EA/EIR is intended to fulfill USACE's NEPA requirements related to these episodes, and preclude emergency declaration. Because the extent and frequency of critical dredging episodes cannot be predicted, appropriate mitigation for these episodes—if warranted based on expected impacts—would be determined in coordination with regulatory agencies at the times they occur.

## Reduced Hopper Dredge Use Alternatives

Two alternatives were considered under which USACE's use of a hopper dredge for maintenance dredging of the federal channels would be reduced, compared to the Proposed Action/Project and No Action/No Project Alternative. The costs for implementing these alternatives are beyond the currently programmed operation and maintenance budget for San Francisco Bay (estimated at an additional \$3 to \$10 million per year). Therefore, before USACE could accomplish the preferred alternatives, should they

<sup>11</sup> As defined in USACE's Raise the Flag Procedure (Headquarters, Civil Works Construction, Operations and Readiness Division [CECW-OD], Revised January 22, 2002), an emergency is a situation that would result in an unacceptable hazard to life, a significant loss of property, or an immediate, unforeseen, and significant economic hardship if corrective action is not undertaken in a time period less than the normal contract procurement process.

<sup>12</sup> As defined in USACE's Raise the Flag Procedure (CECW-OD, Revised January 22, 2002), an urgent dredging requirement is a situation that may be time-sensitive for providing a safe navigation channel that requires prompt action, but does not meet the definition of an emergency.

<sup>13</sup> Critical dredging episodes occur outside the regular annual maintenance dredging of Suisun Bay Channel to remove a hazard to navigation when the channel is less than 35 feet mean lower low water in the area of the shoal.

be adopted by the Regional Water Board, three things typically should occur: first, higher executive branch authority must agree that the increased cost is consistent with the federal standard; second, the additional costs must be included in the annual budget submitted to Congress; and third, Congress must appropriate or reprogram the additional funds. NEPA and CEQA do not restrict consideration of alternatives that are outside the jurisdiction or capability of the lead agency to implement if the alternatives are otherwise reasonable. For the purpose of this EA/EIR, it is assumed that either reduced hopper dredge use alternative would be implemented by fiscal year 2017, as required by a condition of the WQC issued by the Regional Water Board. For both reduced hopper dredge use alternatives, implementation of dredging in fiscal years 2015 and 2016, including purchase of mitigation credit, would be as described under the Proposed Action/Project.

Although it is assumed for the purpose of analysis that the reduced hopper dredge use alternatives could be implemented, it should be noted that if USACE is unable to obtain both the necessary authorization and funding to implement these alternatives, USACE would follow the regulations at 33 C.F.R. pt. 335-338. The process described in these regulations could potentially result in deferred dredging at certain channels (i.e., Richmond Outer, Pinole Shoal, and Suisun Bay Channel and New York Slough). Deferred dredging means that these channels may not be fully maintained by USACE. Funding historically appropriated for dredging the deferred channels may be diverted to other navigation and maintenance projects nationwide, and the USACE San Francisco District may be unable to recover the funding for dredging these channels at future date. In addition, because of scheduling constraints with the government-owned hopper dredges, limiting hopper dredge use to the San Francisco Bay Main Ship Channel (MSC) under Reduced Hopper Dredge Use Alternative 2 could increase the risk that full dredging of the MSC would not be completed within the scheduled availability of the hopper dredge when inclement weather precludes dredging of the MSC.

In the interest of disclosing the potential environmental impacts of deferred or incomplete dredging, such impacts are noted in this EA/EIR. Because it is unknown whether, to what extent, or for how long dredging could be deferred, the impacts of deferred dredging would be speculative and variable. Therefore, discussion of the potential impacts associated with deferred dredging is presented as a brief qualitative assessment in Chapter 3 of this EA/EIR.

### **Reduced Hopper Dredge Use Alternative 1**

Under Reduced Hopper Dredge Use Alternative 1, the government hopper dredge *Essayons*, or similarly sized hopper dredge, would only be used to dredge the MSC, and either the Richmond Outer Harbor or the Pinole Shoal Channel, annually. Because of the strong currents and waves at the MSC, a hopper dredge is the only method that can safely dredge the channel. At times, inclement weather and strong currents at this location create conditions that may preclude safe dredging with a hopper dredge. During such times, dredging at an in-Bay channel would allow for efficient use of the hopper dredge, whereby the dredge would move into San Francisco Bay and work on the identified channel, then return to the MSC as soon as conditions allow. If dredging of the MSC is able to be completed without interruption by inclement weather, then the in-Bay channel (i.e., Richmond Outer Harbor or Pinole Shoal) would be dredged subsequent to the completion of dredging at the MSC. Dredging of the in-Bay channel would occur within the LTMS work window, or after an individual consultation is conducted with the appropriate regulatory agencies to allow dredging to be performed outside the work window.

Selection of the in-Bay channel to be dredged by a hopper, in any given year, would depend on: (a) the amount of shoaled material present at the respective channel; (b) timing and impact to sensitive resources (e.g., compliance with LTMS work windows); and (c) project-specific availability of funds. The additional channel would be identified by USACE in its initial annual maintenance dredging plan, which is prepared at the beginning of each fiscal year, and would be subject to change based on the actual available funds prior to maintenance dredging. Therefore, this alternative would reduce hopper dredge use for maintenance dredging compared to the Proposed Action/Project and No Action/No Project

Alternative, but it would not change the total amount of dredging in the channels, placement sites used, or standard operating procedures.

The MSC is typically dredged in the months of May and June; however, depending on the condition of the channel, equipment availability, and availability of funds, dredging has occurred as late as September. Maintenance dredging of the MSC using a hopper dredge (i.e., the *Essayons*, or similarly sized dredge) typically requires 10 to 14 days. If Pinole Shoal was selected as the additional channel, 5 to 15 days of additional hopper dredge use would occur, for a total of 15 to 29 days of hopper dredge use under this alternative, depending on the duration of dredging at each channel. If Richmond Outer Harbor was selected as the additional channel, 5 to 8 days of additional hopper dredge use would occur, for a total of 15 to 22 days of hopper dredge use under this alternative, depending on the duration of dredging at each channel.

The channel not selected as the additional hopper dredge channel (i.e., either Pinole Shoal or Richmond Outer Harbor) would be dredged with a mechanical dredge. Additionally, Suisun Bay Channel and New York Slough Channel and San Bruno Channel in Redwood City Harbor would be dredged with a mechanical dredge under this alternative, instead of a hopper dredge. The USACE would purchase 0.19 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species if Pinole Shoal is dredged with a hopper. If Richmond Outer Harbor is dredged with a hopper, USACE would purchase 0.34 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species.

All other dredging, placement activities, and BMPs would be as described for the Proposed Action/Project, including urgent action to remove the hazardous shoal at Bulls Head Reach as needed. If feasible, this activity would be completed with a mechanical dredge; however, because of the urgent nature of this activity, a hopper dredge may be used. Regular maintenance dredging of this area would be completed with a mechanical dredge.

## **Reduced Hopper Dredge Use Alternative 2**

Under Reduced Hopper Dredge Use Alternative 2, the government hopper dredge *Essayons*, or similarly sized hopper dredge, would be used to dredge the MSC. The MSC is typically dredged in the months of May and June; however, as stated above, depending on the condition of the channel, equipment availability, and availability of funds, dredging has occurred as late as September. Maintenance dredging of the MSC using a hopper dredge (i.e., the *Essayons*, or similar-sized dredge) typically requires 10 to 14 days; this would be the only hopper dredge use under this alternative, except potential use at Bulls Head Reach as noted below.

Pinole Shoal, Richmond Outer Harbor, Suisun Bay Channel and New York Slough Channel, and San Bruno Channel in Redwood City Harbor would be dredged with a mechanical dredge under this alternative, instead of a hopper dredge. All other dredging, placement activities, and applicable BMPs would be as described for the Proposed Action/Project, including urgent action to remove the hazardous shoal at Bulls Head Reach. If feasible, this activity would be completed with a mechanical dredge; however, because of the urgent nature of this activity, a hopper dredge may be used. Regular maintenance dredging of this area would be completed with a mechanical dredge.

## **ENVIRONMENTAL CONSEQUENCES**

Table ES-3 (at the end of this Executive Summary) presents a summary of impacts for the action alternatives, mitigation measures, and the NEPA and CEQA impact levels for each alternative after mitigation. Impacts of the No Action/No Project Alternative are presented in Chapter 3.0 for comparison to those of the action alternatives. As noted under the reduced hopper dredge use alternatives, the

analysis of impacts is based on the assumption that USACE has obtained the authorization and funding to implement these alternatives by 2017.

## EVALUATION OF ALTERNATIVES

Because the No Action/No Project Alternative represents a continuation of USACE's current maintenance dredging practices, adverse impacts of the No Action/No Project Alternative would be similar to those of the Proposed Action/Project, because both alternatives involve use of the same dredge equipment type. However, adverse impacts to longfin smelt and delta smelt would be greater under the No Action/No Project Alternative, because there would be fewer measures implemented to minimize entrainment impacts to these species; these impacts would be significant under CEQA.

Under the action alternatives, no impacts are expected related to land use plans and hazards and hazardous materials.

Under the Proposed Action/Project and both reduced hopper dredge use alternatives, dredging and placement activities would have equivalent minor adverse impacts on sediments. Although not expected, inadvertent discovery of archaeological or paleontological resources could result in adverse cultural resource impacts under all alternatives; with implementation of the identified mitigation measures, these impacts would not be significant.

All action alternatives would have impacts on water quality, primarily from increased turbidity. Impacts would be greater under the reduced hopper dredge use alternatives compared to the Proposed Action/Project, because mechanical dredging, which would be conducted in place of hopper dredging at certain locations, generates more turbidity than hopper dredging over a longer period of time. Nonetheless, under all alternatives, impacts would be short-term and minor.

Under the reduced hopper dredge use alternatives, there would be a minor increase of emissions compared to the Proposed Action/Project from increased mechanical dredge equipment use; however, the increase would not exceed the Bay Area Air Quality Management District significance thresholds.

All action alternatives would have minor adverse impacts on biological resources including: temporary, localized turbidity impacts on aquatic species and habitat, including eelgrass; temporary, localized disturbance of benthic habitat; temporary adverse effects on fish and marine mammals from underwater noise; temporary, localized interference with the movement or migration of fish and wildlife species (with the exception of entrainment risks discussed below); temporary, and localized impacts on avian foraging and roosting. Under all action alternatives the potential for project activities to result in biotoxicity impacts to aquatic organisms or increase the spread of invasive nonnative species would be minimal. Turbidity impacts on aquatic species from dredging would be longer in duration under the reduced hopper dredge use alternatives than under the Proposed Action/Project, but they would still be less than significant under NEPA and CEQA.

Entrainment of delta smelt and longfin smelt could occur during hopper dredging. Under the Proposed Action/Project, a hopper dredge would be used to dredge three in-bay channels and the Main Ship Channel annually; therefore, of the action alternatives, the Proposed Action/Project would have the greatest potential to result in entrainment impacts. The potential for entrainment impacts would be less under Reduced Hopper Dredge Use Alternative 1 because only one in-Bay channel and the Main Ship Channel would be maintained with a hopper dredge. The potential for entrainment impacts would be largely eliminated under Reduced Hopper Use Dredge Alternative 2 because hopper dredges would not be used for maintaining in-Bay channels after 2016. Under NEPA, project and cumulative impacts to delta smelt and longfin smelt from entrainment would be less than significant under all action alternatives. Under CEQA, project and cumulative impacts to delta smelt and longfin smelt from entrainment would be significant under the Proposed Action/Project, significant but reduced to less than significant with

reduced hopper dredging and minimization and mitigation measures under Reduced Hopper Dredge Use Alternative 1, and less than significant under Reduced Hopper Dredge Use Alternative 2.

Entrainment of other special-status or commercially and recreationally important marine species also could occur during hopper dredging. Under NEPA, these impacts would be less than significant under all alternatives. Under CEQA, these impacts would be significant under all alternatives, but reduced to less than significant with implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment.

Under all action alternatives, dredging activities may occasionally delay or temporarily impede some vessels using the federal navigation channels, resulting in short-term minor impacts on navigation. Mechanical dredges have a greater potential to impact navigation compared to hopper dredges, because they are stationary while operating and involve use of multiple vessels. Therefore, potential navigation impacts would be greatest under Reduced Hopper Dredge Use Alternative 2, because it maximizes use of mechanical dredges, and least under the Proposed Action/Project, but less than significant under any alternative.

In addition to the analysis contained this Environmental Assessment/Environmental Impact Report (EA/EIR), as summarized above, public comments on the Draft EA/EIR related to navigational safety concerns (see Appendix C) were considered in the evaluation and comparison among alternatives.

As noted above, under CEQA, the Proposed Action/Project would have significant cumulative impacts to delta smelt and longfin smelt from entrainment. Under NEPA, the Proposed Action/Project would have less than significant cumulative impacts to delta smelt and longfin smelt from entrainment. Under NEPA and CEQA, the reduced hopper dredge use alternatives would have less than significant cumulative impacts to delta smelt and longfin smelt from entrainment. For all other resource areas under all action alternatives, the project, in combination with other past, present, and reasonably foreseeable future projects, would not contribute to adverse cumulative impacts, or the project's contribution to cumulative impact would not be cumulatively considerable or significant.

## **COORDINATION AND CONSULTATION**

Since early 2013, public and agency participation has occurred as a part of the environmental review process, pursuant to the requirements of the NEPA and CEQA. Stakeholders and public agencies, including those with permitting authority for the project, have been engaged and involved in scoping and alternatives development as detailed in Chapter 4.

**Table ES-3  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<b>Geology, Soils, and Sediment Quality</b>				
<p><b>Impact 3.3-1: Potential for Dredging, Transport, and Placement Activities to Result in Substantial Soil Erosion</b></p> <p>Minimal erosion of the channel sides from sloughing could occur after the channels are dredged due to the disturbance of sediments. Placement of dredged material at beneficial reuse sites would have beneficial impacts on soil resources.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.3-2: Potential for Dredging, Transport, and Placement Activities to Substantially Degrade Sediment Quality</b></p> <p>The USACE’s conformance with established sediment testing and analysis protocols for dredged material would ensure that dredged material placement activities would not substantially degrade sediment quality at the placement sites.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.3-3: Potential for Dredging, Transport, and Placement Activities to Result in Cumulative Impacts on Sediments and Soils</b></p> <p>The project would not result in adverse cumulative impacts on sediments and soils.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Project would not contribute to adverse cumulative impacts.</p> <p><b>CEQA Finding:</b> Project would not contribute to adverse cumulative impacts.</p>	<p><b>NEPA Finding:</b> Project would not contribute to adverse cumulative impacts.</p> <p><b>CEQA Finding:</b> Project would not contribute to adverse cumulative impacts.</p>	<p><b>NEPA Finding:</b> Project would not contribute to adverse cumulative impacts.</p> <p><b>CEQA Finding:</b> Project would not contribute to adverse cumulative impacts.</p>
<b>Hydrology and Water Quality</b>				
<p><b>Impact 3.4-1: Potential to Substantially Degrade Water Quality through Alteration of Water Temperature, Salinity, pH, and Dissolved Oxygen</b></p> <p>Impacts to water quality temperature, salinity, pH, and dissolved oxygen from project activities would be minor, short-term, and localized.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table ES-3  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.4-2: Potential to Substantially Degrade Water Quality Because of Increased Turbidity</b></p> <p>Dredging and placement activities would have minor, short-term, and localized impacts to water quality due to short-term increases in turbidity. Placement of dredged materials at habitat restoration beneficial reuse projects could have long-term beneficial effects on water quality.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.4-3: Potential to Substantially Degrade Water Quality Because of Mobilization of Contaminated Sediments or Release of Hazardous Materials</b></p> <p>Dredging and placement activities would not be expected to increase contaminant concentrations in the water column above baseline conditions, or result in violation of a water quality standard.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.4-4: Potential to Result in Cumulative Impacts to Hydrology or Water Quality</b></p> <p>The project, in combination with other past, present, and reasonably foreseeable future projects, could result in adverse cumulative impacts on water quality; however, the project’s contribution to these cumulative impact would not be cumulatively considerable or significant.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

<b>Air Quality and Global Climate Change</b>				
<p><b>Impact 3.5-1: Conflict with or Obstruct BAAQMD Air Quality Plan Implementation, Exceed Applicable Air Quality Standards, or Contribute Substantially to an Air Quality Violation</b></p> <p>The project would not result in emissions level increases that exceed BAAQMD mass significance thresholds. Therefore, the project would not conflict with or obstruct BAAQMD Air Quality Plan Implementation, exceed applicable air quality standards, or contribute substantially to an air quality violation.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.5-2: Expose Sensitive Receptors to Substantial Pollutant Concentrations</b></p> <p>The impacts of short-term intermittent emissions on sensitive receptors from dredging and dredged material placement activities would be minimal.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.5-3: Create Objectionable Odors</b></p> <p>The project would not create objectionable odors affecting a substantial number of people.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.5-4: Result in Cumulatively Considerable Air Quality Impacts</b></p> <p>The project alternatives would not cause mass emission increases above the BAAQMD significance thresholds, would not be cumulatively considerable, and would not result in significant cumulative air quality impacts.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table ES-3  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.5-5: Generate Greenhouse Gas Emissions, Either Directly or Indirectly, that May Have a Significant Impact on the Environment or Conflict with an Applicable Plan, Policy, or Regulation Adopted for the Purpose of Reducing the Emissions of Greenhouse Gases</b></p> <p>The project alternatives would not cause greenhouse gas emission increases above the BAAQMD significance thresholds or conflict with an applicable plan, policy, or regulation for reducing the emissions of greenhouse gases.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Biological Resources</b></p>				
<p><b>Impact 3.6-1: Potential Adverse Effects of Increased Turbidity Resulting from Maintenance Dredging and Dredged Material Placement on Special-Status Species, Critical Habitat, and Commercially Valuable Marine Species</b></p> <p>Localized and temporary increases in turbidity resulting from dredging and the placement of dredged material may affect marine organisms and aquatic wildlife during various life stages. Impacts may include impaired respiration; reduced visibility and the ability to forage or avoid predators; and alteration of movement patterns. Increases in turbidity from the project are not expected to have substantial effects on special-status species, their critical habitat, or EFH.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table ES-3  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.6-2: Potential Adverse Effects of Maintenance Dredging Resulting from the Disturbance of Benthic Habitat on Special-Status Species, Critical Habitat, and Commercially Valuable Marine Species</b></p> <p>Dredging would have localized, direct impacts on benthic communities through physical disruption and direct removal of benthic organisms. Effects would be temporary because benthic habitat is quickly recolonized.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-3: Potential Adverse Effects of Underwater Noise Generated During Maintenance Dredging on Special-Status Fish and Marine Mammals</b></p> <p>Underwater noise produced during dredging may have temporary adverse effects on fish and marine mammals, include fleeing, the cessation of feeding, or other behavioral changes; but would not be expected to cause injury to fish and marine mammals.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-4: Potential Adverse Effects from Entrainment on Special-Status or Commercially and Recreationally Important Marine Species, Not Including Delta Smelt and Longfin Smelt</b></p> <p>During dredging, organisms on the dredged material may be entrained, in addition to organisms in the water column near the dredging apparatus. With implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment, effects to special-status and commercially important species, not including delta smelt and longfin smelt, would not be significant.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts, reduced to less than significant with implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts, reduced to less than significant with implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts, reduced to less than significant with implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment.</p>

**Table ES-3  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.6-5: Potential Substantial Adverse Effects and Cumulative Impacts to Delta Smelt from Entrainment</b></p> <p>Entrainment of delta smelt could occur during hopper dredging. Under the Proposed Action/Project, a hopper dredge would be used to dredge three in-bay channels and the Main Ship Channel annually; therefore, this alternative would have the greatest potential to result in entrainment impacts. The potential for entrainment impacts would be less under Reduced Hopper Dredge Use Alternative 1 because only one in-Bay channel and the Main Ship Channel would be maintained with a hopper dredge. The potential for entrainment impacts would be largely eliminated under Reduced Hopper Use Dredge Alternative 2 because hopper dredges would not be used for maintaining in-Bay channels.</p>	<p>Minimization measures proposed as part the project description for all action alternatives. Compensatory mitigation (i.e., conservation credit) proposed as part of the project description for the Proposed Action/Project and Reduced Hopper Dredge Use Alternative 1. No additional measures proposed as mitigation.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts, reduced to less than significant with the implementation of reduced hopper dredging.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-6: Potential Substantial Adverse Effects and Cumulative Impacts to Longfin Smelt from Entrainment</b></p> <p>Entrainment of delta smelt could occur during hopper dredging. Under the Proposed Action/Project, a hopper dredge would be used to dredge three in-bay channels and the Main Ship Channel annually; therefore, this alternative would have the greatest potential to result in entrainment impacts. The potential for entrainment impacts would be less under Reduced Hopper Dredge Use Alternative 1 because only one in-Bay channel and the Main Ship Channel would be maintained with a hopper dredge. The potential for entrainment impacts would be largely eliminated under Reduced Hopper Use Dredge Alternative 2 because hopper dredges would not be used for maintaining in-Bay channels.</p>	<p>Minimization measures proposed as part the project description for all action alternatives. **Table ES-3  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.6-7: Dredging and Placement Activities Could Result in the Disturbance of Essential Fish Habitat and “Special Aquatic Sites,” Including Eelgrass Beds and Mudflats.</b> Eelgrass near the Richmond Inner Harbor Channel and Oakland Inner Harbor may be indirectly impacted by turbidity and increased sedimentation from dredging operations. Turbidity plumes from dredging operations may temporarily reduce light penetration in waters adjacent to the plumes. Sediment near areas of dredging may settle on eelgrass blades and affect the viability of the eelgrass in beds adjacent to dredging operations.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-8: Interference with the Movement of Resident or Migratory Fish or Wildlife Species During Dredging and Placement Activities</b> The noise and in-water disturbance associated with dredging and placement activities could cause fish and wildlife species to temporarily avoid the immediate dredging or placement area when work is being conducted. However, the affected area would be limited to the immediate dredging or placement zone, and would not substantially limit the available habitat or movement of fish, seabirds, or marine mammals.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-9: Dredging and Placement Activities Could Disturb Roosting and Foraging by Avian Species</b> Dredging may disturb avian foraging and resting behaviors, decrease time available for foraging, and increase energetic costs as a result of increased flight times and startling responses. Impacts would be temporary, localized, and minor.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table ES-3  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.6-10: Contaminated Sediments Could Become Resuspended During Dredging and Placement Activities, and Could Be Toxic to Aquatic Organisms, Including Plankton, Benthos, Fish, Birds, and Marine Mammals</b> Sediment testing results for previous USACE maintenance dredging episodes indicate that, in general, dredged materials from the subject federal navigation channels have been suitable for unconfined aquatic disposal. Dredging, transport, and placement of dredged material would be conducted in cooperation with the DMMO. This process would identify contaminated sediments and appropriate placement site options for dredged materials, based on the characteristics of the sediment and criteria for each placement site. Adherence to best management practices and conditions in regulatory approvals would minimize the potential for water quality degradation that could impact aquatic organisms.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-11: Dredging and Placement Could Substantially Increase the Spread of Invasive Nonnative Species</b> Dredge equipment would comply with United States Coast Guard regulations for vessels intended to minimize the spread of invasive nonnative species. Beneficial reuse and upland placement site operators are responsible for managing the placement of dredged materials at the placement sites in accordance with conditions of their permits and other regulatory approval, which include measures to minimize the spread of invasive nonnative species. Therefore, project activities would not be expected to substantially increase the spread of invasive nonnative species.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

## CHAPTER 1 PURPOSE AND NEED

### 1.1 INTRODUCTION

The United States Army Corps of Engineers (USACE) proposes to continue maintenance dredging of the federal navigation channels in San Francisco Bay to maintain the navigability of the channels. The San Francisco Bay Regional Water Quality Control Board (Regional Water Board) proposes to issue a Clean Water Act (CWA) Section 401 water quality certification (WQC), and may also issue waste discharge requirements (WDRs) pursuant to the state Porter-Cologne Water Quality Control Act, for USACE's continued maintenance dredging operations in San Francisco Bay. This authorization is referenced throughout as "WQC."

The USACE and Regional Water Board have prepared this Environmental Assessment (EA)/Environmental Impact Report (EIR) to address the environmental effects of the maintenance dredging of federal navigation channels in San Francisco Bay and the associated placement of dredged materials for a period of 10 years. This EA/EIR is prepared in accordance with the National Environmental Policy Act (NEPA) of 1969, 42 U.S.C. § 4321 et seq.; the Council on Environmental Quality (CEQ) regulations for implementing NEPA, 40 C.F.R., pt. 1500-1508; USACE Procedures for Implementing NEPA (Engineer Regulation 200-2-2); USACE regulations for operation and maintenance of civil works projects (33 C.F.R. pt. 335-338); Section 404 of the CWA (33 U.S.C. § 1344 and 33 C.F.R. pt. 320-330); the California Environmental Quality Act (CEQA) of 1970, California Public Resources Code, Section 21000 et seq., as amended, and the Guidelines for Implementation of CEQA, Title 14, California Code of Regulations, Section 15000 et seq. The USACE is the NEPA lead agency, and the Regional Water Board is the CEQA lead agency. The Proposed Action/Project and alternatives are described in Chapter 2.

The dredging process involves the excavation of accumulated sediment from the channel bed, and the subsequent transportation and placement of the sediment at a permitted facility or location in a manner consistent with the permit conditions established by applicable regulatory agencies, after determination of suitability for placement at that site. The environmental impacts of maintenance dredging of the federal navigation channels were initially described in USACE's *Final Composite Environmental Impact Statement for Maintenance Dredging of Existing Navigation Projects, San Francisco Bay Region* in December 1975. The environmental effects of dredged material placement activities associated with dredging the federal navigation channels in San Francisco Bay were analyzed in the *Long-Term Management Strategy for Placement of Dredged Material in the San Francisco Bay Region, Final Policy Environmental Impact Statement/Programmatic Environmental Impact Report* in 1998. Subsequent to the publication of these documents, USACE has conducted NEPA compliance review, and the Regional Water Board has conducted CEQA<sup>1</sup> compliance review, for maintenance dredging activities on an individual channel basis; this NEPA and CEQA compliance has been conducted periodically as warranted by maintenance dredging needs. This document is intended to fulfill USACE's NEPA compliance requirements for maintenance dredging of federal navigation channels it maintains in San Francisco Bay for the federal fiscal years<sup>2</sup> 2015 through 2024. This document is also intended to fulfill the Regional Water Board's CEQA compliance requirements for issuance of a 10-year WQC to USACE.

Longfin smelt and green sturgeon were not protected under the federal or state Endangered Species Acts at the time the Long-Term Management Strategy (LTMS) Environmental Impact Statement (EIS)/EIR was completed. Longfin smelt is a state-listed threatened species, and the green sturgeon southern distinct population segment is a federally listed threatened species. Delta smelt was addressed in the

---

<sup>1</sup> "Maintenance dredging where the spoil is deposited in a spoil area authorized by all applicable state and federal regulatory agencies" is a Class 4 Categorical Exemption under CEQA (CEQA Guidelines, Section 15304). Past WDRs were issued under this Categorical Exemption. The listings of longfin smelt and green sturgeon, noted in the following paragraph, warranted the preparation of an EIR under CEQA.

<sup>2</sup> The federal fiscal year begins October 1 and ends September 30.

LTMS Final EIS/EIR as a federally listed and state-listed threatened species; however, the state elevated its listing status from threatened to endangered in 2010. Listed salmonids were addressed in the LTMS EIS/EIR. Subsequent to the completion of the LTMS EIS/EIR and to the listing of longfin smelt, USACE implemented monitoring to determine whether dredging operations were resulting in take of listed fish species. In 2011, there were occurrences of delta smelt and longfin smelt becoming entrained in hopper dredging equipment during USACE maintenance dredging at certain locations (refer to Section 2.3.1 for a description of hopper dredges). To minimize the potential for future impacts to listed fish species, the proposed project would address aspects of USACE's maintenance dredging and dredged materials placement program that could result in injury or mortality of these species.

Additionally, for those maintenance dredging projects that involve discharge of dredged or fill material into waters of the United States, this document is intended to serve as the Section 404(b)(1) analysis for maintenance dredging in compliance with the CWA.<sup>3</sup> The USACE implements Section 404 of the CWA, and although it does not issue itself permits, USACE must demonstrate compliance with Section 404 of the CWA.

The federal navigation channels and associated placement sites are in the San Francisco Bay LTMS Program Planning Area, which spans 11 counties, including Alameda, Contra Costa, Marin, Napa, Sacramento, San Joaquin, Santa Clara, San Francisco, San Mateo, Solano, and Sonoma.<sup>4</sup> However, the geographic scope of potential impacts of the proposed project are limited to 10 federally authorized navigation channels and associated placement sites in San Francisco Bay.

Chapter 1 of this EA/EIR, Purpose and Need, describes the project need and objectives, the project's relationship to other plans and policies, the federal channels and placement sites, and the regulatory framework. Chapter 2, Alternatives, describes the alternatives development process for the project, and the Proposed Action/Project and its alternatives. Chapter 3, Affected Environment and Environmental Consequences, presents the regulatory and environmental setting for the project, and the environmental impacts of the project alternatives. Chapter 4, Public and Agency Involvement, describes the public scoping and public review process, including agency coordination. Chapter 5, Findings, presents a summary of impacts and mitigations, and a comparison of the project alternatives; it also describes the environmentally superior alternative. Chapter 6, List of Preparers, provides a list of agency and consultant staff who prepared the EA/EIR.

## 1.2 PROJECT PURPOSE, NEED, AND OBJECTIVES

The CEQ's regulations for implementing NEPA require that an EA include a statement of the need to which the federal agency is responding in proposing the project. The CEQA Guidelines require that an EIR contain a "statement of the objectives sought by the proposed project." Under the CEQA Guidelines, "[a] clearly written statement of objectives will help the Lead Agency develop a reasonable range of alternatives to evaluate in the EIR and will aid the decision makers in preparing findings or a statement of overriding considerations. The statement of objectives should include the underlying fundamental purpose of the project" (CEQA Guidelines Section 15124[b]).

The USACE, as mandated by Congress, is responsible for maintaining navigability of federal navigation channels to authorized depth or lesser regulatory depth.<sup>5</sup> Accumulation of sediment that settles in these channels can impede navigability. Maintenance dredging removes this sediment and returns the channels to regulatory depths to provide safe, reliable, and efficient waterborne transportation systems (channels,

<sup>3</sup> Sediment testing will occur in the future, pursuant to the Section 404(b)(1) sediment testing guidelines, per approved sediment sampling and analysis plans.

<sup>4</sup> Although portions of Sacramento and San Joaquin counties were part of the Planning Area for the LTMS EIS/EIR, they are not part of the LTMS Program.

<sup>5</sup> Regulatory depth is the depth to which federal environmental compliance has been completed.

harbors, and waterways) for the movement of commerce, national security needs, and recreation. Therefore, USACE's purpose of the project is to continue maintenance dredging of the federal navigation channels in San Francisco Bay consistent with the goals and adopted plans of the LTMS, while adequately protecting the environment, including listed species. The Regional Water Board's overall project objective is to ensure USACE's consistency with the water quality objectives and beneficial uses adopted in the Water Quality Control Plan for the San Francisco Basin (Basin Plan), as will be addressed through the Section 401 WQC process.

The USACE's specific project objectives are to:

- Provide safe, reliable, and efficient navigation through federal channels in San Francisco Bay in a feasible manner. This objective is considered the underlying fundamental purpose of the proposed project;
- Ensure consistency, to the maximum extent practicable, with the goals of the LTMS program as described in the 1998 LTMS Final EIS/EIR and the 2001 LTMS Management Plan (refer to Section 1.3.1); and
- Conduct dredging in a manner that adequately protects the environment, including listed species.

The Regional Water Board has authority under CWA Section 401 and the Porter-Cologne Act to issue permits governing dredge and fill activities. The Regional Water Board will consider USACE's application for a multi-year WQC for continued maintenance dredging of San Francisco Bay federal channels and associated dredged materials placement. To issue a WQC to USACE, the Regional Water Board, in compliance with CEQA, must analyze and disclose potential water quality and other environmental impacts of the project; consider alternatives that would avoid or substantially reduce potentially significant impacts of the project as approved; adopt or make a condition of approval all feasible mitigation for potentially significant impacts; and demonstrate that all applicable state water quality requirements are met.

### 1.3 RELATIONSHIP TO OTHER PLANS AND POLICIES

The USACE's regulations for its operation and maintenance dredging projects involving the discharge of dredged materials into waters of the United States or ocean waters are detailed in 33 C.F.R. pt. 335-338. The regulations describe the procedures that USACE must follow to conduct dredged material disposal in compliance with Section 404 of the CWA (for disposal in waters of the United States) and the Marine, Protection, Research and Sanctuaries Act (MPRSA) (for disposal in ocean waters). In addition, pursuant to the federal Coastal Zone Management Act (CZMA), USACE's maintenance dredging and dredged material placement needs to be consistent with the state's coastal zone management program and policies to the maximum extent practicable (16 U.S.C. § 1456). The USACE's regulations identify factors to be considered in evaluating the discharge of dredged material into waters of the United States, including navigation and the federal standard;<sup>6</sup> water quality; coastal zone consistency; wetlands; endangered species; and fish and wildlife (35 C.F.R. pt. 336.1[c]). The USACE's evaluation of discharges (i.e., placement) of dredged material in San Francisco Bay and ocean placement sites and compliance with Section 404 of the CWA, the MPRSA, and the CZMA is guided by the LTMS Program, and other plans and policies described in the following sections.

---

<sup>6</sup> The federal standard is defined as the least-costly dredged material disposal or placement alternative consistent with sound engineering practices, and meeting the environmental standards established by the Section 404(b)(1) evaluation process or ocean dumping criteria (33 C.F.R. § 335.7).

### 1.3.1 LTMS Planning Context

The LTMS program was formed in the 1990s in response to the public's growing concern over the potential direct, indirect and cumulative effects of dredging and dredged material disposal activities on the already stressed resources of the San Francisco Bay/Sacramento-San Joaquin Delta Estuary. The 50-year LTMS program comprises state and federal regulatory agencies with primary authority to review and permit dredging and disposal activities in the San Francisco Bay Area. Participating agencies include USACE, United States Environmental Protection Agency (USEPA), Regional Water Board, State Water Resources Control Board, San Francisco Bay Conservation and Development Commission (BCDC), and State Lands Commission.

The LTMS program spans nine counties, including: Marin, Sonoma, Napa, Solano, Contra Costa, Alameda, Santa Clara, San Mateo, and San Francisco. It does not include the mountainous areas or inland areas far removed from navigable waters. The geographic scope of the LTMS program comprises the estuarine waters of the San Francisco Bay region, portions of the Sacramento-San Joaquin Delta west of Sherman Island, and the western portion of the Sacramento River Deep Water Ship Channel and Stockton Deep Water Ship Channel. It also includes the wetlands and shallow intertidal areas that form a margin around the San Francisco Bay and the tidal portions of its tributaries. Lastly, it includes the San Francisco Deep Ocean Disposal Site (SF-DODS), the San Francisco Bar Channel Disposal Site (SF-8) and the nearshore zone off Ocean Beach, as well as the waters that are used by vessels en route to these sites. This geographical area defines the region where navigational dredging covered by the LTMS program may occur, and where dredged material placement sites are located. In some cases, dredged material may be transported outside the region for use in landfills, levee repair, or other beneficial reuse projects.

Formal implementation of the LTMS began in 2001 with the adoption of the LTMS Management Plan. The Management Plan was preceded by an extensive 8-year federal and state planning effort that culminated in the LTMS Final EIS/EIR in October 1998. The environmentally preferred alternative identified in the LTMS Final EIS/EIR includes beneficial reuse of at least 40 percent of material dredged in the San Francisco Bay region, no more than 40 percent placement at SF-DODS, and no more than 20 percent placement at in-Bay sites. The Management Plan was based on average annual dredged material disposal volumes from 1991 through 1999. The Management Plan called for reversing the historic practice of disposing 80 percent or more of all material dredged from San Francisco Bay at in-Bay disposal sites, and requires that at least 80 percent of all dredged material be placed at beneficial reuse sites, upland, or at ocean disposal sites, with only limited volumes of material being placed in-Bay. Over the life of the LTMS, the selected alternative aims to:

- Maintain, in an economically and environmentally sound manner, those channels necessary for navigation in San Francisco Bay, and eliminate unnecessary dredging activities;
- Conduct dredged material disposal in the most environmentally sound manner;
- Maximize the use of dredged material as a resource; and
- Maintain the cooperative permitting framework for dredging and disposal applications.

To implement these goals, the LTMS agencies have instituted an aggressive reduction of in-Bay disposal volumes; worked to establish new beneficial reuse options, including habitat creation benefitting sensitive and listed species; encouraged beneficial reuse where practicable; worked with projects to avoid environmental impacts by dredging only during established environmental work windows as much as possible; continuously improved dredged material testing practices to ensure that contaminant-related impacts to the aquatic environment are minimized; and streamlined the permitting process for the dredging community.

The LTMS agencies adopted a program that created a 12-year transition period for reduction of in-Bay disposal and the development of beneficial reuse sites; this transition period ended on December 31,

2012. The in-Bay disposal volume reduction targets were successfully met for each 3-year period of the 12-year transition, despite overall dredging volumes being greater than during the baseline planning period for the LTMS program (LTMS, 2013a).

As part of the implementation of the LTMS, the agencies initiated state and federal Endangered Species Act consultation with the National Marine Fisheries Service (NMFS), the United States Fish and Wildlife Service (USFWS), and the California Department of Fish and Wildlife (CDFW) for maintenance dredging and disposal projects, covering threatened and endangered species and species of special concern, such as the Pacific herring. These consultations reduced the need for individual consultation for dredging projects through the establishment of programmatic work windows. These programmatic work windows are based on presence/absence information for various sensitive species, and establish times and locations wherein dredging and disposal activities may take place without further (formal or informal) consultation.

In the event that a project cannot be completed during the work window, individual consultations with the appropriate resource agencies would occur. The outcome of the individual consultation would determine whether any additional dredging period for that project is appropriate; and if necessary, provide a “take authorization.”

The programmatic biological opinions issued by NMFS and USFWS provide federal endangered or threatened species “incidental take” authorization for projects operating in the environmental work window for their area. This “take authorization” protects the dredger from enforcement action in the event of accidental harm to a listed species as a result of the dredging project. The programmatic biological opinions<sup>7</sup> issued by NMFS and USFWS do not address incidental take of state-listed species. Coordination with CDFW is necessary if take of state-listed species is expected. As a federal agency, USACE is not required to obtain authorization from CDFW for incidental take of state-listed species but would be required to consult with NMFS and USFWS under the federal Endangered Species Act (ESA) if take of federally listed species is expected. Since 2011, USACE has been required to consult on impacts to delta smelt during dredging of Suisun Bay Channel and New York Slough because of documented occurrences of entrainment during monitoring of hopper dredge use.

In 2012, the LTMS agencies completed a comprehensive 12-year review of the program. The review process involved collecting, analyzing, disseminating, and presenting data about the LTMS program’s performance as well as a series of public meetings (each focused on a different key topic suggested by stakeholders) and preparation of a Final 12-Year Review Report summarizing the review findings. Based on this review process, the LTMS agencies concluded that the LTMS goals remain appropriate and largely implementable, and that the program has been successfully implemented to date. The LTMS agencies recommended that the basic program continue. This continuation requires approximately 80 percent of dredged sediment to be targeted for beneficial reuse or out-of-Bay disposal and only 20 percent targeted for in-Bay disposal. Given the changed conditions since establishment of the program, the LTMS agencies recommended adopting increased flexibility and innovation in implementing the program’s goals. Specifically, the LTMS agencies are assessing potential changes in the program’s implementation to accommodate changing or adding flexibility to in-Bay disposal volume limits, encouraging more beneficial reuse and new kinds of beneficial reuse (LTMS, 2013b).

### **LTMS Program Relationship to San Francisco Bay Plan**

The BCDC regulates dredging and dredged material placement in San Francisco Bay. Under authority of the state McAtteer-Petris Act of 1965, the BCDC prepared the San Francisco Bay Plan; and in 1968, adopted regulations and policies regarding dredging and placement in San Francisco Bay. The San

---

<sup>7</sup> NMFS is revising the 1998 LTMS programmatic biological opinion; the updated biological opinion (expected 2015) will supersede the 1998 document. USACE would comply with the terms and conditions of the updated biological opinion.

Francisco Bay Plan dredging policies were amended to adopt the LTMS findings, including reducing in-Bay disposal, maximizing beneficial reuse, and an allocation strategy to reduce in-Bay disposal. The BCDC is also the state coastal management agency pursuant to the federal CZMA for the San Francisco Bay segment of the California coastal zone. Under the federal consistency provisions of the CZMA, federal projects need to be determined to be consistent with the state's coastal zone management program and policies to the maximum extent practicable (16 U.S.C. § 1456). The consistency determination is made by the lead federal agency, and concurrence is sought from the CZMA managing agency, which has the ability to concur, condition the project to find consistency, or object to the project. The Commission's law and policies are the basis for its federally approved state coastal management program for San Francisco Bay. Dredging and placement projects must be consistent with all Bay Plan policies, to the maximum extent practicable, and USACE requests BCDC's concurrence on USACE's consistency determination prior to commencing dredging activities.

### **LTMS Program Relationship to Regional Water Quality Control Plan**

The Basin Plan, which can be found at the Regional Water Board's website at [http://www.waterboards.ca.gov/sanfranciscobay/basin\\_planning.shtml](http://www.waterboards.ca.gov/sanfranciscobay/basin_planning.shtml), is the primary document used by the Regional Water Board for the regulation of in-Bay dredging. In 2008, the Basin Plan was amended to identify the LTMS strategy as the key process for addressing dredging operations in San Francisco Bay, and for achieving the LTMS goals. The Basin Plan implements the LTMS Management Plan by setting a long-term overall target for in-Bay disposal of dredged material at designated disposal sites of 1.25 million cubic yards (or less) per year, adopting the guidelines contained in the 1998 USACE/USEPA Inland Testing Manual and local implementation procedures developed through the Dredged Material Management Office (DMMO) as the appropriate framework for evaluating the suitability of dredged material for disposal at in-Bay disposal sites, and providing revised permit conditions to reflect requirements of the resource agencies (CDFG, USFWS, and NMFS).

### **LTMS Program Relationship to the Clean Water Act**

San Francisco Bay, along with its tributary rivers, streams, adjacent wetlands, and the Pacific Ocean out to the 3-mile limit, are "waters of the United States" in CWA Section 404 jurisdiction. The USACE, USEPA, and Regional Water Board regulate placement of dredged material in San Francisco Bay pursuant to the CWA through the LTMS DMMO, as described in Section 1.3.2. The USACE implements Section 404 of the CWA, and the USEPA has oversight authority. Section 404(b)(1) of the CWA establishes procedures for the evaluation of permits for discharge of dredged or fill material into waters of the United States. Guidelines (40 C.F.R. pt. 230) were promulgated specifically pursuant to Section 404(b)(1) of the Act. The Section 404(b)(1) Guidelines govern, in part, the issuance of permits by USACE. The USACE's 1986 Regulation 33 C.F.R. pt. 320.4(a)(1) states, "For activities involving 404 discharges, a permit will be denied if the discharge that would be authorized by such permit would not comply with the Environmental Protection Agency's 404(b)(1) Guidelines." In situations where USACE is proposing work that involves discharge of dredged or fill material into waters of the United States, USACE must comply with the requirements of the Section 404(b)(1) Guidelines, although it does not issue itself permits. Discharge of dredged materials into waters of the United States is regulated under Section 404 of the CWA.

Subpart B of the Section 404(b)(1) Guidelines (40 C.F.R. pt. 230.10) establishes the Alternatives Analysis requirements that must be met. In particular, 40 C.F.R. pt. 230.10(a) states that "[N]o discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences".

In addition to consideration of logistics and existing technology, USACE and USEPA application of the Section 404(b)(1) Guidelines allows for consideration of the reasonableness of the cost of an alternative

relative to the nature of the project, the type of project proponent, and the “market” in which the project exists. The market for different kinds of projects, and therefore the range of alternatives and reasonable costs of doing business in that market, varies widely. For maintenance dredging in the San Francisco Bay region, the range of placement options is limited to those that are relatively near the larger and medium-sized dredge projects, and those that are technically feasible and cost effective for larger and medium-sized operations.

### **1.3.2 Management of Dredged Material**

Authorization to discharge dredged material in the open ocean, enclosed coastal waters, upland sites, or for beneficial reuse is provided through a variety of federal and state permitting processes. The USACE and USEPA jointly regulate the discharge of dredged material into waters of the United States and the transportation of dredged material for the purpose of disposal in ocean waters pursuant to Section 404 of the CWA, and the MPRSA (also refer to Sections 1.4.3 and 1.5.1). The Section 404(b)(1) Guidelines at 40 C.F.R. pt. 230 and ocean dumping criteria at 40 C.F.R. pt. 220 implement the environmental protection provisions of the CWA and MPRSA, respectively. As stated above, USACE does not issue itself a CWA Section 404 permit to authorize its discharges of dredged material into waters of the United States, but does apply the Section 404(b)(1) Guidelines and other substantive requirements of the CWA and other environmental laws.

The CWA requires USACE to seek state water quality certification for discharges of dredged or fill material into waters of the United States. Under Section 401 of the CWA, the Regional Water Board must certify that the activity will not violate state water quality standards and other applicable requirements before USACE is authorized to commence dredging. Pursuant to the consistency provisions of the CZMA, BCDC has authority over dredging and disposal of dredged material in San Francisco Bay.

#### **Dredged Material Management Office**

In 1996, the DMMO was created to establish a comprehensive and consolidated approach to eliminate redundancy and delays in the dredged material disposal permitting process. The DMMO reviews dredging projects to determine if they comply with the applicable federal and state laws (depending on if the applicant is a federal or non-federal agency), including the CWA, CZMA, federal ESA, and the California Endangered Species Act (CESA). The DMMO is a joint program composed of USACE, USEPA, BCDC, Regional Water Board, and the State Lands Commission. Participating agencies include CDFW, NMFS, and USFWS.

#### **Testing Requirements for Placement and Beneficial Reuse of Dredged Material**

Material proposed to be dredged and placed at ocean, inland aquatic, or upland/beneficial reuse sites requires sediment characterization to predict the environmental impacts associated with dredging and dredged material placement activities. The objective of the sediment testing requirements is to determine whether disposal of dredged material at designated disposal sites can occur without causing unreasonable degradation to the surrounding environment. Generally, sediments are tested for physical and chemical attributes and/or the potential for biological toxicity. The extent of sediment characterization necessary to ensure compliance with applicable environmental laws and regulations is generally site-specific. The type and extent of testing depends on the physical characteristics of the sediment, as well as the characteristics of the dredged material placement site. The entire dredge prism, which includes 2 feet of overdepth, is characterized. The DMMO reviews sediment testing plans and results, and determines suitability for placement of dredged material at a given location, based on sediment testing results and the LTMS program goals.

For ocean disposal to take place, the material must be acceptable for deep-ocean placement, as regulated by the MPRSA. The standards under CWA and MPRSA for determining the need for testing differ. The

requirement for testing under the CWA is based on reason to believe that contaminants are present in the proposed discharge, and have the potential to result in unacceptable adverse impact (40 C.F.R. pt. 230.60). Testing under the MPRSA is required when the material does not meet the exclusionary criteria in 40 C.F.R. pt. 227.13(b). Once it is determined that testing is required, the physical, chemical, and biological tests relied on for evaluating the material are similar for in-Bay and ocean placement sites.

For placement of dredged material in inland waters, including San Francisco Bay, Section 404 of the CWA, including the Section 404 (b)(1) Guidelines, and the regulations at 40 C.F.R. pt. 230 define the testing requirements. Current guidance for implementing inland aquatic disposal is provided in *Evaluation of Dredged Material Proposed for Disposal in Waters of the U.S. – Testing Manual for Discharge in Inland and Near Coastal Water – Testing Manual* (USACE and USEPA, 1998), referred to as the *Inland Testing Manual*. The regulations allow some temporary effects to the environment, and these effects are based on water quality criteria and Limiting Permissible Concentrations (concentrations of chemicals of concern present in dredged material must be lower than concentrations that cause significant impacts to certain species).

The Section 404 (b)(1) Guidelines at 40 C.F.R. pt. 230 and ocean dumping criteria at 40 C.F.R. pt. 220(a) provide general regulatory guidance and objectives, but not a specific technical framework for evaluating or managing contaminated sediment that must be dredged. If the USACE District Engineer determines the dredged material to be contaminated, USACE will follow the guidance provided in the most current published version of the technical manual for contaminant testing and controls.

In late 1997, NMFS published regulations requiring consultation for projects or programs that may adversely affect Essential Fish Habitat (EFH). Consequently, in 2004, the LTMS agencies and NMFS began preparing a programmatic EFH consultation for the LTMS program. The programmatic EFH agreement was completed in 2011 (USACE and USEPA, 2011). The EFH agreement includes a number of Conservation Measures that enhance the environmental protectiveness of the LTMS program. Conservation Measures 7 and 8, in particular, further improve the sediment testing program for projects proposing in-Bay disposal. Specifically, these Conservation Measures make the requirements for bioaccumulation testing, and “residual” (post-dredge sediment surface) sampling and characterization, more systematic and predictable. These conservation measures also tie the sediment testing program to San Francisco Bay’s existing Total Maximum Daily Loads for mercury and polychlorinated biphenyls, as well as to the established Regional Monitoring Program for San Francisco Bay. This ensures that dredging and dredged material placement will be managed in a manner that directly complements other key pollution-reduction programs for San Francisco Bay.

In the San Francisco Bay Area, placement of dredged material at upland sites or for beneficial reuse is regulated under California’s Porter-Cologne Act and McAtter-Petris Act. Screening guidance is provided in Regional Water Board’s May 2000 staff summary report, *Beneficial Reuse of Dredged Materials: Sediment Screening and Testing Guidelines*, or most current revised version. There are two levels of screening guidelines for beneficial reuse of sediments for wetland restoration: guidelines for cover material; and guidelines for foundation material. Cover material is a class of material that is not expected to pose a threat to water quality or the aquatic environment, even in places where the material is in direct contact with surface waters or aquatic organisms, and is suitable for unconfined aquatic disposal. Wetland foundation material is not of a quality that constitutes a hazardous or listed waste but has a potential for biological effects if directly exposed to organisms. Wetland foundation material is not expected to be a threat to water quality when an adequate amount of cover material is used to reduce the risk of foundation material coming into contact with the aquatic environment. The amount of cover material needed to adequately reduce this risk depends on site-specific characteristics. Placement of dredged sediment at beneficial reuse sites is also often governed by acceptance criteria included in project-specific biological opinions.

### 1.3.3 Overdepth and Advance Maintenance Dredging

The federal navigation channels have Congressionally authorized maximum depths. Not all of the federal navigation channels are dredged to their authorized depth. In these cases, the channels are maintained by USACE to the previously dredged (i.e., regulatory) depth, not the Congressionally authorized depth. Deepening these channels beyond their previously dredged depth would not be considered maintenance dredging, and would require additional regulatory approval. At times, advance maintenance dredging is conducted, which dredges channels slightly deeper than their authorized or regulatory depth, as described below. Overdepth and advance maintenance dredging are part of the USACE's maintenance dredging program and are not considered deepening.

For some projects, overdepth dredging can account for a substantial proportion of the total quantity dredged, while for other projects it may be relatively minor. Overdepth is a total of 2 feet beyond the historically maintained depth for the entirety of the dredged area.<sup>8</sup> The volume represented by overdepth material is fully characterized in pre-dredge sediment testing.

Advance maintenance dredging is dredging to a specified depth and/or width beyond the previously dredged channel dimensions in critical and fast-shoaling areas of a channel to avoid frequent re-dredging, and to ensure the reliability and least overall cost of operating and maintaining the channel's design dimensions. This material is also subject to full characterization as discussed above. The USACE usually decides whether or not to perform advance maintenance after condition surveys are completed in the second quarter of the fiscal year. If the shoaling is light and there is sufficient budget, USACE elects to include advance maintenance. If the shoaling is heavy, USACE typically does not have enough funding for the additional advance maintenance volumes.

## 1.4 USACE MAINTENANCE DREDGING BUDGET PROCESS AND PRIORITIZATION

The USACE has a 3-year budget process for its operations and maintenance program. Year 1 consists of development of the budget within USACE. In Year 2, Congress reviews and appropriates the budget. In Year 3, USACE spends that portion of its Year 1 budget request that has been appropriated by Congress. For example, in spring of 2014, USACE was developing its Fiscal Year (FY) 2016 budget, Congress was reviewing the FY 2015 budget, and USACE was spending the FY 2014 budget.

Various factors are weighed in determining which channels receive funding. Value to the nation in terms of tonnage is considered. In recent years, because of federal budget constraints, Congress has focused appropriation of funding on the highest value projects. In 2012, of 1,067 federally maintained navigation projects nationwide, only 41 received full funding and only 159 projects received partial funding, including 59 high-use projects and 100 moderate-use projects.

Increasing federal fiscal constraints makes maintaining the San Francisco Bay federal navigation channels to their regulatory depths more challenging for USACE. The majority of the San Francisco District's maintenance dredging budget is allotted to high-use annually maintained projects: Oakland Harbor, Richmond Harbor, Pinole Shoal, Suisun Bay Channel and New York Slough, and the Main Ship Channel. Although the San Francisco District has seen an increase in its total maintenance dredging budget over the past decade, the costs of maintenance dredging have also increased. Beginning in 2009, the San Francisco District has only received 32 to 38 percent of its annual maintenance dredging funding needs.

To maximize the effectiveness of its reduced budget nationally (i.e., complete more dredging with appropriated funds), USACE has attempted to increase the use of government-owned hopper dredges in its fleet, as opposed to increasing the use of commercial hopper and clamshell dredges. Government hopper dredges are, on average, 15 to 25 percent less costly than equivalent commercial hopper dredge

---

<sup>8</sup> Overdepth dredging is only allowed in areas where sediment is present above the project regulatory depth.

equipment. Also, analysis completed by the San Francisco District indicates the government-owned hopper dredge Essayons can dredge certain channels in San Francisco Bay at approximately one-third the cost of a clamshell dredge.

The USACE also has a process for reprogramming (or transferring) funds appropriated to other operations and maintenance projects. For reprogramming to occur, the USACE must first identify a project with excess funds to serve as the donor project. Congressional approval is typically required for the reprogramming of funds to occur. It is not typical that projects have excess funds available for reprogramming.

## **1.5 LOCATION AND DESCRIPTION OF FEDERAL NAVIGATION CHANNELS AND PLACEMENT SITES**

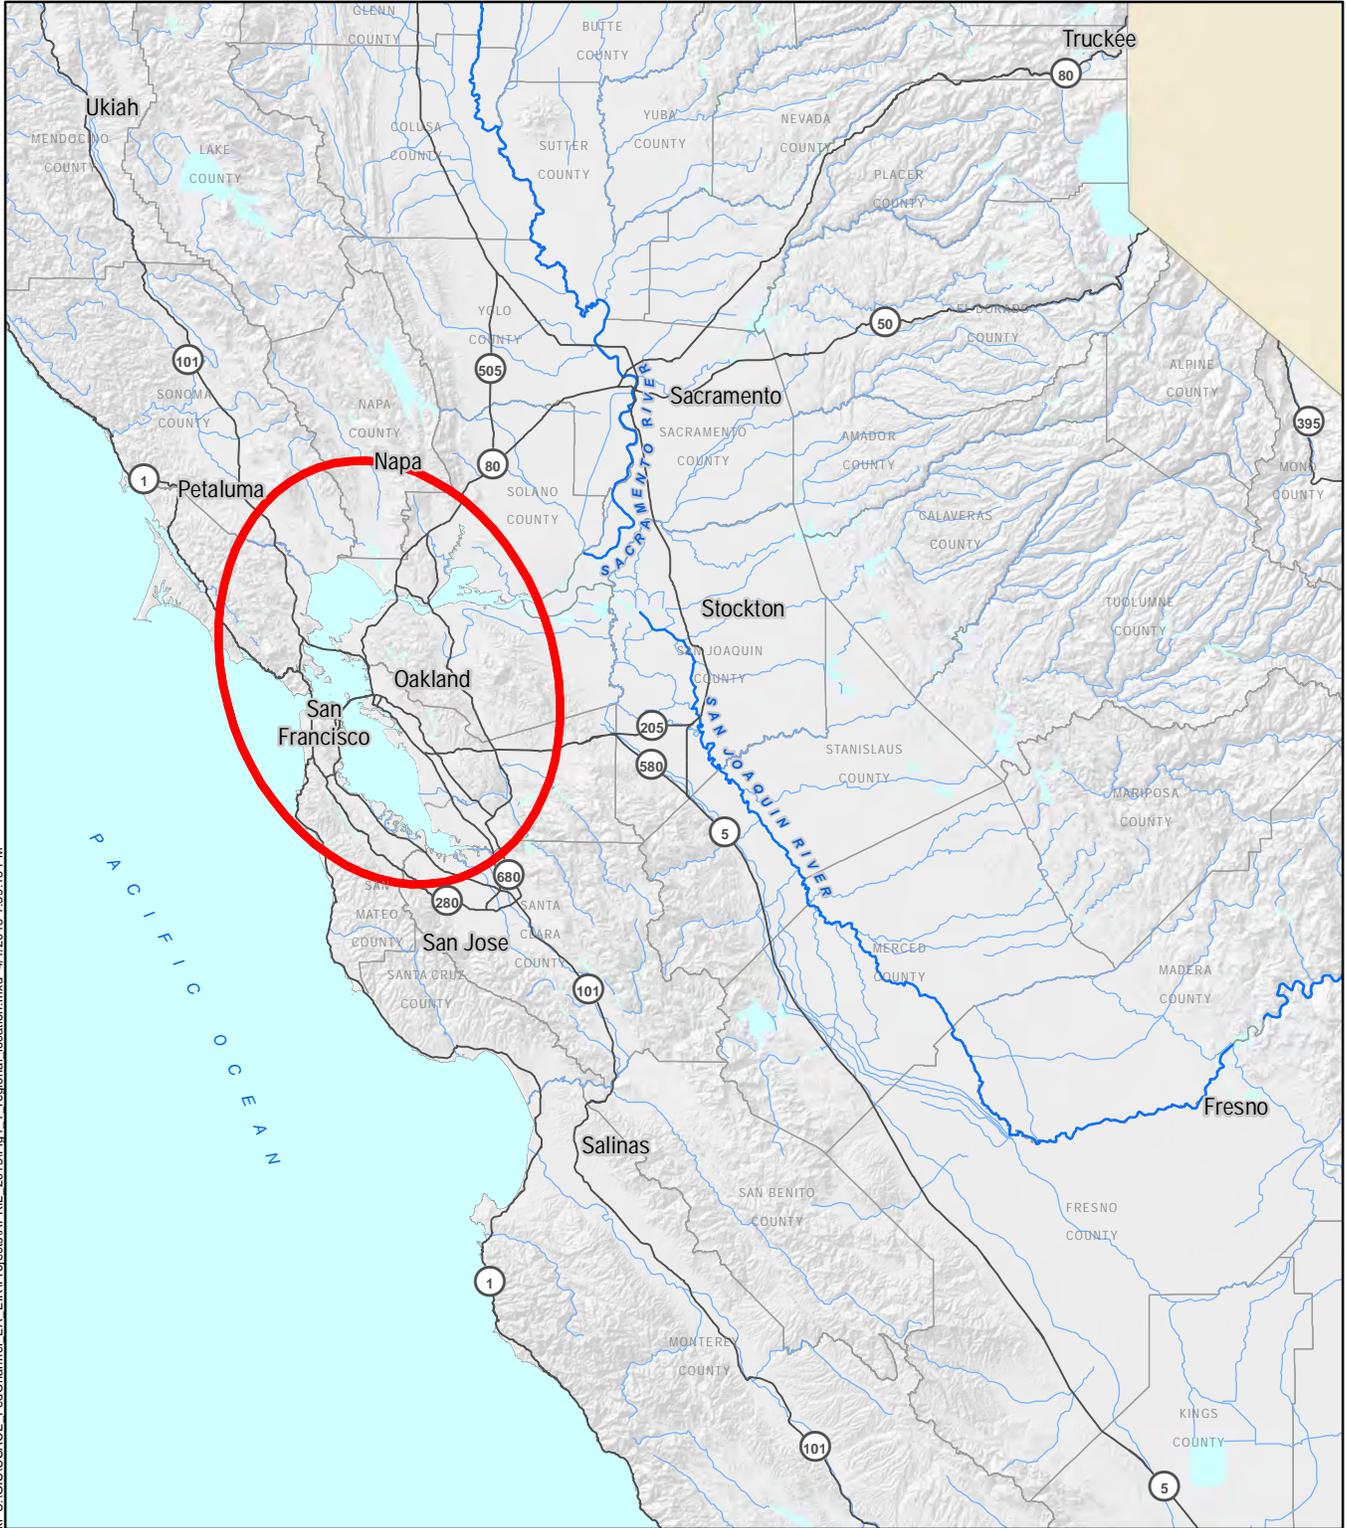

### **1.5.1 Regional Context**

The San Francisco Bay/Delta Estuary (Figure 1-1) is one of the critical maritime thoroughfares in the nation, supporting international trade, commercial and recreational fishing, and recreation. For over a century, navigational channels were created, deepened, and maintained by dredging to enable ships to navigate safely into and out of ports, harbors, and marinas without running aground. A vital USACE mission is to provide a safe, reliable, and efficient waterborne transportation system (federal channels, harbors, and waterways) for the movement of commerce, national security, and recreation. Successfully accomplishing this mission, which requires maintaining the federal channels to their regulatory depths, is critical to the region's maritime trade and to the regional and national economies. In 2010, approximately 63 million tons of commodities, valued at approximately \$68 billion, moved through the federal channels in San Francisco Bay. Dredging the region's channels, ports and associated docking, and berthing and other facilities will continue to be necessary to maintain adequate depths for vessels to maneuver in a safe and efficient manner.

### **1.5.2 Description of USACE Maintained Federal Navigation Channels**

The USACE's maintenance dredging program provides for annual maintenance of six federal channels in the San Francisco Bay Area. The total authorized surface area of these federal channels is 4,866 acres, which is 1.98 percent of the total surface area of San Francisco Bay. There are eleven federal channels in total in San Francisco Bay. They include the six channels dredged annually, and five channels with non-annual dredging cycles, and have a combined surface area of 5,699 acres, which is 2.22 percent of the total surface of San Francisco Bay.

The USACE's Congressionally-authorized maintenance dredging projects in San Francisco Bay are shown on Figures 1-2 and 1-3, and are described below. As further described in Chapter 2, elements of these dredging projects make up USACE's proposed project. Each authorized project comprises individual components, such as channels and turning basins. In general terms, a channel is a deeper course through a river, bay, or other water body. A navigational channel is a deeper channel cut into a river, bay, or other water body to enable vessels to pass through to a port or other destination. Channels are characterized as shallow draft (i.e., equal to or less than 15 feet deep) or deep draft (i.e., greater than 15 feet deep). A turning basin is a wider area of water at the end of a channel to permit vessels to turn around or to enable long barges in a channel to turn a sharp corner.

**STUDY AREA**

Federal Navigation Channels EA/EIR  
U.S. Army Corps of Engineers  
Bay Area, California

April 2015

**FIGURE 1-3**

Table 1-1 provides the authorized or regulatory dimensions,<sup>9</sup> type of dredge equipment commonly used, dredging cycle (i.e., frequency of dredging), last fiscal year the project was dredged, and the historic dredged material placement site for each project. Placement sites are described in Sections 1.4.3 and 1.4.4. General descriptions of dredging and disposal practices are presented in Section 2.3.1.

Whether or not dredging is needed at a given site is dependent on shoaling; whether or not dredging is executed is dependent on funding. Shoaling is not constant. Different areas of San Francisco Bay will experience sedimentation at different rates, and sedimentation in any one area will be different from year to year. Similarly, costs and funding for USACE's maintenance dredging program may vary annually. Nationwide, costs for dredging and dredged material management have increased in recent years. USACE's Navigation Construction Index (i.e., measure of cost escalation) has increased by approximately 70 percent since 2000 (LTMS, 2013b), but the cost evaluation conducted for the LTMS 12-year review process did not identify clear patterns or causes for specific costs incurred in the San Francisco Bay Area. For example, USACE's overall costs for contract dredging have followed a trend similar to the national pattern, but there is great variability in costs from project to project, and even from year to year on the same project. Every dredging project has different challenges that can affect cost. Typical issues that can affect cost for any dredging project include design depth; project volume; dredging equipment type; dredge timing; local constraints (such as the ability to work 24 hours per day); competition issues (including equipment availability); distance to disposal or placement sites; and any offloading or placement site costs. A host of other project-specific issues may also be relevant, including, but not limited to, whether sediment rehandling would be involved; special dredging techniques or equipment are needed (e.g., for contaminated sediment or when dredging adjacent to sensitive resources); compensatory mitigation is required (such as when eelgrass is destroyed or take of special status species would occur); or contractors demand a premium for last-minute projects (LTMS, 2013b). Budget availability often affects how early in the dredging window a project can start. Therefore, although USACE's maintenance program includes prescribed dredging cycles for each channel, it is difficult to predict the frequency of dredging for all projects.

## Richmond Harbor

Richmond Harbor consists of the Inner Harbor and Outer Harbor. Construction of the federal channel in Richmond Inner Harbor was authorized by the Rivers and Harbors Act of 1917, as amended. Construction of the Outer Harbor was authorized under the Rivers and Harbors Act of 1935, as amended. The Port of Richmond is the nonfederal sponsor<sup>10</sup> for the Richmond Harbor project.

Richmond Outer Harbor is on the eastern side of central San Francisco Bay within the boundaries of Contra Costa County, with the exception of the Southampton Shoal Channel, which is predominately in San Francisco County. Project maintenance provides for annual dredging of the Outer Harbor Channel 600 feet wide to a depth of 45 feet mean lower low water (MLLW), from Southampton Shoal in central San Francisco Bay to the Richmond Long Wharf, including the Maneuvering Area. Richmond Outer Harbor was last deepened in 1965 to 45 feet MLLW. Richmond Outer Harbor provides deep-draft navigation access to the Richmond Long Wharf and Port of Richmond marine terminals. Deep-draft tankers use the harbor for loading and off-loading petroleum products at the Chevron Long Wharf facility. Last dredged in 2014, Richmond Outer Harbor is typically dredged annually using a hopper dredge, although bucket-clamshell equipment has been used on occasion. Dredged material from the Outer Harbor has typically been less than 80 percent sand, and placed at the Alcatraz Island placement site (SF-11).

<sup>9</sup> Authorized dimensions are the depth and width of the channel authorized by Congress to be constructed and maintained by USACE. These authorized channel dimensions are generally based on maximizing net transportation savings.

<sup>10</sup> The non-federal sponsor is responsible for obtaining the non-federal share of project costs.

Indicates dredge project location that will not be dredged by USACE in the planning horizon of this EA/EIR								

The Richmond Inner Harbor (Figure 1-4) is on the eastern side of central San Francisco Bay within the boundaries of Contra Costa County. The Inner Harbor consists of the Inner Harbor Entrance Channel, Inner Harbor Approach Channel, and Santa Fe Channel. Project maintenance provides for annual dredging of the Inner Harbor Entrance Channel 600 feet wide to 38 feet MLLW to Point Richmond; the Inner Harbor Approach Channel 500 feet wide to 38 feet MLLW to a 1,260-foot-diameter turning basin at Point Potrero, and then 850 feet wide to 38 feet MLLW to the Santa Fe Channel; and the Santa Fe Channel, which is 200 feet wide and 30 feet MLLW deep. Richmond Inner Harbor was last deepened in 1998. The current depth of the entire Inner Harbor is 38 feet MLLW, with an allowable overdepth of 2 feet; the Inner Harbor has not previously been dredged to—nor is it maintained at—its federally authorized depth of 41 feet MLLW. The Inner Harbor Channel provides commercial navigation access to privately owned and City of Richmond-owned marine terminals, including the Point Potrero Marine Terminal. Richmond Inner Harbor, with the exception of the Santa Fe Channel, is typically dredged annually using clamshell-bucket equipment. Richmond Inner Harbor was last dredged in 2014, except for the Santa Fe Channel, which has not been dredged since 1999. Dredged material from the Inner Harbor has typically been less than 80 percent sand, and placed at SF-DODS and SF-11. The Santa Fe Channel is not anticipated to be dredged within the planning horizon (i.e., 2015 through 2024), and therefore is not a part of the proposed project, and not addressed in this EA/EIR.

### **San Francisco Harbor – Main Ship Channel (Bar Channel)**

San Francisco Harbor consists of a deep-draft navigation channel (the Main Ship Channel) immediately offshore San Francisco Bay on the San Francisco Bar; and in-Bay components.

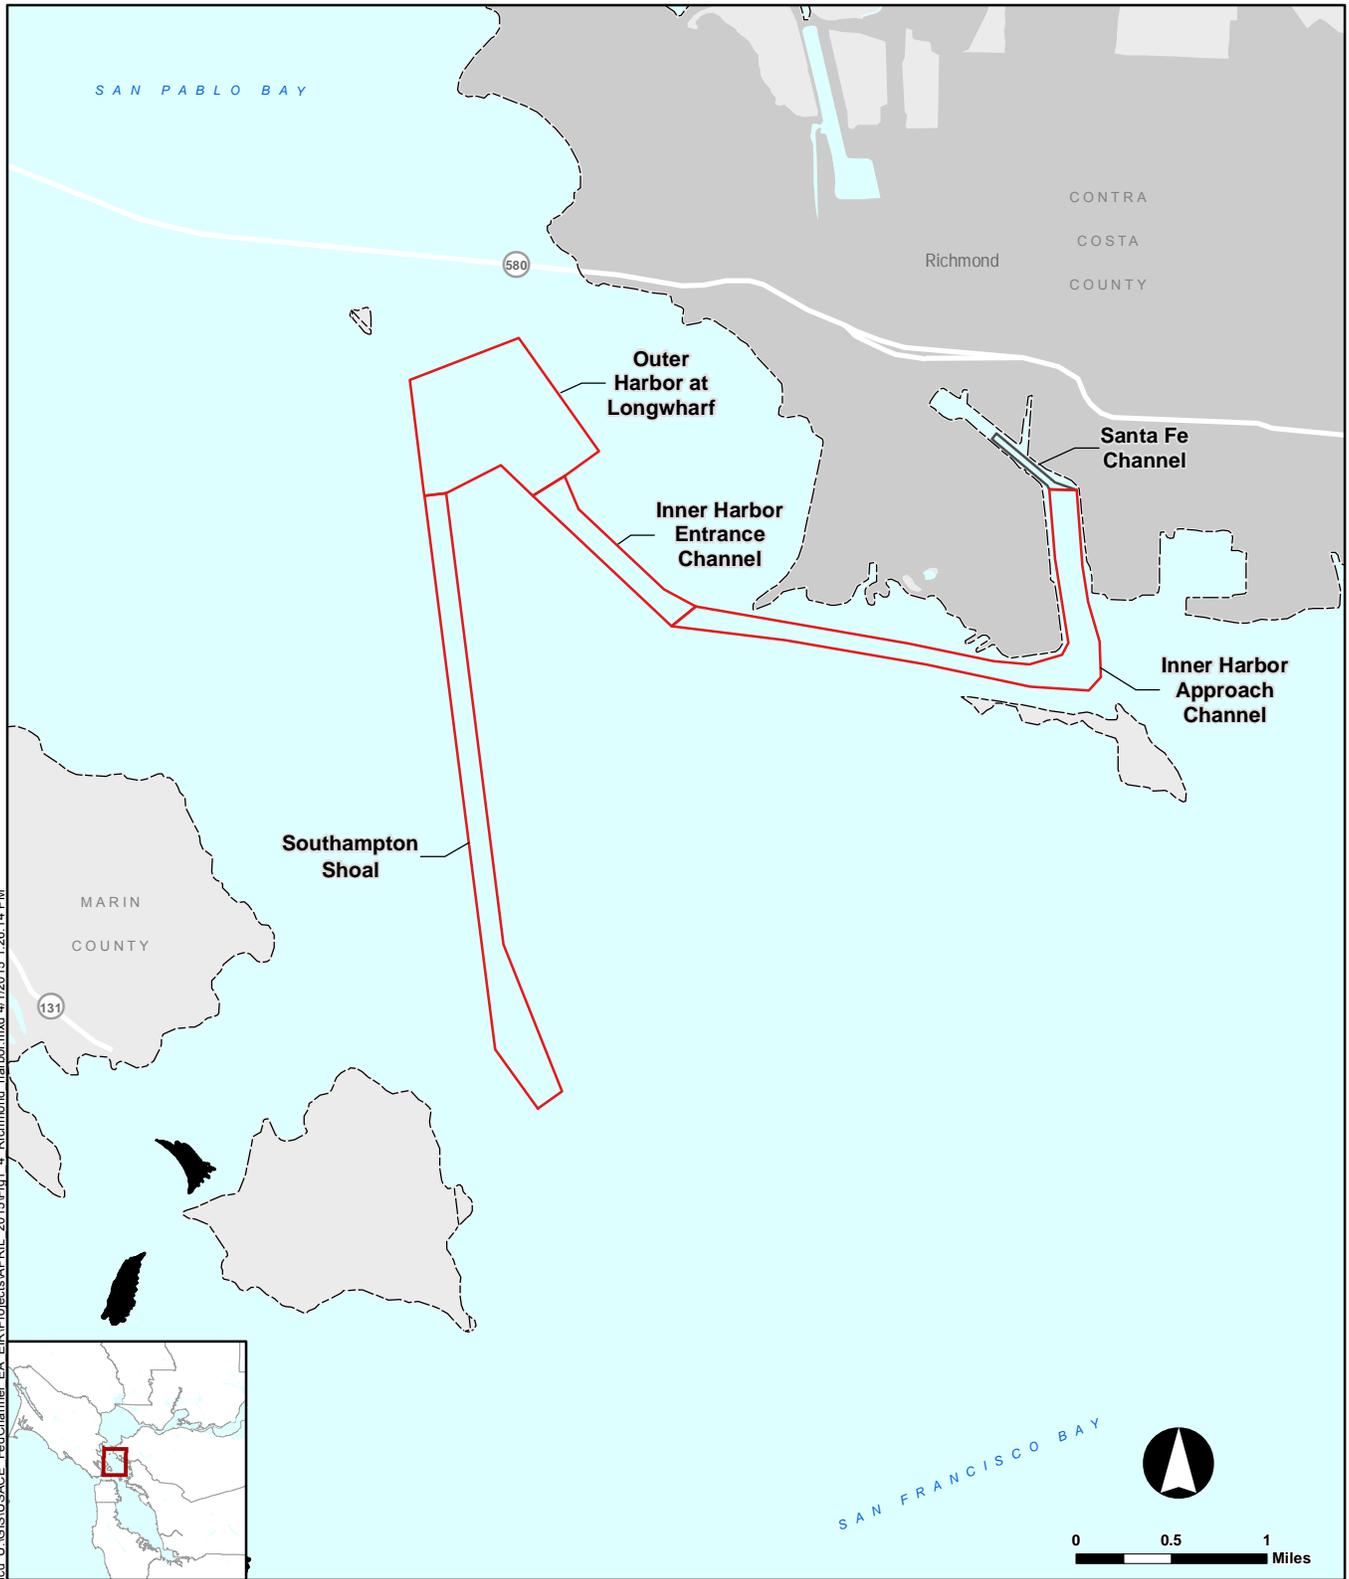

Construction of a federal channel on the San Francisco Bar was authorized by the Rivers and Harbors Act of 1935, as amended, Pub. L. No. 74-409, 49 Stat. 1028 (August 30, 1935). The Main Ship Channel (MSC) was last deepened in 1974. Current project depth is 55 feet MLLW, with an allowable overdepth of 2 feet. As a regional multi-user channel, the MSC does not have a nonfederal sponsor.

The MSC (Figure 1-5) is approximately 5 miles west of the Golden Gate Bridge, and extends across the arc-shaped, submerged, San Francisco Bar in the Gulf of the Farallones. It is approximately 16,000 feet long and 2,000 feet wide. The MSC is the only deep-draft ocean entrance to San Francisco Bay, and is used by all ocean-going shippers to San Francisco Bay and inland ports. It is typically dredged annually, and was last dredged in 2014. The MSC must be dredged with a hopper dredge because it is the only type of dredge that can safely operate at this channel, because of the combination of the depth of the channel and open-sea wave conditions. Even with the hopper dredge, bad weather conditions can preempt dredging of the MSC because of safety considerations. Dredged material from the MSC is greater than 80 percent sand, and has been placed at SF-8 and the nearshore Ocean Beach placement site (SF-17).

In-Bay components of San Francisco Harbor include Marinship Channel in Richardson Bay, Larkspur Ferry Channel, Alameda Point Navigation Channel, Berkeley Marina Channel, Northship Channel, West Richmond Channel, and several shoal areas. These areas are not anticipated to be dredged within the planning horizon, and therefore are not a part of the proposed project, and not addressed in this EA/EIR.

### **Napa River**

The Napa River consists of a downstream reach from Mare Island Strait Causeway to Asylum Slough, and an upstream reach from Asylum Slough to Third Street. This project (Figure 1-6) is a shallow-draft, predominately light commercial and recreational channel. The Rivers and Harbors Acts of August 30, 1935 and July 24, 1946 authorized construction and maintenance of the navigation channel in the Napa River. The Napa County Flood Control and Water Conservation District is the nonfederal sponsor for the Napa River project.

**NAPA RIVER CHANNEL**  
 Federal Navigation Channels EA/EIR  
 U.S. Army Corps of Engineers  
 April 2015  
 Bay Area, California

**FIGURE 1-6**

Project maintenance provides for dredging of the Napa River Channel to a depth of 15 feet MLLW from Mare Island Strait Causeway to Asylum Slough, and to a depth of 10 feet MLLW to the head of navigation at the Third Street Bridge in the City of Napa; the channels were deepened to these depths in 1952. The project is approximately 100 feet wide and 16 miles long. Dredging has historically been conducted using a hydraulic cutterhead dredge. Dredged material from the Napa River has typically been less than 80 percent sand, and placed at the sponsor-provided upland sites. The Napa River is on a 6-year dredging cycle. The Napa River has not been dredged since 1999 because of insufficient funds, and is considered overdue for dredging.

### **Petaluma River**

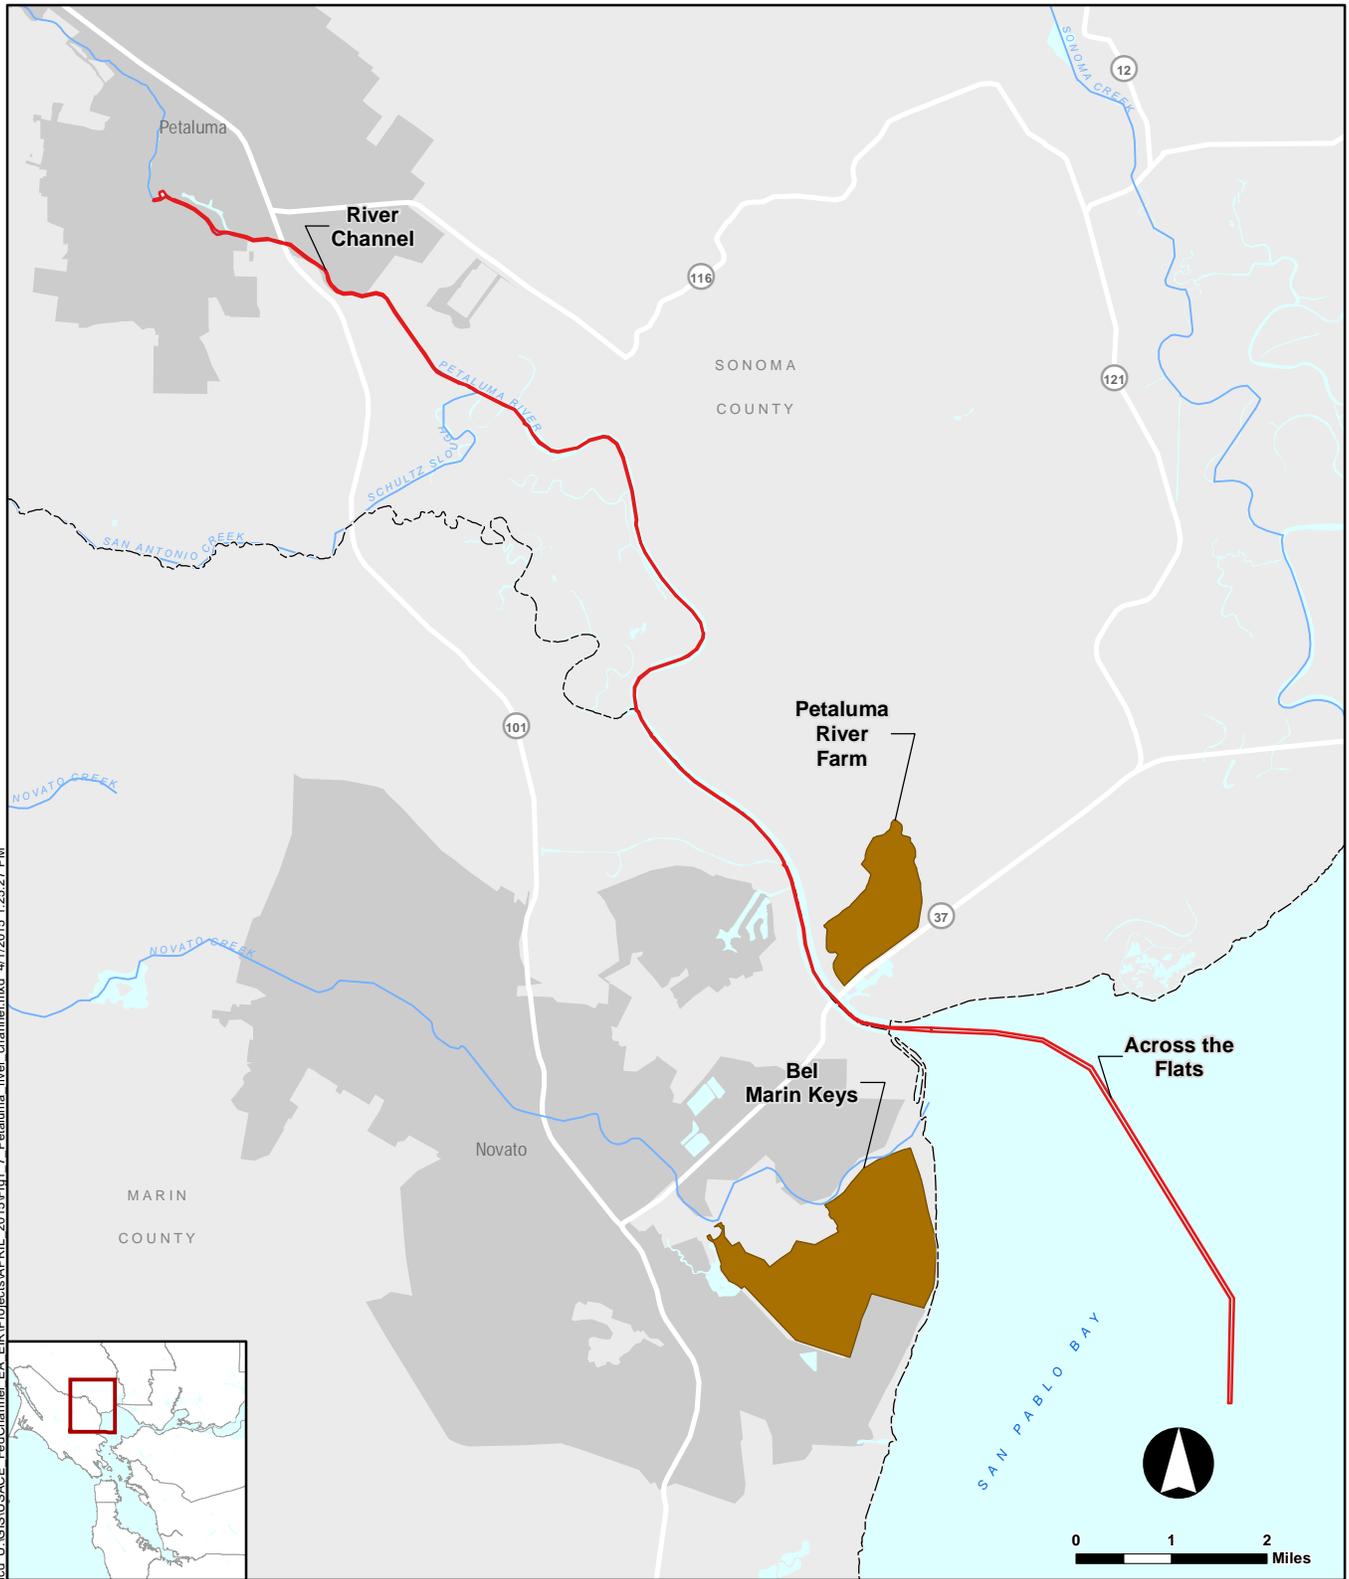

The Petaluma River project consists of two segments: one known as “Across the Flats” starting in San Pablo Bay and going up to the mouth of the river; and another in the river channel. The Petaluma River Channel was authorized by the Rivers and Harbors Act of 1930, as amended. The Petaluma River (Figure 1-7) is in Sonoma and Marin counties, California, on San Pablo Bay. The City of Petaluma is the nonfederal sponsor for the Petaluma River project.

Project maintenance provides for dredging the channel 200 feet wide to a depth of 8 feet MLLW for the Across the Flats segment, and 100 feet wide to 8 feet MLLW thereafter to Western Avenue in Petaluma (River Channel), including a turning basin 300 to 400 feet wide to 8 feet MLLW. Both segments were initially dredged to a depth of 8 feet MLLW in 1933. Dredging has been conducted using clamshell-bucket equipment for Across the Flats, and a hydraulic cutterhead dredge for the upriver channel. Dredged material from Across the Flats has typically been less than 80 percent sand, and placed at the San Pablo Bay placement site (SF-10). Dredged material from the upriver channel has typically been less than 80 percent sand, and placed at sponsor-provided upland sites. The Across the Flats Channel is on a 3-year dredging cycle, and the River Channel is on a 4-year dredging cycle. The Petaluma River Channel has not been dredged since 2003 because of insufficient funds, and Across the Flats has not been dredged since 1998; these areas are considered overdue for dredging.

### **San Rafael Creek**

San Rafael Creek consists of the Across the Flats Channel, Inner Canal Channel, and a 200-foot-wide turning basin near the western terminus of the Inner Canal Channel. San Rafael Creek (Figure 1-8) is north of San Francisco Bay in Marin County. This project is a shallow-draft, predominately light commercial and recreational channel. The existing federal project for the construction and maintenance of the Across the Flats Channel, the Inner Canal Channel, and the turning basin was authorized by the Rivers and Harbors Act of March 2, 1919. The channels were deepened in 1925. The City of San Rafael is the nonfederal project sponsor.

Project maintenance provides for dredging the Across the Flats Channel in San Francisco Bay to the mouth of San Rafael Creek to a depth of 8 feet MLLW (plus 2 feet of allowable overdepth); and 6 feet MLLW (plus 2 feet of allowable overdepth) for the Inner Canal Channel to the head of navigation at the Grand Street Bridge in the City of San Rafael. On average, Across the Flats is dredged every 7 years, and the Inner Canal Channel and turning basin are dredged every 4 years. Across the Flats was last dredged in 2012 to a depth of 5 feet MLLW. The Inner Canal Channel was last dredged in 2011; the turning basin was last dredged in 2003. Dredging has historically been conducted using clamshell-bucket equipment or a hydraulic cutterhead dredge. Dredged material has typically been less than 80 percent sand, and placed at SF-11. In 2002 and 2010, sampling and testing of the shoaled sediment revealed that upstream of Station 175+00 in the Inner Canal Channel, pesticide and PCB concentrations were at levels that are not suitable for in-Bay placement; this material was placed at Winter Island in 2002. Downstream of Station 175+00, the shoaling is relatively “clean,” and deemed suitable for in-Bay placement. Follow-up analysis in June 2011 confirmed that there has been no downstream migration of the contaminated sediment beyond Station 175+00 since the 2010 sampling and testing event.

## San Pablo Bay and Mare Island Strait

The San Pablo Bay and Mare Island Strait project consists of the Pinole Shoal Channel and Mare Island Strait. The Pinole Shoal Channel (Figure 1-9) is in Contra Costa County, in southern San Pablo Bay. The federal Pinole Shoal Channel was authorized by the Rivers and Harbors Act of 1917, as amended. As a regional multi-user channel, the Pinole Shoal project does not have a nonfederal sponsor.

Pinole Shoal Channel provides deep-draft navigation in and through San Pablo Bay, and is an integral part of the San Francisco Bay to Stockton project (i.e., navigation channel). Shipping operations out of the Port of Stockton, Port of Sacramento, Suisun Bay, San Pablo Bay, and Carquinez Strait make the channel a significant waterway. In addition to being a major link in the navigation system to inland ports of Sacramento and Stockton, the Pinole Shoal Channel allows deep-draft access to several oil refineries adjacent in the vicinity of Carquinez Strait. Pinole Shoal Channel is used for commercial traffic, including deep-draft, merchant, and oil tanker vessels. It also provides navigational access for recreational boaters to many marinas and small individual docks.

The San Pablo Bay project provides for maintenance dredging of: (1) a 600-foot-wide channel to a depth of 35 feet MLLW, which is approximately 11 miles long, in San Pablo Bay across Pinole Shoal with a maneuvering area adjacent to Oleum Pier at the mouth of Carquinez Strait (i.e., the Pinole Shoal Channel); (2) a 600-foot-wide channel to 30 feet MLLW through Mare Island Strait, flaring to a turning basin generally 1,000 feet wide, from former dike number 6 to within 75 feet south of the causeway between Mare Island and Vallejo; (3) a channel to 30 feet MLLW up the Napa River, except (4) at the northerly end, at the City of Vallejo Marina, where the project depth is 26 feet MLLW.

The Pinole Shoal Channel is typically dredged annually using a hopper dredge; however, bucket-clamshell equipment has occasionally been used to dredge the channel. Pinole Shoal Channel was last dredged in 2014. The sediment composition of dredged material from Pinole Shoal Channel varies along the channel, with the eastern and western ends of the channel typically being sandy. Dredged material from Pinole Shoal Channel is typically placed at SF-10.

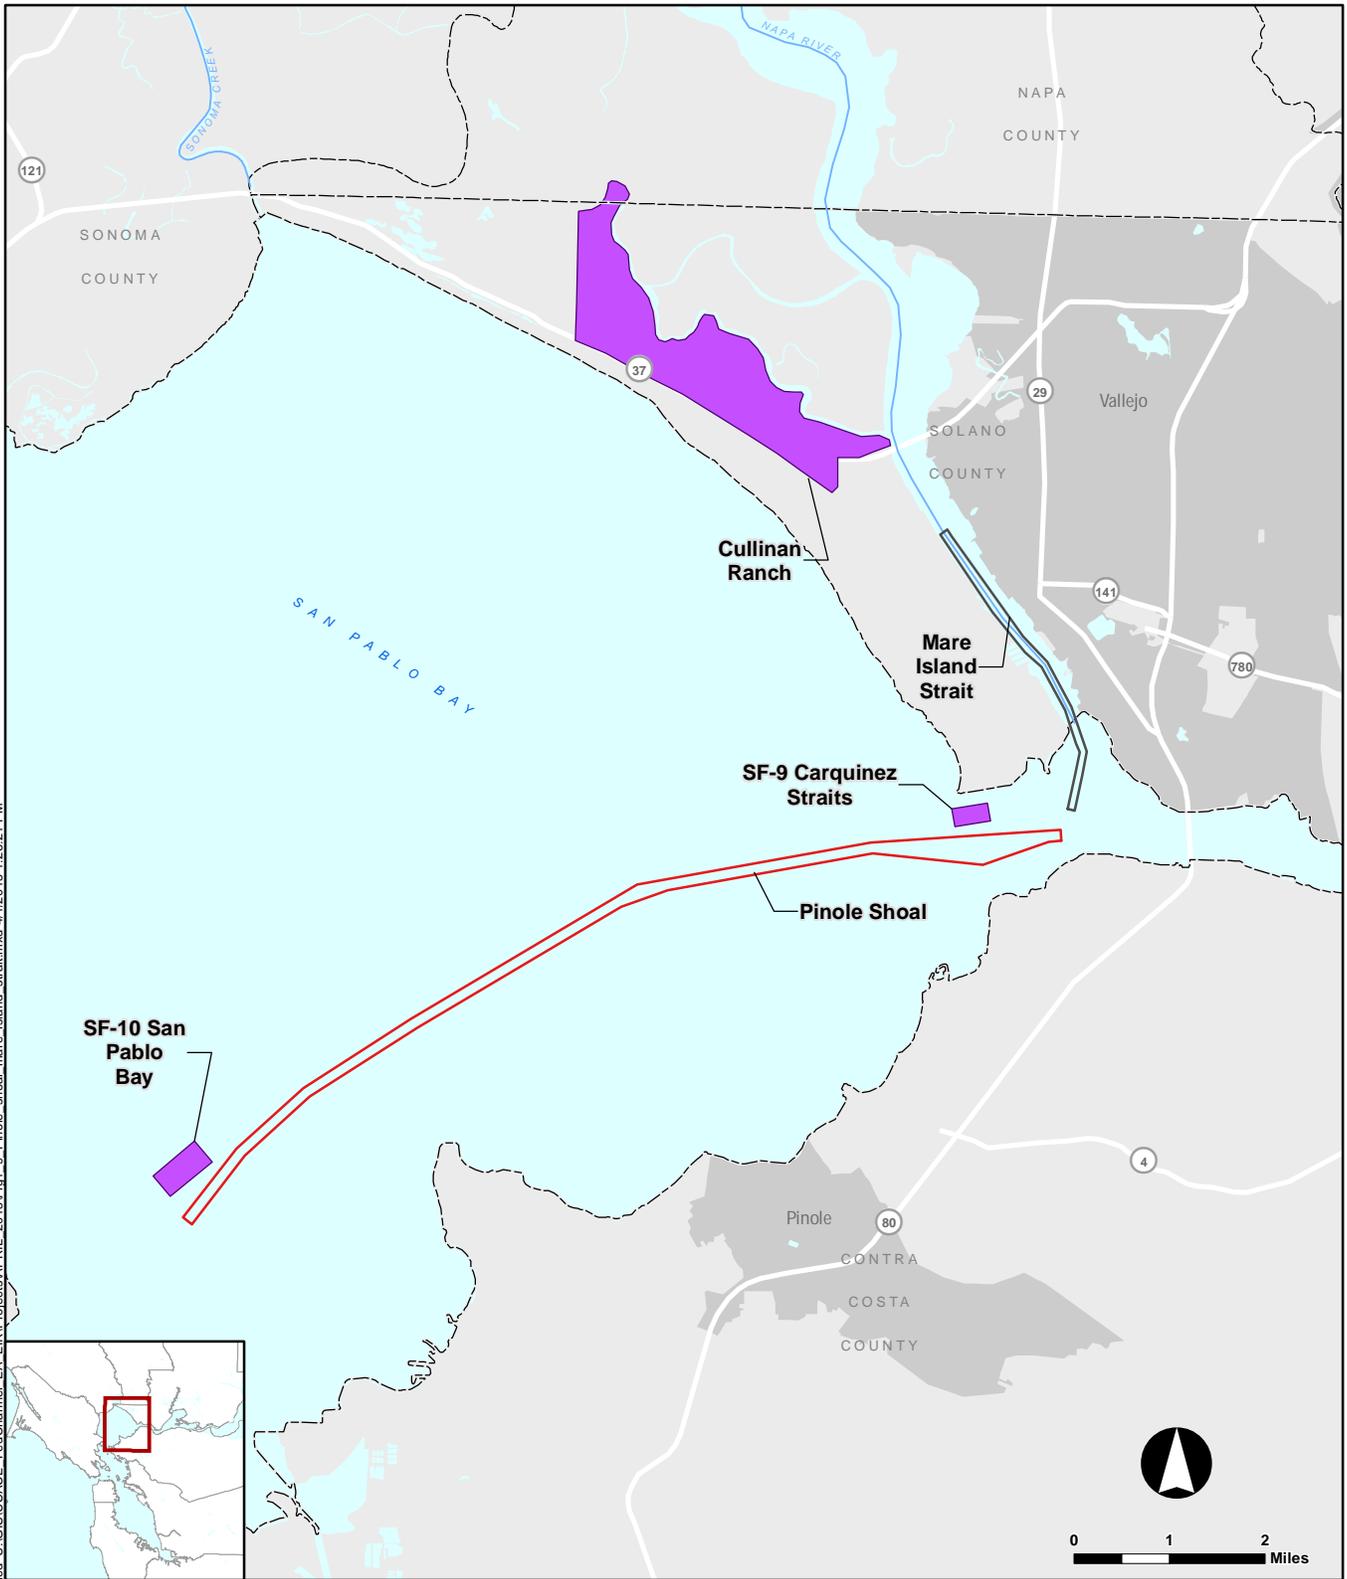

The channel is authorized for a depth of 45 feet MLLW, but is only maintained to a depth of 35 feet MLLW plus 2 feet of allowable overdepth (i.e., total maintained depth of 37 feet MLLW). In 2009 and 2010, USACE conducted 2 feet of advance maintenance in areas that tended to aggressively shoal. This included the southern edge of the channel, between buoy markers 10 and 12; and further east along the northern edge of the channel, starting at buoy marker 11 to just east of buoy 13. The extent of the advance maintenance dredging in these two areas was 200 feet wide and 2 feet deep.

Beginning in 2011, the lower end of Pinole Shoal Channel was slightly realigned to the north. The realigned channel experiences substantially less shoaling than the old alignment, and thus requires less dredging. Since the realignment of the channel, advance maintenance has not been required.

The Mare Island Strait portion of this authorized project is not anticipated to be dredged within the planning horizon, and therefore is not a part of the proposed project, and not addressed in this EA/EIR.

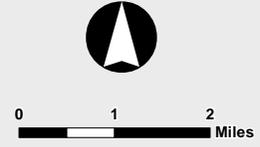

## Suisun Bay Channel and New York Slough

Suisun Bay Channel consists of Bulls Head Reach, Suisun Bay Main Channel, New York Slough, and the South Seal Island Channel. The Suisun Bay Channel (Figure 1-10) is in Suisun Bay, 30 miles northeast of San Francisco, in the counties of Contra Costa and Solano. The Rivers and Harbors Act of 1919 authorized the construction of a federal channel in Suisun Bay. Construction of the New York Slough Channel was authorized by the Rivers and Harbors Act of 1927, as amended. Suisun Bay Channel was deepened to 35 feet MLLW in 1960; Bulls Head Reach and New York Slough were deepened to 35 feet MLLW in 1968. Contra Costa County is the nonfederal project sponsor.

I:\GIS\USACE\_FedChannel\_EA\_EIR\Projects\APRIL\_2015\Fig1\_9\_Pinole\_shoal\_mare\_island\_strait.mxd 4/12/2015 1:26:21 PM

**SUISUN BAY CHANNEL**

Federal Navigation Channels EA/EIR  
 U.S. Army Corps of Engineers  
 Bay Area, California

April 2015

**FIGURE 1-10**

The channel is an integral part of the San Francisco Bay to Stockton project, providing deep-draft access to the Pacific Ocean from the inland ports of Stockton and Sacramento. The 300-foot-wide Main Channel runs 25,000 feet along the southern shore of Suisun Bay through Point Edith and Middle Ground Shoals to the mouth of New York Slough at Pittsburg, and includes Bulls Head Reach, which extends from the Benicia Bridge to the Avon Pier. New York Slough stretches from Pittsburg to Antioch, a distance of approximately 4 miles. The Suisun Bay Channel and New York Slough are maintained to a depth of 35 feet MLLW. The Main Channel and New York Slough are typically dredged annually using a hopper dredge and were last dredged in 2014. Dredged material from Suisun Bay Channel has typically been greater than 80 percent sand, and placed at the Suisun Bay placement site (SF-16) and occasionally the Carquinez Strait placement site (SF-9).

At Bulls Head Reach, past maintenance has included dredging up to 4 feet of advance maintenance material to accommodate rapid shoaling. Because of the variable shoaling rate at this location, this practice is reviewed annually to determine if it remains effective. In the case of Bulls Head Reach Shoal, USACE typically elects to perform advance maintenance every year because that area shoals faster than the annual dredging cycle, and it is essential for USACE to maintain the utility of the channel as long as possible before needing to address any shoaling issues outside of the work window. In recent years, advance maintenance at Bulls Head Reach has reduced USACE's critical dredging episodes outside of the work window.

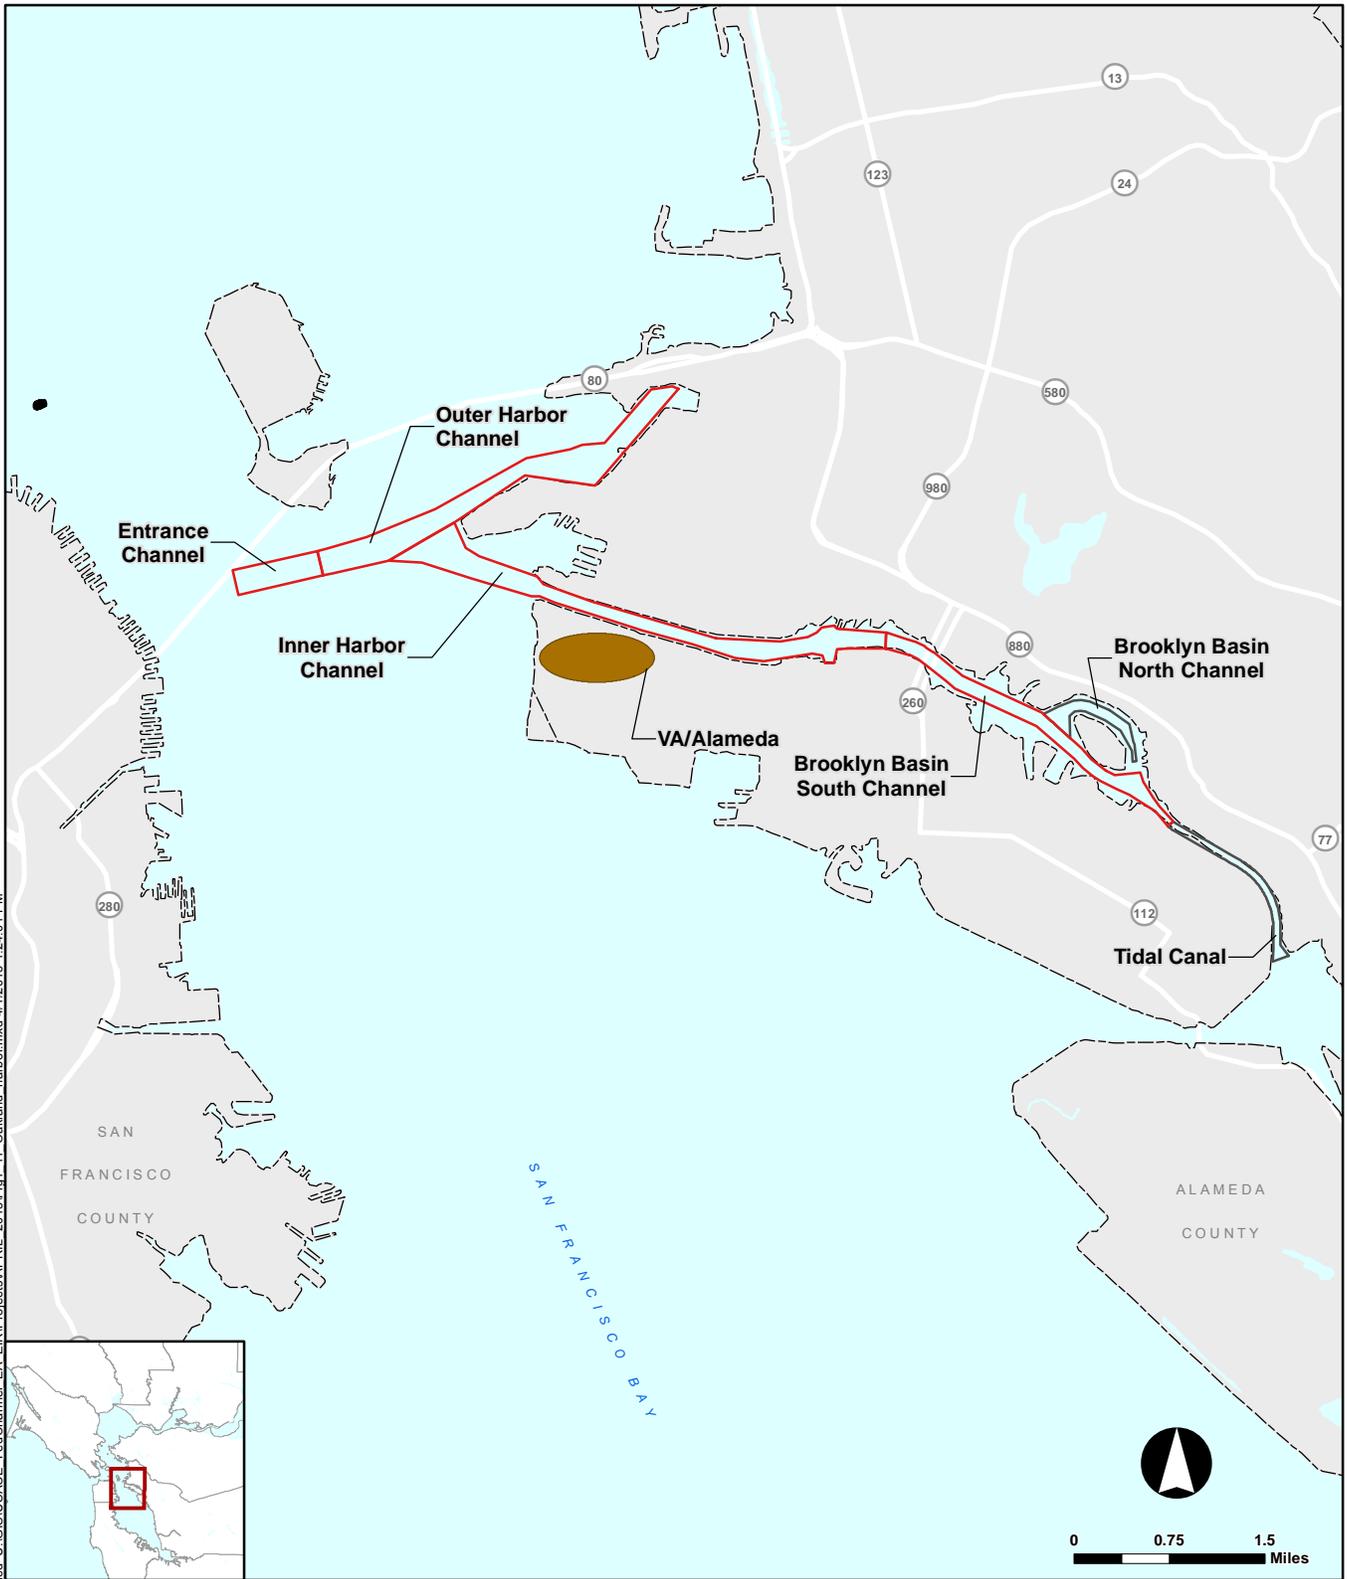

The South Seal Island portion of this project is not anticipated to be dredged within the planning horizon; it therefore is not a part of the proposed project, and not addressed in this EA/EIR.

## **Oakland Harbor**

Oakland Harbor includes the Entrance Channel, Outer Harbor Channel, Inner Harbor Channel, Brooklyn Basin South Channel, Brooklyn Basin North Channel, and Tidal Canal. Oakland Harbor (Figure 1-11) is in the City of Oakland, on the eastern shore of central San Francisco Bay immediately south of the San Francisco-Oakland Bay Bridge. Construction of, improvements to, and maintenance dredging of the federal project were accomplished pursuant to the following authorities: Rivers and Harbors Act of 1910; Rivers and Harbors Appropriations Act of 1917; Rivers and Harbors Act of 1927; Rivers and Harbors Act of 1930; Rivers and Harbor Acts of 1945; Rivers and Harbors Act of 1962; and the Water Resources Development Act of 1986. Deepening of the Entrance Channel, Outer Harbor Channel, and Inner Harbor Channel to 50 feet MLLW was completed early in 2010. The Port of Oakland is the nonfederal sponsor for the Oakland Harbor project.

The Entrance Channel, Outer Harbor Channel, and Inner Harbor Channel are typically dredged annually using clamshell-bucket equipment; these areas were last dredged in 2014. Dredged material from Oakland Harbor has typically been less than 80 percent sand. Prior to 1999, all dredged material from Oakland Harbor was placed at SF-11; since 1999, it has been placed at SF-DODS, Montezuma Wetlands Restoration Project, Hamilton Wetlands Restoration Project and SF-11.

Brooklyn Basin was historically used as a turning basin. It has an authorized depth of 35 feet MLLW. While in use, it required little dredging as a result of the number of ships that used it for turning, which created currents to push sediment out of the area. When the Oakland Channel was deepened to 42 feet MLLW in 1998 and a new turning basin was dredged near Howard Terminal, the use of Brooklyn Basin diminished. The basin has not been used by commercial deep-draft vessels since the Oakland channel was deepened to 50 feet MLLW. As a result, Brooklyn Basin has not required dredging. The primary vessels using the Inner Harbor Channel beyond the Howard Terminal are operated by the U.S. Coast Guard. The U.S. Coast Guard has requested that USACE maintain the Brooklyn Basin South Channel to the authorized depth of 35 feet MLLW in support of the fleet of National Security Cutters. The USACE would dredge Brooklyn Basin based on shoaling and the availability of funding in the 10-year planning horizon.

The North Channel and Tidal Canal portions of the Oakland Harbor project are not anticipated to be dredged within the planning horizon, and therefore are not a part of the proposed project, and not addressed in this EA/EIR.

### **San Leandro Marina (Jack D. Maltester Channel)**

The Jack D. Maltester federally authorized channels are located in the San Leandro Marina, on the eastern shore of South San Francisco Bay, in the city of San Leandro, Alameda County (Figure 1-12). The project includes the Main Access Channel and Interior Access Channel. The City of San Leandro is the nonfederal sponsor for the San Leandro Marina project. Authorization to construct the San Leandro Marina federal channels was provided by Section 201 of the Flood Control Act of 1965, 89 Pub. L. No. 298, and approved by resolution adopted by the Committee on Public Works and Transportation of the House of Representatives on June 22, 1971, and by the Committee on Environment and Public Works of the Senate on December 15, 1970; the authorization was modified by Section 102 of the Water Resources Development Act of 1992. The channels were last deepened in 1965. The authorized project depth is 8 feet MLLW. However, because of the sponsor's inability to contribute the full amount of matching funds required to dredge to authorized depths during the initial deepening project, the channels are federally maintained at depths proportionate to the sponsor's matching funds.

Project maintenance provides for dredging of the 200-foot-wide Main Access Channel to 6 and 7 feet MLLW, and the 140-foot-wide Interior Access Channel to 7 feet MLLW. Last dredged in 2009, these channels are typically dredged every 4 to 6 years using a cutterhead dredge. Dredged material has typically been less than 80 percent sand, and placed at a sponsor-provided upland site.

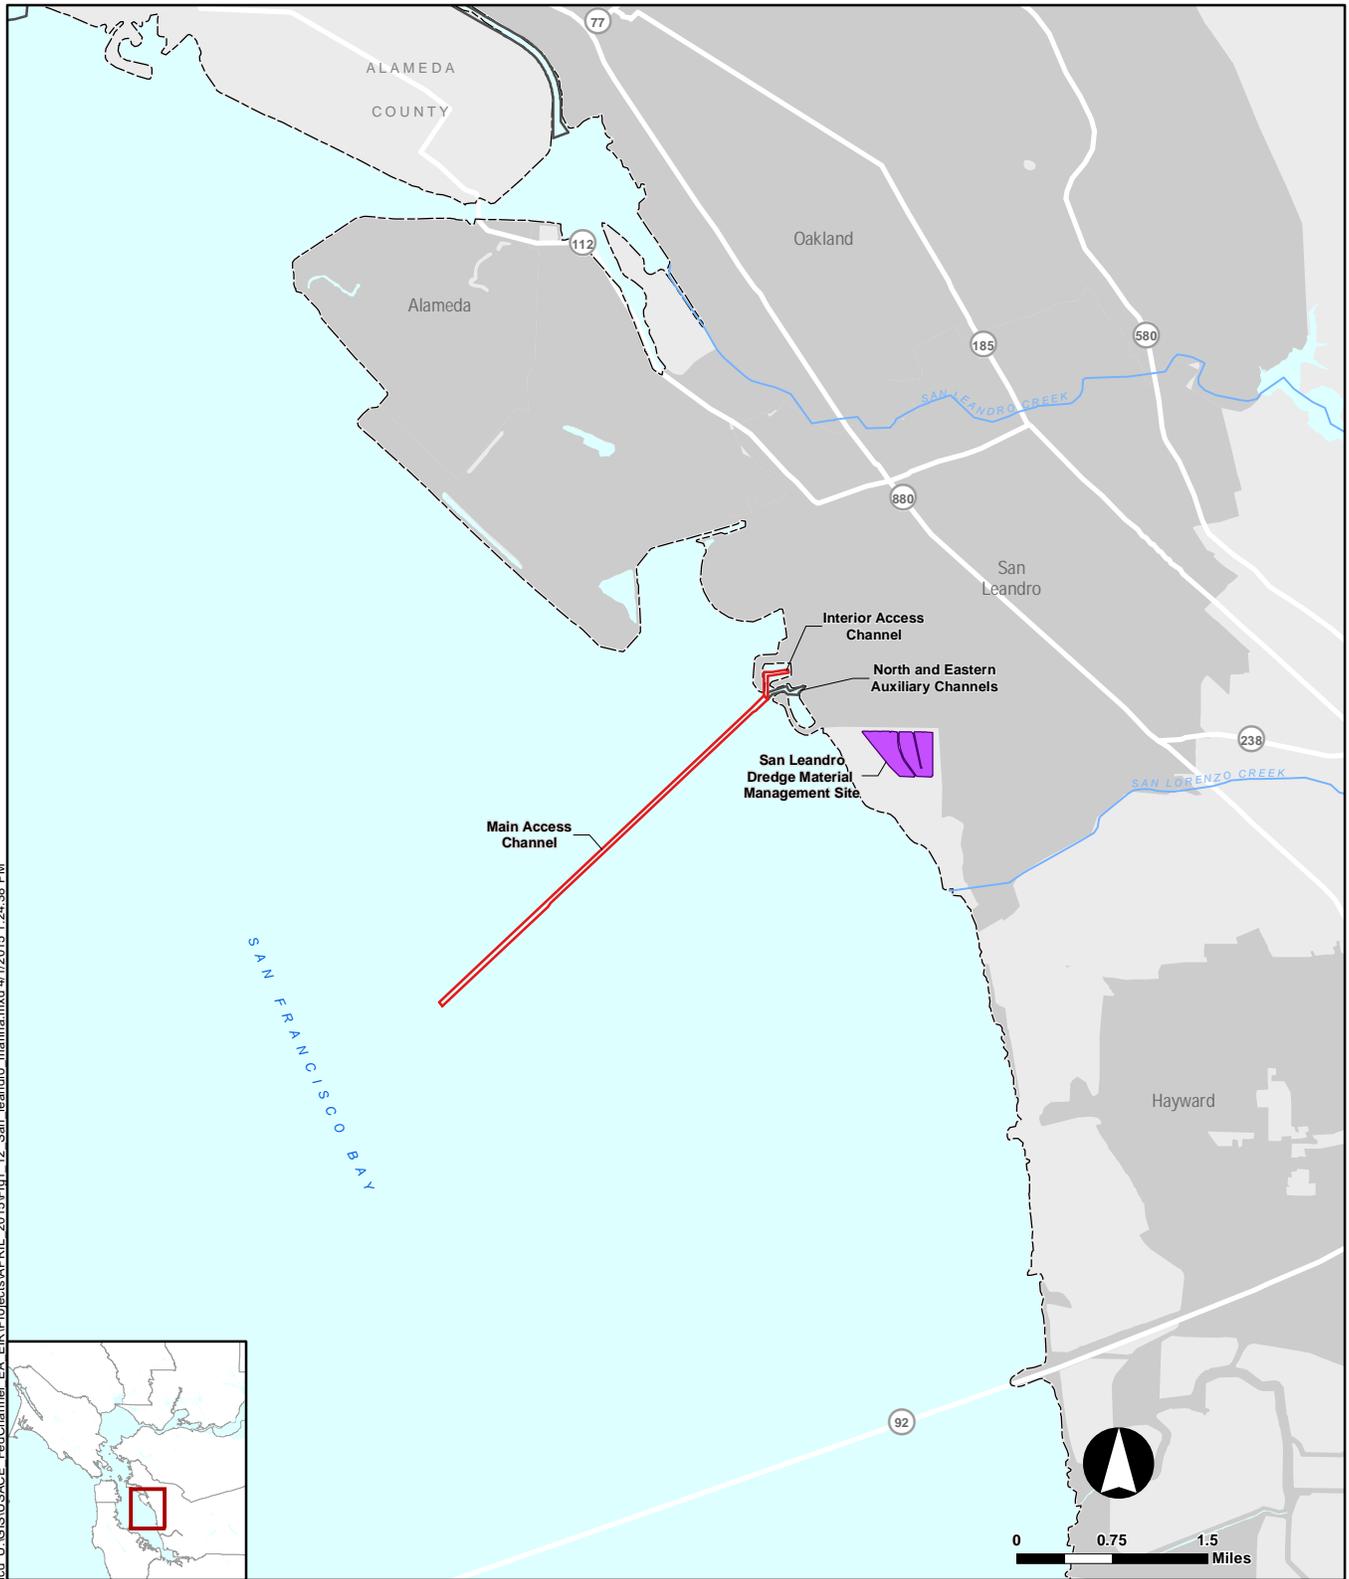

The federally authorized channels provide maintenance access to the 2-mile-long, 8-foot-diameter East Bay Authority sanitary outfall, and provide waterborne search and rescue access to Oakland International Airport. The project area is a designated point of emergency response supporting the combined efforts of the City of San Leandro, County of Alameda, Port of Oakland, and the U.S. Coast Guard Aircraft Accident Readiness Team. In addition, the project provides for recreational boating.

The Jack D. Maltester federally authorized channels originally included the North and Eastern Auxiliary Channels, but these channels were de-authorized in 1992, are not a part of the proposed project, and not addressed in this EA/EIR.

### **Redwood City Harbor**

The Port of Redwood City (Figure 1-13) is approximately 18 nautical miles south of San Francisco on the western side of South San Francisco Bay. It provides deep-draft access to the mid-Peninsula and San Jose metropolitan areas. Redwood City Harbor is situated within the confines of Redwood Creek, and consists of San Bruno Channel, the harbor Entrance Channel, the Outer Turning Basin, Connecting Channel, the Inner Turning Basin, and Inner Channel. The Inner Channel mainly supports recreational craft, and is currently not maintained by the federal government. The federal channels were authorized the Rivers and Harbors Acts of 1884, 1902, 1910, 1930, 1945, and 1950. The Port of Redwood City is the nonfederal project sponsor.

Redwood City Harbor was last deepened in 1962. Project maintenance provides for dredging of the channels and turning basins, which range in width from 300 feet to 900 feet, to 30 feet MLLW. The Entrance Channel, Outer Turning Basin, Connecting Channel, and Inner Turning Basin are typically dredged every 1 to 2 years using clamshell-bucket equipment; these areas were partially dredged in 2014. San Bruno Channel is dredged using a hopper dredge at 10-year intervals or greater, and was last dredged in 2005. Dredged material from Redwood City Harbor has typically been less than 80 percent sand, and placed at SF-11.

## Suisun Slough Channel

Suisun Slough Channel connects the City of Suisun near Fairfield, California to Grizzly Bay, and then to Suisun Bay 30 miles northeast of San Francisco. Project maintenance provides for an entrance channel in Grizzly Bay that is 13 miles long, 200 feet wide, with a depth of 8 feet MLLW, a channel to the head of navigation at Suisun City that is 100 to 125 feet wide, with a depth of 8 feet MLLW, and a turning basin. Last dredged in 1991, this channel is maintained on an infrequent basis. This project is not anticipated to require dredging within the planning horizon, and therefore is not a part of the proposed project, and not addressed in this EA/EIR.

### 1.5.3 Description of Existing Placement Sites

Descriptions of in-Bay, ocean, and beneficial reuse placement sites that are currently being used (and expected to be used under the proposed project) for USACE's maintenance dredging program during the 10-year planning horizon are provided below. The placement sites in this section are already permitted, and/or sites for which the site owners have completed environmental review.

There are costs associated with use of all sites; these costs vary depending on the dredge equipment used, proximity of the dredged channel to the placement site, and any applicable tipping fees. Typically, the federal standard placement site is used; however, dredging contractors may propose to use other permitted upland locations as an alternative to the disposal site or sites identified in a given solicitation for maintenance dredging contracts, as long as the cost of the site is comparable to the cost of the federal standard. All necessary environmental documentation, including regulatory and resource agency review and approvals, must be completed for a site prior to it receiving any dredged material from the federal channels maintained by USACE.

The open-water disposal that occurs at in-Bay and ocean placement sites is considered unconfined, meaning the dredged materials are in direct contact with aquatic environs. Only dredged material determined suitable for unconfined aquatic disposal may be placed at these sites. Open-water disposal sites can be either predominantly nondispersive (i.e., dredged materials largely remain at the placement location), or predominantly dispersive (i.e., dredged materials disperse from the site during placement or over time). With the exception of SF-DODS, all in-Bay and open water placement sites below are considered dispersive (LTMS, 1998). Confined disposal is placement of dredged material in diked nearshore or upland confined disposal facilities so that dredged materials are not in direct contact with aquatic environs. Some beneficial reuse sites, such as Montezuma, may allow for both unconfined and confined placement, as noted below. Open water/unconfined disposal, confined disposal, and beneficial reuse are further described in Section 2.3.1.

The USEPA and USACE jointly regulate dredged material disposal under federal authorities provided by the MPRSA, which is also known as the Ocean Dumping Act, and Section 404 of the CWA. Section 102 of the MPRSA requires USEPA, in consultation with USACE, to develop environmental criteria that must be met before any proposed ocean disposal activity is allowed to proceed. Section 102 also gives USEPA authority to designate ocean disposal sites in and beyond the territorial sea, and directs USACE to use such EPA-designated sites, as opposed to other ocean disposal locations, to the maximum extent feasible (MPRSA Section 102[c] and Section 103[b]). SF-DODS and SF-8 are designated disposal sites under MPRSA Section 102. The Section 404(b)(1) Guidelines for Specification of Disposal Sites for Dredged or Fill Material (40 C.F.R. pt. 320) are applicable to the specification of disposal sites for discharges of dredged or fill material into waters of the United States, and authorize the USEPA and USACE to designate disposal sites. SF-9, SF-10, SF-11, and SF-16 are designated disposal sites pursuant to CWA Section 404. SF-9, SF-10, and SF-11 are available to multiple users, while SF-16 is for use by USACE only. The Ocean Beach nearshore placement site (SF-17) is in the process of being formally designated as a disposal site under Section 404 of the CWA. Under Section 103 of the MPRSA, USACE regulates the transportation of dredged material for the purpose of dumping it into ocean waters. USACE

regulations at 33 C.F.R. § 324.4(b) state, in part, “Applications for permits for the transportation of dredged material for the purpose of dumping it in ocean waters will be evaluated to determine whether the proposed dumping will unreasonably degrade or endanger human health, welfare, amenities, or the marine environment, ecological systems or economic potentialities.”

Sediment testing requirements under the CWA and MPRSA, used to determine the suitability of dredged material for ocean disposal, inland aquatic disposal, or upland/beneficial reuse, are described in Section 1.3.2.

The sites are shown on Figure 1-3. The proposed project’s use of placement sites is described under the description of the alternatives in Chapter 2.

## **In-Bay Placement Sites**

### **SF-9 Carquinez Strait Placement Site**

The SF-9 placement site is a 1,000-foot by 2,000-foot rectangle, approximately 10 to 55 feet deep, 0.9 mile west of the entrance to Mare Island Strait in eastern San Pablo Bay in Solano County (Figure 1-9). Disposal is limited to 1.0 million cubic yards (CY) of dredged material per month and a maximum of 3.0 million CY per year during wet or above-normal water flow years; and 2.0 million CY per year during all other years.

### **SF-10 San Pablo Bay Placement Site**

The SF-10 placement site is a 1,500-foot by 3,000-foot rectangle, approximately 30 to 45 feet deep, 3.0 miles northeast of Point San Pedro in southern San Pablo Bay in Marin County (Figure 1-9). Disposal is limited to 500,000 CY of dredged material per year.

### **SF-11 Alcatraz Placement Site**

The SF-11 placement site is a 1,000-foot-radius circular area, approximately 40 to 70 feet deep, approximately 0.3 mile south of Alcatraz Island in the Central Bay (Figure 1-5). Since at least 1972, SF-11 has been the most heavily used disposal site in San Francisco Bay. Placement is currently regulated at a maximum of 400,000 CY per month from October to April; and 300,000 CY per month from May to September. Disposal is limited to 4.0 million CY of dredged material per year.

### **SF-16 Suisun Bay Placement Site**

The SF-16 placement site is a single-user in-Bay unconfined disposal site reserved for sand dredged from the Suisun Channel and New York Slough projects only. SF-16 is a 500-foot by 11,200-foot rectangle adjacent to the northern side of Suisun Bay Channel, approximately 1 mile upstream of the Interstate 680 Bridge (Figure 1-10). The depth at this site is approximately 30 feet MLLW. Currently, the site is authorized to receive 200,000 CY of dredged sand per year.

## **Ocean Placement Sites**

### **San Francisco Deep Ocean Disposal Site**

Approximately 55 miles (48 nautical miles) west of the Golden Gate Bridge, SF-DODS is the farthest offshore and deepest (8,000 to 10,000 feet) dredged material placement site in the United States. SF-DODS is authorized to receive up to 4.8 million CY of dredged material per year; however since 2000, annual disposal at SF-DODS for all dredging projects in San Francisco Bay, not just the federal navigation channels maintained by USACE, has averaged less than 1 million CY (LTMS, 2013b). From 2006 through 2013, the amount of dredged material placed annually at SF-DODS by USACE ranged

from 0 CY to 1,473,200 CY, and averaged 471,590 CY. Annual monitoring by USACE has confirmed that disposal at SF-DODS has occurred without causing significant impacts to the ocean and the marine biology in and around SF-DODS.

Sediment disposed at SF-DODS can have levels of contaminants slightly above that of sediment disposed at in-Bay disposal sites. Therefore, the LTMS EIS/EIR determined disposal at SF-DODS to be environmentally superior to disposal of the same material at the traditional unconfined disposal sites in the more sensitive San Francisco Bay and Delta Estuary.

### **SF-8 San Francisco Bar Channel Disposal Site**

The SF-8 disposal site is a 15,000- by 3,000-foot-wide rectangle 7,500 feet south of the San Francisco Bar Channel in the Pacific Ocean (Figure 1-5). Depths at SF-8 range from approximately 30 to 45 feet MLLW. Disposal is limited to sandy material dredged by USACE from the San Francisco Bar Channel. However, the easternmost portion of SF-8 is within the 3-mile limit, and sand from other San Francisco Bay Area dredging projects can be permitted there as beneficial reuse for beach nourishment. The trapezoidal portion of SF-8 that is within the 3-mile limit is approximately 3,000 feet long by 430 feet at its northern end; and 1,000 feet wide at its southern end. There is no set limit on disposal at SF-8.

It was expected that sand placed at SF-8 would eventually move shoreward to the surf zone and beach; however, surveys indicate that spreading occurs at a much slower rate than expected. Operation reports from the captain of USACE's hopper dredge *Essayons* state that vessel maneuverability is impaired during times of rough seas because sand is being placed faster than it disperses. Instead of dispersing, sand has mounded and remained on site to the point that safe operation of the *Essayons* (and other large hopper dredges) in much of SF-8 is often restricted or precluded during the rough seas that commonly occur on the San Francisco Bar. Shoaling at SF-8 was unexpected because pre-site-designation studies concluded that the area would be dispersive, meaning that waves would spread the sand at such a rate that accumulation would be minimal. SF-8 remains a placement site option; however, because of this shoaling, USACE limits the use of SF-8 to the extent feasible.

### **SF-17 Ocean Beach Nearshore Placement Site and Ocean Beach Demonstration Site**

The Ocean Beach demonstration site, which is encompassed by the SF-17 placement site, is in waters of the Pacific Ocean adjacent to the south-of-Sloat-Boulevard stretch of Ocean Beach, and outside of the southern section of the San Francisco Bar (Figure 1-5). SF-17's eastern boundary is approximately 0.35 mile offshore from the back-beach bluff; its center is 4 miles southwest of SF-8; and the site's area is 3.3 square miles. Water depths along the shoreward boundary range from approximately 25 to 35 feet MLLW, and depths along the seaward boundary ranges from approximately 37 to greater than 50 feet MLLW. Although SF-8 was established to disperse sandy material dredged from the San Francisco Bar Channel within the littoral cell, sufficient material has not reached the southern reach of Ocean Beach to protect infrastructure from storm damage. The Ocean Beach demonstration site was chosen as a demonstration site because it is in a location where waves can potentially feed sediment toward that reach of Ocean Beach, which may ultimately help mitigate ongoing shoreline erosion in the area that threatens expensive municipal infrastructure, including segments of the Great Highway. SF-17 is in the process of being proposed as a beneficial use placement site for sand, primarily from the MSC (i.e., as an alternative to SF-8).

## **Beneficial Reuse Placement Sites**

### **Cullinan Ranch**

The 1,575-acre Cullinan Ranch Restoration Project is part of the San Pablo Bay National Wildlife Refuge (Figure 1-6). The USFWS operates the site for the purpose of increasing habitat for salt marsh harvest

mouse and Ridgway's rail by restoring diked baylands to historic tidal marsh conditions. The southern property boundary is a naturally formed levee that is the base for State Highway 37. Cullinan Ranch is permitted to restore approximately 290 acres of tidal marsh habitat through the importation of approximately 2.8 million cubic yards of dredged material via an offloading facility temporarily located in the Napa River near its confluence with Dutchman Slough, which will accommodate deep draft barges.

### **Montezuma Wetlands Restoration Project**

The Montezuma Wetlands Restoration Project (MWRP) is a privately owned and operated, approximately 1,800-acre site adjacent to Montezuma Slough in Solano County (Figure 1-10); the owner/operator is Montezuma Wetlands LLC. MWRP has a remaining capacity of approximately 12 million CY. Imported material is being used to create wetlands. The site can accept both cover and foundation quality material (as described in Section 1.3.2). The site has deep-water access, as well as a docking area and dredged material off-loading equipment. The offloading equipment can accommodate most dredged material transport scows with 1,000 CY or greater capacity. Montezuma Wetlands LLC cannot guarantee complete offloading of flat-bottom scows or scows with capacity less than 1,000 CY or, and pocket scows are not allowed at this site.

### **Winter Island**

Winter Island is a privately owned and operated site located at the confluence of the Sacramento and San Joaquin rivers and Suisun Bay in Contra Costa County (Figure 1-10). Dredged material suitable for unconfined aquatic disposal is imported onto the site to re-nourish the island and maintain 5 miles of perimeter levees. Winter Island has the capacity to take up to 200,000 CY of material a year, but only 50,000 CY can be sand.

### **Sponsor Provided Upland Placement Sites**

#### **Imola Avenue, Napa**

The Napa County Flood Control and Water Conservation District's Imola Avenue dredged material beneficial reuse site is in the City of Napa (Figure 1-6) on the eastern bank of the Napa River, at the previous location of the Napa Sanitation District. The accumulated dredged material placed at the Imola Avenue site was used by USACE in 2006 as part of the Napa River/Napa Creek Flood Protection Project. The overall capacity of the Imola Avenue site is 60,000 CY. During placement of dredged materials, any decant water is discharged into Tulocay Creek, which is connected to the Napa River to the west.

#### **San Leandro Dredged Material Management Site**

The City of San Leandro owns and operates the San Leandro Dredged Material Management Site (DMMS), a 100-acre onshore facility used for drying sediment dredged from the San Leandro Marina prior to offsite reuse. The DMMS is south of the Estudillo Flood Control Channel, in the Roberts Landing area of southwestern San Leandro (Figure 1-12). It is bordered on the west by the Monarch Bay Golf Course (formerly Tony Lema Golf Course), and on the south and east by restored tidal and nontidal salt marshlands. The DMMS was first used in 1973 for the management of dredged material from the maintenance dredging of the San Leandro Marina, and Jack D. Maltester approach channel. The site was reconfigured in 1993 according to a management plan approved by Regional Water Board staff. In addition to providing adequate capacity to contain and dry the dredged material for ultimate removal and reuse while meeting water quality criteria, a goal of the reconfiguration of the DMMS is to provide resting habitat for migrating shorebirds during high tide periods in San Francisco Bay, when mudflats used by the birds for foraging are unavailable.

#### 1.5.4 Future Placement Sites

The USACE, Regional Water Board, USEPA, and BCDC have identified the following placement sites as reasonably foreseeable future sites. The sites are shown on Figure 1-3. Because the environmental review process has not been completed for these sites, insufficient information was available on these sites to fully analyze the potential impacts of placing dredged materials at these locations in this EA/EIR. Potential impacts related to use of these sites are disclosed on a broad level in Chapter 3 because these sites may become authorized placement sites within the 10-year planning horizon for this document. Use of these sites by USACE would be conditioned upon the completion of supplemental environmental review under NEPA and/or CEQA, and acquisition of required environmental approvals from resource and regulatory agencies.<sup>11</sup> The ability of USACE to use a given site for placement would be dependent on the accessibility of the site to different dredge equipment; types of dredged materials authorized for placement at the site; cost; and other parameters.

##### **Antioch Dunes**

The Antioch Dunes National Wildlife Refuge, managed by the USFWS, is in the San Francisco Bay-Delta area, along the southern shore of the San Joaquin River (Figure 1-3). The sand dunes on the refuge provide habitat for endangered plants and insects. The refuge accepts dredged material to reconstruct the sand dunes in areas where sand was previously mined down to the clay substrate. The dredged material placement area is approximately 10 acres.

##### **Bel Marin Keys Addition to Hamilton Wetland Restoration Project (Beneficial Reuse)**

The roughly 1,000-acre Hamilton Wetland Restoration Project (HWRP) is 25 miles north of San Francisco in the City of Novato, Marin County, on the western shore of San Pablo Bay (Figure 1-7). The former airfield portion of HWRP stopped accepting dredged material in 2011 and the outboard levees were breached in 2014. The adjacent Bel Marin Keys Unit V site, authorized by the Water Resources Development Act of 2007, would expand HWRP by 1,576 acres, for a total of nearly 2,600 acres of restored wetlands. The Bel Marin Keys Unit V site was converted from salt marsh habitat to agricultural use over the past 150 years. The site would add an additional 13 million CY of capacity for dredged material into wetlands.

##### **Edgerly Island (Sponsor-Provided Upland Site)**

The Napa County Flood Control and Water Conservation District's Edgerly Island dredged material beneficial reuse site is in Napa County (Figure 1-6) on the northeastern side of the island. In 1981, the Napa County Flood Control and Water Conservation District developed a 45-acre wetland mitigation site adjacent to the Edgerly Island disposal site. Dredged materials were placed at the site in 1987 and 1988. In 1994, the dredged material was removed. In 2002, the site was reconstructed by raising the levees and increasing the overall capacity of the site to approximately 330,000 CY. During placement of dredged materials, any decant water would be discharged into Mud Slough, which is connected to the Napa River to the south.

##### **Ocean Beach Onshore Placement (Beneficial Reuse)**

The USACE and City and County of San Francisco, in coordination with Golden Gate National Recreation Area, are evaluating beneficially using sediment from maintenance dredging of the San Francisco MSC for direct beach nourishment at Ocean Beach between Sloat Boulevard and Fort Funston, (Figure 1-4). The proposed beach nourishment project includes the construction of a 4,000-foot-long

---

<sup>11</sup> The USACE would also consider use of other beneficial reuse sites not identified in Section 1.5.4 that may become available by FY 2024, and that have obtained required environmental approvals from regulatory agencies.

sacrificial dune, using approximately 270,000 to 300,000 CY of dredged sand. Placement of material on the beach is contingent upon availability of funds, approvals from applicable resource and regulatory agencies, and the availability of appropriate dredging equipment.

### **Petaluma River Farm**

Petaluma River Farm, previously known as Carneros River Ranch, is in southern Sonoma County, near the mouth of the Petaluma River, approximately 1,500 feet upstream from the State Highway 37 overpass (Figure 1-7). Dredged material would be hydraulically pumped from barges to a portion of the bermed property, where it would be dried, tilled, and subsequently farmed. Because of significant subsidence and the need for raised elevations required to create a root zone above brackish groundwater (to optimize crop production), the site operator estimates that Petaluma River Farm has a potential sediment capacity of approximately 18 million CY.

### **Sherman Island (Beneficial Reuse)**

Sherman Island is one of eight islands in the Delta on which the Department of Water Resources was directed to develop and implement flood protection projects (Figure 1-3). The Sherman Island Demonstration Project began in late 1990 under a permit from the Central Valley Regional Water Quality Control Board, which required an extensive monitoring and testing program.

### **Shollenberger Park (Sponsor-Provided Upland Site)**

The City of Petaluma (the City) purchased this 165-acre ranch along the Petaluma River for the purpose of using it as a dredged materials placement site. In 1975, an agreement was reached between the City and the former California Department of Fish and Game (now CDFW) regarding management of the site. Pursuant to this agreement, the City dedicated, in perpetuity, the 80-acre Alman Marsh for open space and fish and wildlife uses. The City also executed an open-space deed restriction for approximately 65 acres of the dredged material placement site. The City continues to protect and maintain Alman Marsh and the 65-acre area for the agreed upon uses. In 2002, the City began the formal process to continue using the Shollenberger site as a decant area for dredged materials. In response to resource agency requirements pertaining to salt marsh harvest mouse habitat on the site, the City proposed development and implementation of a management, maintenance, and monitoring plan to operate a 48-acre mitigation site adjacent to the dredged materials placement site. The City prepared the Shollenberger Marsh Plan and constructed a berm to separate the mitigation area from the dredged material placement area.

### **South Bay Salt Ponds (Beneficial Reuse)**

The South Bay Salt Pond Restoration Project (Figure 1-13) proposes to convert 15,100 acres of commercial salt ponds at the southern end of San Francisco Bay to a mix of tidal marsh, mudflat, and other wetland habitats. The property was purchased by the State of California and the federal government from Cargill Salt as part of a larger land transaction which includes 1,400 acres of salt crystallizer ponds on the eastern side of the Napa River; construction of the Napa River restoration portion of the project is complete. The acquisition of the South Bay salt ponds provides an opportunity for landscape-level wetlands restoration, improving the physical, chemical, and biological health of San Francisco Bay. The goals of the project are to restore and enhance a mix of wetland habitats, to provide wildlife-oriented public access and recreation, and to provide for flood management in the South Bay.

### **VA/Alameda (Beneficial Reuse)**

The Department of Veterans Affairs Northern California Health Care System and National Cemetery Administration are seeking to establish a single location at the former Naval Air Station Alameda (Figure 1-11) to construct and operate facilities to serve, care for, honor, and memorialize San Francisco

Bay Area veterans. It is anticipated that more than 400,000 CY of fill material would be needed to prepare the site for construction. The development site, in close proximity to the San Francisco Bay and Oakland Inner Harbor Channel, provides an opportunity for beneficial reuse of dredged material.

## **1.6 REGULATORY AUTHORITIES**

Key federal and state laws applicable to the development of this EA/EIR, the proposed dredging and dredged material placement activities, and the protection of aquatic resources are summarized below. Additional details on these laws, as well as other laws governing the protection of environmental resources, are presented in the Regulatory Setting section for each environmental resource topic analyzed in detail in Chapter 3.

### **1.6.1 Federal Laws**

#### **33 C.F.R. pt. 335-338**

Implementation of USACE's maintenance dredging program is governed by 33 C.F.R. pt. 335-338. Part 335 describes the applicable laws and definitions, including the federal standard. Part 336 outlines factors to be considered in the evaluation of USACE dredging projects involving the discharge of dredged material into waters of the United States and ocean waters, including compliance with Section 404(b)(1) of the CWA, and Section 103 of the MPRSA. Part 337 outlines the procedures to be followed in implementing state requirements, emergency actions, and identification and use of disposal sites. Procedures applicable to other USACE activities (e.g., erosion protection along the banks of navigation channels) are addressed in Part 338.

#### **Clean Water Act**

The federal CWA (33 U.S.C. § 1257 et seq.) requires states to set standards to protect water quality. The objective of the federal CWA is to restore and maintain the chemical, physical, and biological integrity of the nation's waters. Specific sections of the CWA control discharge of pollutants and wastes into marine and aquatic environments, as further discussed in Section 3.4.1. Following public review of the Draft EA/EIR, USACE submitted an application to the Regional Water Board for a Section 401 water quality certification.

#### **Coastal Zone Management Act**

The CZMA, established in 1972 and administered by the NOAA's Office of Ocean and Coastal Resource Management, provides for management of the nation's coastal resources through a state and federal partnership. Under the federal consistency provisions of the CZMA, federal projects need to be consistent with the state's coastal zone management program and policies to the maximum extent practicable (16 U.S.C. § 1456); this determination is made by the lead federal agency, and concurrence is requested from the state or local agency responsible for implementing the CZMA. For San Francisco Bay, the BCDC is the state's coastal zone management agency responsible for issuing concurrence with consistency determinations under the CZMA. The San Francisco Bay Plan is BCDC's policy document specifying goals, objectives, and policies for BCDC jurisdictional areas. For portions of the study area outside of San Francisco Bay, concurrence with consistency determinations is issued by the California Coastal Commission. The USACE requests consistency determination concurrence from the BCDC or California Coastal Commission prior to commencing dredging activities. Following public review of the Draft EA/EIR, USACE submitted a CZMA federal consistency determination to BCDC.

## **Endangered Species Act**

Under the federal ESA (16 U.S.C. §§ 1531-1544), all federal agencies shall, in consultation with the Secretary of the Interior or Secretary of Commerce, use their authorities to ensure that any action authorized, funded, or carried out by such agency is not likely to jeopardize the continued existence of any endangered or threatened species, or result in the destruction or adverse modification of habitat determined under the ESA to be critical. The ESA provides a program for conserving threatened and endangered plants and animals, and the habitats in which they are found. It is designed to protect critically imperiled species from extinction. The ESA is administered by the USFWS and the NMFS. In general, NMFS is responsible for protection of ESA-listed marine species and anadromous fishes, while other species are under USFWS jurisdiction. Under the ESA, USFWS and NMFS must authorize the take of listed species, and the federal action agency must implement all reasonable and prudent measures necessary to minimize the impacts of take. As described in Section 1.3.1, programmatic federal ESA consultation was completed for the LTMS (USFWS, 1999; USFWS, 2004a; NMFS 1998). No further ESA consultation is required for USACE maintenance dredging in San Francisco Bay performed within the work windows established through the formal programmatic federal ESA consultations for the LTMS, with the exception of impacts to delta smelt during dredging of Suisun Bay Channel and New York Slough. The USFWS has indicated that a 10-year programmatic biological opinion would not be provided. Rather, it plans to issue annual biological opinions for each year. Therefore, the USACE will request consultation under Section 7 annually, and the USFWS would issue a biological opinion each year prior to maintenance dredging of Suisun Bay and New York Slough. Pursuant to the ESA, any projects proposing deviation from the work windows for federally listed species are required to undergo consultation with NMFS and/or USFWS, as appropriate.

NMFS is revising the 1998 LTMS programmatic biological opinion; the updated biological opinion (expected 2015) will supersede the 1998 document. USACE will comply with the terms and conditions of the updated biological opinion.

## **Magnuson-Stevens Fishery Conservation and Management Act**

The Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) establishes a management system for national marine and estuarine fishery resources. This legislation mandates the identification, conservation, and enhancement of EFH, which is defined as “waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity,” for all managed species. Federal agencies consult with NMFS on proposed actions that may adversely affect EFH. The main purpose of the EFH provisions of the act is to avoid loss of fisheries due to disturbance and degradation of the fisheries habitat. No further EFH consultation is required for USACE maintenance dredging in San Francisco Bay performed in accordance with the provisions established through the formal programmatic federal EFH consultations for the LTMS (USACE and USEPA, 2011).

## **Marine Protection, Resources, and Sanctuaries Act**

The MPRSA is the United States’ implementation of an international treaty, the Convention on the Prevention of Marine Pollution by Dumping of Waste and Other Matter (also known as the “London Convention”). Section 102 of the MPRSA authorizes USEPA to establish criteria for evaluating all dredged material proposed for ocean dumping. These criteria are published separately in the Ocean Dumping Regulations at 40 C.F.R. pt. 220-228. Section 102 also authorizes the USEPA to designate permanent ocean-dredged material disposal sites in accordance with specific site selection criteria designed to minimize the adverse effects of ocean disposal of dredged material. Section 103 of the MPRSA authorizes USACE to issue permits, subject to USEPA concurrence or waiver, for dumping dredged materials into the ocean waters. It requires public notice, opportunity for public hearings, compliance with criteria developed by the USEPA (unless a waiver is granted), and the use of designated sites whenever feasible. Although USACE does not issue itself permits, USACE and USEPA apply these

standards to USACE projects as well. This EA/EIR evaluates the impacts of the ocean disposal of dredged material from USACE-maintained federal navigation channels in San Francisco Bay, and incorporates impact analysis on ocean disposal from the LTMS EIS/EIR (1998).

### **National Environmental Policy Act**

Under NEPA, federal agencies must consider the environmental consequences of proposed major federal actions. The spirit and intent of NEPA is to protect and enhance the environment through well-informed federal decisions, based on sound science. NEPA is premised on the assumption that providing timely information to the decision maker and the public about the potential environmental consequences of proposed actions would improve the quality of federal decisions. Thus, the NEPA process includes the systematic interdisciplinary evaluation of potential environmental consequences expected to result from implementing a proposed action. The CEQ sets forth regulations implementing NEPA. This document is intended to fulfill the requirements of NEPA, the CEQ regulations (40 C.F.R. pt. 1500-1508), and USACE Procedures for Implementing NEPA (Engineer Regulation 200-2-2).

### **Rivers and Harbors Act**

Rivers and Harbors Act refers to a conglomeration of many pieces of legislation and appropriations passed by Congress since the first such legislation in 1824. The Rivers and Harbors Act of 1899 was the first federal water pollution act in the United States. It focuses on protecting navigation, protecting waters from pollution, and acted as a precursor to the CWA of 1972. Section 10 of the Rivers and Harbors Act of 1899 regulates alteration of and prohibits unauthorized obstruction of navigable waters of the United States. Original construction of the federal navigation channels was authorized under the Rivers and Harbors Act, and USACE's maintenance dredging maintains the navigability of the channels in accordance with their authorized dimensions.

## **1.6.2 State Laws**

### **California Endangered Species Act**

The CESA (California Fish and Game Code 2050-2116) operates in a similar fashion to the federal ESA, but is administered by CDFW. Certain species that are federally listed may not be listed on the CESA or vice-versa, or may have a different listing status. Similar to the federal ESA, CESA and the Native Plant Protection Act authorize CDFW to designate, protect, and regulate the taking of protected species in the State of California. Section 2080 of the California Fish and Game Code prohibits the taking of state-listed plants and animals. CEQA lead agencies considering the approval of proposed projects that may adversely impact state-listed threatened or endangered species must consult with CDFW as a trustee agency. There has been no clear and explicit waiver of federal sovereignty with respect to CESA. Accordingly, as a federal agency, USACE is not seeking incidental take authorization or other authorization under CESA. In issuing a WQC, however, the Regional Water Board must comply with CESA. In addition, pursuant to the Porter-Cologne Act and the CWA, the Regional Water Board's environmental review must give consideration to rare and endangered species, as protected by the Basin Plan in the beneficial uses protecting Preservation of Rare and Endangered Species, and Fish Migration. Similarly, in the NEPA significance criteria, USACE must consider special-status species and whether the action threatens the violation of federal, state, or local law or requirements imposed for the protection of the environment (40 C.F.R. § 1508.27[b][9-10]). For these reasons, this document analyzes impacts to species listed under CESA to facilitate issuance of a WQC.

### **California Environmental Quality Act**

The CEQA was closely modeled on NEPA, and requires public agencies to consider and disclose to the public the environmental implications of proposed actions. CEQA applies to all discretionary activities

that are proposed or approved by California public agencies, including state, regional, county, and local agencies, unless an exemption applies. Unlike NEPA, CEQA imposes an obligation to implement measures or project alternatives to avoid or mitigate significant adverse environmental effects, when feasible. When avoiding or mitigating significant environmental impacts of a proposed project is not feasible, CEQA requires that agencies either disapprove of the project, or prepare a written statement of the overriding considerations with approval of such project. Under the direction of CEQA, the California Natural Resources Agency has adopted regulations, known as the Guidelines for Implementation of the CEQA (CEQA Guidelines, California Code of Regulations Title 14, Section 15000 et seq.), which provide detailed procedures that agencies must follow to implement the law. This document is intended to fulfill the requirements of CEQA and the CEQA Guidelines with respect to the Regional Water Board's issuance of a WQC. As a federal agency, USACE is not required to comply with CEQA.

### **McAteer-Petris Act**

The McAteer-Petris Act (California Government Code Section 66000, et seq.), first enacted in 1965, created the BCDC to prepare a plan to protect the San Francisco Bay and shoreline, and provide for appropriate development and public access. The Act directs BCDC to exercise its authority to issue or deny permit applications for placing fill, dredging, or changing the use of any land, water, or structure in the area of its jurisdiction (San Francisco Bay waters and within 100 feet of the shoreline). As stated above, the BCDC also reviews determinations of consistency with the CZMA for federally sponsored projects. The San Francisco Bay Plan, first adopted in 1969, and most recently updated in 2011, is BCDC's policy document specifying goals, objectives, and policies for BCDC jurisdictional areas. Pursuant to the federal CZMA, USACE is required to be consistent, to the maximum extent practicable, with the enforceable policies of the San Francisco Bay Plan.

### **Porter-Cologne Act**

The Porter-Cologne Water Quality Control Act of 1969 (Porter-Cologne Act), and associated regulations found in California Code of Regulations Title 23, establish a comprehensive program for the protection of water quality and the beneficial uses of waters of the state. It addresses both point and nonpoint source discharges, to both surface and ground waters. The State Water Resources Control Board and nine regional water quality control boards are the principal state agencies with primary responsibility for water quality control. The Porter-Cologne Act provides for the adoption of water quality control plans to designate beneficial uses of water, set water quality objectives to protect beneficial uses, and provide for a program to achieve those objectives. The plans may include prohibitions against the discharges of waste or certain types of waste, in specified areas or under specified conditions. The Basin Plan is the San Francisco Bay Regional Water Board's master water quality control planning document. Pursuant to the Porter-Cologne Act and Title 23, the Regional Water Board is authorized to issue WDRs and WQCs (i.e., permits) for activities that may affect water quality. These permits must implement the Basin Plan, the Clean Water Act for point source discharges to waters of the United States, and statewide plans and policies, including, but not limited to, Resolution No. 68-16, "Statement of Policy with Respect to Maintaining High Quality of Water in California," which generally restricts dischargers from degrading water quality. As a federal agency, USACE is not required to apply for WDRs; however, the Regional Water Board may issue WDRs with the WQC.

## **1.7 ADDITIONAL ENVIRONMENTAL COMPLIANCE REQUIREMENTS**

In addition to complying with NEPA and CEQA, USACE and the Regional Water Board, as the lead agencies, are responsible for documenting compliance with relevant federal and state environmental laws and regulations, as well as permit requirements needed to implement the chosen alternative. Table 1-2 lists agencies and their permit and authorizing responsibilities. Coordination with the issuing agencies is discussed below as appropriate.

<b>Table 1-2 Environmental Compliance Requirements</b>	
<b>Permits and Approvals</b>	<b>Agency</b>
Section 404, Clean Water Act	USACE
Section 401, Clean Water Act Water Quality Certification	Regional Water Board
Endangered Species Act Section 7 consultation	United States Fish and Wildlife Service, National Marine Fisheries Service
Essential Fish Habitat consultation; Sections 305(b)(1)(D) and 305(b)(2-4) of the Magnuson-Stevens Fishery Conservation and Management Act	National Marine Fisheries Service
California Endangered Species Act coordination <sup>1</sup>	California Department of Fish and Wildlife
Coastal Zone Management Act Consistency Determination	Bay Conservation and Development Commission
Notes: Regional Water Board = San Francisco Bay Regional Water Quality Control Board USACE = United States Army Corps of Engineers <sup>1</sup> State law that the Regional Water Board is required to comply with, but that USACE is not.	

## CHAPTER 2 ALTERNATIVES

This Environmental Assessment (EA)/Environmental Impact Report (EIR) includes four alternatives for detailed evaluation: the No Action/No Project Alternative, the Proposed Action/Project, and two Reduced Hopper Dredge Use Alternatives. These alternatives are described in Section 2.3. This chapter also describes the alternatives development process and screening criteria, and the alternatives that were considered but not carried forward for detailed evaluation in this EA/EIR.

### 2.1 NEPA AND CEQA REQUIREMENTS FOR EVALUATION OF ALTERNATIVES

Both the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA) Guidelines emphasize the need for an evaluation of a range of alternatives. The federal NEPA lead agency and the CEQA lead agency are responsible for selecting the range of alternatives.

NEPA requires that federal agencies explore and objectively evaluate a range of reasonable alternatives to a Proposed Action to provide a clear basis for choice among options by the decision-makers and the public (Title 40 C.F.R. pt. 1502.14). Project alternatives and the No Action Alternative must be evaluated. The No Action Alternative examines the future without project conditions; that is, the future if the Proposed Action is not implemented. The No Action Alternative is used as a point of comparison for the action alternatives, providing a baseline against which the impacts of pursuing a particular action may be compared with the consequences of taking no action, and thereby requires decision-makers to consider not moving ahead with any action.

The CEQA Guidelines (Section 15126.6[c]) state that an EIR should briefly describe the rationale for selecting the alternatives to be discussed; identify any alternatives that were considered by the lead agency but were eliminated as infeasible; and briefly explain the reasons underlying the lead agency's determination.

The CEQA Guidelines (Section 15126.6) require that an EIR “describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects.” Every conceivable alternative does not need to be considered, but a reasonable range of potentially feasible alternatives should be considered to foster informed decision-making and public participation. Similar to NEPA, CEQA requires analysis of the No Project Alternative in an EIR to allow decision-makers to compare the impacts of approving a project against the impacts of not approving a project.

The range of alternatives required to be evaluated in an EIR is governed by a “rule of reason” that requires the EIR to consider only those alternatives necessary to permit a reasoned choice. The EIR need examine in detail only those alternatives that the lead agency determines could avoid or substantially reduce a potentially significant impact of the proposed project while feasibly attaining most of the basic project objectives, taking into account factors that include site suitability; economic viability; availability of infrastructure; general plan consistency; other plans or regulatory limitations; jurisdictional boundaries; and whether the proponent can reasonably acquire, control, or otherwise have access to an alternative site (CEQA Guidelines Section 15126.6[f]).

Consistent with NEPA regulations and the CEQA Guidelines, United States Army Corps of Engineers (USACE) and the San Francisco Bay Regional Water Quality Control Board (Regional Water Board) considered a range of alternatives that: 1) could feasibly attain most of the basic project objectives; and 2) would avoid or substantially lessen any of the potentially significant impacts of the project.

## 2.2 ALTERNATIVES DEVELOPMENT AND SCREENING PROCESS

One of the most important aspects of the environmental review process is the identification and assessment of reasonable alternatives that could potentially avoid or minimize the impacts of a project. The USACE and the Regional Water Board formulated a reasonable range of alternatives that would achieve the specific project objectives through consideration of the following:

- Changes in environmental resource conditions in the study area and the regulatory setting since the publication of the Long-Term Management Strategy (LTMS) Final Environmental Impact Statement/EIR;
- Input from regulatory agencies; and
- Comments received during the public scoping process.

The USACE and Regional Water Board engaged regulatory agencies early in the planning process to obtain input on the development of alternatives. Regulatory agencies were invited to participate in an alternatives development workshop on February 20, 2013. The meeting was attended by representatives of USACE, the Regional Water Board, the United States Environmental Protection Agency, the United States Fish and Wildlife Service (USFWS), the California Department of Fish and Wildlife (CDFW), and the San Francisco Bay Conservation and Development Commission. Discussion at the workshop focused on potential modifications to USACE's equipment use and dredging operations that could be considered in the development of alternatives.

The USACE and Regional Water Board used an assessment framework matrix to refine possible alternatives. The matrix included various equipment, operation, timing, and placement options for each dredge location. Once all the options were identified, a range of alternatives was generated by selecting from the options available for each channel.

Under NEPA, USACE is required to consider in detail a range of alternatives that is considered "reasonable," usually defined as alternatives that are realistic (not speculative), technologically and economically feasible, and that respond to the purpose of and need for the Proposed Action. Similarly, CEQA requires a "reasonable range" of alternatives that is feasible and that satisfies most of the project sponsor's objectives. Section 15126.6(f)(1) of the CEQA Guidelines states that factors to be considered when addressing the feasibility of alternatives are site suitability, economic viability, availability of infrastructure, general plan consistency, other plans or regulatory limitations, and jurisdictional boundaries.

Alternatives considered by USACE and the Regional Water Board, along with those suggested by the public during the scoping process, were evaluated using the following criteria:

- Does the alternative fulfill the purposes, needs, and objectives identified in Chapter 1?
- Does the alternative avoid or minimize effects on human/environmental resources?
- Is the alternative feasible for USACE to implement?

Alternatives that met the criteria described above were carried forward for analysis, and are detailed in Section 2.3. Those that were eliminated from detailed analysis are described in Section 2.4, along with the reasons for elimination.

## 2.3 PROPOSED ACTION/PROJECT AND ALTERNATIVES

This section provides a general description of dredging and disposal practices that would be implemented under the project alternatives, followed by descriptions of the four alternatives that are analyzed in detail in this EA/EIR.

### 2.3.1 General Description of Dredging and Disposal Practices

Maintenance dredging typically involves four steps: 1) testing for sediment quality; 2) excavating recently shoaled sediment from the dredging site to restore previously dredged channel dimensions; 3) transporting the dredged material via scows, hopper dredges, or pipeline to the disposal, placement, or beneficial reuse site; and 4) placing and managing the dredged material at the designated site for disposal or reuse at that site, or transfer to another permitted location for disposal or reuse.

Prior to conducting dredging activities, sediment sampling is conducted and results are reviewed by the Dredged Material Management Office to determine if the sediment is suitable for aquatic or upland disposal, or beneficial reuse (sediment testing requirements are discussed in Section 1.3.2).

Typical methods of maintenance dredging include hydraulic or mechanical dredging. Hydraulic dredging usually involves hopper dredges (a ship with a hopper bin to store and transport material dredged) or suction/cutterheads attached to hydraulic pipelines that convey the dredged material to a scow or directly to a placement site. Mechanical dredging usually involves bucket or clamshell dredges, which scoop material from the channel bed and place it directly into a scow for transport to a placement site. The various methods of dredging and equipment used are discussed below.

Once the material is dredged, it is transported to, and placed at, a designated dredged material placement site. Dredged material placement in the San Francisco Bay Area includes unconfined aquatic placement at designated in-Bay and ocean disposal sites, beneficial reuse, and transfer or rehandling sites; these sites are described in Sections 1.4.3 and 1.4.4.

Barring and knockdowns may be implemented complementary to dredging, but are not cost-effective practices for large areas. Barring, which involves pulling a weighted bar (e.g., an I-beam) across a channel bottom, may be used as part of a dredging episode to smooth out high-spots as needed after dredging has occurred; during mechanical dredging, the bucket can also be used to smooth out small peaks. Similar to barring, knockdowns (i.e., knocking down isolated shoals or high-spots) provide an additional method to alleviate shoaling in marinas, ports, and in some navigation channels; however, knockdowns are typically conducted to improve channel conditions between dredging episodes. Knockdowns use the same equipment and procedures as barring.

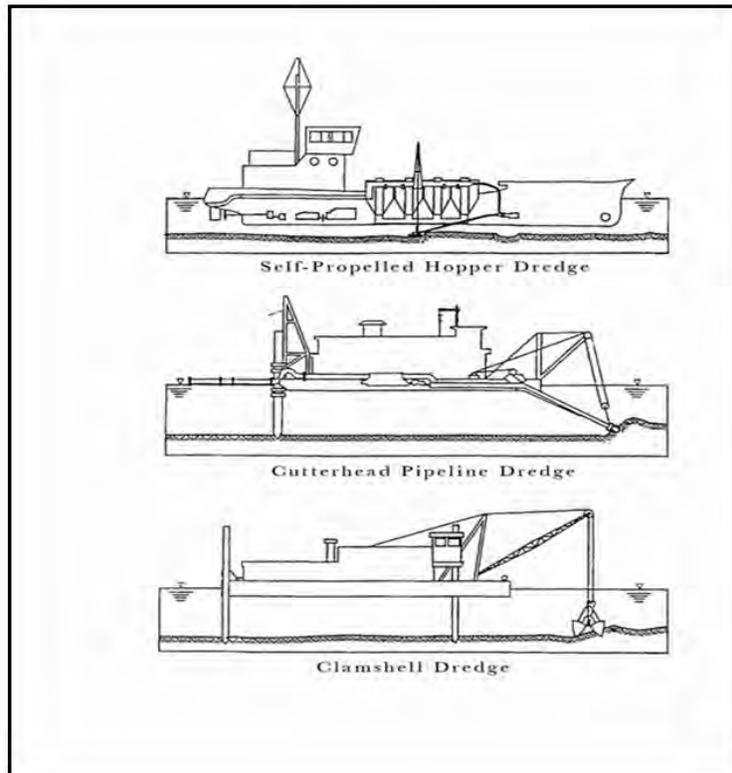

#### Dredge Equipment and Methods

Dredging methods for a specific area are typically based upon site-specific characteristics, such as substrate type, water quality, site bathymetry, wave energy, dredging depth, desired production rate (i.e., cubic yards per hour), method of disposal, distance to disposal area, levels of constituents of concern, and spatial feasibility. Additionally, costs and availability of dredge equipment factor into selection of a type of dredging method. Dredging equipment and techniques vary; however, for the purposes of this EA/EIR, dredging equipment is categorized by two mechanisms:

1. Hydraulic dredging – Removal of loosely compacted materials by cutterheads, dustpans, hoppers, hydraulic pipeline, plain suction, and sidecasters.
2. Mechanical dredging – Removal of loose- or hard-compacted materials by clamshell, bucket, excavator, dipper, or ladder dredges. Unlike hydraulic dredging, mechanical dredges use mechanical systems to remove sediments from the dredging site.

The schematics of the various dredge types are presented on Figure 2-1, and further discussed below.

**Figure 2-1  
Typical Dredge Equipment**

Source: USACE Engineer Research and Development Center

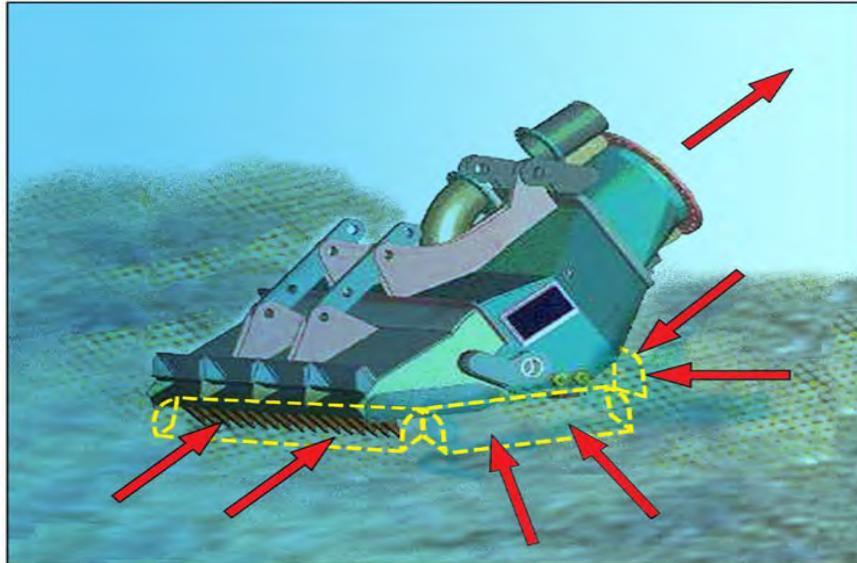

### **Hydraulic Dredges**

Hydraulic dredges remove and transport sediment in liquid slurry form (generally a ratio of 80 percent water and 20 percent sediment by weight). Hopper dredges are included in the category of hydraulic dredges, even though the dredged material is hydraulically pumped into the self-contained hopper in the dredge, rather than through a pipeline or to a scow. Hopper dredges are a type of hydraulic dredge that hydraulically pumps sediment into a self-contained hopper bin for temporary storage and transport. Other hydraulic dredges, including cutterhead dredges, are usually barge-mounted and carry diesel or electric-powered centrifugal pumps with discharge pipes ranging in diameter from 6 to 48 inches. The pump produces a vacuum on its intake side, which forces water and sediments through the suction pipe. The slurry is then transported by a pipeline or scow to the dredged material placement site.

### **Hopper Dredges**

Hopper dredges are seagoing vessels designed to dredge and transport material from navigation channels to open-water disposal areas. Hopper dredges are equipped with a drag arm on each side of the dredge. The drag arms are long suction pipes with drag heads attached to their ends (Figure 2-2). During active dredging, the drag arms are lowered through the water column until the drag heads are on the channel bottom; next the suction is turned on, and the drag heads are slowly dragged across the shoaled material by the forward motion of the vessel. Sediment and water slurry are drawn up through the drag heads and drag arms by on-board pumps, and deposited in the hopper bin, in the vessel's midsection. When the hopper bin is full, the dredge raises the drag arms and moves to a designated disposal area to empty the dredged material through large doors at the bottom of the dredge.

**Figure 2-2  
Hopper Drag Head Schematic**

Source: USACE Engineer Research and Development Center.

Advantages of a hopper dredge include the ability to work in rough, open water; the ability to move quickly to a project site under its own power; and the ability to not interfere with or obstruct vessel traffic during operation. The use of a hopper dredge also generally reduces the sediment resuspension at the dredging site, compared to mechanical dredging. Limitations include draft and maneuvering requirements that preclude use in shallow water and narrow channels; continuously interrupted production while transiting to and from placement sites; and difficulty dredging around structures.

Although USACE sometimes uses contract hopper dredges, USACE primarily uses two federally owned hopper dredges in the San Francisco Bay Area: the *Essayons* and the *Yaquina*. The *Essayons* is the larger of the two dredges, and commonly works in San Francisco Bay. The *Yaquina* does not often dredge in San Francisco Bay, but did dredge in San Francisco Bay in 2012 through 2014. Table 2-1 provides the specifications of USACE's hopper dredges.

Both the *Essayons* and the *Yaquina* function similarly, with only minor differences. When positioned over a shoal, the drag head is slowly lowered to just above the sediment surface. The drag heads are primed, meaning the pumps are turned on and water is hydraulically vacuumed through the drag head, up the drag arm, and into the hopper of the dredge. Once water begins to flow into the hopper, the drag head is immediately lowered into the sediment (often referred to as being buried in the sediment) for active dredging. Priming the dredge takes approximately 15 to 40 seconds, and occurs no more than 3 feet above the surface of the sediment. The purpose of priming is to fill the pipeline from the drag head to the pump with water to remove all of the air from the system. The drag arms on the *Essayons* are self-priming so there is no separate priming pump on the *Essayons*. The *Yaquina* has a priming system, and once the system is full of water, the main pump can be activated, and will have a ready load of water to push against (i.e., pump). On the *Yaquina*, the priming pump continues to operate until the main pump is operating normally. If there is any air in the system when the main pump is activated, a process called cavitation takes place and prevents the main pump from operating smoothly or at all. Cavitation is also harmful to the machinery and can cause the main pump to fail. Given that the priming operation and the main pump activation overlap each other, it does not provide an opportunity to divert any of the priming water before it is picked up by the main pump.

<b>Parameter</b>	<b>Essayons</b>	<b>Yaquina</b>
Length	350 feet	200 feet
Drag arm extension	94 feet MLLW	45 to 55 feet MLLW
Hopper capacity	6,000 CY	1,050 CY
Draft (when fully loaded)	27 feet MLLW	14 feet MLLW
Max speed (when fully loaded)	13.5 knots	10.5 knots
Size of intake pipe	28 inches	20 inches
Size of drag head	100 × 100 inches	54 × 54 inches
Pump size (gpm)	2 at 28,500	2 at 15,000
Water: Sediment <sup>1</sup>	80:20	80:20
Production Rate <sup>2</sup>	43,000 CY/day	13,000 CY/day
Locations dredged Annually	<ul style="list-style-type: none"> <li>▪ San Francisco Harbor (Main Ship Channel)</li> <li>▪ Richmond Outer Harbor</li> <li>▪ Pinole Shoal</li> <li>▪ Suisun Bay Channel and New York Slough</li> </ul>	Varies annually <sup>3</sup>
Volume dredged Annually	800,000 – 1,000,000 CY (annual average)	Varies annually <sup>3</sup>
Notes: <sup>1</sup> Average ratio; actual ratio varies by sediment type. <sup>2</sup> Average Daily Production <sup>3</sup> The <i>Yaquina</i> does not often dredge in the San Francisco Bay Area. At times, it is scheduled to dredge the federal navigation channels in place of the <i>Essayons</i> . As such, volumes of dredged material vary annually. CY = cubic yard CY/day = cubic yards per day FY = fiscal year <div style="display: flex; justify-content: space-between; margin-top: 5px;"> <span>gpm = gallons per minute</span> <span>MLLW = mean lower low water</span> </div>		

With the drag head buried in the sediment, the dredge moves forward cutting the shoaled sediment, thereby removing the sediment, along with water, in a slurry. The slurry is hydraulically vacuumed through drag arm to the hopper where it is temporarily stored. If the drag head or the drag arm become clogged during dredging, the drag head may be temporarily lifted out of the sediment, allowing water to be pumped through the drag arm to clear the clog. Once a cut is finished, the drag head is lifted out of the sediment, and water is pumped through the drag arm to clear sediment from the drag arm. Similar to priming, clearing clogs and sediment from the drag arm takes approximately 15 to 40 seconds, and occurs no more than 3 feet above the surface of the sediment. If the main pump is run in reverse to back flush a clog, the system will have to be re-primed.

The drag head does not have a watertight door or valve at the end that would prevent water from leaving the pipe. Once the drag head is lifted out of the water and the pipe reaches an angle that lets air into the pipe, the system is no longer closed (i.e., watertight). Sometimes, the drag heads must be lifted out of the water to manually open or close the water intake doors on the drag head; this requires the system to be re-primed before dredging can resume.

Both the *Essayons* and the *Yaquina* are equipped with four water intake doors directly on top of each of the drag heads (Figure 2-3). Each door is approximately 6 inches square. If the drag arms become clogged during dredging, one or more of the doors can be opened to draw water through the drag arm to facilitate flow. Dredging with all of the doors closed is preferable because it results in increased production; therefore, the doors are only temporarily opened to alleviate clogging. The doors are operated manually. To open the doors, the drag heads are lifted out of the water and the doors are tied back. Typically, the drag arms do not clog when dredging areas composed mostly of sand; however, in areas with more silt or mud, one or two doors may need to be opened.

**Figure 2-3**  
***Essayons* Drag Head and Water Intake Doors**

Once the hopper is full, or the 15-minute overflow limitation is met (discussed below), the drag heads are completely raised out of the water and positioned in their resting place on the side of the dredge, and the dredge transits to a placement site.

At the placement site, the hopper doors (at the bottom of the dredge's hull) open, and dredged material falls through the doors and settles on the floor of the placement site. Sandy material settles more quickly than finer-grained material (silts and clays), which tends to stay suspended in the water column longer. Water is used to flush the hopper bin. The water that is taken in at the bottom of the ship<sup>1</sup> and stored in the sea chest<sup>2</sup> is used to both cool the engines and flush the bins. On the *Yaquina* or a contractor hopper dredge, the water to flush the bin could also come from the drag arms. In conditions where the water is drawn from the drag arms, the drag arms are placed in the water just below the surface. In general, for drawing water in, the drag head must be maintained near the surface of the water because lowering it too

<sup>1</sup> The *Essayons* and *Yaquina* have screened water intake ports at the bottom of the hull which draw up water to cool the ship's engines; such water intake ports are typical features on ships for the purpose of obtaining engine cooling water.

<sup>2</sup> A sea chest is a water tank that is used with systems that use more than one pump to move water to flush the hopper and cool the engines. It compensates for the differences in inflow rate versus outflow rate, and allows for water to be pumped out at a constant rate without overrunning the rate at which water enters the tank, or being overrun by the rate at which water is supplied. Sea chests are typical features on ships for pumping engine-cooling water.

deep would compromise the maneuverability of the vessel, and pose a safety concern. The *Yaquina* uses a jetting system with a screened water intake on its sea chest. The *Yaquina* has four sea chests, two forward and two aft. The depth of the sea chests varies because of displacement. On the bow, it can vary from 8 to 16 feet deep, and on the stern, it can vary from 11 to 14 feet deep. The *Essayons* has six sea chests. Four are for flushing the hopper and two are for cooling the engines. The forward location varies from 12 to 25 feet deep, and the aft location varies from 18 to 29 feet deep. For both *Yaquina* and *Essayons*, the hopper is flushed after each in-Bay placement occurrence; this process takes 5 to 10 minutes.

It is often advantageous to overflow, or decant, excess water from hopper dredges to increase the sediment load carried; however, because of water quality concerns near the dredging site, overflow may be restricted. Overflow dredging occurs when the hopper is full of sediment slurry, and pumping continues to fill the hopper with water and sediment. The heavier, coarser material settles out to the bottom of the hopper; and lighter, finer sediments remain suspended in the water. For the first 6 to 7 minutes of dredging, all material dredged is retained in the hopper, then overflow begins. As dredging continues, excess water begins to fall back into San Francisco Bay. This excess water is called overflow, and is where fine material is returned to the water column. The amount of fine-grained material that is returned to the water column depends on the type of sediment being dredged. For hopper maintenance dredging in San Francisco Bay, overflow dredging is limited to 15 minutes at all times for fine-grained sediments; overflow is unrestricted for sandy sediments (i.e., greater than 80 percent sand) because there is little fine-grained material that remains suspended in the overflow.

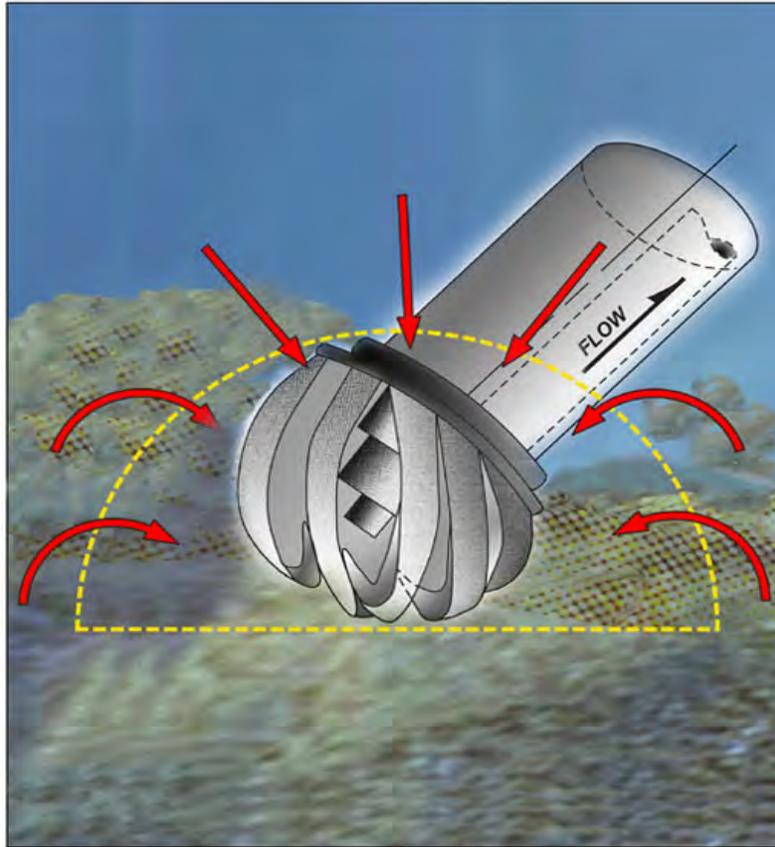

The *Essayons* overflow falls into overflow weirs (tubes that span from the top of the hopper bin to the bottom of the vessel) and into the water column at the level of the draft of the vessel. On the *Yaquina*, a skimmer, or pipe that floats on top of the sediment slurry inside of the sediment collection bin, removes excess water and drains it internally inside the ship's hull and into a collection tank, which then releases the water through a valve in the ship's hull below the surface of the water. Unlike the *Yaquina*, the *Essayons* is equipped with anti-turbidity valves on its overflow weirs, which reduce the water quality impacts caused by the dredging overflow process. Once the hopper is filled with water and sediment slurry, water and fine-grained sediment fall into the overflow weirs. The process of loading the hopper and overflow from the hopper tends to entrap air into the overflowed materials. This entrapment of air causes many fine materials, which might otherwise sink, to become buoyant and rise; or remain on the surface of the water. The anti-turbidity valves are butterfly-type valves that restrict the volume of water that can pass through the overflow tube. The anti-turbidity valves reduce the amount of air that is entrained in the overflow slurry water and cause the water level to back up the tube over the top of the weir. Instead of the water falling uncontrolled down into the overflow tube, the top half of the overflow tube and the weir become filled with water, then the water runs down the side of the overflow tube more evenly, without drawing in large amounts of air. By reducing the quantity of entrapped air in the overflows, the materials will more readily sink below the surface and settle back to the bottom more quickly, reducing turbidity.

When using a diesel-powered hopper dredge in California, the diesel generators on the hopper dredge must be equipped with timing retards and turbo charging to reduce nitrogen oxide emissions. The *Essayons'* and *Yaquina's* engines meet applicable (Tier II) standards. The USACE maintains the necessary air resource agency permits for operation of the *Essayons* and the *Yaquina*.

### **Cutterhead-Pipeline Dredges**

Cutterhead-pipeline dredges are hydraulic dredges that use a cutterhead at the end of a pipeline (Figure 2-4). A cutterhead-pipeline dredge has onboard pumps that suction material through one end, the intake pipe, and then push it out the discharge pipeline directly onto the placement site. Because cutterhead-pipeline dredges pump directly to the placement site, they operate continuously and can be more cost-efficient than other types of dredges.

**Figure 2-4  
Cutterhead Dredge Schematic**

Source: USACE Engineer Research and Development Center.

A cutterhead is a mechanical device that has rotating blades or teeth to break up or loosen the bottom material so that it can be suctioned through the dredge. Some cutterheads are rugged enough to break up and remove rock. Cutterhead-pipeline dredges work best in areas with deep shoals where the cutterhead is buried in the sediment. The pipeline is constructed of durable plastic material and is slightly buoyant, designed to float approximately 2 inches above the water's surface when empty, and to sink to the bottom when filled with the dredge slurry mixture. Water pumped with the dredged material must be contained in the placement site until the solids settle out. It is then discharged, usually back into the waterway. Cutterhead-pipeline dredges are not suitable for use in areas where sediments are contaminated with chemicals that would dissolve in the dredge water, and be spread to the environment during discharge.

Pipeline dredges are mounted on barges. Usually, they are not self-powered, and therefore are towed to the dredging site and secured in place by special anchor pilings, called spuds or pivot pipes. Once the dredge is positioned, the pipeline and cutterhead are lowered to the bottom of the channel by the ladder. The cutterhead then begins to slowly rotate, at about 30 revolutions per minute, breaking up the sediment. As it becomes buried in the sediment, the dredge pumps are on, and sediment slurry is suctioned through the pipeline to the placement site. During operation, the cutterhead swings from side to side, alternately using the port and starboard spuds as a pivot. Cables attached to anchors on either side of the dredge control its lateral movement and help "walk" the dredge forward.

Advantages of a cutterhead-pipeline dredge include the ability to excavate most types of material and pump it long distances; to operate continuously, and therefore economically; and to dredge some rock formations using larger machines without blasting. Limitations include being unsuitable for open, rough water projects; increased turbidity over ambient conditions during dredging; requiring towboats to move between locations; difficulties working in strong currents; and navigation impacts caused by the pipeline from the dredge to the disposal site, especially in areas of confined, heavy traffic.

### **Mechanical Dredges**

Mechanical dredges remove bottom sediments by direct application of mechanical force to dislodge sediments, scooping the sediments from the bottom and placing them into a barge or scow for transport to a dredged material placement site. Mechanical dredges can work in tightly confined areas, because they are mounted on a barge, towed to the dredging site, and secured in place by a system of anchors or anchor piling (i.e., spuds). Mechanical dredges allow for accuracy in the positioning of the equipment and the dredge cut. They are often used in harbors, around docks and piers, and in relatively protected channels, but may be less effective when dredging areas with high traffic or rough seas, because they can become unstable in these conditions. Additionally, mechanical dredges are effective for removal of moderately compacted materials, and are able to pick up large particles and debris; however, they are inefficient and unsuitable for light, free-flowing materials, and are unable to dig in relatively hard material.

Generally, two or more scows or barges are used in conjunction with the mechanical dredge. While one barge is being filled, another is being towed to the dredged material placement site. Using multiple barges, work can proceed continuously, only interrupted by changing scows/barges or moving the dredge. This makes mechanical dredges particularly well-suited for dredging projects where the disposal site is many miles away.

Often, water quality at dredging and disposal sites is a particularly important consideration in the choice of dredge equipment used. Hydraulic dredging can reduce disturbance and resuspension of sediments at the dredging site, and is often the first choice when dredging occurs in enclosed water bodies or in locations near aquatic resources that are especially sensitive to temporary increases in suspended solids or turbidity. However, because hydraulic dredging typically entrains additional water that is many times the volume of sediment removed, water management and water quality must be controlled at the placement site (hopper dredges are an exception). In contrast, mechanical dredging creates little additional water management concern at the disposal site, because little water is entrained by mechanical dredging equipment. However, typical mechanical dredge equipment often creates more disturbance and resuspension of sediment along the bottom of the dredging site as a result of mechanical force against the substrate. In addition, as the dredge is raised through the water column, sediment-laden water can leak from the clamshell, dipper, or other type of bucket, generating increased suspended solids throughout the vertical water column.

### **Clamshell Dredge**

A clamshell dredge employs a vertical-loading grabber connected to a wire rope (see Figure 2-5). Bucket, dipper, and backhoe dredges are also considered mechanical dredges, and operate similarly to clamshell dredges. Clamshells have the capability of using several diverse bucket configurations that optimize removal of different sediment types (e.g., silt, mud, clay, sand, gravel, rock, boulders). The dredge operates by lowering the vertical-loading grabber in the open position; the weight of the grabber penetrates the substrate; and the bucket is closed around the material, then raised above the level of the scow or barge and placed inside.

**Figure 2-5**  
**Clamshell Dredge**

Source: USACE Engineer Research and Development Center.

The loading grabbers/buckets can be sized up to 50 cubic yards (CY); however, most often 10- to 20-CY grabbers are used, and 1-CY buckets can be used for smaller projects. Larger, custom-fabricated sizes exist for special dredging projects. The depth at which a clamshell dredge can operate is determined by the length of the wire rope. Production rate is generally determined by cycle time, bucket size, dredging depth, type of material, thickness of cut, and transport equipment. Based on a study completed by USACE San Francisco District, dredging a channel with a clamshell bucket dredge can take up to ten times longer than dredging with a hopper dredge (USACE, 2013d).

Environmental buckets are used mainly for maintenance dredging because they are not configured for digging or excavating hard material. They resemble and operate like a regular clamshell bucket except they do not have digging teeth. They have a seal where the teeth would be on a normal clamshell bucket. This allows environmental buckets to retain most of the water and fine sediment that would typically escape a normal clamshell bucket. Although typically not required for USACE maintenance dredging contracts in San Francisco Bay, use of environmental buckets on mechanical dredges is at the discretion of the contractor; in some circumstances (e.g., dredging of contaminated sediments), use of environmental buckets may be required.

## **Barring and Knockdown Dredging**

### ***Barring***

The USACE implements “barring” as a routine part of dredging episodes to smooth out high-spots as needed after dredging has occurred. This method involves using a tug to pull a weighted blade across the channel bottom. As the blade encounters material, it scrapes the material into the adjoining areas with deeper depressions, redistributing the shoaled material in each channel. Barring is restricted to the dredging footprint and the project depth, including the over-dredge depth allowance.

### ***Knockdowns***

Separate from barring, which is implemented at the end of dredging episodes, “knockdown” events may be implemented to improve channel conditions between dredging episodes. Knockdowns use the same equipment and procedures as barring, but apply to isolated shoals or high-spots, rather than the entire dredging footprint. Knockdowns are most useful when time constraints may not allow for normal dredging, or when a

shoal threatening navigation covers a small portion of a project area that is otherwise at or below its permitted depth. Conducting separate knockdown operations is often more efficient than mobilizing dredging equipment and transporting the material to a disposal site. Because knockdowns typically create less resuspension than full dredging episodes (especially in the upper water column), they have at times been approved in the San Francisco Bay Area to minimize necessary work outside environmental work windows.

### **Transportation of Dredged Material**

Transportation methods generally used to move dredged material include the following: pipelines, hopper dredges, barges or scows, and rarely trucks or trains. Pipeline transport is the method most commonly associated with cutterhead, dustpan, and other hydraulic dredges. Dredged material may be directly transported by hydraulic dredges through pipelines for distances of up to several miles, depending on a number of conditions. Longer pipeline pumping distances are feasible with the addition of booster pumps, but the cost of transport greatly increases. Hopper dredges are capable of transporting the material for long distances in a self-contained hopper. Hopper dredges normally discharge the material from the bottom of the vessel by opening the hopper doors; however, some hopper dredges are equipped to pump out the material from the hopper,<sup>3</sup> much like a hydraulic pipeline dredge. Barges and scows, used in conjunction with mechanical dredges, are one of the most widely used methods of transporting large quantities of dredged material over long distances. Truck and train transport is typically more expensive than barge transport; it is generally only used for transport of material not suitable for unconfined aquatic disposal that requires rehandling (i.e., movement of the material to a secondary placement site after it has dried).

### **Material Placement or Disposal Operations**

Selection of proper dredging and transport equipment and techniques must be compatible with disposal site and other management requirements. Disposal or placement options are open-water disposal, confined disposal, and beneficial reuse. Although some placement sites are primarily characterized as open-water or confined disposal, they may also provide for beneficial reuse (e.g., the Ocean Beach nearshore placement site [SF-17]). Each of these options involves its own set of unique considerations, and selection of an option is based on environmental, technical, and economic considerations.

#### ***Open-Water Disposal***

Dredged material can be placed in open-water sites using direct pipeline discharge, direct mechanical placement, or release from hopper dredges or scows. The potential for environmental impacts is affected by the physical behavior of the open-water discharge. The physical behavior of the discharge depends on the type of dredging and disposal operation used, the nature of the material (its physical characteristics), and the hydrodynamics of the disposal site. For San Francisco Bay dredging projects, open-water disposal, also referred to as unconfined aquatic disposal, occurs at both designated in-Bay sites and open-ocean locations west of the Golden Gate Bridge.

Open-water disposal sites can be either predominantly nondispersive or predominantly dispersive. At predominantly nondispersive sites, most of the material is intended to remain on the bottom following placement, and may be placed to form mounds. At predominantly dispersive sites, the material may be dispersed either during placement, or eroded from the bottom over time and transported away from the disposal site by currents and/or wave action. However, both predominantly dispersive and predominantly nondispersive sites can be managed in a number of ways to achieve environmental objectives or reduce potential operational conflicts.

#### ***Confined Disposal***

Confined disposal is placement of dredged material in diked nearshore or upland confined disposal facilities (CDFs) by way of pipeline or other means. CDFs may be constructed as upland sites;

---

<sup>3</sup> The *Essayons* and *Yaquina* do not currently have pump-out capabilities.

nearshore sites with one or more sides in water (sometimes called intertidal sites); or as an island containment area. There are presently no CDFs in the San Francisco Bay area.

The main objectives inherent in design and operation of CDFs are to provide for adequate storage capacity for meeting dredging requirements; to maximize efficiency in retaining solids; and to control the release of any contaminants present in the dredged material.

When the dredged material is initially deposited in the CDF, it may occupy several times its original volume because of water content. The settling process is a function of time, but the sediment will eventually consolidate to its in situ volume or less if desiccation (drying) occurs. Adequate volume must be provided during the dredging operation to contain both the original volume of sediment to be dredged, and any water added during dredging and placement.

### **Beneficial Reuse**

For a project to be considered a beneficial reuse site, it must demonstrate that what it proposes to accomplish is needed, that its benefits outweigh any environmental impacts or trade-offs, and that these impacts will be mitigated. Generally, beneficial reuse includes habitat development (restoration and enhancement), levee maintenance and rehabilitation, various uses at existing sanitary landfills; agricultural use; development of commercial products (e.g., low-density aggregate, soil supplements), and general construction uses. Use categories other than habitat restoration or levee maintenance and stabilization often require dredged material processing at a rehandling facility prior to reuse. Rehandled/processed dredged material can be used for habitat restoration and levee maintenance and rehabilitation when direct barge access is not possible, or material stockpiling capacity is limited. Beneficial reuse placement sites are present in the uplands, diked former baylands, and wetlands surrounding the margins of San Francisco Bay.

### **2.3.2 No Action/No Project Alternative**

Under NEPA, in cases where the project involves modification of an existing program or management plan, No Action may be defined as no change from current program implementation, or no change in management direction or intensity. As such, the No Action Alternative may be thought of in terms of continuing with the present course of action until that action is changed. Similarly, Section 15126.6 (e)(3)(A) of the CEQA Guidelines states that “when the project is the revision of an existing land use or regulatory plan, policy or ongoing operation, the no project alternative will be the continuation of the existing plan, policy or operation into the future.” Therefore, under the No Action/No Project Alternative, USACE would continue current maintenance dredging practices for the projects it maintains in San Francisco Bay (Table 2-2), and the Regional Water Board would consider issuing a water quality certification (WQC) based on USACE’s current dredging practices. Current maintenance dredging practices were determined through a review of maintenance dredging activities for fiscal year (FY) 2000 through FY 2012 to determine the typical dredge equipment type, frequency of dredging, volumes dredged, and placement site(s) for each specific maintenance dredging project. Table 2-2 and the following sections describe maintenance dredging and placement activities that would occur under the No Action/No Project Alternative, based on these current practices.<sup>4</sup> Some historic placement sites have reached capacity and would not be available for use; these sites are not included under the No Action/No Project Alternative. For all dredged material determined not suitable for unconfined aquatic disposal (NUAD), placement options include upland sites, and in some cases the Montezuma Wetlands Restoration Project (MWRP).

Under the No Action/No Project Alternative, dredging and placement would be conducted in accordance with the following:

- Dredging at each project location would continue to be limited to the design (i.e., regulatory) depth, with no more than 2 feet of over-depth allowance;

<sup>4</sup> Under any alternative, the channels proposed for dredging with a hydraulic dredge could also be dredged with a mechanical dredge, with the exception of the San Francisco Bay Main Ship Channel; however, for the purpose of the analysis in the EA/EIR, use of a hydraulic dredge was assumed because that is the equipment typically used.

Channel	Dredge Type	Typical Dredging Frequency (years)	Range of Volume Dredged per Episode (CY) <sup>1</sup>	Median Volume Dredged Per Episode (CY) <sup>2</sup>	Placement Site
Richmond – Inner Harbor Outer Harbor	Clamshell-Bucket	1	11,000 – 631,000	390,000	SF-DODS, SF-11 <sup>3</sup>
	Hopper	1	78,000 – 318,000	190,000	SF-11
San Francisco Harbor – Main Ship Channel	Hopper	1	78,000 – 613,000	306,000	SF-8, SF-17
Napa River Channel*	Cutterhead-Pipeline	6-10	140,000 <sup>4</sup>	140,000 <sup>4</sup>	Upland (Sponsor Provided)
Petaluma River Channel (and Across the Flats*)	Cutterhead-Pipeline (River Channel) Clamshell-Bucket (Across the Flats)	4-7	250,000 <sup>4</sup>	250,000 <sup>4</sup>	Upland (Sponsor Provided) for the River Channel SF-10 for Across the Flats
San Rafael Creek Channel	Clamshell-Bucket	4-7	78,000 – 87,000 <sup>4</sup>	83,000 <sup>4</sup>	SF-11
Pinole Shoal	Hopper	1	80,000 – 487,000	146,000	SF-10
Suisun Bay Channel and New York Slough	Hopper	1	21,000 – 423,000	159,000	SF-16
Oakland Inner and Outer Harbor	Clamshell-Bucket	1	122,000 – 1,055,000 <sup>5</sup>	330,000	SF-DODS, MWRP
San Leandro Marina (Jack D. Maltester Channel)	Cutterhead-Pipeline	4-6	121,000 – 187,000 <sup>4</sup>	154,000 <sup>4</sup>	Upland (Sponsor Provided)
Redwood City Harbor	Clamshell-Bucket (Harbor Channels) San Bruno Channel (Hopper)	1-2	10,000 – 560,000	179,000	SF-11

## Notes:

\* For areas not dredged since 2000, the last dredging event is reported.

<sup>1</sup> Range of volume dredged per fiscal year since 2000 (USACE, 2014). For areas not dredged since 2000, the last dredging event is reported.

<sup>2</sup> Median volume dredged per fiscal year since 2000. For areas not dredged since 2000, the last dredging event is reported.

<sup>3</sup> SF-11 was used for Richmond Inner Harbor during the 2000 to 2012 baseline period, but is no longer approved as a placement option for Richmond Inner Harbor.

<sup>4</sup> Due to the lower frequency at which these channels are dredged, future dredge volumes could be greater.

<sup>5</sup> Due to the deepening of Oakland Harbor completed in 2010, future dredge volumes could be greater.

CY = cubic yards

MWRP = Montezuma Wetlands Restoration Project (in Solano County)

SF-8 = San Francisco Bar Channel Disposal Site (ocean site)

SF-10 = San Pablo Bay placement site (in-Bay site)

SF-11 = Alcatraz Island placement site (in-Bay site)

SF-16 = Suisun Bay placement site (in-Bay site)

SF-17 = Ocean Beach placement site (nearshore site, includes the Ocean Beach demonstration site)

SF-DODS = San Francisco Deep Ocean Disposal Site (approximately 55 miles [48 nautical miles] west of Golden Gate)

- Knockdowns may be performed in all locations except the San Francisco Main Ship Channel;
- No overflow would be discharged from any barge, with the exception of spillage incidental to clamshell dredge operations;
- Overflow from hopper-type suction dredges would continue to be limited to no longer than 15 minutes at the dredge site during any one excavation action (cut). Overflow would be unrestricted when dredging material is greater than 80 percent sand;
- Dredging and disposal activities would continue to be limited to the work windows set out by CDFW, the National Marine Fisheries Service (NMFS), and the USFWS in their Biological Opinions on the LTMS (USFWS, 1999; USFWS, 2004a; NMFS 1998)<sup>5</sup> (Figure 2-6). Work conducted outside of the work windows would require written approval from the appropriate agencies;
- Dredging would stop immediately following any fuel or hazardous waste leaks or spills, and cleanup actions would be implemented; and
- During dredging and disposal activities, notes to mariners and navigational warning markers would continue to be used as needed to prevent navigational hazards for recreational boaters.

Additionally, as determined through previous coordination with CDFW and USFWS, the following measures would continue to be implemented for hydraulic dredging to protect longfin smelt and delta smelt:

- Dredging may proceed anywhere when water temperature exceeds 22.0 degrees Celsius;<sup>6</sup>
- No dredging would occur in water ranging from 0 to 5 parts per thousand salinity between December 1 and June 30;
- At the beginning and end of each hopper load, pump priming, drag head clearing, and suction of water would be conducted within 3 feet of the seafloor.
- Hopper drag head suction pumps would be turned off when raising and lowering the dragarms from the seafloor when turning the dredge vessel; and
- The USACE would implement a worker education program for listed fish species that could be adversely impacted by dredging. The program would include a presentation to all workers on biology, general behavior, distribution and habitat needs, sensitivity to human activities, legal protection status, and project-specific protective measures. Workers would also be provided with written materials containing this information.<sup>7</sup>

---

<sup>5</sup> NMFS is revising the 1998 LTMS programmatic biological opinion; the updated biological opinion (expected 2015) will supersede the 1998 document. The USACE will comply with the terms and conditions of the updated biological opinion. The revised biological opinion may expand the salmonid work windows to year-round if dredging is conducted with a clamshell dredge and dredged material is placed at a beneficial reuse site that NMFS agrees will provide aquatic habitat benefits, such as a tidal wetlands restoration. Should the updated biological opinion allow for this, USACE may opt to dredge certain federal navigation channels with a clamshell dredge outside the work windows and place sediment at a beneficial reuse site. All other dredging outside the work window (i.e., hydraulic dredging or clamshell dredging with placement at a non-beneficial reuse site) would require consultation with NMFS.

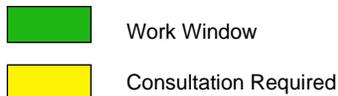

<sup>6</sup> To the extent feasible, hydraulic dredging in the Napa and Petaluma rivers and San Leandro Marina would only occur when water temperatures are above 22 degrees Celsius. If hydraulic maintenance dredging occurs when water temperatures are less than 22 degrees Celsius, USACE would coordinate mitigation, as appropriate, with USFWS, NMFS, and CDFW at the times such dredging episodes occur.

<sup>7</sup> The USACE has implemented this program in compliance with a condition in the San Francisco Bay Conservation and Development Commission's Letter of Agreement for USACE's coastal zone consistency determination for maintenance dredging in San Francisco Bay. Although the condition in the Letter of Agreement was specific to longfin smelt, USACE's worker education program, overseen by a USACE regional fisheries biologist, also includes information on other special-status fish species that could be impacted by dredging activities (i.e., those fish species considered in the LTMS work windows).

Note:  
 This chart is for operations and maintenance dredging of existing navigational facilities.  
 Other species may be affected by work in other areas. For more detailed information, see Appendix F of the LTMS Management Plan or the LTMS EIR/EIS.

(1) Depths are represented in MLLW, and are project depth, not including over dredge allowance.

### LTMS MAINTENANCE DREDGING WORK WINDOWS BY AREA AND SPECIES

Federal Navigation Channels EA/EIR  
 U.S. Army Corps of Engineers

April 2015

Bay Area, California

**FIGURE 2-6**

The USACE would meet all federal environmental compliance requirements (e.g., Clean Water Act Sections 401 and 404, Endangered Species Act), including those federal requirements implemented by state agencies (e.g., Clean Water Act Section 401, Coastal Zone Management Act). The USACE would undertake mitigation, as appropriate, in meeting its compliance requirements. In the past, USACE purchased a total of 1.4 mitigation credits at the Liberty Island Conservation Bank for potential impacts to listed species for 2011 and 2012 maintenance dredging activities in San Francisco Bay.

## **Richmond Harbor**

### ***Inner Harbor (excluding the Santa Fe Channel)***

The inner reaches of Richmond Channel, excluding the Santa Fe Channel, would be dredged annually using clamshell-bucket equipment. Placement of the dredged material normally would occur at the San Francisco Deep Ocean Disposal Site (SF-DODS). Maintenance dredging activities would occur for a period of approximately 45 days between June 1 and November 30, as feasible. Annually, the volume of dredged material generated by the Inner Harbor Channel would range between 11,000 and 631,000 CY; the median volume of dredged material for the 10-year planning horizon would be approximately 390,000 CY. The Santa Fe Channel is not anticipated to be dredged within the planning horizon (i.e., 2015 through 2024).

### ***Outer Harbor Channel (Long Wharf and Southampton Shoal)***

The Long Wharf and Southampton Shoal portions of the Outer Harbor would be dredged annually using a hopper dredge. Placement of the dredged material normally would occur at SF-11. Maintenance dredging activities would occur for a period of approximately 5 to 8 days between June 1 and November 30, as feasible. Annually, the volume of dredged material generated by the Outer Harbor Channel would range between 78,000 and 318,000 CY; the median volume of dredged material for the 10-year planning horizon would be approximately 190,000 CY.

## **San Francisco Harbor – Main Ship Channel**

The San Francisco Harbor Main Ship Channel would be dredged annually using a hopper dredge. Maintenance dredging activities would occur for a period of approximately 10 to 14 days in the months of May and June, but may occur as late as September. Dredging of the Main Ship Channel typically occurs with USACE's hydraulic dredge, *Essayons*, with the precise timing dependent on the sea conditions being such that this large hopper dredge can safely operate. Dredged material normally would be transported to either the San Francisco Bar Channel Disposal Site (SF-8) or SF-17 via a hopper dredge and deposited by open-water dumping. Annually, the volume of dredged material generated by the San Francisco Harbor Main Ship Channel would range between 78,000 and 613,000 CY; the median volume of dredged material for the 10-year planning horizon would be approximately 306,000 CY.

## **Napa River Channel**

The Napa River Channel would be dredged every 6 to 10 years. Dredging normally would be accomplished using a cutterhead attached to hydraulic pipelines that convey the dredged material to a scow, or directly to a permitted upland placement site provided by the project sponsor (e.g., Imola Avenue). Maintenance dredging activities would occur for a period of approximately 40 days between August 1 and October 15, if feasible. The volume of dredged material generated by the Napa River Channel per dredge event would be approximately 140,000 CY; however, because of the lower frequency at which this channel is dredged, future dredge volumes could be greater than historical volumes.

## **Petaluma River Channel (River Channel and Across the Flats)**

The Petaluma River Channel would be dredged every 4 to 7 years. Dredging of the River Channel normally would be accomplished using a cutterhead attached to hydraulic pipelines that convey the

dredged material to a scow, or directly to a permitted upland placement site provided by the project sponsor. Dredging of Across the Flats would be accomplished using a clamshell dredge, and placement would occur at the San Pablo Bay placement site (SF-10). Maintenance dredging of the River Channel would occur for a period of approximately 65 days between August 1 and October 15, if feasible. Maintenance dredging of Across the Flats would occur for a period of approximately 45 days between June 1 and November 30, if feasible. The volume of dredged material generated by the Petaluma River Channel per dredge event would be approximately 250,000 CY; however, because of the lower frequency at which this channel is dredged, future dredge volumes could be greater than historical volumes.

### **San Rafael Creek Channel (Across the Flats Channel and Inner Canal Channel)**

The San Rafael Creek Channel, which includes Across the Flats Channel and Inner Canal Channel, would be dredged every 4 to 7 years using a clamshell dredge. Placement of dredged material normally would occur at SF-11. Maintenance dredging activities would occur for a period of approximately 35 days between June 1 and November 30, if feasible. The volume of dredged material generated by the San Rafael Creek Channel would range between 78,000 and 87,000 CY; the median volume of dredged material for the 10-year planning horizon would be approximately 83,000 CY.

Inner Canal Channel has a known area of NUAD material. If this area is dredged, the NUAD material would be placed at a placement site approved for receipt of NUAD material, as determined by the Dredged Material Management Office. If necessary based on sediment testing results, the NUAD material would ultimately be placed at a landfill.

### **Pinole Shoal Channel**

The Pinole Shoal Channel would be dredged annually using a hopper dredge. Placement of dredged material normally would occur at SF-10. Maintenance dredging activities would occur for a period of approximately 5 to 15 days between June 1 and November 30, if feasible. Annually, the volume of dredged material generated by the Pinole Shoal Channel would range between 80,000 and 487,000 CY; the median volume of dredged material for the 10-year planning horizon would be approximately 146,000 CY.

Advance maintenance may be performed in areas where it has previously been conducted. This includes the southern edge of the channel, between buoy markers 10 and 12; and further east along the northern edge of the channel starting at buoy marker 11 to just east of buoy 13. The extent of the advance maintenance dredging in these two areas would be 200 feet wide and 2 feet deep.

### **Suisun Bay Channel and New York Slough Channel**

The Suisun Bay Channel and New York Slough Channel would be dredged annually using a hopper dredge. Placement of dredged material normally would occur at the Suisun Bay placement site (SF-16). Maintenance dredging activities would occur for a period of up to 30 days between August 1 and November 30, if feasible. Annually, the volume of dredged material generated by the Suisun Bay Channel and the New York Slough Channel would range between 21,000 and 423,000 CY; the median volume of dredged material for the 10-year planning horizon would be approximately 159,000 CY.

At Bulls Head Reach, past maintenance has included dredging up to 4 feet of advance maintenance material to accommodate rapid shoaling. This practice would continue to be reviewed annually, and implemented as warranted during the regularly scheduled maintenance dredging with a hopper dredge. In the case of Bulls Head Reach Shoal, USACE typically elects advance maintenance every year because that area shoals faster than the annual dredging cycle, and it is essential for USACE to maintain the utility of the channel as long as possible before needing to address any shoaling issues outside of the work

window. In recent years, advance maintenance at Bulls Head Reach has reduced USACE's critical dredging episodes<sup>8</sup> outside of the work window.

### **Oakland Harbor (Inner and Outer Harbor)**

The Oakland Inner and Outer Harbor would be dredged annually using a clamshell. Placement of dredged material normally would occur at the SF-DODS and MWRP or other upland beneficial reuse sites. Dredging activities would occur for a period of approximately 60 days between August 1 and November 30, if feasible. Annually, the volume of dredged material generated by the Oakland Harbor would range between 122,000 and 1,055,000 CY; the median volume of dredged material for the 10-year planning horizon would be 330,000 CY.

### **San Leandro Marina (Jack D. Maltester) Channel**

The San Leandro Marina Channel would be dredged every 4 to 6 years using a cutterhead and pipeline. Placement of dredged material normally would occur at a permitted upland location (e.g., San Leandro Dredged Material Management Site), which would likely be provided by the nonfederal sponsor, the City of San Leandro. Maintenance dredging activities would occur for a period of approximately 45 days between August 1 and November 30, if feasible. Annually, the volume of dredged material generated by the San Leandro Marina would range between 121,000 and 187,000 CY; the median volume of dredged material for the 10-year planning horizon would be approximately 154,000 CY.

### **Redwood City Harbor Channel**

The Redwood City Harbor Channel would be dredged every 1 to 2 years, except for the San Bruno Channel, which would be dredged every 10 years. Dredging of the San Bruno Channel would be accomplished using a hopper dredge. Dredging of the remainder of the harbor would be accomplished using a clamshell dredge. Placement of dredged material normally would occur at SF-11. Maintenance dredging activities would occur for a period of approximately 45 days between August 1 and November 30, if feasible, for San Bruno Channel; and between September 16 and November 30, if feasible, for the remainder of the harbor. Annually, the volume of dredged material generated by the Redwood City Harbor Channel would range between 10,000 and 560,000 CY; the median volume of dredged material for the 10-year planning horizon would be approximately 179,000 CY.

### **2.3.3 Proposed Action/Project**

Under USACE's Proposed Action/Project Alternative, USACE would perform dredging practices for the projects it maintains in San Francisco Bay. The dredge equipment type, frequency of dredging, and volumes dredged would be the same as under the No Action/No Project Alternative. Table 2-3 identifies the federal standard placement site and proposed alternate placement sites that would be used for each location, as well as expected dredge volumes. The USACE would beneficially reuse dredged material for to the maximum extent its authorities allow. Although it is assumed, for the purpose of this EA/EIR, that placement would occur at the identified federal standard<sup>9</sup> sites,<sup>10</sup> USACE would place dredged material at beneficial reuse sites when costs are equivalent to the federal standard or a cost-sharing partner is

<sup>8</sup> Critical dredging episodes occur outside the regular annual maintenance dredging of Suisun Bay Channel to remove a hazard to navigation when the channel is less than 35 feet MLLW in the area of the shoal.

<sup>9</sup> The federal standard is defined as the least-costly dredged material disposal or placement alternative consistent with sound engineering practices, and meeting the environmental standards established by the Section 404(b)(1) evaluation process or ocean dumping criteria (33 C.F.R. § 335.7).

<sup>10</sup> The USACE may be forced by logistical constraints to use the alternate placement sites. Examples of logistical constraints include: 1) unsafe condition at the placement site (e.g., weather/wave conditions); 2) an event blocking access to a placement site (this occurred during America's Cup 34); and 3) the federal standard site reaching its monthly disposal limit (as established by the Bay Plan and Basin Plan).

**Table 2-3  
Proposed Action/Project Summary (Continued)**

<b>Channel</b>	<b>Dredge Type</b>	<b>Typical Dredging Frequency (years)</b>	<b>Range of Volume Dredged per Episode (CY)<sup>1</sup></b>	<b>Median Volume Dredged Per Episode (CY)<sup>2</sup></b>	<b>Federal Standard Placement Site<sup>3</sup></b>	<b>Placement Site Alternate 1<sup>4</sup></b>	<b>Placement Site Alternate 2<sup>4</sup></b>	<b>Placement Site Alternate 3<sup>4</sup></b>
San Leandro Marina (Jack D. Maltester Channel)	Cutterhead-Pipeline	4-6	121,000 – 187,000 <sup>5</sup>	154,000 <sup>5</sup>	Upland (Sponsor Provided such as San Leandro DMMS)	In-Bay Site	Upland Beneficial Reuse	N/A
Redwood City Harbor	Clamshell-Bucket (Harbor Channels) Hopper (San Bruno Channel)	1-2	10,000 – 560,000	179,000	SF-11	Other In-Bay Site	Upland Beneficial Reuse except for San Bruno Channel; SF-DODS for San Bruno Channel	Upland Beneficial Reuse for San Bruno Channel only

Notes:

- \* For areas not dredged since 2000, the last dredging event is reported.
- <sup>1</sup> Range of volume dredged per fiscal year since 2000. For areas not dredged since 2000, the last dredging event is reported.
- <sup>2</sup> Median volume dredged per fiscal year since 2000. For areas not dredged since 2000, the last dredging event is reported.
- <sup>3</sup> The federal standard is defined as the least-costly dredged material disposal or placement alternative consistent with sound engineering practices, and meeting the environmental standards established by the 404(b)(1) evaluation process or ocean dumping criteria (33 C.F.R. pt. 335.7).
- <sup>4</sup> The USACE would not use the future placement sites identified in Section 1.5.4 until supplemental environmental review under NEPA and/or CEQA and acquisition of required environmental approvals from resource and regulatory agencies are completed.
- <sup>5</sup> Due to the lower frequency at which these channels are dredged, future dredge volumes could be greater.
- <sup>6</sup> Aside from regularly scheduled maintenance of this navigation project, USACE would take urgent action outside the work window, as needed, to remove the hazardous shoaling at Bulls Head Reach, as described in Section 2.3.3.
- <sup>7</sup> Due to the deepening of Oakland Harbor completed in 2010, future dredge volumes could be greater.

CEQA = California Environmental Quality Act

CY = cubic yards

NEPA = National Environmental Policy Act

Ocean Beach Onshore = Onshore Ocean Beach placement site

San Leandro DMMS = Upland San Leandro Dredged Material Management Site

SF-8 = San Francisco Bar Channel Disposal Site (ocean site)

SF-9 = Carquinez Strait placement site (in-Bay site)

SF-10 = San Pablo Bay placement site (in-Bay site)

SF-11 = Alcatraz Island placement site (in-Bay site)

SF-16 = Suisun Bay placement site (in-Bay site)

SF-17 = Ocean Beach placement site (nearshore site, includes the Ocean Beach demonstration site)

SF-DODS = San Francisco Deep Ocean Disposal Site (approximately 55 miles [48 nautical miles] west of Golden Gate)

USACE = United States Army Corps of Engineers

supporting the beneficial reuse. For all NUAD material, placement options include upland sites, and in some cases MWRP. The USACE would not use the future placement sites identified in Section 1.5.4 until supplemental environmental review under NEPA and/or CEQA, and acquisition of required environmental approvals from resource and regulatory agencies is completed.

Dredging and placement would be conducted in accordance with the conditions described under the No Action/Project Alternative. In addition, USACE would implement the following best management practices (BMPs) to minimize impacts to longfin smelt and delta smelt:

- Completing hydraulic dredging in the Central Bay later in the year (from August 1 to November 30) during the June-to-November environmental dredging window, to the extent feasible,<sup>11</sup> to allow young-of-the-year longfin smelt to grow large and spawning adults to return upstream;
- Completing hydraulic dredging in Suisun Bay between August 1 and September 30, to the extent feasible, to avoid impacts to spawning adult longfin and delta smelt;
- Maintaining contact of drag head, cutterheads, and pipeline intakes with the seafloor during suction dredging;<sup>12</sup> and
- Closing the drag head water intake doors in locations most vulnerable to entraining or entrapping smelt. In circumstances when the doors need to be opened to alleviate clogging, the doors would be opened incrementally (i.e., the doors would be opened in small increments and tested to see if the clog is removed) to ensure that doors are not fully opened unnecessarily. It may take multiple iterations to fine tune the exact intake door opening necessary to prevent clogging. For each project, the intake door opening will be different because the sediment in each location is different. The sediment physical characteristics (e.g., sand versus mud) determine how much water is needed to slurry the sediment adequately. Typically, the drag arms do not clog when dredging areas composed mostly of sand.

The USACE would purchase 0.92 acre mitigation credit at the Liberty Island Conservation Bank, or other approved site, annually for potential impacts to listed species. The 0.92 acre mitigation credit was calculated from an equation ( $3.0 \text{ million acre-feet} / 800 \text{ acres} = \text{volume dredged} / X \text{ acres of mitigation habitat}$ ) that was developed by resource agencies to determine mitigation requirements for other projects with entrainment impacts as a result of pumping water, including the State Water Project. For volume dredged, available government-hopper-dredge-pumped total sediment and water volumes for 2006 through 2012 were reviewed. The highest volume for each of the in-Bay channels (Pinole Shoal, Richmond Outer Harbor, and Suisun Bay Channel/New York Slough) from this period was used in the calculation. Of the 0.92 acre mitigation credit, 0.19 acre mitigation credit would be for Pinole Shoal, 0.34 acre mitigation credit would be for Richmond Outer Harbor, and 0.39 acre mitigation credit would be for Suisun Bay Channel and New York Slough.

To the extent feasible, hydraulic dredging in the Napa and Petaluma rivers and San Leandro Marina would only occur when water temperatures are above 22 degrees Celsius. If hydraulic maintenance dredging occurs when water temperatures are less than 22 degrees Celsius, USACE would coordinate mitigation, as appropriate, with USFWS, NMFS, and CDFW at the times such dredging episodes occur. For hydraulic dredging of San Bruno Shoal, USACE would conduct compensatory mitigation using the

<sup>11</sup> Feasibility is contingent upon the availability of federal funds (e.g., timing of Congressional appropriations) to execute the dredging work, as well as by the availability of dredging equipment to perform the dredging work at the referenced time and locations.

<sup>12</sup> The seafloor surface is not uniform and is undulating, which could cause the drag head to lose contact with the seafloor. The hopper dredge also has to contend with sea state (i.e., swells and wave action) in the bay which also affects the drag head's contact with the channel bottom. The dredge's swell compensator provides an opposing force to maintain contact with the seafloor when the bottom is uneven or there is wave/swell action.

equation above; however, because this channel is so rarely dredged and volumes are not known, USACE would determine the amount of mitigation when/if this channel is dredged.

In addition, an approximate 1/2-mile portion of Bulls Head Reach, just east of the Benicia-Martinez Bridge in Suisun Bay Channel, shoals rapidly and becomes a navigation hazard that requires urgent action by USACE to maintain navigational safety in a critical maneuvering area. Knockdown and barring activities in lieu of dredging have not been effective tools in managing the rapid shoaling in this area. Because of the channel configuration, sediment type, and currents, the sediment that is dislodged during knockdown/barring gets trapped in the eddy that creates the shoal and is re-deposited in the same shoal area. If the shoaling is allowed to progress unabated, it would naturally develop into a sand bar that would stretch across the channel. The shoal restricts the available draft and handling of ships that transit to the Ports of Stockton and West Sacramento, and other locations along the channel.

The shoal becomes a hazard to navigation when the channel is shallower than 35 feet mean lower low water (MLLW) because of the increased risk of a ship grounding or allision,<sup>13</sup> which could result in an oil spill or release of other hazardous material into the environment. The shoal has developed to hazardous levels in the spring and early summer, outside the Suisun Bay Channel dredging work window of August 1 through November 30.

The United States Coast Guard considers shoaling in Bulls Head Reach to be a hazard to navigation for deep draft vessels transiting Suisun Bay when the channel is shallower than 35 feet MLLW, particularly because it is in the Benicia-Martinez Railroad Drawbridge Regulated Navigation Area where it is critical for vessels to be in the center of the 350-foot-wide channel to safely pass under the bridge (USCG, 2012a). In the past, USACE has been requested by the United States Coast Guard to make an emergency<sup>14</sup> declaration to conduct maintenance dredging of this area outside of the LTMS work window, and completed NEPA and other environmental compliance requirements pursuant to the Clean Water Act, federal Endangered Species Act, and the Coastal Zone Management Act after the maintenance dredging occurred. Table 2-4 presents the critical dredging episodes at Bulls Head Reach from 2000 through 2012.

Under the Proposed Action, USACE would take urgent<sup>15</sup> action outside the work window, as needed, to remove the hazardous shoal at Bulls Head Reach, in a manner consistent with USACE's Raise the Flag Procedure.<sup>16</sup> Removal of the shoal would likely involve 1 to 5 days of dredging to clear the hazard area to authorized depth (35 feet MLLW) plus 2 feet of overdepth (i.e., total maintained depth of 37 feet MLLW). The dredge equipment used would be based on availability, and could be completed by either mechanical or hopper equipment. Because the extent and frequency of critical dredging episodes cannot be predicted, appropriate mitigation for these episodes, if warranted based on expected impacts, would be determined in coordination with regulatory agencies at the times they occur.

---

<sup>13</sup> As defined by maritime law, the running of one vessel against another that is stationary. It is distinguished from collision in that collision means the running of two vessels against each other.

<sup>14</sup> As defined in USACE's Raise the Flag Procedure (Headquarters, Civil Works Construction, Operations and Readiness Division [CECW-OD], Revised January 22, 2002), an emergency is a situation that would result in an unacceptable hazard to life, a significant loss of property, or an immediate, unforeseen, and significant economic hardship if corrective action is not undertaken in a time period less than the normal contract procurement process.

<sup>15</sup> As defined in USACE's Raise the Flag Procedure (CECW-OD, Revised January 22, 2002), an urgent dredging requirement is a situation that may be time-sensitive for providing a safe navigation channel that requires prompt action, but does not meet the definition of an emergency.

<sup>16</sup> The Raise the Flag (CECW-OD, Revised January 22, 2002) procedure provides a systematic method to identify and respond to the nation's urgent or emergency dredging needs. This procedure is applicable to all USACE navigation projects that may be maintained by hopper dredges.

<b>Year</b>	<b>Dredge Type</b>	<b>Volume (CY)</b>
2000	Hopper	21,000
2001, Episode 1	Cutterhead-Pipeline and Clamshell-Bucket	28,000
2001, Episode 2	Hopper	17,000
2009	Clamshell-Bucket	12,000
2010	Hopper	9,000
2012	Hopper	16,000
Notes: CY = cubic yards		

Material dredged from Bulls Head Reach would be placed at either SF-16 or the Carquinez Strait placement site (SF-9). As the baseline data in Table 2-4 indicates, the past critical dredging episodes have not occurred at a regular or predictable frequency; therefore, USACE estimates urgent removal of this shoal may be required in any given year within the 10-year planning horizon. Analysis of impacts related to the removal of this shoal in this EA/EIR is intended to fulfill USACE's NEPA requirements related to these episodes, and possibly preclude emergency declaration. USACE would complete environmental compliance requirements under authorities (e.g., federal Endangered Species Act) separately.

### **2.3.4 Reduced Hopper Dredge Use Alternatives**

This section presents two alternatives under which USACE's use of a hopper dredge for maintenance dredging of the federal channels would be reduced, compared to the Proposed Action/Project and No Action/No Project Alternative. The costs for implementing these alternatives are beyond the currently programmed operation and maintenance budget for San Francisco Bay (estimated at an additional \$3 to \$10 million per year). Therefore, before USACE could accomplish the preferred alternatives, should they be adopted by the Regional Water Board, three things typically should occur: first, higher executive branch authority must agree that the increased cost is consistent with the federal standard; second, the additional costs must be included in the annual budget submitted to Congress; and third, Congress must appropriate or reprogram the additional funds. NEPA and CEQA do not restrict consideration of alternatives that are outside the jurisdiction or capability of the lead agency to implement if the alternatives are otherwise reasonable.

For the purpose of analysis in this EA/EIR, it is assumed that either reduced hopper dredge use alternative would be implemented by FY 2017, as required by a condition of the WQC issued by the Regional Water Board. Because USACE has a 3-year budget process, as described in Section 1.4, the earliest USACE could implement these alternatives would be FY 2017. For both reduced hopper dredge use alternatives, implementation of dredging in FY 2015 and FY 2016, including purchase of mitigation credit, would be as described under the Proposed Action/Project.

Although it is assumed for the purpose of analysis that the reduced hopper dredge use alternatives could be implemented, it should be noted that if USACE is unable to obtain both the necessary authorization and funding to implement these alternatives, USACE would follow the regulations at 33 C.F.R. pt. 335-338. The process described in these regulations could potentially result in deferred dredging at certain channels (i.e., Richmond Outer, Pinole Shoal, and Suisun Bay Channel and New York Slough). Deferred dredging means that these channels may not be fully maintained by USACE. Funding historically appropriated for dredging the deferred channels may be diverted to other navigation and maintenance projects nationwide, and the USACE San Francisco District may be unable to recover the funding for dredging these channels at future date. In addition, because of scheduling constraints with the

government-owned hopper dredges, limiting hopper dredge use to the San Francisco Bay Main Ship Channel (MSC) under Reduced Hopper Dredge Use Alternative 2 could increase the risk that full dredging of the MSC would not be completed within the scheduled availability of the hopper dredge when inclement weather precludes dredging of the MSC.

In the interest of disclosing the potential environmental impacts of deferred or incomplete dredging, such impacts are noted here, and discussed further in Chapter 3 for resources where adverse impacts could result. Because it is unknown whether, to what extent, or for how long dredging could be deferred, the impacts of deferred dredging would be speculative and variable. Therefore, discussion of the potential impacts associated with deferred dredging is presented as a brief qualitative assessment.

### Reduced Hopper Dredge Use Alternative 1

Under Reduced Hopper Dredge Use Alternative 1, the government hopper dredge *Essayons*, or similarly sized hopper dredge, would only be used to dredge the MSC, and either the Richmond Outer Harbor or the Pinole Shoal Channel, annually. As described earlier, because of the strong currents and waves at the MSC, a hopper dredge is the only method which can safely dredge the channel. At times, inclement weather and strong currents at this location create conditions that may preclude safe dredging with a hopper dredge. Conditions that may inhibit USACE's ability to dredge the MSC include rough seas, strong tides, fog, heavy rain, strong winds, heavy vessel traffic, or a combination of these factors. For example, in 2013 and 2014, dredging of the MSC was delayed on four different days, for a total of 25 hours, because of unfavorable wind and sea conditions. During such times, dredging at an in-Bay channel would allow for efficient use of the hopper dredge, whereby the dredge would move into San Francisco Bay and work on the identified channel, then returns to the MSC as soon as conditions allow. If dredging of the MSC is able to be completed without interruption by inclement weather, then the in-Bay channel (i.e., Richmond Outer Harbor or Pinole Shoal) would be dredged subsequent to the completion of dredging at the MSC. Dredging of the in-Bay channel would occur within the LTMS work window (Figure 2-6), or after an individual consultation is conducted with the appropriate regulatory agencies to allow dredging to be performed outside the work window.

Selection of the in-Bay channel to be dredged by a hopper, in any given year, would depend on: (a) the amount of shoaled material present at the respective channel; (b) timing and impact to sensitive resources (e.g., compliance with LTMS work windows); and (c) project-specific availability of funds. The additional channel would be identified by USACE in its initial annual maintenance dredging plan, which is prepared at the beginning of each fiscal year, and would be subject to change based on the actual available funds prior to maintenance dredging. Therefore, this alternative would reduce hopper dredge use for maintenance dredging compared to the Proposed Action/Project and No Action/No Project Alternative, but it would not change the total amount of dredging in the channels, placement sites used, or standard operating procedures.

The MSC is typically dredged in the months of May and June; however, depending on the condition of the channel, equipment availability, and availability of funds, dredging has occurred as late as September. Maintenance dredging of the MSC using a hopper dredge (i.e., the *Essayons*, or similarly sized dredge) typically requires 10 to 14 days. If Pinole Shoal was selected as the additional channel, 5 to 15 days of additional hopper dredge use would occur, for a total of 15 to 29 days of hopper dredge use under this alternative, depending on the duration of dredging at each channel. If Richmond Outer Harbor was selected as the additional channel, 5 to 8 days of additional hopper dredge use would occur, for a total of 15 to 22 days of hopper dredge use under this alternative, depending on the duration of dredging at each channel.

The channel not selected as the additional hopper dredge channel (i.e., either Pinole Shoal or Richmond Outer Harbor) would be dredged with a mechanical dredge. Additionally, Suisun Bay Channel and New

York Slough Channel and San Bruno Channel in Redwood City Harbor<sup>17</sup> would be dredged with a mechanical dredge under this alternative, instead of a hopper dredge. The USACE would purchase 0.19 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species if Pinole Shoal is dredged with a hopper. If Richmond Outer Harbor is dredged with a hopper, USACE would purchase 0.34 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species.

All other dredging, placement activities, and BMPs would be as described for the Proposed Action/Project, including urgent action to remove the hazardous shoal at Bulls Head Reach as needed. If feasible, this activity would be completed with a mechanical dredge; however, because of the urgent nature of this activity, a hopper dredge may be used. Regular maintenance dredging of this area would be completed with a mechanical dredge.

### **Reduced Hopper Dredge Use Alternative 2**

Under Reduced Hopper Dredge Use Alternative 2, the government hopper dredge *Essayons*, or similarly sized hopper dredge, would be used to dredge the MSC. The MSC is typically dredged in the months of May and June; however, as stated above, depending on the condition of the channel, equipment availability, and availability of funds, dredging has occurred as late as September. Maintenance dredging of the MSC using a hopper dredge (i.e., the *Essayons*, or similar-sized dredge) typically requires 10 to 14 days; this would be the only hopper dredge use under this alternative, except potential use at Bulls Head Reach as noted below.

Pinole Shoal, Richmond Outer Harbor, Suisun Bay Channel and New York Slough Channel, and San Bruno Channel in Redwood City Harbor would be dredged with a mechanical dredge under this alternative, instead of a hopper dredge. All other dredging, placement activities, and applicable BMPs would be as described for the Proposed Action/Project, including urgent action to remove the hazardous shoal at Bulls Head Reach. If feasible, this activity would be completed with a mechanical dredge; however, because of the urgent nature of this activity, a hopper dredge may be used. Regular maintenance dredging of this area would be completed with a mechanical dredge.

## **2.4 ALTERNATIVES CONSIDERED BUT ELIMINATED FROM FURTHER CONSIDERATION**

Several other alternatives to the Proposed Action were identified and evaluated during project planning and development, but were eliminated from detailed analysis and are therefore not analyzed in detail in this EA/EIR. These alternatives were eliminated from analysis because one or more of the following criteria apply, as discussed for each alternative below:

- It is ineffective (it would not respond to project purpose and need);
- Its implementation would not minimize effects on human/environmental resources;
- It is technologically infeasible; or
- Its implementation is remote or speculative.

### **2.4.1 No Maintenance Dredging**

Under this scenario, USACE would cease all maintenance dredging of the federal navigation channels in San Francisco Bay, which would eventually leave the channels unnavigable for commerce and recreation. This alternative was eliminated from further consideration because it would not meet the purpose and need of the project to maintain safe navigation of all the federal navigation channels, and would be expected to have significant economic and safety impacts.

---

<sup>17</sup> San Bruno Channel is dredged at intervals of 10 years or greater.

## 2.4.2 Maintenance Dredging of Select Federal Channels

Under this scenario, USACE would conduct maintenance dredging for some, but not all, of the federal navigation channels in San Francisco Bay during the 10-year planning period to reduce the impacts from maintenance dredging. This would leave the unmaintained channels unusable. Similar to the no maintenance dredging of all channels alternative above, this alternative was eliminated from further consideration because it would not meet the purpose and need of the project to maintain safe navigation of all the federal navigation channels, and would be expected to have significant economic and safety impacts.

## 2.4.3 Eliminate the Use of Hydraulic Dredging

Under this scenario, USACE would cease use of hydraulic equipment for any maintenance dredging. This alternative is not feasible. Primarily, this alternative would not allow for dredging of the Main Ship Channel, which requires use of a hopper dredge because it is the only type of dredge that can safely operate at this channel, as explained under Section 2.3.4. Therefore, this alternative was eliminated because it would not meet the purpose and need of the project to maintain safe navigation of all the federal navigation channels.

## 2.4.4 Eliminate the Use of Mechanical Dredging

Under this scenario, USACE would use hydraulic equipment only for maintenance dredging of the federal navigation channels in San Francisco Bay. This alternative is not feasible because it would limit USACE's ability to complete maintenance dredging of all the channels because of channel features (e.g., depth, sediment characteristics, and environmental conditions), current placement practices, and costs. Increased use of hydraulic dredge equipment could also increase the likelihood of entrainment of protected fish species. Therefore, this alternative was eliminated because it would not meet the purpose and need of the project.

## 2.4.5 Screening Water Intakes on USACE Hopper Dredges

The USACE considered the addition of screening the grating at the bottom of the drag heads and the water intake doors on top of the drag heads on hopper dredges to protect small fish from being entrained. CDFW established velocity criterion of 0.2 foot per second to protect small fish from being impinged.

The USACE's hopper dredges *Essayons* and *Yaquina* use California drag heads. The basic operating principle of a California drag head is erosion (i.e., creating high water velocity at the solid/water interface to entrain solids). The dredge pumps create the pressure difference across the drag head, inducing high entrance velocities around the periphery of the bottom grating and into the intake doors on the drag head (if opened). The pumps are large enough to maintain sufficient velocity of the solids/water mixture once it has passed through the drag head into the dredge suction and discharge piping to keep the solids in suspension. That velocity is called the depositional velocity. For the *Yaquina*, the depositional velocity is 16.4 feet per second; for the *Essayons*, the depositional velocity is 20 feet per second.

For the opened vacuum-relief doors to perform their intended function, the water velocity through them could exceed CDFW's criteria by up to 50 times. Attaching a pipe or screen of sufficient area to the drag head doors to reduce water velocity to meet CDFW's criterion would be extremely impractical or unworkable for the following reasons:

- The dredge operates at varying water depths, in heavy sea states, over undulating bottom contours, all of which change the angle of the drag head with respect to the drag arm, requiring a robust, flexible connection between the screen appendage and drag head.

- The screen appendage would need to be very large to achieve an open area sufficient to reduce water velocity to 0.2 foot per second (i.e., 165 square feet for the *Yaquina* and 595 square feet for the *Essayons*).
- The screen support would need to be of sufficient strength to withstand the severe environment in which the drag arms operate. The drag arms operate in a very physical environment, often physically impacting with the dredge's bottom, sideshell, and/or davit/cradle when being breasted-in/out. The drag arms often experience impact with floating and submerged debris such as logs, rope, cable, chain, etc.
- The appendage would add significant weight to the drag arm, jeopardizing sufficiency of the drag arm lifting infrastructure.
- Sediment would create blockage on the screens, and it would be extremely impractical to create a cross-flow or to stop dredging every few minutes to clean the screens.

Therefore, this alternative was eliminated from further consideration as technologically infeasible.

#### **2.4.6 Modification of the Federal Navigation Channels**

The USACE considered modification of the federal navigation channels, including realignment of the channels to different location(s), and the institution of scouring systems or other structural channel modifications. These alternative options were eliminated because they are outside the current scope of USACE's maintenance program for the existing federally authorized channels. Moreover, such an undertaking would require years of study, modeling, and more funding than USACE currently has available in its budget. Realignment channels and other options considered here would result in an unacceptable level of impact on benthic and aquatic habitats. The degree of environmental impact and the time necessary to implement this alternative were inconsistent with the basic project objectives, so this alternative was eliminated from consideration.

## CHAPTER 3 AFFECTED ENVIRONMENT AND ENVIRONMENTAL CONSEQUENCES

### 3.1 SCOPE OF ENVIRONMENTAL ANALYSIS

This chapter describes the affected environment and the environmental impacts associated with the alternatives, as well as mitigation—where applicable—to reduce potential impacts.

The affected environment sections provide an environmental baseline of each resource category, describing the conditions in the study area at the time this document was prepared. The environmental conditions described in the affected environment sections constitute the baseline conditions against which impacts are assessed. The California Environmental Quality Act (CEQA) Guidelines, Section 15125, describe the baseline as “the physical environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation is published.” Because maintenance dredging of the federal navigation channels has occurred on a regular basis for several decades, the action of the United States Army Corps of Engineers’ (USACE’s) maintenance dredging and the environmental impacts that have occurred on a regular basis over time from the maintenance dredging of the federal navigation channels are considered part of the existing conditions that comprise the baseline. Accordingly, USACE’s existing maintenance dredging practices, as represented by the No Action/No Project Alternative, and the environmental impacts of these practices, are part of the baseline conditions to which the impacts of the action alternatives are compared.

The environmental consequences discussion provides an analysis of the potential adverse and beneficial environmental impacts that could result from implementing the Proposed Action/Project and action alternatives<sup>1</sup> compared to the No Action/No Project Alternative. Impacts from dredging, transport of dredged materials, and placement of dredged materials are evaluated. Specific analysis of dredged material placement is limited to the existing placement sites listed in Section 1.5.3. Where possible, potential impacts associated with the use of future placement sites identified in Section 1.5.4 are broadly discussed; however, use of these sites by the USACE would be conditioned upon the completion of separate, site-specific supplemental environmental review under the National Environmental Policy Act (NEPA) and/or CEQA, and acquisition of required environmental approvals from resource and regulatory agencies.

#### 3.1.1 Resources Not Applicable to the Project Alternatives

The following resources were considered, but were not addressed in the detailed impact analysis, because the resources are not present in the federal navigation channels or dredged material placement sites, and therefore have no potential to be adversely impacted by the project alternatives.

#### Forestry

The proposed dredging and dredged material placement activities would be in offshore waters, waters in San Francisco Bay, and at coastal and upland sites approved for the placement of dredged materials. The San Francisco Bay Area has a variety of forest types throughout the region. Forests are generally at higher elevations of the Coastal Range in areas with sufficient moisture. Forest resources are not present in the federal navigation channels or placement sites, and therefore would not be impacted by dredging and placement activities.

---

<sup>1</sup> For fiscal years 2015 and 2016, before reduced hopper dredge use is implemented, impacts under the reduced hopper dredge use alternatives would be the same as under the Proposed Action/Project.

### 3.1.2 Resources Not Considered in Detail

The following resources were considered, but were not addressed in the detailed impact analysis, because the project alternatives would have no or negligible impacts on these resources.

#### Agriculture

The proposed dredging and dredged material placement activities would be in offshore waters, waters in San Francisco Bay, and at coastal and upland sites approved for the placement of dredged materials. Agricultural resources are not present in the channels or existing placement areas, and therefore would not be impacted by dredging and placement activities.

Part of one of the potential future placement sites, Bel Marin Keys V, is presently used for agriculture. Additionally, beneficial reuse at Petaluma River Farm would support agricultural production. The USACE would not use this or the other future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation of impacts to agricultural resources.

#### Public Services

Evaluation of impacts to public services typically involves determining whether the proposed dredging and dredged material placement activities would affect level of service and the need for facility expansion for fire protection, police enforcement, school capacity, parks, and libraries. Public services are predominately land-based services; however, the waters of San Francisco Bay are used for maritime enforcement and emergency response. The USACE's continued dredging of the federal navigation channels would maintain the safe navigability of the channels, providing a beneficial impact to maritime enforcement or emergency response actions. Refer to Section 3.10, Transportation, for additional detail regarding navigation policy and procedures in San Francisco Bay. The proposed dredging and dredged material placement activities under all action alternatives would not increase the service population in the San Francisco Bay Area, and therefore would not result in increased demand on public services, the need for construction of new public facilities, or the expansion of existing public facilities. Therefore, implementation of the project alternatives would have no adverse impacts on public services, and this resource is not evaluated further in this Environmental Assessment (EA)/Environmental Impact Report (EIR).

#### Minerals

The considered alternatives would not involve construction or operation of any facilities on or adjacent to any land-based mineral resource areas delineated on land use plans, and therefore would not result in the loss of availability of a land-based mineral resource. Sand is mined from the San Francisco Bay for industrial and agricultural uses. Geographically, mining activity occurs in three areas: the Central Bay west of Angel Island; at Middle Ground Shoal just east of Port Chicago; and in the eastern portion of Suisun Channel (USACE, 2012e). The USACE's continued maintenance of the federal navigation channels, and placement of dredged materials under any of the action alternatives would not adversely impact sand mining because it would not interfere with sand mining activities. Sediments in the San Francisco Main Ship, Pinole Shoal, and Suisun Bay channels are primarily sand. The federal standard placement site for each of these channels is in water and adjacent to or very near the channel. Therefore, USACE's continued maintenance dredging and placement activities would not be expected to deplete sand mineral resources, because dredged material would be redeposited relatively close to the location where it was removed. Beneficial impacts could result if USACE contracted maintenance dredging of a federal channel with sand mineral resources (e.g., Suisun Bay Channel) to a sand mining contractor, thereby facilitating mining of this resource. Sand miners would be responsible for meeting all legal requirements, obtaining any necessary permits or licenses, and adhering to all provisions and contractual

obligations in any agreement with USACE. Because the project alternatives would not result in adverse impact on minerals, this resource is not evaluated further in this EA/EIR.

## Noise

The majority of the federal navigation channels are not near sensitive receptors (e.g., residences, schools, and hospitals). Commercial and recreational ship traffic is an ambient noise source at the federal navigation channels. Several of the channels (e.g., Richmond Harbor, Oakland Harbor) are also in areas with surrounding commercial and industrial operations that are additional sources of ambient noise; noise from dredging at these locations would not be expected to exceed ambient conditions. Noise during transport of dredged materials would not be noticeable in the context of other vessel traffic in San Francisco Bay.

However, there are sensitive receptors in close proximity to some of the federal channels, specifically those along the San Rafael Creek, Napa River, and Petaluma River. Sensitive receptors typically include land uses such as recreational areas, residential homes, schools, hospitals, and churches where noise may cause an annoyance and affect daily activities.

Given that project activities could occur in several different jurisdictions, the Federal Transit Administration (FTA) for assessment of noise impacts for construction activity can be used as thresholds. Using the FTA guidelines provides a uniform method for analyzing noise impacts, and is a commonly accepted industry standard for analysis of noise impacts. Under the FTA guidelines, for residential land uses, the daytime noise standard during construction is 90 A-weighted decibels (dBA) equivalent continuous sound level over a 1-hour period and for an industrial area 100 dBA equivalent continuous sound level over a 1-hour period (FTA, 2006).

Noise from dredging equipment such as an excavator and a dredging ship can generate noise levels of approximately 78 to 82 dBA. Based on these levels, construction noise thresholds in the FTA guidelines would not be exceeded (Department for Environment Food and Rural Affairs, 2005). In addition, in consideration of the ambient noise from existing vessel traffic and the lower frequency at which these channels are dredged, the impacts of short-term intermittent noise from dredging would be negligible. The in-Bay and offshore placement sites are over open waters, there are no sensitive receptors in close proximity to these sites. Short-term noise impacts may occur during placement at upland and beneficial re-use site. However, the placement of dredged materials has occurred regularly in the past at these locations, and ongoing noise from placement activities is part of the existing condition. In this context, noise impacts specific to placement of dredged materials from the federal navigation channels would be negligible. The USACE would not use the future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation of noise impacts.

Therefore, implementation of the project alternatives would have no adverse impacts on the human noise environment, and this resource is not evaluated further in this EA/EIR. Noise impacts on biological resources are discussed in Section 3.6, Biological Resources.

## Utilities

Evaluation of impacts to public utilities includes analysis of whether the proposed dredging and dredged material placement activities would result in the expansion of landfills or facilities that treat or convey wastewater, stormwater, or potable water. The project alternatives would not create residences or commercial facilities that would increase the service population in the San Francisco Bay Area. The maintenance dredging of the federal channels to previously dredged depths and use of existing approved placement sites would not disturb existing utilities. The USACE would not use the future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation of noise impacts.

Placement of dredged material at the Ocean Beach nearshore placement site (SF-17) is ultimately anticipated to have indirect benefits of protecting the infrastructure at Ocean Beach, including the Southwest Ocean Outfall, by providing additional protection to the eroding shoreline.

Therefore, the project alternatives would not adversely impact utilities, and this resource is not evaluated further in this EA/EIR.

## Energy

Although dredging and placement activities do require consumption of nonrenewable energy resources, the project alternatives would not require substantially more energy than USACE's historic and current maintenance dredging operations in San Francisco Bay. Therefore, energy impacts are considered negligible, and this resource is not evaluated further in this EA/EIR.

## Recreational Resources

The proposed dredging and dredged material placement activities would not involve the construction of recreation facilities, would not create demand for new recreational facilities, and would not result in increased use and deterioration of existing recreational facilities.

The project alternatives may occasionally delay or temporarily impede recreational water craft during dredging and placement activities. In most locations, there would be sufficient room for recreational vessels to maneuver around dredge equipment, and therefore, impacts are expected to be negligible. During dredging and placement activities, notes to mariners and navigational warning markers would be used as needed to prevent navigational hazards. In addition, dredging would create a long-term positive effect for small craft by allowing for safe navigation.

The SF-17 placement site boundary is adjacent to the outer boundary of the National Park Service's Golden Gate National Recreation Area, which is one-quarter of a mile seaward of mean sea level. Use of SF-17 as a nearshore beneficial use dredged material placement site would involve either movement of a hydraulic dredge (e.g., USACE-operated *Essayons*) for the purpose of placing thin layer of sand along this nearshore area, or use of an alternate hydraulic dredge with pump-off capabilities. Placement of sandy dredged material at the Ocean Beach Demonstration Site has not shown any adverse impacts or physical degradation of existing recreational resources, change in use of existing recreational resources, or any potential harm to the integrity of the Golden Gate National Recreation Area's cultural and natural resources (USACE, 2013a). Placement of dredged material in a thin layer would not change the existing surf breaks; therefore, no change in wave patterns is expected to occur. Although the surface area of SF-17 is greater than that of the Ocean Beach demonstration site, adverse direct impacts to recreational resources and uses are not expected. Conversely, indirect beneficial effects to recreational activities from the creation of a wider beach area are expected to occur because of the placement of sandy material at this site.

With the exception of SF-17, land-based recreational resources near the existing placement sites identified in Section 1.5.3 are extremely limited; offshore placement at SF-17 would not impact land-based recreation, and nearshore placement of dredged material would have beneficial impacts, as described above. The placement of dredged materials at existing placement sites is an ongoing activity; therefore, dredged material placement at these locations is part of the existing condition, and would not result in any new impacts on recreation.

If onshore placement were to occur at Ocean Beach in the future, beach access may be temporarily restricted during placement activities. Placement activities would be short in duration, and recreationists would have access to other beach areas nearby; therefore, impacts are expected to be negligible. The

USACE would not use Ocean Beach and other the future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation of impacts on recreation.

Therefore, the project alternatives would not adversely impact recreational resources, and this resource is not evaluated further in this EA/EIR.

### **Aesthetics and Visual Resources**

Although aesthetic evaluations are inherently subjective, certain views are widely held to be scenic. Such vistas typically comprise or partially encompass natural landscapes and notable landmarks of the built environment. In the project study area, the important natural scenic resources include the Pacific Coast, San Francisco Bay, Mount Tamalpais, and Mount Diablo. Scenic features of the built environment include the San Francisco skyline, several large buildings in the East Bay Hills, and San Francisco Bay Area bridges. To some observers, the aesthetics may be considered to be slightly degraded during dredging and placement activities from the presence of dredge equipment and turbidity produced during dredging and placement activities. These impacts would be temporary and would occur in locations where dredging and placement activities have occurred regularly in the past. In addition, the waters of San Francisco Bay already include similar uses and equipment, such as ferry terminals, ports, barges, and industrial and commercial shipping operations that are part of the existing visual landscape. In this context, impacts to aesthetics and visual resources from the project alternatives would be negligible. The USACE would not use the future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation of impacts on visual resources and aesthetics.

Therefore, the project alternatives would not adversely impact aesthetics and visual resources, and this resource is not evaluated further in this EA/EIR.

### **Population and Housing, Socioeconomics, and Environmental Justice**

The proposed dredging and dredged material placement activities would not result in construction or modification of residences or commercial facilities, and would not require a large workforce. Therefore, the project alternatives would have no adverse effect on population and housing or socioeconomics. The USACE's dredging of the federal navigation channels provides a beneficial socioeconomic impact by maintaining navigability of the channels and access to local ports and harbors that is critical to maritime commerce and the regional economy.

Based on the nature and location of the proposed dredging and dredged material placement activities, no adverse impacts resulting from the project alternatives would be disproportionately borne by minority or low-income populations. The project represents a continuation of USACE's current activities, for which there are no known environmental justice impacts. Therefore, no environmental justice impacts would occur under the project alternatives. The USACE would not use the future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation of environmental justice impacts.

Therefore, the project alternatives would not adversely impact population and housing, or socioeconomics, and would not result in disproportionately high and adverse impacts to environmental justice populations. Therefore, these resources are not evaluated further in this EA/EIR.

### **Regional Growth**

The proposed dredging and dredged material placement activities would not result in any new residences or infrastructure that could facilitate growth in the San Francisco Bay Area. Maintenance dredging, transport, and placement would not require the expansion of water or energy conveyance, nor would the project alternatives require construction of new roads. The project alternatives would not remove any

existing obstacles to growth. Therefore, the project alternatives would have no impact on regional growth, and this topic is not further evaluated in this EA/EIR.

### 3.1.3 Resources Considered in Detail

The resources discussed in the sections that follow are:

- Geology, soils, and seismicity
- Hydrology and water quality
- Air quality, climate change, and greenhouse gases
- Biological resources
- Cultural and paleontological resources
- Land use
- Hazards and hazardous materials
- Transportation and circulation, including navigation

For each resource section, the analysis is presented as follows:

1. Under “Regulatory Setting,” the federal, state, and local regulatory framework applicable to implementation of the project alternatives is described. Section 1.6 provides an additional overview of legal authorities relevant to the project alternatives.
2. Under “Environmental Setting,” the existing environmental conditions in the study area are described. The region of influence varies by resource, and is defined—where appropriate—for each resource.
3. Under “Methodology and Thresholds for Significance,” there is a discussion of the scope considered in the analysis; the approach to the analysis; and those areas where none of the alternatives would have an impact, and which are therefore not discussed in more detail in that section.
4. Under “Impacts and Mitigation Measures,” direct, indirect, and cumulative impacts are then analyzed, and a full description is provided of the mitigation measures that are recommended or required to reduce project impacts for that resource area.

Direct, indirect, and cumulative impacts were evaluated. Direct impacts are the primary effects that are caused by the alternative, and occur at the same time and place. Indirect impacts are secondary effects that are reasonably foreseeable and caused by the alternative, but occur at a different time or place. Cumulative impacts result from the incremental impact of the proposed project alternatives when added to other past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such other actions (see below for further discussion of cumulative impacts).

Significance criteria for each resource topic were used to assess the severity of the environmental impacts of the proposed project alternatives and, for CEQA compliance purposes, determine when mitigation measures to avoid or substantially reduce the significant impact may be required. Unlike CEQA, NEPA does not have specific impact thresholds that are used to assess the significance of impacts on a given resource topic, but rather states that when assessing whether a proposed action would significantly affect the quality of the human environment, the environmental impacts should be evaluated in terms of their context, intensity, and duration (40 C.F.R. pt. 1508.27). Context refers to the geographic area (spatial extent) of impact, which varies with the physical setting of the activity and the nature of the resource being analyzed. Intensity refers to the severity of the impact; evaluation of the intensity of an impact considers the sensitivity of the resource, as well as other factors. The duration of the impact is described as short-term or long-term. For CEQA, the mandatory findings of significance (California Public Resources Code Sections 21001(c), 21083; 14 California Code of Regulations Section 15065) and the

Environmental Checklist (Appendix G of the CEQA Guidelines) are the primary tools used to define thresholds for determining significance for each environmental topic.

The significance criteria presented in this chapter were developed to satisfy the requirements of both NEPA and CEQA, when feasible, and are primarily adapted from Appendix G of the CEQA Guidelines and relevant agency thresholds. Where possible, significance criteria are based on state or federal standards. For example, air quality criteria, or thresholds, are based on the state and federal ambient air quality standards. In other cases where there are no formal regulatory standards, such as geology, soils, and seismicity, the analysis is based on professional standards. When warranted, different significance criteria are identified for NEPA and CEQA because of different regulatory standards or compliance requirements for USACE as a federal agency and the Regional Water Board as a state agency. In addition, because of differences between NEPA and CEQA guidance, a significant impact under CEQA does not necessarily equate to significant impact under NEPA (i.e., some impacts determined to be significant under CEQA may not be of sufficient context and intensity to be determined significant under NEPA).

In each resource section, discussion of impacts is organized according to the impact type. Under each impact type title, impacts are analyzed for each alternative, and a determination of the level of the impact pursuant to NEPA and CEQA is presented. Where impacts would be the same for one or more alternatives, the impact discussion for these alternatives is combined to avoid redundancy.

Impacts analyzed pursuant to NEPA are classified as beneficial, negligible, less than significant, or significant, which are defined as follows:

- A beneficial impact would generally be regarded as an improvement over current conditions;
- A negligible impact would cause a slight adverse change in the environment, but one that generally would not be noticeable;
- A less-than-significant impact would cause an adverse change in the environment that would likely be noticeable, but does not meet or exceed the defined significance criteria; and
- A significant impact would cause a substantial adverse change in the environment that would exceed the defined significance criteria;

Impacts analyzed pursuant to CEQA are classified as having no impact, less-than-significant impact, less-than-significant impact with mitigation, or potentially significant impact. CEQA specifically refers to effects and impacts as synonymous referring to them as a “physical change,” and directs the lead agency to focus its analysis on the project’s potential to cause an “adverse change in any of the physical conditions within the area affected by the project” (14 California Code of Regulations Sections 15358, 15378, 15382). CEQA does not specifically recognize beneficial effects as an impact.

Avoidance or mitigation measures are identified to reduce the project’s impacts, where feasible. Mitigation measures in this EA/EIR are formulated to be consistent with the definitions of mitigation found in the Council on Environmental Quality NEPA regulations, Section 1508.20, and the CEQA Guidelines Section 15370.

“Cumulative impacts” refers to two or more individual effects that, when combined, are considerable; or that compound or increase other environmental impacts (CEQA Section 15355). Cumulative impacts can result from individually minor but collectively significant impacts taking place over time (Council on Environmental Quality NEPA regulations, Section 1508.7). The discussion of cumulative impacts provides an analysis of cumulative impacts of the project, taken together with other past, present, and reasonably foreseeable future projects producing related impacts. The goal of this analysis is twofold:

first, to determine whether the overall long-term impacts of all such projects would be cumulatively significant; and second, to determine whether the project itself would cause a “cumulatively considerable” incremental contribution to any such cumulatively significant impacts. In other words, the required analysis first creates a broad context in which to assess the project’s incremental contribution to anticipated cumulative impacts, viewed on a geographic scale beyond the project site itself; and then determines whether the project’s incremental contribution to any significant cumulative impacts from all projects is itself significant (i.e., “cumulatively considerable”).

Table 3.1-1 identifies the other past, present, and reasonably foreseeable projects considered in the cumulative analysis. This list includes projects that are likely to result in impacts similar to those of the project alternatives. The list of projects generally includes those in close proximity to the federal channels and placement site (i.e., those that could result in overlapping impacts, such as navigation and air quality), or other projects along San Francisco Bay that could result in overlapping impacts to resources such as biological resources and water quality.

### 3.1.4 Potential Impacts of Deferred Dredging

For the purpose of analysis in this EA/EIR, it is assumed that either reduced hopper dredge use alternative would be implemented by fiscal year 2017. As explained in Section 2.3.4, the costs for implementing these alternatives are beyond the currently programmed operation and maintenance budget for San Francisco Bay. Therefore, before USACE could accomplish the preferred alternatives, should they be adopted by the Regional Water Board, three things typically should occur: first, higher executive branch authority must agree that the increased cost is consistent with the federal standard; second, the additional costs must be included in the annual budget submitted to Congress; and third, Congress must appropriate or reprogram the additional funds. If USACE was unable to obtain both the necessary authorization and funding to implement these alternatives, USACE would follow the regulations at 33 C.F.R. pt. 335-338. The process described in these regulations could potentially result in deferred dredging at certain channels (i.e., Richmond Outer, Pinole Shoal, and Suisun Bay Channel and New York Slough). Deferred dredging means that these channels may not be fully maintained by USACE. In the interest of disclosing the potential environmental impacts of deferred or incomplete dredging, such impacts are noted here, and discussed further in this chapter for resources where adverse impacts could result. Because it is unknown whether, to what extent, or for how long, dredging could be deferred, the impacts of deferred dredging would be speculative and variable. Therefore, discussion of the potential impacts associated with deferred dredging is presented as a brief qualitative assessment for resources areas where potentially adverse impacts could occur.

Due to an overall reduction in dredging activities in San Francisco Bay with the deferral of dredging, impacts from dredging operations on geology and soils, water quality, air quality and greenhouse gases, biological resources (including listed species), and cultural resources would be reduced, compared to the Proposed Action/Project and No Action/No Project Alternative. However, with the reduced, or lack of, maintenance of certain channels, there would be an increased risk of a navigational hazard that would result in vessel groundings, allisions, or collisions, as well as an oil spill that could result from such incidents. Furthermore, the lack of or reduced maintenance of the Main Ship Channel, Richmond Outer Harbor, Pinole Shoal Channel, and Suisun Bay Channel, and New York Slough could impact access to the ports these channels serve and could result in adverse economic impacts. Refer to Sections 3.9 and 3.10 for additional discussion of potential impacts related to hazards, hazardous materials, navigation, and the economy.

**Table 3.1-1  
Cumulative Scenario – Present and Reasonably Foreseeable Projects**

<b>Project Number</b>	<b>Project Name/ Location</b>	<b>Status/ Anticipated Timeline</b>	<b>Project Summary</b>	<b>Source</b>
1	Nonfederal Maintenance Dredging in San Francisco Bay	Ongoing	More than 100 marinas, ports, and berthing slips are maintenance dredged in the San Francisco Bay/Estuary. Most of the nonfederal maintenance projects are along the shorelines and in the tributaries of the Estuary.	USACE and USEPA, 2009
2	Hamilton-Bel Marin Keys Aquatic Transfer Facility	Planning phase could occur within 10-year planning horizon	The California State Coastal Conservancy and USACE are the project sponsors for a 58-acre in-water basin that would be used for stockpiling and transporting dredged sediment to the Bel Marin Keys Unit V Expansion portion of the Hamilton Wetlands Restoration Project in San Pablo Bay.	CSCC, 2013
3	San Francisco Bay and Delta Sand Mining Project	10-year leases to continue mining sand (until 2022)	The California State Lands Commission action is a 10-year General Lease through December 31, 2022. Hanson Marine Operations proposed new 10-year mineral extraction leases to enable the continuation of dredge mining of construction-grade sand from certain delineated areas of Central San Francisco Bay, Suisun Bay, and the western Sacramento-San Joaquin River Delta area.	CSLC, 2012; CEQAnet, 2013
4	South San Francisco Shoreline Study	Planning phase; construction could begin in 2017	Congressionally authorized study by USACE together with the Santa Clara Valley Water District and the CSCC to identify and recommend flood risk management and ecosystem restoration projects along South San Francisco Bay for federal funding.	South Bay Shoreline, 2013
5	South Bay Salt Pond Restoration	Expected completion of 230 acres of pond reconfiguring in 2014; trail construction and public use slated by 2015	The CSCC, the California Department of Fish and Wildlife, and the United States Fish and Wildlife Service are the project sponsors for this tidal wetland restoration project that, when complete, will restore approximately 15,000 acres of industrial salt ponds to tidal wetlands, mudflats, and other wetland habitats.	South Bay Salt Pond, 2013a and 2013b

**Table 3.1-1  
Cumulative Scenario – Present and Reasonably Foreseeable Projects (Continued)**

<b>Project Number</b>	<b>Project Name/ Location</b>	<b>Status/ Anticipated Timeline</b>	<b>Project Summary</b>	<b>Source</b>
6	Sacramento Deep Water Ship Channel	Planning phase could occur within 10-year planning horizon	The USACE is the project sponsor for the Sacramento River Deep Water Ship Channel, a 43-mile-long channel in Contra Costa, Solano, Sacramento, and Yolo Counties that serves the marine terminal facilities at the Port of West Sacramento. The 30-foot-deep SRDWSC joins the 35-foot-deep John F. Baldwin Ship Channel, allowing access to the San Francisco Bay Area harbors and the Pacific Ocean. The project involves resuming construction of the 35-foot-deep channel, as authorized in 1986. A Limited Reevaluation Report and Supplemental Environmental Impact Statement/Report are being prepared.	USACE, 2013b
7	San Francisco Bay to Port of Stockton John F. Baldwin Ship Channel Phase III Navigation Improvement Project	Planning phase	The USACE is the project sponsor for deepening the original channel to 45 feet MLLW and the Stockton Deep Water Channel to 40 feet MLLW for draft navigation.	USACE, 2012f
8	Stockton Deep Water Ship Channel Operations and Maintenance	Ongoing	Maintenance dredging of the Stockton portion of the channel to 35 MLLW by USACE Sacramento District.	USACE, 2012f
9	Brooklyn Basin (formerly called Oak-to-Ninth District)	Construction planned for 2015	The California Department of Toxic Substances Control is leading the development of the Brooklyn Basin project, which would create 3,100 housing units, 200,000 square feet of retail and commercial space, 30 acres of parks and trails, and a marina with up to 200 boat slips on a 64-acre former marine industrial area. The Port of Oakland owns the property.	DTSC, 2013
10	Marine Ocean Terminal Concord	Planning phase	The U.S. Department of the Navy is the project sponsor for proposed modernization and repair of Piers 2 and 3 of the Military Ocean Terminal Concord due to structural decay, marine borer damage, and fungal decay. Piers 2 and 3 are used to transport military supplies in the Pacific region.	DoD, 2013

**Table 3.1-1  
Cumulative Scenario – Present and Reasonably Foreseeable Projects (Continued)**

<b>Project Number</b>	<b>Project Name/ Location</b>	<b>Status/ Anticipated Timeline</b>	<b>Project Summary</b>	<b>Source</b>
11	Redwood City Deepening Project	Planning phase	Joint studies under way by the Port of Redwood City and USACE to deepen and improve Redwood City Channel and San Bruno Channel to a depth of 34 to 35 feet.	Caltrans, 2013
12	Napa Salt Marsh Restoration Project	Ongoing	USACE, CSLC, and the CDFW are implementing the Napa Sonoma Marsh Restoration project. The first two phases are complete, with the last phase restoring the final 1,900 acres of wetlands and associated habitats in the 10,000-acre project.	Napa Sonoma Marsh, 2013
13	Suisun Marsh Restoration Plan	Planning phase	The United States Department of the Interior is the project sponsor for tidal restoration targets of 5,000 to 7,000 acres and 44,000 to 46,000 acres of managed wetlands during the 30-year implementation period.	U.S. Department of the Interior, USFWS, and CDFW, 2011
14	San Francisco Bay Area Water Emergency Transportation Authority (WETA) Berkeley Ferry Terminal	Planning phase	WETA is the project sponsor. The Locally Preferred Alternative includes the construction of a new ferry pier on the Berkeley waterfront between the existing Berkeley Fishing Pier and Hs Lordships restaurant. The proposed improvements include a pier for berthing two vessels, and for loading and unloading ferry passengers and dredged channels.	WETA, 2013a
15	WETA Downtown San Francisco Ferry Terminal Expansion Project	Planning phase; construction activities as early as 2016 and completed by 2020	WETA is the project sponsor for the proposed expansion of berthing capacity (new gates and overwater berthing facilities, additional passenger waiting and queuing areas, circulation improvements, and other water-transit-related amenities) at the Downtown San Francisco Ferry Terminal to accommodate future planned water transit services between San Francisco and Antioch, Berkeley, Martinez, Hercules, Redwood City, Richmond, and Treasure Island, as well as emergency operation needs.	WETA, 2013b

**Table 3.1-1  
Cumulative Scenario – Present and Reasonably Foreseeable Projects (Continued)**

<b>Project Number</b>	<b>Project Name/ Location</b>	<b>Status/ Anticipated Timeline</b>	<b>Project Summary</b>	<b>Source</b>
16	WETA Central Bay Operations and Maintenance Facility Project	Construction activities as early as 2015	The Central Bay Operations and Maintenance Facility project is being developed by WETA to provide a central San Francisco Bay base for WETA's ferry fleet. The project site is near Pier 3 of the Naval Air Station Base Realignment and Closure area known as Alameda Point. The project would include construction of a multi-story building that would provide for WETA's operational needs such as light repair work, diesel fuel storage, spare parts storage, concession supply, administrative staff office space, records storage and deliveries. The facility will also include a system of floating docks and gangways that would provide daytime and overnight berthing capacity for up to 11 vessels.	WETA, 2013c
17	WETA Richmond Ferry Terminal and Service	Planning phase	WETA is proposing to establish a new ferry route between the existing San Francisco Ferry Terminal and a new ferry terminal on the Ford Peninsula in the City of Richmond. The proposed new terminal would replace an existing ferry facility consisting of a gangway, float, ramping system and piles.	WETA, 2013d
18	WETA Vallejo-Baylink Ferry Maintenance Facility Project	Construction phase	The Vallejo-Baylink Ferry Maintenance Facility Project would replace the existing maintenance facility at a location approximately half a mile downstream from the existing maintenance facility. The project site is in the former Mare Island Naval Shipyard, which is on the western edge of the City of Vallejo. The project includes an administration office, maintenance and fueling facilities, and berthing.	Winzler and Kelly, 2011
19	WETA Treasure Island Terminal	Planning phase	Ferry service between the west side of Treasure Island and the San Francisco Ferry building is planned as part of the project. A new Ferry Terminal would be constructed, including a Ferry Terminal building, a ferry quay and docks, breakwaters, and the ferry basin enclosed by the breakwaters.	CCSF Planning, 2010

**Table 3.1-1  
Cumulative Scenario – Present and Reasonably Foreseeable Projects (Continued)**

<b>Project Number</b>	<b>Project Name/ Location</b>	<b>Status/ Anticipated Timeline</b>	<b>Project Summary</b>	<b>Source</b>
20	Dutra Haystack Landing Asphalt and Recycling Facility	Operations anticipated to commence Summer 2015	Operate an asphalt batch plant, an asphalt and concrete recycling facility, and an aggregate materials off-loading, storage, and distribution facility for Dutra Materials. The proposal includes the construction and operation of new dock facilities in and adjacent to the Petaluma River.	Sonoma County, 2008
21	San Pablo Bay Restoration Project	Ongoing operation	The USACE is the project sponsor for efforts to support construction of replacement wetlands, protection from additional pollution, and creation of habitats to increase the biodiversity and habitat values in the watershed in the San Pablo Bay area.	USACE, 2013c
22	Sears Point Wetland and Watershed Restoration Project	First phase: September 2012 through September 2015	The 2,327-acre Sears Point property is in southern Sonoma County, just north of San Pablo Bay. The Sonoma Land Trust, in cooperation with CDFW and the USFWS, proposes to restore tidal wetlands and rehabilitate diked wetlands and upland habitats, and to develop public access and educational opportunities.	USFWS, 2012a
23	San Leandro Shoreline Development	Planning phase; construction anticipated to start in May 2016	The City of San Leandro is proposing to develop an approximately 40-acre portion of the 1,800-acre publically owned shoreline, which would include a 250,000-square-foot office campus, 225 room hotel, 15,000-square-foot conference center, 188 units of housing, three new restaurants (total 21,000 square feet), 40,000 square feet of mixed-use office and retail, a library, and a parking structure.	City of San Leandro, 2013a; 2013b
24	Cullinan Ranch Tidal Restoration Project	Construction phase	The USFWS and the CDFW propose to construct a levee for portions of Highway 37, provide erosion protection on highway embankment slopes, construct access improvements, construct public use facilities (trails, a fishing pier, and a kayak launching dock), and breach and lower of tidal levees.	Restore Cullinan, 2013

**Table 3.1-1  
Cumulative Scenario – Present and Reasonably Foreseeable Projects (Continued)**

Project Number	Project Name/ Location	Status/ Anticipated Timeline	Project Summary	Source
25	WesPac Energy Pittsburg Marine Terminal Renovation	Construction planned for late 2014	WesPac Energy proposes to modernize and reactivate an existing oil storage and transfer facility at the Pittsburg Generating Station. The project site is at 696 West 10th Street in Pittsburg, and consists of approximately 125 acres of land stretching from the existing West 10th Street north, to the southern shoreline of the Suisun Bay. In addition, approximately 39 acres of submerged tidelands would be leased from the City of Pittsburg for the marine terminal portion of the facility.	City of Pittsburg, 2012 and CSLC, 2013b
26	Brooklyn Basin Deepening	Planning phase	The Brooklyn Basin Deepening project would likely entail widening and deepening of the segment of Oakland Inner Harbor from Washington Bridge to Park Street to a depth of 35 feet MLLW. In addition, the deepening project could include deepening and widening of the North Channel to 25 feet and 35 feet MLLW in various locations. The Brooklyn Basin Harbor is primarily used by USCG for use by the National Security Cutters. In the 1980s when the environmental documentation for the deepening the entire Oakland Inner Harbor was evaluated, deepening of the Brooklyn Basin Harbor was not carried through mainly because of the lack of economic justification. As of this writing, deepening of the Brooklyn Basin Harbor remains a project with low probability of occurrence due to lack of funding and environmental documents. However, because national security needs for this portion of the Inner Oakland Harbor may change abruptly, the project is considered for cumulative impact analysis.	USACE San Francisco District

 USCG = United States Coast Guard  
 USFWS = United States Fish and Wildlife Service

### 3.2 DOCUMENTS INCORPORATED BY REFERENCE

Incorporation of previous analysis by reference is encouraged by both the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA). For NEPA, the Council on Environmental Quality regulations (40 C.F.R. §§ 1500.4, 1502.21) state that agencies shall incorporate material by reference when the effect will be to reduce bulk without impeding agency and public review of the project alternatives. The incorporated material shall be cited, and its content summarized. No material may be incorporated by reference unless it is reasonably available for inspection by potentially interested persons within the time allowed for comment. Material based on proprietary data which are themselves not available for review and comment shall not be incorporated by reference. Under CEQA, incorporation by reference is authorized (California Public Resources Code Sections 21093 and 21094; State CEQA Guidelines Section 15150).

This Environmental Assessment (EA)/Environmental Impact Report (EIR) incorporates by reference information contained in the following documents:

- *The Final Composite Environmental Statement for Maintenance Dredging of Existing Navigation Projects, San Francisco Bay Region* was issued by the San Francisco District in 1975 (USACE, 1975). This document analyzed the environmental impacts associated with maintenance dredging of 20 federal navigation projects in San Francisco Bay, including the ten federal navigation projects that are the subject of this EA/EIR.
- *Final Policy Environmental Impact Statement/Programmatic Environmental Impact Report (EIS/EIR), Long Term Management Strategy (LTMS) for the Placement of Dredged Material in the San Francisco Bay Region* (LTMS, 1998). The LTMS EIS/EIR was jointly published by the LTMS agencies to select the overall long-range approach to conduct necessary dredging and dredged material disposal in an environmentally sound and economically prudent manner, to maximize the beneficial reuse of dredged material, and to develop a coordinated permit review process for dredging projects. Three alternative long-term approaches were evaluated in the LTMS EIS/EIR that would achieve the LTMS goals to various extents.
- *Record of Decision, LTMS for the Placement of Dredged Material in the San Francisco Bay Region* (USACE et al., 1999). The Record of Decision identified, from the alternatives considered in the LTMS EIS/EIR, the alternative selected by the United States Army Corps of Engineers (USACE) and United States Environmental Protection Agency to guide dredged material placement decisions in the San Francisco Bay Region for a period of 50 years.
- *Final Long Term Management Strategy Management Plan for Placement of Dredged Materials in the San Francisco Bay Region* (USACE et al., 2001). This document describes the detailed measures by which the LTMS agencies are implementing the EIS/EIR's long-term plan.
- *LTMS National Marine Fisheries Service Biological Opinion* (NMFS, 1998). This document transmits the National Marine Fisheries Service (NMFS) biological opinion for the LTMS Program and its effects on federally listed species under NMFS' jurisdiction at the time the consultation was completed. The biological opinion outlines implementing procedures and minimization measures. NMFS is revising the 1998 biological opinion; the updated biological opinion (expected 2015) will supersede the 1998 document.
- *LTMS U.S. Fish and Wildlife Service Biological Opinion* (USFWS, 1999). This document transmits the United States Fish and Wildlife Service Biological (USFWS) biological opinion for the LTMS Program and its effects on federally listed species under USFWS' jurisdiction at the time the consultation was completed. The biological opinion outlines criteria for inclusion of projects under the programmatic consultation, implementing procedures, and minimization measures. The

biological opinion was amended in 2004 to modify certain restrictions and minimization measures (USFWS, 2004).

- *LTMS California Department of Fish and Game Concurrence on Biological Opinions* (CDFG, 1998). In this document, the California Department of Fish and Game (now the California Department of Fish and Wildlife) concurred with the USFWS and NMFS biological opinions on the LTMS Program.
- *Delta Smelt: 2004 Formal Programmatic Consultation with the U.S. Fish and Wildlife Service* (USFWS, 2004). The USFWS issued a programmatic biological opinion on the issuance of Rivers and Harbors Act Section 10 permits and Clean Water Act Section 404 permits for projects with relatively small effects on delta smelt and its critical habitat in the jurisdiction of USFWS' Sacramento Field Office. It should be noted that since 2011, USACE has been required to consult on impacts to delta smelt during dredging of Suisun Bay Channel and New York Slough because of documented occurrences of entrainment during monitoring of hopper dredge use. Since 2011, USACE has received nonjeopardy opinions from USFWS to maintain Suisun Bay Channel with a hopper or clamshell dredge.
- *Programmatic Essential Fish Habitat (EFH) Assessment for the Long-Term Management Strategy for the Placement of Dredged Material in the San Francisco Bay Region* (USACE and USEPA, 2009). Pursuant to Section 305(b)(2) of the Magnuson-Stevens Fishery Conservation and Management Act of 1976 (16 U.S.C. § 1855[b]), USACE and USEPA submitted a Programmatic EFH Assessment to NMFS for the San Francisco Bay Region LTMS. This document provides an assessment of the potential effects to EFH from the ongoing dredging and dredged material placement activities of all federal and nonfederal maintenance dredging projects in the San Francisco Bay Region.
- *Agreement on Programmatic EFH Conservation Measures for Maintenance Dredging Conducted Under the LTMS Program* (USACE and USEPA, 2011). This document identified a comprehensive suite of EFH conservation measures developed in coordination with NMFS and completed the programmatic EFH consultation covering all maintenance dredging projects under the LTMS Program.

Relevant portions of all documents incorporated by reference into this EA/EIR are summarized throughout this EA/EIR where specifically noted.

### 3.3 GEOLOGY, SOILS, AND SEDIMENT QUALITY

This section evaluates the project alternatives' potential effects related to erosion and sediment quality. Sediment-related impacts on water quality (e.g., turbidity, contaminant suspension) from dredging and placement activities are discussed in Section 3.4, Hydrology and Water Quality. Potential impacts associated with sediment quality impacts on fisheries and other aquatic species are addressed in Section 3.6, Biological Resources.

#### 3.3.1 Regulatory Setting

As detailed in Section 1.3.2, authorization to discharge dredged material in the open ocean, enclosed coastal waters, upland sites, or for beneficial reuse is provided through a variety of federal and state permitting processes. The United States Army Corps of Engineers (USACE) and United States Environmental Protection Agency (USEPA) jointly regulate the discharge of dredged material into waters of the United States and the transportation of dredged material for the purpose of disposal of ocean waters pursuant to Section 404 of the Clean Water Act (CWA), and the Marine Protection, Research and Sanctuaries Act (MPRSA) (also refer to Sections 1.4.3 and 1.5.1). Under Section 401 of the CWA, the Regional Water Board must certify that the disposal will not violate state water quality standards and other applicable requirements; and the state further has the authority to regulate disposal of dredged material into state waters under the Porter-Cologne Act. In addition, pursuant to the federal Coastal Zone Management Act, USACE's maintenance dredging and dredged material placement needs to be consistent with the state's coastal zone management program and policies to the maximum extent practicable (16 U.S.C. § 1456).<sup>1</sup> In San Francisco Bay, state and regional regulations also apply to dredged material disposal. In 1996, the Dredged Material Management Office (DMMO) was created as part of the Long Term Management Strategy (LTMS) Program to establish a comprehensive and consolidated approach to eliminate redundancy and delays in the dredged material placement permitting process in the San Francisco Bay Area. Sediment testing requirements are dictated by a combination of federal and state guidance, as overseen by the DMMO.

#### Dredged Material Management Office

The DMMO is a joint program of USACE, USEPA, the Regional Water Board, San Francisco Bay Conservation and Development Commission, and California State Lands Commission. Participating agencies include the California Department of Fish and Wildlife, National Marine Fisheries Service, and the U.S. Fish and Wildlife Service. The purpose of the DMMO is to cooperatively review sediment quality sampling plans, analyze the results of sediment quality sampling, and make suitability determinations for material proposed for placement in San Francisco Bay, ocean placement, and beneficial reuse. The DMMO promotes use of beneficial reuse sites in support of the LTMS goals of beneficial reuse of at least 40 percent of material dredged in the San Francisco Bay region; no more than 40 percent placement at the San Francisco Deep Ocean Disposal Site (SF-DODS); and no more than 20 percent placement at in-Bay sites.

The process for obtaining approvals for dredging or dredged materials placement has three phases: (1) suitability determination; (2) permit process; and (3) episode approval. The suitability determination phase occurs at the DMMO level. The DMMO provides a venue for group discussion regarding material suitability for reuse or disposal based on sediment testing data.

The applicant must submit results from recent sediment testing, or provide sufficient data to support a finding by the agencies that the subject sediments are suitable for the proposed placement environment.

---

<sup>1</sup> Pursuant to the federal Coastal Zone Management Act, USACE is required to be consistent to the maximum extent practicable with the enforceable policies of the California Coastal Act and the San Francisco Bay Plan, including those on water quality and dredging. The proposed project's consistency with the Coastal Zone Management Act is discussed in Section 3.8, Land Use.

The applicant submits to the DMMO either a sediment Sampling and Analysis Plan and Quality Assurance Project Plan, or a written request (with supporting information) for an exclusion from testing requirements based on factors such as previous testing history, and physical characteristics of the material proposed for dredging (e.g., Tier I analysis). The applicant must submit the sampling results to the DMMO for review, and the DMMO will make a determination regarding suitability for placement at the proposed placement site, or recommend alternate sites.

Although the DMMO provides initial review of permit applications and suitability recommendations, applicants must obtain separate approval from the appropriate DMMO member agencies (such as a CWA Act Section 401 Water Quality Certification from the Regional Water Board); each agency issues permit conditions and specific requirements associated with how the project is to be performed.

In February 2004, the DMMO adopted a Master Sampling and Analysis Plan (Master SAP) to streamline the process for composing and reviewing sampling and analysis plans for individual USACE maintenance dredging projects. The Master SAP describes the manner in which material should be collected, shipped, stored, handled, and tested for certain physical, chemical, and biological analyses. An updated Master SAP was approved by the DMMO in 2014.

### **Sediment Testing Requirements**

Material proposed to be dredged and placed in ocean, inland aquatic, or upland/beneficial reuse sites requires sediment characterization to predict the environmental impacts associated with dredging and dredged material placement activities. The objective of the sediment testing requirement is to determine whether placement of dredged material at designated placement sites can occur without causing unacceptable degradation to the surrounding environment. Most sediments undergo physical, chemical, and biological (i.e., benthic and water column toxicity) testing. The extent of sediment characterization necessary to ensure compliance with applicable environmental laws and regulations is generally site-specific.

For ocean placement, the material must be acceptable for deep-ocean placement, as regulated by the MPRSA. Section 102 of the MPRSA authorizes USEPA to establish criteria for evaluating all dredged material proposed for ocean dumping. These criteria are published separately in the Ocean Dumping Regulations at 40 C.F.R. pt. 220-228. Section 103 of the MPRSA authorizes USACE to issue permits, subject to USEPA concurrence or waiver, for dumping dredged materials into the ocean waters. The Ocean Testing Manual (OTM) (USACE and USEPA, 1991), commonly referred to as the Green Book, provides national guidance for determining the suitability of dredged material for ocean disposal.

For placement of dredged material in inland waters, including San Francisco Bay, Section 404 of the CWA and the regulations at 40 C.F.R. pt. 230 define the testing requirements. Current guidance for implementing inland aquatic dredged material placement is provided in *Evaluation of Dredged Material Proposed for Disposal in Waters of the U.S. – Testing Manual for Discharge in Inland and Near Coastal Water – Testing Manual* (USACE and USEPA, 1998), referred to as the Inland Testing Manual (ITM). In 2001, the DMMO released *Guidelines for Implementing the Inland Testing Manual in the San Francisco Bay Region* (USACE, 2001). The DMMO agencies apply these guidelines, or the most current version, when determining the dredged material testing that will be required for dredging projects proposing disposal at designated sites in waters of the United States in San Francisco Bay. These local guidelines supplement the more detailed information in the ITM, and are not intended to be used on their own.

In the San Francisco Bay Area, screening guidance for placement of dredged material at upland sites or for beneficial reuse is provided in the Regional Water Board's May 2000 staff summary report, *Beneficial Reuse of Dredged Materials: Sediment Screening and Testing Guidelines*, or most current revised version. For upland placement that is not beneficial reuse, or for material not suitable for aquatic placement, guidance may also come from the Upland Testing Manual (UTM) (USACE, 2003). Other criteria for upland beneficial reuse are contained in the permit conditions for each placement site.

Sediment testing is conducted in accordance with a tiered sampling framework for projects ranging from low- to high-potential impacts. Testing requirements increase from Tier I up to Tier IV. The terms Tier I, Tier II, Tier III and Tier IV are defined in the OTM, ITM and UTM; however, the DMMO also uses the terms.

The term Tier I is an evaluation system used by the DMMO to determine suitability of sediment for unconfined aquatic placement without additional testing. This determination is granted when the existing sediment data are sufficient for regulatory agencies to determine placement suitability. Criteria that may preclude the need for further testing include:

- 1) The dredged material is composed predominantly of sand, gravel, rock, or any other naturally occurring bottom material with particle sizes larger than silt, and the material is found in areas of high current or wave energy; or
- 2) The dredged material is for beach nourishment or restoration and is composed predominantly of sand, gravel, or shell with particle sizes compatible with material on the receiving beaches; or
- 3) When:
  - a. The material proposed for dumping is substantially the same as the substrate at the proposed site; and
  - b. The proposed dredging site is far removed (by distance or depth) from known existing and historical sources of pollution so as to provide reasonable assurance that such material has not been contaminated by such pollution.

Tier II testing typically requires physical and chemical analysis such as total solids, total organic carbon, grain size, metals, butyltins, pesticides, polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons. Tier III testing may require biological evaluations, such as water column toxicity, benthic toxicity, and benthic bioaccumulation tests, in addition to physical and chemical analysis. Tier IV testing requires more comprehensive, case-specific evaluations. The programmatic essential fish habitat agreement for the LTMS program also includes requirements for bioaccumulation testing (USACE and USEPA, 2011, Item E7).

Additional testing requirements may include confirmatory grain size analysis, and the Modified Elutriate Test. Confirmatory grain size analysis is a physical analysis of sediment grain size, total organic carbon, and total solids. The Modified Elutriate Test is designed to measure and predict the release of contaminants from sediment into the water column, and any toxicity associated with decant water that could be discharged from upland placement sites to adjacent surface waters..

### **3.3.2 Environmental Setting**

#### **Study Area**

The study area is the geologic and tectonic setting of the San Francisco Bay Area. From the edge of the continental shelf near the Farallon Islands, it extends inland to the western margin of the Sacramento-San Joaquin Valley; and from the southern end of the Santa Clara Valley, it extends northward to the northern end of the Sonoma Valley. This region incorporates the major tectonic elements that define the structure and geologic characteristics of, or affecting, the San Francisco Bay Area.

#### **Regional Geological Setting**

The San Francisco Bay Area has a structurally controlled topography that consists primarily of north- to northwest-trending mountain ranges and intervening valleys that are characteristic of the Coast Ranges geomorphic province. The Coast Ranges are composed of a thick sequence of late Mesozoic (200 to 70 million years old) and Cenozoic (less than 70 million years old) sedimentary strata. The northern part of the Coast Range is dominated by the Franciscan assemblage.

San Francisco Bay is a topographic trough formed by a combination of warping and faulting, and is underlain by a down-dropped or tilted block (the Bay Block) (Olson and Zoback, 1998). This trough in the Coast Ranges allows the San Joaquin and Sacramento rivers to drain to the ocean. San Francisco Bay is about 55 miles long, and from 3 to 5 miles wide. Constrictions divide San Francisco Bay into Suisun, San Pablo, and the Central and South San Francisco bays.

The geology of the San Francisco Bay Area is made up primarily of three different geologic provinces: the Salinian block, the Franciscan complex, and the Great Valley sequence. The Salinian block is west of the San Andreas Fault. It is composed primarily of granitic plutonic rocks, which are similar to those found in the Sierra Nevada, and are believed to be rocks of the Sierra Nevada Batholith that have been displaced along the San Andreas Fault. To the east of the San Andreas Fault, and bounded on the east by the Hayward Fault, is the Mesozoic Franciscan complex. The Franciscan rocks represent pieces of former oceanic crust that have accreted to North America by subduction and collision. These rocks are primarily deep marine sandstone and shale. However, chert and limestone are also found in the assemblage. To the east of the Hayward Fault is the Great Valley sequence. This is composed primarily of Cretaceous and Tertiary marine sedimentary rocks in the San Francisco Bay Area.

The trough-like depression that underlies San Francisco Bay has been nearly filled with sediments, some of which have come from erosion of surrounding hills, and some of which consist of later marine deposits. For example, the marine clay-silt deposit termed “Bay Mud” is present throughout most of San Francisco Bay, several feet beneath the soft, more recently deposited muds. An ancient fine-grained sand deposit known as Merritt Sand occurs in the vicinity of Oakland and Alameda, in places relatively close to the sediment surface. Also, natural peat deposits can be found underlying more recent San Francisco Bay sediments in some areas of the San Pablo Bay, Suisun Bay, and the Delta. The thickness of the various historic sediment formations varies throughout the Estuary, but they can be several hundred feet thick overall. The upper several feet of the sediment profile in most locations consists of more recently deposited marine and riverine sediments. Sediments in the Estuary fall into three categories: sandy bottoms in the channels; shell debris over a wide expanse of the South Bay (derived from remnants of oyster beds); and soft deposits (known as Bay Mud) underlying the vast expanses of shallow water. Regions of the Estuary where currents are strong, including the deep channels of San Francisco Bay and the central channels of the major rivers in the Delta, generally have coarser sediments (i.e., fine sand, sand, or gravel). Areas where current velocities are lower, such as the shallow fringes of each subembayment of San Francisco Bay, are covered with Bay Mud (LTMS, 1998).

### **Recent Geologic History**

The present Estuary formed less than 10,000 years ago as the global climate warmed and sea levels rose. Marine water re-entered San Francisco Bay approximately 10,000 years ago, and by about 4,000 years ago had reached its present level. With the establishment of estuarine conditions, sedimentation in San Francisco Bay changed from alluvial sands and silts to dark-colored estuarine clays and silts, commonly called Bay Mud. Deposition of sandier sediment was confined to channels.

Since approximately 1850, human activities have made significant modifications to San Francisco Bay, causing changes in the patterns of circulation and sedimentation. Between 1856 and 1900, hydraulic mining in the Sierra foothills deposited several feet of sediment throughout San Francisco Bay. Starting in the 1800s, the construction of levees and dikes altered the patterns of drainage and annual flooding in the Sacramento River Delta. Also, the placement of fill at numerous localities around the San Francisco Bay margins has dramatically altered the shoreline profile during historic time.

In general, the surficial sediments in San Francisco Bay have been deposited since industrialization began in California, and therefore may have been exposed to anthropogenic sources of pollutants. These “industrial age” sediments can be encountered in maintenance dredging. Recent sand deposits—either riverine sand in portions of San Pablo and Suisun bays and the lower Sacramento River, or sand bars maintained by strong currents in central San Francisco Bay and the San Francisco Bar—also may be exposed to anthropogenic

sources of pollutants, but typically do not accumulate significant concentrations of them. There have been several programs in San Francisco Bay that have monitored concentrations of contaminants in sediments from various embayments. Data indicate that, overall, the peripheral industrialized areas indeed have higher mean contaminant concentrations than do the central basins (LTMS, 1998).

Whether of terrestrial or marine origin, the older deposits that pre-date European settlement in California generally are very hard-packed, low in moisture content, low in organic carbon (except for peat deposits), and have low concentrations of chemicals such as heavy metals and organic compounds. The chemical levels that are measurable in these historic deposits represent natural concentrations for the sediment type. These deposits are not typically dredged during maintenance dredging (LTMS, 1998).

### Regional Sediment Quality

**San Francisco Bay.** Since 1993, the San Francisco Estuary Institute has administered a Regional Monitoring Program (RMP) for the Regional Water Board and major San Francisco Bay dischargers. The San Francisco Estuary Institute's RMP includes sampling and testing of sediments from San Francisco Bay since 1993. Sediment samples are collected during the wet season and the dry season in alternating years, and analyzed for conventional sediment quality, trace metals, and trace organics. Samples are collected from the near surface (top 2 inches of sediment). Additional information on the RMP related to water quality is presented in Section 3.4, Hydrology and Water Quality.

RMP monitoring results indicate that sediment toxicity in San Francisco Bay has consistently been observed in a large proportion of samples tested, but varies over time (SFEI, 2006). These variations probably reflect changes in sediment contamination and toxicity related to seasonal and annual changes in run-off, salinity, and contaminant loadings.

The Bay Protection and Toxic Cleanup section of the California Water Code (Division 7, Sections 13390-13396.5) established a program to identify and plan remediation of toxic hot spots in bays and estuaries. The Consolidated Toxic Hot Spots Cleanup Plan (SWRCB, 2003) identified sediments in the entire San Francisco Bay as a high-priority toxic hot spot for mercury, selenium, polycyclic aromatic hydrocarbons, and dieldrin.

The continual re-suspension of sediments in the San Francisco Estuary system also means it can be expected that sediments accumulating in navigation channels may have been exposed to pollutant sources in several locations, far removed from the dredging site. This helps to explain why almost all maintenance dredging projects from throughout San Francisco Bay show at least some degree of elevated (above ambient or "background") concentrations of trace contaminants. However, particles carrying pollutants also may get diluted with particles from other areas that settle in the same location that have lower concentrations of associated contaminants. Thus, the sediment from many dredging projects, even when trace pollutants are present, is not contaminated to a degree that causes toxicity, or that otherwise represents any significant environmental risk (LTMS, 1998).

**Offshore.** Based on sampling conducted between 1996 and 2007, measured chemical concentrations in the sediment at SF-DODS have generally not exceeded those background values found either at the site prior to disposal or at a SF-DODS reference area; the few chemical compounds whose concentrations have exceeded background values have still been well below any value to cause any potential concern for biological effects (Germano and Associates, 2008).

### Sediments in the Federal Navigation Channels

Sediment dredged from most of the federal navigation channels is typically characterized as Bay Mud—the exceptions being the San Francisco Main Ship Channel (MSC), Suisun Bay Channel and New York Slough, and portions of Pinole Shoal Channel, which have historically been greater than 80 percent sand.

Sediments in all remaining channels (Richmond Harbor, San Rafael Creek, Oakland Harbor, Napa River, Petaluma River, San Leandro Marina, Redwood City Harbor, and remaining portions of Pinole Shoal) contain less than 80 percent sand.

DMMO requirements for sediment testing conducted prior to each maintenance dredging episode are based on a tiered structure, and depend on the placement sites being considered, and past testing results. Table 3.3-1 presents the DMMO-approved 5-year sediment testing schedule through 2018 for the federal shipping channels in and around San Francisco Bay. The schedule only includes channels that are dredged annually, not those dredged at less-frequent intervals. Assuming future sediment testing results are consistent with historic results, it is expected that the schedule represented in Table 3.3-1 would continue through the 2024 planning horizon for this EA/EIR.

<b>Table 3.3-1 2013-2018 Sampling and Testing Schedule for Federal Navigation Channels Maintained by USACE Annually</b>						
<b>Channel</b>	<b>2013 Completed</b>	<b>2014</b>	<b>2015</b>	<b>2016</b>	<b>2017</b>	<b>2018</b>
Oakland Outer Harbor*	<b>Tier III, MET (3-year cycle, samples collected prior to 2012 dredging)</b>	Tier I (No testing)	Tier I (No testing)	<b>Tier III, MET (3-year cycle)</b>	Tier I (No testing)	Tier I (No testing)
Oakland Inner Harbor*		Tier I (No testing)	Tier I (No testing)	<b>Tier III, MET (3-year cycle)</b>	Tier I (No testing)	Tier I (No testing)
Richmond Inner Harbor*	Tier I (No testing)	Tier I (No testing)	<b>Tier III, MET (3-year cycle)</b>	Tier I (No testing)	Tier I (No testing)	<b>Tier III, MET (3-year cycle)</b>
Richmond Outer Harbor*	<b>Tier III, MET (Only for material in the Longwharf Area)</b>	Tier I (No testing)	<b>Tier III, MET (3-year cycle)</b>	Tier I (No testing)	Tier I (No testing)	<b>Tier III, MET (3-year cycle)</b>
Suisun Bay	Tier I (No testing)	<b>Confirmatory Grain Size Analysis (5-year cycle)</b>	Tier I (No testing)	Tier I (No testing)	Tier I (No testing)	Tier I (No testing)
New York Slough	Tier I (No testing)	<b>Confirmatory Grain Size Analysis (5-year cycle)</b>	Tier I (No testing)	Tier I (No testing)	Tier I (No testing)	Tier I (No testing)
SF Main Ship	Tier I (No testing)	Tier I (No testing)	Tier I (No testing)	Tier I (No testing)	Tier I (No testing)	<b>Confirmatory Grain Size Analysis (8-year cycle)</b>
Redwood City Harbor*	Tier I (No testing)	<b>Tier III, MET (3-year cycle, depending on dredging cycle)</b>	Tier I (No testing)	Tier I (No testing)	<b>Tier III, MET (3-year cycle, depending on dredging cycle)</b>	Tier I (No testing)
Pinole Shoal (San Pablo Bay)*	Tier I (No testing, Testing Cycle Extended 1 Year)	<b>Tier III, MET (3-year cycle)</b>	Tier I (No testing)	Tier I (No testing)	<b>Tier III, MET (3-year cycle)</b>	Tier I (No testing)
Notes:						
Tier III = Physical/Chemical Analysis, Benthic and Water Column Toxicity Tests and Bioaccumulation when necessary. Inland Testing Manual (ITM) or Ocean Testing Manual (OTM) requirements will be determined based on placement locations.						
Confirmatory Grain Size Analysis = Physical Analysis (grain size, total organic carbon, and total solids)						
MET = Modified Elutriate Test						
* These projects have potential placement at upland wetland restoration projects. If placement at a wetland restoration project is being proposed, then the sediments shall be analyzed for the constituents required by those projects' permits.						

Recent sampling results are summarized for each of the federal navigation projects below. Results are reported with respect to whether or not they were determined to be suitable for placement at the placement site(s) being considered that year. Because the Petaluma River Channel and Napa River Channel have not been dredged in over 10 years, no recent sampling results are available for these channels; USACE would conduct sediment testing prior to dredging these channels.

The summary for each federal navigation project below only presents the most recent results for the baseline evaluation period (2000 through 2012) based on analysis conducted for placement sites USACE was considering for the year reported. Table 1-1 in Chapter 1 provides a review of the type of dredge equipment commonly used, dredging cycle (i.e., frequency of dredging), last fiscal year the project was dredged, and the historic dredged material placement site for each navigation project, which includes additional sites for which dredged materials from each navigation project have been found suitable for placement.

### **Richmond Harbor**

Based on sediment testing conducted for the 2012 calendar year dredging episode, the DMMO determined that material to be dredged from Richmond Inner Harbor was suitable for placement at SF-DODS, the Montezuma Wetlands Restoration Project site, and Winter Island. Sediment from the Richmond Inner Harbor federal channel has historically been 73 percent to 99 percent fines (USACE, 2012c).

Based on the 2012 sediment testing, dredged material from Richmond Outer Harbor was determined suitable to be placed at one or a combination of the following locations: the Alcatraz Island placement site (SF-11), the San Pablo Bay placement site (SF-10), Cullinan Ranch, or at other upland sites with criteria similar to or less-stringent than Cullinan Ranch. Sediment grain size from the Richmond Outer Harbor has historically varied between 10 percent and 67 percent sand and gravel, depending on sample location and the sampling year (USACE, 2012c).

The United Heckathorn Superfund site is in Richmond Harbor, and includes 5 acres of land and approximately 15 acres of marine sediments in the Parr and Lauritzen channels. Unacceptable levels of dichloro-diphenyl-trichloroethane (DDT) and dieldrin remain in the waters and sediments of the Lauritzen channel (refer to Section 3.9, Hazards and Hazardous Materials). During the baseline evaluation period (2000-2012), USACE avoided dredging portions of the federal channel adjacent to the Heckathorn site.

### **San Francisco Main Ship Channel**

Sediment collected from MSC in 2010 ranged from 93 percent to 99 percent sand, which is consistent with the historical results of 90 percent to 99 percent sand. The total organic carbon levels in composite samples (total of two composites) ranged from 0.11 percent to 0.35 percent for samples collected in 2010. This is considered to be low, and in the highly suitable range for beneficial reuse. Throughout the years that MSC has been tested for maintenance dredging purposes, the sediment has been determined to be suitable for unconfined aquatic placement at the San Francisco Bar Channel Disposal Site (SF-8) or the Ocean Beach Demonstration Site. Based on the 2010 testing results, the DMMO's determination and recommendations for suitability determination of MSC sediments has been that a Tier I exclusion from testing is appropriate for the sediment proposed for dredging of the MSC (USACE, 2013).

Sediment sampling by the U.S. Geological Survey in 2010 indicated that the mean grain size in most of the San Francisco Bight (i.e., coastal and offshore area) falls in the fine-sand range (0.125 to 0.250 millimeters [mm]) with fine to medium sand (0.250 to 0.500 mm) occurring along Ocean Beach and on the inner part of the bar. Coarse sand (0.500 to 1.000 mm) was restricted to areas closest to the Golden Gate, where strong tidal currents effectively wash away finer sand. The physical characteristics of material dredged from the MSC are generally compatible with the sand in the Ocean Beach nearshore environment (USACE, 2013).

## **San Rafael Creek**

In 2002 and 2010, sampling and testing of the shoaled sediment revealed that upstream of Station 175+00 (Figure 3.3-1) in the Inner Canal Channel, pesticide and PCB concentrations were at levels that rendered the sediment not suitable for in-Bay placement. Downstream of Station 175+00, the sediment was deemed suitable for in-Bay placement. The 2011 sampling event confirmed that, at that time, there was no downstream migration of the contaminated sediment beyond Station 175+00, and sediments were determined to be suitable for unconfined aquatic placement at SF-10 and SF-11 (USACE, 2011a). Dredged material has typically been less than 80 percent sand.

## **Pinole Shoal**

Testing of the Pinole Shoal took place in 2010, and sediments were determined to be suitable for unconfined aquatic placement at the Carquinez Strait placement site (SF-9) and SF-10. Historically, physical analysis of the channel bottom sediments has determined a highly varied sand content, ranging between 10 percent and 98 percent. Sandier sediment is generally found along the eastern portion of the channel and in the maneuvering area, closer to where high-energy currents flow out of the Carquinez Strait (USACE, 2012d).

## **Suisun Bay Channel and New York Slough**

Grain-size testing of Suisun Bay Channel and New York Slough sediments has historically shown that shoaling in these areas ranges between 94 percent and 99 percent sand. Historically, the sediment has been deemed suitable for in-Bay placement at SF-9 and Suisun Bay placement site (SF-16). In 2009, confirmatory chemistry tests were run, in addition to the usual grain-size testing; these tests showed that no potential contaminant exceeded acceptable limits. Since 2009, USACE has sought—and annually received—a Tier I exclusion from sediment testing from the DMMO for its annual maintenance dredging of these channels (USACE, 2012e).

## **Oakland Harbor**

Sediment testing for the Oakland Inner and Outer Harbors channels for the 2009, 2010, and 2011 dredging episodes indicated that dredged material from these channels was suitable for placement at SF-11, SF-DODS, and certain upland beneficial reuse sites for which the placement criteria were met (USACE, 2012b). Dredged material from Oakland Harbor has typically been less than 80 percent sand.

## **San Leandro Marina (Jack D. Maltester Channel)**

Sediment testing for the San Leandro Marina/Jack D. Maltester Channel was last conducted in 2009. Sediment in this channel is composed of silt and clay, and has been demonstrated to be suitable for upland placement since 1978, and for in-Bay placement in 1997. Because in-Bay placement was not considered in 2009, it was only evaluated for upland placement at that time (USACE, 2009).

## **Redwood City Harbor**

Testing of the Redwood City Harbor channels took place in 2011, and sediments were determined to be suitable for unconfined aquatic placement at SF-11 and SF-DODS. The sediment is predominantly silt and clay, with 2 percent or less sand and gravel (USACE, 2011b).

### **3.3.3 Methodology and Thresholds of Significance**

The project alternatives neither propose construction of new structures nor introduce elements that would increase potential risks related to rupture of a known earthquake fault; seismic shaking; or seismic-related

- ▭ Dredge Locations Included in EA/EIR

ground failure, including liquefaction; or landslides. Similarly, because channels would be dredged to previously maintained depths, the project alternatives would not involve activities that would cause geologic units or soils to become unstable, and potentially result in onsite or offsite landslide, lateral spreading, subsidence, liquefaction, or collapse; this excludes minor erosion of the channel sides from sloughing that may occur after the channels are dredged (see Impact 3.3-1). Placement of dredged material at existing permitted placement sites would not be expected to result in onsite or offsite landslide, lateral spreading, subsidence, liquefaction, or collapse because the placement of dredged material at these sites is managed and monitored to avoid such impacts. Because the project alternatives would have no potential impacts related to seismic risks or unstable geologic resources, these topics are not further addressed in this section. Additionally, as described in Section 3.1.2, because the proposed project would not result in adverse impact on minerals, this resource is not evaluated further in this EA/EIR.

Therefore, the analysis considers whether the proposed project would:

- Result in substantial soil erosion, or
- Substantially degrade sediment quality (i.e., substantially increase sediment contaminant concentrations above ambient conditions).

### 3.3.4 Impacts and Mitigation Measures

#### ***Impact 3.3-1: Potential for Dredging, Transport, and Placement Activities to Result in Substantial Soil Erosion***

##### **No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

Under all alternatives, dredging would remove sediment that has accumulated since the prior dredging event. The design dimensions of the channels are intended to preclude sloughing of the channel sides. Although the alternatives may result in minimal erosion of the channel sides from sloughing after the channels are dredged due to the disturbance of sediments, historic patterns of erosion and sediment accumulation would not be expected to change. Transport of dredged materials would not disturb sediments, and therefore would not result in any erosion impacts.

The potential for erosion impacts due to placement activities would be minimal. Open-water placement sites can be either predominantly nondispersive (i.e., dredged materials largely remain at the placement location), or predominantly dispersive (i.e., dredged materials disperse from the site during placement or over time). With the exception of SF-DODS, all of the other open-water placement sites, both inside and outside San Francisco Bay, are considered dispersive (LTMS, 1998). Therefore, although sediments placed at in-Bay locations may disperse, no erosion impacts would be expected. As noted in Section 1.5.3, some shoaling has occurred at SF-8; however, USACE limits the use of SF-8 to the extent feasible. The disposition of dredged material at beneficial reuse and upland placement sites is managed by site operators so that substantial erosion impacts do not occur. Furthermore, at beneficial reuse sites, placement of dredged material would have beneficial impacts on soil resources by providing sediments needed to implement the site-specific intended beneficial reuse (e.g., habitat restoration, flood protection).

Additional beneficial impacts would result from the placement of dredged material at Ocean Beach nearshore placement site (SF-17), which includes the Ocean Beach demonstration site and Ocean Beach. Sand placed in SF-17 is expected to stay in the nearshore, slowly moving shoreward while dispersing, and creating shallower depths. This scenario could lead to a slowing of bluff erosion as more wave energy is dissipated further offshore. Also, having a larger volume of sand at or inside the breaker zone (i.e., where wave and tidal currents can drive shore-normal and shore-parallel sand transport) is expected to extend the length of time sand remains on the beach. This is because each storm has the potential to erode a

given volume of sand from the nearshore, beach, and bluffs; therefore, having more sand in the nearshore would likely result in a smaller cross-shore transport potential for beach erosion and bluff failure (USACE, 2013). Newly placed sand at both SF-17 and the Ocean Beach nourishment site would immediately start dispersing. Post-placement surveys show that the elevation of the mound above the pre-placement bottom decreases by 1 to 2 feet in the year between placements. Consequently, placement of additional sand in the littoral zone would temporarily change existing erosion and accretion patterns offshore and along the beaches of Ocean Beach. However, those changes are not considered to be significant given the small placement footprint. Overall, the purpose of placement at SF-17 and Ocean Beach is to alleviate the beach erosion occurring along Ocean Beach by having more sand in the littoral system off of the south of Sloat Boulevard stretch of Ocean Beach. The changes to erosion and accretion patterns from both options are considered to be temporary and not significant (USACE, 2013), and would be outweighed by the beneficial effects on shoreline stabilization.

**NEPA Determination:** Under all alternatives, erosion impacts would be less than significant. The placement of dredged material at beneficial reuse sites would have beneficial impacts on soil resources.

**CEQA Determination:** Under all alternatives, erosion impacts would be less than significant.

### ***Impact 3.3-2: Potential for Dredging, Transport, and Placement Activities to Substantially Degrade Sediment Quality***

#### **No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

Generally, based on historic sediment testing data, dredged material from the federal navigation channels has been determined suitable for placement at the federal standard, and proposed potential alternate placement sites identified for each channel in Chapter 2. Over time, some isolated areas in, or adjacent to, the channels have been identified as containing sediment that is not suitable for unconfined aquatic disposal (NUAD); USACE would continue to avoid dredging areas (e.g., portions of the Richmond Harbor federal channel adjacent to the United Heckathorn site) that it has been able to avoid dredging in the past. Under all alternatives, USACE would continue to conduct testing following guidelines in the Master SAP, OTM, ITM, UTM, and the *Guidelines for Implementing the Inland Testing Manual in the San Francisco Bay Region*; obtain suitability determinations from the DMMO for the placement of dredged materials; and conduct placement in accordance with the LTMS goals to ensure beneficial reuse, as appropriate and feasible. If future testing identifies NUAD material that must be dredged, all NUAD dredged material would be placed at upland sites, and in some cases Montezuma Wetlands Restoration Project, as determined during DMMO review. Conformance with the above processes would ensure that dredged material placement activities would not substantially degrade sediment quality at the placement sites.

The USACE would also implement sediment bioaccumulation testing as detailed in the *Agreement on Programmatic EFH Conservation Measures for Maintenance Dredging Conducted Under the LTMS Program* (USACE and USEPA, 2011). Per this agreement, if residual layer contamination that would be exposed after maintenance dredging is greater than that in the overlying sediment, and exceeds the bioaccumulation trigger values established in the agreement, consideration of the need for potential management actions to address the residual contamination would be taken on a case-by-case basis.

**NEPA Determination:** Under all alternatives, impacts to sediment quality would be less than significant.

**CEQA Determination:** Under all alternatives, impacts to sediment quality would be less than significant.

**Impact 3.3-3: Potential for Dredging, Transport, and Placement Activities to Result in Cumulative Impacts on Sediments and Soils****No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

The reasonably foreseeable actions in Table 3.1-1 include several projects that would involve dredging and dredged material placement that could result in the same type of impacts on sediments and soils as the proposed project. The cumulative effect of dredging activities in San Francisco Bay, particularly new dredging projects and deepening of channels, could impact sediment volume and transport in San Francisco Bay by modifying historic patterns of sediment movement. As stated under Impact 3.3-1, USACE's maintenance dredging would not be expected to change historic patterns of erosion and sediment accumulation. In addition, it is expected that other dredging projects would comply with the guidelines of the DMMO for dredged material testing and placement. Therefore, there would be no adverse cumulative impacts to sediments and soils.

**NEPA Determination:** The project alternatives would not result in cumulative impacts on sediments and soils.

**CEQA Determination:** The project alternatives would not result in cumulative impacts on sediments and soils.

### 3.4 HYDROLOGY AND WATER QUALITY

This section describes the existing hydrologic and water quality regulatory and environmental setting of San Francisco Bay and the offshore ocean environment, and analyzes the potential impacts of the project alternatives on water resources. Existing conditions and potential impacts associated with plans and water quality policies pursuant to compliance with the Coastal Zone Management Act (CZMA) are addressed in Section 3.8, Land Use. Existing conditions and potential impacts associated with water quality impacts on fisheries and other aquatic species are addressed in Section 3.6, Biological Resources.

#### 3.4.1 Regulatory Setting

##### Federal

##### Clean Water Act

The federal Clean Water Act (CWA) (33 U.S.C. § 1257 et seq.) requires states to set standards to protect water quality. The objective of the federal CWA is to restore and maintain the chemical, physical, and biological integrity of the nation's waters. Specific sections of the CWA control discharge of pollutants and wastes into marine and aquatic environments, as further discussed below.

**Section 303 – Water Quality Standards and Implementation Plans.** Title 40 of the C.F.R. pt. 131.2, describes water quality standards as the water quality goals for a particular water body. These water quality goals are the designated uses for the water and the criteria to protect those uses.

A water quality standard defines the water quality goals of a water body, or portion thereof, by designating the use or uses to be made of the water, and by setting criteria necessary to protect the uses. States adopt water quality standards to protect public health or welfare, enhance the quality of water, and serve the purposes of the CWA. To serve the purposes of the CWA, as defined in sections 101(a)(2) and 303(c), means that water quality standards should, wherever attainable, provide water quality for the protection and propagation of fish, shellfish, and wildlife, and provide water quality for recreation in and on the water. The standards should consider the use and value of public water supplies, propagation of fish, shellfish, and wildlife, recreation in and on the water, and agricultural, industrial, and other uses including navigation. Such standards serve the dual purposes of both establishing the water quality goals for a specific water body and also serving as the regulatory basis for the establishment of water-quality-based treatment controls and strategies beyond the technology-based levels of treatment required by sections 301(b) and 306 of the CWA.

Title 40 of the C.F.R. § 131.4, states: “Water quality standards consist of a designated use and water quality criteria for such waters based upon such uses.” CWA Section 303 states that water quality standards adopted by the state and approved by the United States Environmental Protection Agency (USEPA) govern actions that affect navigable waters. Pursuant to the CWA, the San Francisco Bay Regional Water Quality Control Board (Regional Water Board) adopted the Water Quality Control Plan for the San Francisco Bay Basin (Basin Plan). The Basin Plan includes rare and endangered species as a protected beneficial use, stating that: “The water quality criteria to be achieved that would encourage development and protection of rare and endangered species should be the same as those for protection of fish and wildlife habitats generally. However, where rare or endangered species exist, special control requirements may be necessary to assure attainment and maintenance of particular quality criteria, which may vary slightly with the environmental needs of each particular species. Criteria for species using areas of special biological significance should likewise be derived from the general criteria for the habitat types involved, with special management diligence given where required.” The Basin Plan also includes fish migration as a beneficial use, defined as: “Uses of water that support habitats necessary for migration, acclimatization between fresh water and salt water, and protection of aquatic organisms that are temporary inhabitants of waters within the region.”

Finally, the Basin Plan's water quality objective relating to population and community ecology states: "[T]he health and life history characteristics of aquatic organisms in waters affected by controllable water quality factors shall not differ significantly from those for the same waters in areas unaffected by controllable water quality factors."

**Section 303 – Impaired Water Bodies and Total Maximum Daily Loads.** Under Section 303(d) of the CWA, each state is required to identify those waters within its boundaries for which effluent limits required by Section 301 are not stringent enough to meet water quality standards. The state must establish priority rankings for these waters, and develop Total Maximum Daily Loads (TMDLs) to maintain beneficial uses and improve water quality. Seasonal variations in loading and a margin of safety are considered when TMDLs are established. In California, the State Water Resources Control Board (SWRCB) and Regional Water Quality Control Boards prepare the CWA Section 303(d) List of Water Quality Limited Segments Requiring TMDLs.

San Francisco Bay is listed as impaired for pesticides (e.g., chlordane, dichloro-diphenyl-trichloroethane (DDT), dieldrin, dioxin, and furan compounds), mercury, invasive species, polychlorinated biphenyls (PCBs), selenium, and trash. In greater San Francisco Bay, Suisun Bay and San Pablo Bay are listed for these same parameters, except for trash. The Napa River is listed as impaired for nutrients, pathogens, and sedimentation/siltation. The tidal portion of the Petaluma River, which extends upstream of the City of Petaluma's urban core to the confluence of the river with Lynch Creek, is listed as impaired for diazinon, nutrients, pathogens, and nickel (SWRCB, 2010).

**Section 311 – Oil Pollution Act.** CWA Section 311, as amended by the Oil Pollution Act of 1990, provides for spill prevention requirements, spill reporting obligations, and spill response planning and authorities. It regulates the prevention of, and response to, accidental releases of oil and hazardous substances into navigable waters, on adjoining shorelines, or affecting natural resources belonging to or managed by the United States. The United States Coast Guard is responsible for regulations and enforcement related to vessels and marine transportation, and the USEPA is responsible for non-transportation-related facilities and onshore operations.

**Section 313(a) – Federal Facilities Pollution Control.** Congress expressly authorizes state regulation of federal activities that result in discharge or water pollution.

**Section 401 – Water Quality Certification.** Under Section 401 of the CWA, water quality certification (WQC) is required for any activity that requires a federal permit or license, and that may result in discharge into navigable waters. To receive certification under Section 401, an application must demonstrate that activities or discharges into waters are consistent with state effluent limitations (CWA Section 301), water quality effluent limitations (CWA Section 302), water quality standards and implementation plans (CWA Section 303), national standards of performance (CWA Section 306), toxic and pretreatment effluent standards (CWA Section 307), and "any other appropriate requirements of State law set forth in such certification" (CWA Section 401). In California, the authority to grant water quality certification is delegated to the SWRCB, and in the San Francisco Bay area, applications for certification under CWA Section 401 are processed by the Regional Water Board. The CWA and United States Army Corps of Engineers (USACE) regulations (33 C.F.R. § 336.1[a][1]) require USACE to seek state WQC for discharges of dredged or fill material into waters of the United States.

The Regional Water Board reviews a proposed project before granting or denying certification. Pursuant to 33 C.F.R. § 337.8(a)(4), action is required by the USACE Division Engineer or Chief of Engineers when "...the state denies or unreasonably delays a water quality certification or issues the certification with conditions or controls not related to maintenance or enforcement of state water quality standards or significantly exceeding the federal standard." Based on a report prepared by the District, the Chief of Engineers would make a determination as to whether to defer the dredging and seek Congressional appropriations for the added expense. Alternatively, the issue could be referred to the Secretary of the

Army to determine whether it is appropriate to maintain navigation, as provided by sections 511(a) and 404(t) of the CWA.

**Section 404 – Discharge of Dredged or Fill Material.** Section 404 of the CWA regulates the discharge of dredged or fill material (e.g., fill, pier supports, and piles) into waters of the United States, which includes San Francisco Bay. The USACE implements Section 404 of the CWA, and USEPA has oversight authority. Section 404(b)(1) of the CWA establishes procedures for the evaluation of permits for discharge of dredged or fill material into waters of the United States. In situations where USACE is proposing work that involves discharge of dredged or fill material into waters of the United States, USACE must comply with the requirements of the Section 404(b)(1) Guidelines, although it does not issue itself permits.

### **Marine Protection, Resources, and Sanctuaries Act**

The Marine Protection, Resources, and Sanctuaries Act (MPRSA) is the United States' implementation of an international treaty, the Convention on the Prevention of Marine Pollution by Dumping of Waste and Other Matter (also known as the "London Convention"). Section 102 of the MPRSA authorizes USEPA to establish criteria for evaluating all dredged material proposed for ocean dumping. These criteria are published separately in the Ocean Dumping Regulations at 40 C.F.R. pt. 220-228. Section 102 also authorizes USEPA to designate permanent ocean-dredged material disposal sites in accordance with specific site selection criteria designed to minimize the adverse effects of ocean disposal of dredged material. Section 103 of the MPRSA authorizes USACE to issue permits, subject to USEPA concurrence or waiver, for the transport and placement of dredged material at a designated ocean disposal site. It requires public notice, opportunity for public hearings, compliance with criteria developed by USEPA (unless a waiver has been granted), and the use of designated sites whenever feasible. Although USACE does not issue itself permits, USACE and USEPA apply these standards to USACE projects as well.

### **Rivers and Harbors Act**

Rivers and Harbors Act refers to a conglomeration of many pieces of legislation and appropriations passed by Congress since the first such legislation in 1824. The Rivers and Harbors Act of 1899 was the first federal water pollution act in the United States. It focuses on protecting navigation, protecting waters from pollution, and acted as a precursor to the CWA of 1972. Section 10 of the Rivers and Harbors Act of 1899 regulates alteration of, and prohibits unauthorized obstruction of, navigable waters of the United States. Original construction of the federal navigation channels was authorized under the Rivers and Harbors Act, and USACE's maintenance dredging maintains the navigability of the channels in accordance with their authorized dimensions. The USACE, as the implementing authority of Section 10 of Rivers and Harbors Act, ensures its work or structures do not impede navigation in waters of the United States, and, therefore, does not need to issue itself a permit pursuant to Section 10.

### **International Convention for the Prevention of Pollution from Ships**

Prevention of pollution from ships is regulated under Prevent Pollution from Ships, 1980 (33 U.S.C. §§ 1901–1911); and the International Convention for the Prevention of Pollution from Ships, 1973, as modified by the Protocol of 1978 (referred to as MARPOL 73/78). The regulations cover the prevention of pollution by oil, noxious liquids, harmful substances, and garbage from operational measures, as well as from accidental discharges. The U.S. Coast Guard is the responsible enforcement agency.

### **Coastal Zone Management Act**

The CZMA, established in 1972 and administered by the National Oceanic and Atmospheric Administration's Office of Ocean and Coastal Resource Management, provides for management of the nation's coastal resources, including water quality. The overall purpose of the act is to balance competing

land and water issues in the coastal zone. For San Francisco Bay, the San Francisco Bay Conservation and Development Commission (BCDC) is the regional coastal zone management agency, and is responsible for issuing concurrence with consistency determinations under the CZMA. The San Francisco Bay Plan (Bay Plan), first adopted in 1969 and most recently updated in 2011, is BCDC's policy document specifying goals, objectives, and policies for BCDC jurisdictional areas. Pursuant to the federal CZMA, USACE is required to be consistent to the maximum extent practicable with the enforceable policies of the Bay Plan. For activities outside of the Golden Gate, consistency determinations are issued by the California Coastal Commission. The proposed project's consistency with the CZMA is discussed in Section 3.8, Land Use.

### **Floodplain Management**

Executive Order 11988 requires that federal agency construction, permitting, or funding of a project must avoid incompatible floodplain development, be consistent with the standards and criteria of the National Flood Insurance Program, and restore and preserve natural and beneficial floodplain values. As described in Section 3.4.3, the project alternatives are not expected to result in adverse impacts on floodplain management.

### **State**

#### **Porter-Cologne Act**

The Porter-Cologne Water Quality Control Act of 1969 (Porter-Cologne Act), and associated regulations found in California Code of Regulations Title 23, establish a comprehensive program for the protection of water quality and the beneficial uses of waters of the state. It addresses both point and nonpoint source discharges, to both surface and ground waters. The SWRCB and nine regional water quality control boards are the principal state agencies with primary responsibility for water quality control. The Porter-Cologne Act provides for the adoption of water quality control plans to designate beneficial uses of water, set water quality objectives to protect beneficial uses, and provide for a program to achieve those objectives. The plans may include prohibitions against the discharges of waste or certain types of waste, in specified areas or under specified conditions. The Basin Plan is the Regional Water Board's master water quality control planning document. Pursuant to the Porter-Cologne Act and Title 23, the Regional Water Board is authorized to issue waste discharge requirements (WDRs) and WQCs (i.e., permits) for activities that may affect water quality. These permits must implement the Basin Plan, the Clean Water Act for point source discharges to waters of the United States, and statewide plans and policies, including, but not limited to, Resolution No. 68-16, "Statement of Policy with Respect to Maintaining High Quality of Water in California," which generally restricts dischargers from degrading water quality. As a federal agency, USACE is not required to apply for WDRs; however, the Regional Water Board may issue WDRs with the WQC.

### **Regional**

#### **McAteer-Petris Act**

The McAteer-Petris Act (California Government Code Section 66000, et seq.), first enacted in 1965, created BCDC to prepare a plan to protect the San Francisco Bay and shoreline, and provide for appropriate development and public access. The Act directs BCDC to exercise its authority to issue or deny permit applications for placing fill, dredging, or changing the use of any land, water, or structure in the area of its jurisdiction (i.e., San Francisco Bay waters and within 100 feet of the shoreline). As stated above, BCDC also carries out determinations of consistency with the CZMA for federally sponsored projects. As noted above, the Bay Plan is BCDC's policy document specifying goals, objectives, and policies for BCDC jurisdictional areas. Pursuant to the federal CZMA, USACE is required to be

consistent to the maximum extent practicable with the enforceable policies of the Bay Plan. The proposed project's consistency with the Bay Plan is discussed in Section 3.8, Land Use.

### **Dredged Material Management Office**

The Dredged Material Management Office (DMMO) is a joint program of USACE, USEPA, the Regional Water Board, BCDC, and California State Lands Commission. Participating agencies include the California Department of Fish and Wildlife, National Marine Fisheries Service, and the U.S. Fish and Wildlife Service. The purpose of the DMMO is to cooperatively review sediment quality sampling plans, analyze the results of sediment quality sampling, and make suitability determinations for material proposed for placement in San Francisco Bay.

Applicants must submit results from recent sediment testing, or submit sufficient data to support a finding by the agencies that the sediments are suitable for the proposed placement environment. An applicant submits to the DMMO either a sediment Sampling and Analysis Plan and Quality Assurance Project Plan, or a written request (with supporting information) for an exclusion from testing requirements. The exclusion request can be based on the exclusion criteria in the testing manuals and DMMO guidelines or existing data sufficient to make a determination (refer to Section 3.3, Geology, Soils, and Sediment Quality for additional information on sediment testing requirements). The applicant must submit the sampling results to the DMMO for review, and the DMMO will make a determination about where the materials can be disposed.

Although the DMMO provides initial review of permit applications, applicants must eventually obtain separate approval from the appropriate DMMO member agencies (e.g., CWA Section 401 WQC from the Regional Water Board); each agency issues permit conditions and specific requirements about how the project is to be performed.

## **3.4.2 Environmental Setting**

### **Study Area**

The study area for hydrology and water quality is the San Francisco Bay hydrologic region, which covers an area of approximately 4,603 square miles, extending from southern Santa Clara County north to Tomales Bay in Marin County, and inland to the confluence of the Sacramento and San Joaquin rivers (Regional Water Board, 2010). Rivers and streams in the region flow to San Francisco Bay or directly to the Pacific Ocean. The dominant feature is the San Francisco Bay/Delta Estuary (Estuary), where fresh water from the Central Valley mixes with saline water from the Pacific Ocean.

San Francisco Bay is composed of distinct hydrographic regimes: the South Bay, which extends from the Bay Bridge to the southern terminus of San Francisco Bay in San Jose; and the Central, Suisun, and San Pablo bays, which connect the Delta and the Pacific Ocean.

Outside of the Golden Gate, the study area includes the San Francisco Main Ship Channel, the San Francisco Bar Channel Disposal Site (SF-8), and the nearshore zone off Ocean Beach, as well as the waters that are used by vessels en route to these sites. The Main Ship Channel is approximately 5 miles west of the Golden Gate Bridge, and extends across the arc-shaped, submerged, San Francisco Bar in the Gulf of the Farallones. Further offshore, the study area also includes waters in the proximity of the San Francisco Deep Ocean Disposal Site (SF-DODS). The SF-DODS is in the open ocean on the lower continental slope approximately 55 miles (48 nautical miles) west of San Francisco. The SF-DODS is approximately 6 nautical miles west of the outer boundary of the Gulf of Farallones National Marine Sanctuary, and approximately 25 nautical miles west of the Farallon Islands. Water depth at the site ranges between approximately 2,500 meters and 3,000 meters (LTMS, 1998).

The existing hydrologic setting and water quality conditions for San Francisco Bay and the offshore ocean environment are described below.

### **Hydrologic Setting**

**San Francisco Bay.** The northern reach of the San Francisco Bay (comprising Suisun Bay, Carquinez Strait, and San Pablo Bay) is geographically and hydrologically distinct from the Central and South bays. The South Bay is a tidally oscillating, lagoon-type estuary, where variations are determined by water exchange between the northern reach and the ocean. Water residence times are much longer in the South Bay than in Suisun and San Pablo bays. The northern reach is a partially to well-mixed estuary (depending on the season) that is dominated by seasonally varying river inflow. The timing and magnitude of the highly seasonal river inflow modulates permanent estuarine circulation, which is largely maintained by salinity controlled density differences between river and ocean waters. Water flows in the Estuary follow complex daily and seasonal patterns. Circulation is affected by tides, local winds, basin bathymetry, and the local salinity field (LTMS, 1998).

Suisun and San Pablo bays receive the majority of freshwater input, where density/salinity-driven currents show ebb dominance of the surface water and flood dominance of the bottom water. Thus, waters in these embayments are characterized as being oxygenated, of low to moderate salinity, and high in suspended solids. Central Bay is most strongly influenced by tidal currents because of its proximity to the Pacific Ocean. The Central Bay is characterized by Pacific waters that are cold, saline, and low in total suspended sediment. The South Bay receives less than 10 percent of the freshwater budget of San Francisco Bay. It also receives the majority of wastewater discharged to San Francisco Bay (greater than 75 percent). Because the South Bay receives only minor amounts of freshwater in-flow from the surrounding watershed, it is essentially a tidal lagoon with a relatively constant salinity (LTMS, 1998).

The bathymetry of San Francisco Bay is an important factor affecting sediment dynamics. San Pablo Bay, Suisun Bay, and the South Bay are characterized by broad shallows that are incised by narrow channels, which are typically 33 to 66 feet deep. These shallower areas are more prone to wind-generated currents and sediment resuspension than deeper areas such as the Central Bay. Net circulation patterns in San Francisco Bay are influenced by Delta inflows, gravitational currents, and by tide- and wind-induced horizontal circulation (LTMS, 1998).

**Offshore Ocean Environment.** Outside of San Francisco Bay, the California Current is a broad offshore flow that transports cold, low-salinity, subarctic waters toward the equator. However, because of the proximity of Point Reyes, two northerly flows—the Coastal Countercurrent and the California Undercurrent—dominate the flow regime in the vicinity of the Farallon Islands throughout most of the year. The Coastal Countercurrent generally moves nutrient-poor surface water over the continental shelf northward. The California Undercurrent is a strong northerly flow over the slope that dominates in depths ranging from 100 to 1,000 meters. Semidiurnal and diurnal tides together account for 35 to 60 percent of the total variability in the currents on the shelf. These tidal currents can affect the resuspension of material deposited on the seabed and dispersion of material suspended in the water column. However, studies by USEPA indicate that the ocean bottom in the vicinity of SF-DODS (and generally across the region at depths greater than 600 to 800 meters) is depositional. In addition, currents in the vicinity of SF-DODS are generally slow, which aids in minimizing the spread of water column plumes during and immediately following placement events. The wave climate is seasonally variable. Wave heights are usually greater during the late fall, winter, and spring because of the presence of storms and generally stronger, sustained winds (LTMS, 1998).

## Water Quality

### Physical and Chemical Characteristics

**San Francisco Bay.** Temperature exerts a major influence on biological activity and growth in San Francisco Bay. Temperature is also important because of its influence on water chemistry. The seasonal range of water temperature in San Francisco Bay is from about 8 degrees Celsius to about 23 degrees Celsius. At a given location, there can be small, irregular temperature changes with depth.

The salinity of the Estuary's northern reach varies considerably, and increases along a gradient from the Delta to Central Bay. In the southern reach, salinities remain at near-ocean concentrations (i.e., 32 parts per thousand) during much of the year. However, during the summer, high evaporation rates may cause salinity in South Bay to actually exceed that of ocean water. The pH (measure of the acidity or basicity of an aqueous solution) of waters in San Francisco Bay is relatively constant and typically ranges from 7.8 to 8.2 (LTMS, 1998; SFEI, 2013).

The water in San Francisco Bay is considered to be generally well oxygenated, except during the summer in the extreme southern end of the South Bay, where concentrations are reduced by poor tidal mixing and high water temperature. Typical concentrations of dissolved oxygen in most of San Francisco Bay range from 9 to 10 milligrams per liter (mg/L) during high periods of river flow, 7 to 9 mg/L during moderate river flow, and 6 to 9 mg/L during the late summer months, when flows are lowest (SFEI, 2008).

**Offshore Ocean Environment.** Offshore surface waters show a great deal of variability in temperature-salinity properties. Water discharged from San Francisco Bay into the Gulf of the Farallones has a higher temperature and lower salinity, and therefore lower density, than water in the Gulf (LTMS, 1998).

Dissolved oxygen concentrations in surface waters are approximately 8 mg/L. Concentrations decline through the mixed layer, and reach minimum values of about 0.5 mg/L at a depth of 800 meters. Below 800 meters, dissolved oxygen concentrations increase to over 3 mg/L at depths greater than 2,000 meters (LTMS, 1998).

### Suspended Sediments/Turbidity

**San Francisco Bay.** Turbidity is an optical property related to clarity of water; it causes light to be scattered and absorbed rather than transmitted in straight lines. Turbidity is caused by the presence of suspended and dissolved matter such as clay, silt, finely divided organic matter, plankton, other microscopic organisms, organic acids, and dyes. Factors affecting turbidity include shape, size, refractive index, color, and absorption spectra of particles. Turbidity is expressed in Nephelometric Turbidity Units (NTUs).

Total suspended solids, on the other hand, are a measure of the amount of dry-weight mass of nondissolved solids suspended per unit of water (often measured in mg/L). Total suspended solids include inorganic solids (clay, silt, and sand) and organic solids (algae and detritus). Increased suspended solids affect aquatic ecosystems in three ways: (1) physical impacts related to the physical properties of suspended sediments (i.e., reduced light transmission-or increased turbidity-and biological effects); (2) chemical impacts, related to the chemicals associated with suspended solids (including effects on biological receptors); and (3) resettling effects that can smother aquatic benthic habitats and organisms. Fine sediments (clay and silt) remain suspended in the water column longer than coarse sediments (sand).

Sources of new sediment into the Estuary system include the Sacramento River, which flows through the Carquinez Strait into the northeastern end of San Pablo Bay; the Napa, Sonoma, and Petaluma rivers; and a variety of smaller streams and other drainages (including storm drains and flood control channels). As observed in a study from 1995-2010, small tributaries adjacent to San Francisco Bay, supply 61 percent

of the new suspended sediment to San Francisco Bay (McKee et al., 2013). This represents a shift in the primary source of new sediment to the Estuary, which had previously been the Sacramento River. The shift likely reflects the effect of dams on the Sacramento-San Joaquin watershed. The dams effectively block sediment transport from nearly half of the watershed area and reduce peak flows during floods (McKee et al., 2013). Recent research also reinforces that episodic sediment loads, primarily during storm events, dominate the sediment supply to San Francisco Bay (Barnard et al, 2013). Over the last half-century, sediment loss trends have been documented in San Pablo Bay, Suisun Bay, and Central Bay, while the South Bay has shown net accretion (Barnard et al, 2013). An overall decrease in suspended sediment concentrations in the Estuary has been broadly attributed to a reduction in sources of erodible sediment due to the cessation of hydraulic mining, urbanization, river bank protection, and sediment trapping behind dams and flood control by-passes (Barnard et al, 2013). Aside from new sediment, existing deposits of typical fine-grained surface sediments in the extensive shallow areas of the Estuary are subject to hydraulic movement (resuspension) by riverine, tidal, and wind-driven currents, and are the primary source of suspended particulate matter and turbidity throughout the Estuary.

Total suspended solids (TSS) levels in the Estuary vary greatly, ranging from 10 mg/L to over 100 mg/L (SFEI, 2011). In general, higher TSS results in more turbid water. There is also variability in TSS concentrations, depending on the specific location in the Estuary, with shallow areas—and channels adjacent to shallow areas—having the highest suspended sediment concentrations. TSS levels vary throughout the Estuary, depending on season, tidal stage, and depth. The Central Bay generally has the lowest TSS concentrations; however, wind-driven wave action and tidal currents, as well as dredged material placement and sand mining operations, cause elevations in suspended solids concentrations throughout the water column (LTMS, 1998).

**Offshore Ocean Environment.** Turbidity conditions on the continental shelf near the Golden Gate are affected by seasonal and tidal flows of turbid waters from San Francisco Bay. In the vicinity of SF-DODS, the background TSS values are variable, but mean values range from 1 to 3 mg/L (LTMS, 1998).

### Contaminants

Suspension of sediment can mobilize sediment-bound contaminants into the water column, where they have the potential to become dissolved into the water itself. However, most contaminants bind to finer sediment, such as silt, clay, and organic matter, and are not readily water soluble (LTMS, 1998).

**San Francisco Bay.** Since 1993, the San Francisco Estuary Institute (SFEI) has administered a Regional Monitoring Program (RMP) for the Regional Water Board and major San Francisco Bay dischargers. In order to comply with the receiving water monitoring requirements of their permits, most dischargers to San Francisco Bay, including dredgers, choose to participate in the RMP. SFEI conducts monitoring to assess spatial patterns and long-term trends in contamination. The RMP measures concentrations of various constituents in water, sediment, bivalves, bird eggs, and fish at various locations in the Estuary.

To assess water quality, trace metals (including copper, mercury, nickel, selenium, silver, and zinc) and trace organics are measured in water samples collected during the dry season. Water samples have been analyzed for polybrominated diphenyl ethers (PBDEs) annually, and all other organic parameters (e.g., pesticides, polycyclic aromatic hydrocarbons [PAHs], and PCBs) on a biennial basis; however, beginning in 2014, monitoring to evaluate open Bay status and trends will be conducted at a reduced frequency of sampling for selected parameters in the various matrices. According to the 2011 Pulse of the Estuary (SFEI, 2011), results of the RMP show significant improvements in basic water quality conditions due to investments in wastewater treatment. Contamination due to toxic chemicals has also generally declined since the 1950s and 1960s.

Other trends noted by SFEI (SFEI, 2011; 2012) include:

- In addition to historic industrial sources along the San Francisco Bay margins, increasing population and motor vehicle use in the San Francisco Bay Area suggest that PAH concentrations could increase over the next 20 years, as a result of deposition of combustion products from the air directly into San Francisco Bay, and from roadway runoff and into San Francisco Bay via stormwater.
- Small tributaries are the dominant loading pathway for suspended sediments, PCBs, and mercury.
- Mercury concentrations in striped bass, a key mercury indicator species for the Estuary, have shown little change since 1970.
- Average PCB concentrations in San Francisco Bay sediment have been highest in the southern reach of the Estuary (Central Bay, South Bay, and Lower South Bay).
- Concentrations of DDT, chlordane, and other legacy pesticides have declined. On the other hand, concentrations of chemicals used in more recent years, such as pyrethroid insecticides and PBDEs, have increased; however, the rate of increase appears to be leveling off.
- Sediment cores from open-water sites exhibited total mercury and PCB concentrations in deeper sediments that were generally similar to surface sediments, suggesting diminished concern for prolonged recovery due to erosion of contaminated subsurface material.

Since the LTMS Management Plan took effect, new limitations on discharges of mercury and PCBs into San Francisco Bay have been instituted by the Regional Water Board and approved by the USEPA. The LTMS agencies worked with the Regional Water Board to clarify how the TMDLs would apply to dredged material management. Through this process, the Regional Water Board recognized that dredging projects managed under the LTMS program were “net removers” of mercury and PCBs from San Francisco Bay. As a result, dredging does not have a waste load allocation for these pollutants; rather, dredged material containing mercury and PCBs is regulated based on current “ambient” levels in San Francisco Bay sediment (LTMS, 2013b).

**Offshore Ocean Environment.** Studies have documented trace amounts of contaminants, including PAHs, PCBs, pesticides, and trace metals in waters over the continental shelf and shelf edge (LTMS, 1998); however, waters offshore typically contain low concentrations of contaminants compared to sites along the California coast near urban areas or discrete sources of pollutants.

### **Sea Level Rise**

Sea levels along California’s coast have risen about 7 inches over the past century (CEC, 2008 and 2009). Sea level rise occurred at a rate of approximately 0.07 inch per year from 1961 to 2003, with an accelerated average rate of about 0.12 inch per year during the last decade (CEC, 2009).

Studies that account for climate change as a result of global warming predict that sea level rise will accelerate and proceed at significantly higher rates than previously thought. The Intergovernmental Panel on Climate Change (IPCC) published projections on global sea level rise in 2001, and refined estimates in 2007. The projections considered thermosteric sea level change (expansion of sea water as it warms), and eustatic sea level changes due to increased freshwater inflows from melting sea and glacial ice, under a range of emission scenarios. These earlier studies had estimated that sea level would rise by as much as 20 inches by 2100, which corresponds to an average rate of approximately 0.2 inch per year, or about twice the historical average rate.

Recent studies focus on two of the emission scenarios from the earlier studies, and include adjustments that consider the effects of dams on sea level rise. These current studies predict that sea level rise may accelerate faster than the earlier IPCC studies had indicated (BCDC, 2009; CEC, 2009). In addition, an Independent Science Board contracted by the State of California has recommended that the state adopt conservative estimates for sea level rise to account for accelerating contributions from ice sheet melting, and use the most conservative methodologies. Based on these emission scenarios, sea level rise estimates range from 20 to 55 inches by 2100. It should be noted that the estimated increase of 55 inches is more than 2.5 times the IPCC's 2007 estimate.

Beneficial reuse that has occurred at some of the existing placement sites provides protection against sea level rise. For example, the beneficial reuse of dredged material for wetland restoration provides additional protection against rising water levels because wetlands function as natural sponges that trap and slowly release surface and flood waters.

### 3.4.3 Methodology and Thresholds of Significance

This section includes an analysis and determination of the impacts of the project alternatives on hydrology and water quality. Water quality variables that can be affected by dredging operations include turbidity, suspended solids, and other variables that affect light transmittance; dissolved oxygen; nutrients; salinity; temperature; pH; and concentrations of trace metals and organic contaminants if they are present in the sediments.

The analysis considered whether the project would:

- Substantially degrade water quality through alteration of temperature, salinity, pH, and dissolved oxygen;
- Substantially degrade water quality because of increased turbidity; or
- Violate any water quality standards, or substantially degrade water quality because of mobilization of contaminated sediments or release of hazardous materials during dredging and placement activities.

Actions required under existing regulations and programs, and best management practices (BMPs) that address potential water resource impacts, are described as appropriate.

Because of the nature of the proposed project, there would be no project impacts that would:

- Substantially deplete groundwater supplies or interfere with groundwater recharge. The alternatives would not involve excavation to depths that would affect aquifer systems or groundwater movement, and would not involve the construction of substantial new impervious surfaces that would impede groundwater recharge. Therefore, no impacts related to groundwater would occur.
- Substantially alter currents or existing drainage patterns. Given the frequent modifications to current and circulation from large-vessel traffic, the project alternatives would not significantly impact existing currents or circulation patterns. Maintenance dredging would not alter the course of any of the waterways. Dredged material placement at existing placement sites would not impact existing current and circulation patterns. Additionally, data collection and modeling results demonstrate placement of dredged sand at the Ocean Beach nearshore placement site (SF-17), or beach nourishment would not significantly alter nearshore current and circulation patterns (USACE, 2013). The alternatives would not involve the construction of substantial new impervious surfaces that would increase the amount of runoff, resulting in erosion or siltation, or affecting flooding on or off placement sites. Therefore, impacts related to alteration of existing drainage patterns are not discussed further.

- Create or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems. The alternatives would not involve the construction of substantial new impervious surfaces that would increase the amount of runoff, and would not result in any new sources of runoff.
- Expose people or structures to a significant risk of loss, injury, or death involving flooding, including future flood risks (sea level rise induced by climate change). The project would not place within a 100-year flood hazard area structures that would impede or redirect flood flows which could result in increased risk of flooding. The beneficial reuse of dredged material for wetland restoration (e.g., Cullinan Ranch, Montezuma Wetlands Restoration Project) or levee protection (e.g., Winter Island) would have beneficial impacts by providing additional protection against rising water levels. As stated above, wetlands function as natural sponges that trap and slowly release surface and flood waters. Although the primary function of levees is to provide flood protection, they could also serve as a physical barrier against rising sea levels.
- Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map. The project would not include the construction of housing.
- Expose people or structures to a significant risk of loss, injury, or death involving mudflow, inundation by tsunami, failure of a levee, or failure of a dam. The project is not near geologic or topographic conditions that would generate mudflows. The project would not involve the construction of any new structures or public use areas that result in increased risk of inundation by a tsunami. The alternatives would not involve any activities that would potentially result in the failure of a levee or dam.
- Substantially degrade water quality because of nutrient loading. Based on current scientific understanding, in-Bay dredged material placement is not a significant contributor to San Francisco Bay nutrient loading relative to other sources. However, the Regional Water Board, in conjunction with other agencies and interested parties, is further evaluating this contribution as a part of the ongoing Bay Nutrient Science Strategy, initiated in 2011.

#### 3.4.4 Impacts and Mitigation Measures

##### ***Impact 3.4-1: Potential to Substantially Degrade Water Quality through Alteration of Water Temperature, Salinity, pH, and Dissolved Oxygen***

##### **No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

Studies have shown placement of dredged material from hopper, cutterhead, and clamshell-bucket dredges into the water column does not cause substantial short- or long-term changes in salinity, temperature, or pH (USACE, 1976a; 1976b). A USACE study (USACE, 1976a) found that changes in these parameters were localized and short in duration; ambient concentrations of these parameters were usually regained within 10 minutes following material release (USACE, 1998).

Localized minor and temporary dissolved oxygen level reductions (1 to 2 parts per million) may occur during dredging, including barring and knockdown practices, and placement; however, the ambient conditions are shortly regained following settlement of the suspended sediment (USACE, 1976a).

The movement of vessels for transport of dredged materials would not be expected to impact water temperature, salinity, pH, or dissolved oxygen.

**National Environmental Policy Act (NEPA) Determination.** The project alternatives' impact to water quality temperature, salinity, pH, and dissolved oxygen would be short-term and less than significant.

**California Environmental Quality Act (CEQA) Determination.** The project alternatives' impact to water quality temperature, salinity, pH, and dissolved oxygen would be short-term and less than significant.

### **Impact 3.4-2: Potential to Substantially Degrade Water Quality Because of Increased Turbidity**

#### **No Action/No Project Alternative and Proposed Action/Project**

Under all project alternatives, dredging would cause a local resuspension of sediments, and a temporary decrease in water clarity. Fine sediments (clay and silt) remain suspended in the water column longer than coarser sediments (sand); therefore, turbidity returns to ambient levels more quickly during dredging of sandy materials. Increased turbidity effects from dredging are short term, minor, and greatly diminish with distance from the activity. Generally, hydraulic dredging (i.e., hopper and cutterhead-pipeline dredges) reduces disturbance and resuspension of sediments at a dredging site compared to mechanical dredges.

Because hydraulic dredges operate by suction, sediment resuspension at the channel bottom is minimized. Both hopper and cutterhead-pipeline dredges contain sediment as it is pumped to the surface. With hopper dredges, turbidity may increase during overflow operations as fine sediment is returned to the water column in the overflow (refer to the description of hopper dredge operations in Section 2.3.1). The USACE's hopper dredge *Essayons* is equipped with an anti-turbidity valve on its overflow weirs, which reduces the water quality impacts caused by the dredging overflow process. Because cutterhead-pipeline dredges pump directly to the placement site and the pipeline is monitored to avoid leakage; typically, turbidity from this method of dredging primarily occurs from sediment resuspension caused by bottom disturbance.

During mechanical dredging, sediments may become suspended because of the clamshell bucket's impact to the channel bottom, material washing from the top and side of the bucket as it passes through the water column, sediment spillage as it breaks the water surface, spillage of material during barge loading, and intentional overflow in an attempt to increase the barge's effective load (permissible only for material that is 80 percent or more sand). A study characterizing the spatial extent of turbidity plumes during mechanical dredging operations in Oakland Harbor (MEC Analytical Systems, 2004) found that in both ebb and flood surveys, plumes were distinct above background TSS concentrations for distances up to 400 meters from the source. Ambient concentrations varied throughout the study area, but were generally less than 50 mg/L. TSS concentrations exceeding 275 mg/L were measured only in immediate proximity (within 110 meters) to the source. TSS concentrations tended to decay fairly rapidly with increasing distance. In general, TSS concentrations above 100 mg/L were distributed in small pockets that primarily flowed just above the channel bottom, but occasionally dispersed into midwater depths (MEC Analytical Systems, 2004). Generally, mechanical dredges result in greater suspended sediment during dredging activities than hydraulic dredges, and therefore result in greater increases in turbidity (Anchor, 2003).

Short-term increases in turbidity generated by knockdown and barring operations are typically concentrated in the lower portion of the water column in the local area of disturbance (U.S. Army ERDC and Weston Solutions, 2005).

Because sediment resuspension from dredging vessel movement would be limited, the movement of vessels for transport of dredged materials would not be expected to increase turbidity above ambient ranges generated by natural hydrologic processes, weather, and existing vessel traffic.

Some degree of increased turbidity will occur with placement of dredged material in any of the placement environments, and at any placement volume. Water quality effects from ocean or in-Bay placement could be associated with plumes from the initial placement event; or in some cases, from subsequent

resuspension (from dispersive sites). In most cases, such effects would be limited to the area of the plume following placement, and would be temporary and localized. The USACE studies show turbidity plumes at placement sites last only 20 minutes, and plume duration is even less during placement of sandy material because there coarse sediments settle out of the water column more quickly than fine sediments (USACE 1976a; LTMS, 1998; Anchor, 2003). Therefore, effects on turbidity from placement of dredged material would be minor and temporary.

Both computer modeling and real-time field monitoring of dredged material placement at SF-DODS have shown that sediment plumes dissipate quickly to background levels, and that this occurs entirely within the boundaries of the placement site. Because SF-DODS is a depositional site (in contrast to in-Bay sites), disposed material is not expected to resuspend into the water column, and therefore would not continue to affect water quality after its initial placement. All of the existing in-Bay placement sites are dispersive sites in shallow, estuarine waters, so dredged material may resuspend in the water column following initial placement. Therefore, compared to in-water placement at SF-DODS, there is greater potential for turbidity impacts to be associated with placement at any of the in-Bay sites (LTMS, 1998).

Placement of dredged materials at habitat restoration beneficial reuse projects (particularly wetland restoration) could result in a net benefit to water quality by increasing sediment retention, filtration of pollutants, and shoreline stabilization over the long term. However, short-term, localized increases in turbidity levels could result during placement activities.

**NEPA Determination.** The No Project/No Action Alternative and Proposed Action/Project's impact to water quality due to short-term increases in turbidity would be less than significant. Placement of dredged materials at habitat restoration beneficial reuse projects could have long-term beneficial effects on water quality.

**CEQA Determination.** The No Project/No Action Alternative and Proposed Action/Project's impact to water quality due to short-term increases in turbidity would be less than significant.

### **Reduced Hopper Dredge Use Alternatives 1 and 2**

Water quality impacts resulting from increased turbidity during dredging would be greater under Reduced Hopper Dredge Use Alternatives 1 and 2, as compared to the No Action/No Action Alternative and Proposed Action/Project, because there would be increased use of mechanical dredges. Under Reduced Hopper Dredge Use Alternative 1, Suisun Bay Channel/New York Slough and either Pinole Shoal or Richmond Outer Harbor would be dredged with clamshell-bucket equipment instead of a hopper dredge. Under Reduced Hopper Dredge Use Alternative 2, Suisun Bay Channel/New York Slough, Pinole Shoal and Richmond Outer Harbor would all be dredged with clamshell-bucket equipment instead of a hopper dredge. Under both alternatives, San Bruno Channel in Redwood City Harbor would also be dredged with clamshell-bucket equipment instead of a hopper dredge.<sup>1</sup> Short-term increases in turbidity at Pinole Shoal, Richmond Outer Harbor, and San Bruno Channel would be higher when they are dredged with a clamshell-bucket dredge instead of a hopper dredge because mechanical dredging generates more turbidity than hopper dredging, as described above. In addition, turbidity impacts would be longer in duration at these locations because dredging a channel with a clamshell bucket dredge can take up to ten times longer than dredging with a hopper dredge (USACE, 2013d). Nonetheless, as described under the No Action/No Project Alternative and Proposed Action/Project, impacts from dredging would be temporary and minor. Dredging Suisun Bay Channel/New York Slough with a mechanical dredge instead of a hopper dredge would not be expected to result in a noticeable increase in turbidity because the material is greater than 80 percent sand.

<sup>1</sup> San Bruno Channel is dredged at intervals of 10 years or greater.

Impacts from the transport and placement of dredged material would be similar to those under the No Action/No Project Alternative and Proposed Action Project.

**NEPA Determination.** The Reduced Hopper Dredge Use Alternatives 1 and 2 impacts to water quality due to short-term increases in turbidity would be less than significant. Placement of dredged materials at habitat restoration beneficial reuse projects could have long-term beneficial effects on water quality.

**CEQA Determination.** The Reduced Hopper Dredge Use Alternatives 1 and 2 impacts to water quality due to short-term increases in turbidity would be less than significant.

***Impact 3.4-3: Potential to Substantially Degrade Water Quality Because of Mobilization of Contaminated Sediments or Release of Hazardous Materials***

**No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

Dredging of contaminated sediments does present the potential for release of contaminants to the water column. However, most contaminants are tightly bound in the sediments and are not easily released during short-term resuspension. Sediments are tested prior to dredging, and the results are reviewed by the DMMO prior to dredging and placement, including evaluation of the potential for water quality impacts. As in Section 3.3.2, sediment testing results for previous USACE maintenance dredging episodes indicate that, in general, dredged materials from the subject federal navigation channels have been suitable for unconfined aquatic disposal. Over time, some isolated areas in, or adjacent to, the channels have been identified as containing sediment that is not suitable for unconfined aquatic disposal (NUAD); USACE would continue to avoid dredging areas (e.g., portions of the Richmond Harbor federal channel adjacent to the United Heckathorn site) that it has been able to avoid dredging in the past. If future testing identifies NUAD material that must be dredged, USACE would place all NUAD material at would be placed at upland sites, and in some cases the Montezuma Wetlands Restoration Project, as determined during DMMO review. Therefore, dredging and placement activities would not be expected to increase contaminant concentrations in the water column above baseline conditions, or result in violation of a water quality standard.

Dredging, transport, and placement of dredged material would be conducted in cooperation with the DMMO. This process would identify contaminated sediments and appropriate placement site options for dredged materials based on the characteristics of the sediment and criteria for each placement site. Additionally, USACE would implement BMPs and comply with water quality protection measures included as conditions to the WQC issued by the Regional Water Board and the letter of agreement issued by the BCDC for USACE's consistency determination. Adherence to these measures and BMPs would minimize the potential for water quality degradation.

Vessels would be operated in compliance with all applicable regulations related to the prevention of water pollution by fuel, harmful substances, and garbage, as well as from accidental discharges. During transport, the dredged material would be secured, with precautions in place to minimize any risk of spills. Therefore, the potential for the release of hazardous substances from vessel operations during dredging, transport, and placement activities would be minimal.

**NEPA Determination.** The project alternatives' impact to water quality as a result of potential mobilization of contaminated sediments or hazardous materials release would be less than significant.

**CEQA Determination.** The project alternatives' impact to water quality as a result of potential mobilization of contaminated sediments or hazardous materials release would be less than significant.

**Impact 3.4-4: Potential to Result in Cumulative Impacts to Hydrology or Water Quality****No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

Any alternative would result in minor, short-term water quality impacts during dredging and placement activities due to short-term turbidity increases or the potential for releases of contaminants from sediments or vessel into the water. Other dredging projects and waterfront construction projects listed in Table 3.1-1 would also involve activities that could result in similar short-term impacts. Cumulative water quality impacts could include increases in turbidity; disturbance and release of contaminated sediments; or accidental release of hazardous materials such as diesel fuel from vessels. As stated above, the proposed project's potential impacts on water quality due to mobilization of contaminated sediments and release of hazardous materials would be minimal. Although USACE's maintenance dredging and placement activities could overlap with other projects that would disturb sediments and result in increased turbidity, impacts would be isolated and short-term, and would not be substantial in the greater geographic context of the study area. Additionally, other projects involving dredging and construction in the marine environment would be subject to permitting/regulatory approval processes similar to those for the proposed project, and would be required to implement similar measures to minimize water quality impacts.

**NEPA Determination.** The project alternatives would not contribute to significant cumulative water quality impacts.

**CEQA Determination.** The project alternatives would not contribute to significant cumulative water quality impacts.

### 3.5 AIR QUALITY AND GLOBAL CLIMATE CHANGE

This section describes the air quality and climate change regulations applicable to the proposed project; summarizes the existing air quality conditions in the local air basin; identifies the analysis methodology; and discusses the potential impacts that the project alternatives may have on air quality and climate change.

#### 3.5.1 Regulatory Setting

##### Federal

##### Federal Clean Air Act

At the federal level, the United States Environmental Protection Agency (USEPA) has been charged with implementing national air quality programs. USEPA's air quality mandates are drawn primarily from the federal Clean Air Act (CAA).

The CAA required the USEPA to establish primary and secondary National Ambient Air Quality Standards (NAAQS). The CAA also required each state to prepare an air quality control plan, referred to as a State Implementation Plan (SIP). The CAA Amendments of 1990 added requirements for states with nonattainment areas to revise their SIPs to incorporate additional control measures to reduce air pollution. The SIP is periodically modified to reflect the latest emissions inventories, planning documents, and rules and regulations of the air basins, as reported by their jurisdictional agencies. USEPA has responsibility to review all state SIPs for conformity with the mandates of the CAA, and to determine whether implementation will achieve air quality goals (BAAQMD, 2012a).

The Bay Area Air Quality Management District (BAAQMD) prepares plans to attain ambient air quality standards in the San Francisco Bay Area Air Basin (SFBAAB). The BAAQMD implements programs and regulations required by the CAA, CAA amendments, and the California Clean Air Act (CCAA) (BAAQMD, 2012a). The clean air strategy of the BAAQMD includes preparing plans for the attainment of ambient air quality standards, adopting and enforcing rules and regulations concerning sources of air pollution, and issuing permits for stationary sources of air pollution. As part of these plans, BAAQMD developed project-level thresholds and guidance for use during the California Environmental Quality Act (CEQA) evaluation process such that projects would not violate the CAA, as discussed in more detail below.

##### *General Conformity Regulations*

The USEPA promulgated the General Conformity Regulations to implement Section 176(c) of the CAA. Under the General Conformity Regulations, federal agencies must work with state, tribal, and local governments in a nonattainment or maintenance area to ensure that federal actions conform to the air quality plans established in the applicable state or tribal implementation plan. Federal actions that are exempt from the General Conformity Regulations include (USEPA, 2012a):

- Actions covered by transportation conformity;
- Actions with emissions clearly at or below *de minimis* levels;
- Actions listed as exempt in the rule; or
- Actions covered by a Presumed-to-Conform approved list.

Title 40 of the C.F.R. § 51.853(c)(2)(ix) states that "Maintenance dredging and debris disposal where no new depths are required, applicable permits are secured, and disposal will be at an approved disposal site" is exempt from conformity analyses. In accordance with 40 C.F.R. § 51.853(c)(2)(ix), USACE has determined the proposed agency action is exempt from the requirement to prepare a conformity

determination with the SIP under the CAA because the project consists of maintenance dredging, no new depths are required, and placement would be at approved placement sites.

### **National Environmental Policy Act**

On February 18, 2010, the Council on Environmental Quality released, for public consideration and comment, draft guidance on the ways in which federal agencies can improve their consideration of the effects of greenhouse gas (GHG) emissions and climate change in their evaluation of proposals for federal actions under the National Environmental Policy Act (NEPA). The memorandum (CEQ, 2010) stated that if a proposed action would be reasonably anticipated to cause direct emissions of 25,000 metric tons or more of carbon dioxide-equivalent (CO<sub>2</sub>e) GHG emissions on an annual basis, agencies should consider this an indication that a quantitative and qualitative assessment may be meaningful to decision makers and the public; this threshold was also included in the Council on Environmental Quality's revised guidance for analyzing GHG emissions and climate change, dated December 18, 2014. For long-term actions that have annual direct emissions of less than 25,000 metric tons of CO<sub>2</sub>e, the Council on Environmental Quality encourages federal agencies to consider whether the action's long-term emissions should receive similar analysis. Section 3.5.5 includes analysis of the GHG emission effects of the project alternatives.

### **Supreme Court Ruling on California Clean Air Act Waiver**

On April 2, 2007, the U.S. Supreme Court ruled that carbon dioxide (CO<sub>2</sub>) is an air pollutant as defined under the CAA, and that the USEPA has the authority to regulate emissions of GHGs. However, there are no federal thresholds regarding GHG emissions directly applicable to the proposed project. In June 2009, the USEPA granted California a waiver under the CAA, allowing the state to impose its own, stricter GHG regulations for vehicles beginning in 2009.

### **State Regulations**

#### **California Clean Air Act**

The California Air Resources Board (CARB) is the agency responsible for coordination and oversight of state and local air pollution control programs in California, and for implementing the CCAA. The CCAA requires that all air districts in the state endeavor to achieve and maintain the California Ambient Air Quality Standards by the earliest practical date. The act specifies that districts should focus particular attention on reducing the emissions from transportation and area-wide emission sources, and provides districts with the authority to regulate indirect sources.

CARB is primarily responsible for developing and implementing air pollution control plans to achieve and maintain the NAAQS. CARB is primarily responsible for statewide pollution sources, and produces a major part of the SIP. Local air districts are still relied on to provide additional strategies for sources under their jurisdiction. CARB combines these data and submits the completed SIP to the USEPA.

Other CARB duties include monitoring air quality (in conjunction with air monitoring networks maintained by air pollution control and air quality management districts); establishing the California Ambient Air Quality Standards (CAAQS), which in many cases are more stringent than the NAAQS; determining and updating area designations and maps; and setting emissions standards for new mobile sources, consumer products, small utility engines, and off-road vehicles (BAAQMD, 2012a).

#### **Executive Order S-3-05**

Executive Order S-3-05 sets forth a series of target dates by which statewide GHG emissions would be progressively reduced: by 2010, reduce emissions to 2000 levels; by 2020, reduce emission to 1990

levels; and by 2050, reduce GHG emissions to 80 percent below 1990 levels. Section 3.5.5 includes analysis of the GHG emission effects of the project alternatives.

### **Assembly Bill 32 and the California Climate Change Scoping Plan**

The California Global Warming Solutions Act of 2006 and Assembly Bill (AB) 32 establish a cap on statewide GHG emissions, and set forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, GHG are defined as CO<sub>2</sub>, methane (CH<sub>4</sub>), nitrogen dioxide (N<sub>2</sub>O), hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride.

Pursuant to AB 32, CARB adopted a Scoping Plan in 2008, outlining measures to meet the 2020 GHG reduction limits (CARB, 2008). To meet these goals, California must reduce its GHG emissions by 30 percent below projected 2020 business-as-usual emission levels, or about 15 percent from today's levels. The Scoping Plan estimates a reduction of 174 million metric tons of CO<sub>2</sub>e from the transportation, energy, agriculture, forestry, and high global warming potential (GWP) sections. Section 3.5.5 includes analysis of the GHG emission effects of the project alternatives.

### **Executive Order S-1-07**

Executive Order S-1-07 established a goal of reducing the carbon intensity of transportation fuels sold in California by 10 percent by 2020. CARB determined that a Low Carbon Fuel Standard could be adopted as a discrete, early-action measure to meet the mandates in AB 32. CARB adopted the Low Carbon Fuel Standard on April 23, 2009.

### **Senate Bill 97**

Senate Bill 97 acknowledges that climate change is an important environmental issue that requires analysis under CEQA. The bill directed the California Office of Planning and Research to prepare and develop guidelines for the feasible mitigation of GHG emissions or the effects of GHG emissions, and transmit those guidelines to the California Natural Resources Agency by July 1, 2009. The California Natural Resources Agency certified those CEQA guidelines on December 30, 2009, and they became effective March 18, 2010 (CNRA, 2012). Section 3.5.5 includes analysis of the GHG emission effects of the project alternatives.

## **Regional Regulations**

### **Bay Area Air Quality Management District Air Quality Regulations**

The BAAQMD manages air quality conditions in the SFBAAB through a comprehensive program of planning, regulation, enforcement, technical innovation, and promotion of the understanding of air quality issues. The clean air strategy of the BAAQMD includes preparing plans for the attainment of ambient air quality standards, adopting and enforcing rules and regulations concerning sources of air pollution, and issuing permits for stationary sources of air pollution. The BAAQMD also inspects stationary sources of air pollution and responds to citizen complaints; monitors ambient air quality and meteorological conditions; and implements programs and regulations required by the CAA, CAA amendments, and the CCAA (BAAQMD, 2012a).

As stated above, the BAAQMD prepares plans to attain ambient air quality standards in the SFBAAB. The BAAQMD prepares ozone attainment plans for the national ozone standard, and clean air plans for the California standard, in coordination with both the Metropolitan Transportation Commissions (MTC) and the Association of Bay Area Governments. As part of these plans, BAAQMD developed project-level thresholds and guidance for use during the CEQA evaluation process as discussed in more detail below.

## BAAQMD CEQA Guidelines

On June 2, 2010, the BAAQMD's Board of Directors unanimously adopted thresholds of significance to assist in the review of projects under CEQA. These thresholds are designed to establish the level at which the BAAQMD believed air pollution emissions would cause significant environmental impacts under CEQA, and were posted on BAAQMD's website and included in the BAAQMD's May 2011 updated CEQA Guidelines (BAAQMD, 2012b).

On March 5, 2012, the BAAQMD's Air Quality CEQA Thresholds of Significance were challenged by an order issued in *California Building Industry Association v. BAAQMD*, Alameda Superior Court Case No. RGI0548693. The order requires the BAAQMD thresholds to be subject to further environmental review. The claims made in the case concerned the CEQA impacts of adopting the thresholds (i.e., how the thresholds would affect land use development patterns), and petitioners argued that the thresholds for Health Risk Assessments encompassed issues not addressed by CEQA. On August 13, 2013, a court of appeal rejected the challenge to the BAAQMD's Air Quality CEQA Thresholds of Significance. This decision is under further appeal. The California Supreme Court is reviewing this matter and an opinion may be issued prior to the conclusion of this Environmental Assessment/Environmental Impact Report.

In response to the court's order, BAAQMD stated that lead agencies will need to determine appropriate air quality thresholds of significance based on substantial evidence in the record. BAAQMD has indicated that although lead agencies may rely on the May 2011 updated CEQA Guidelines for assistance in calculating air pollution emissions, obtaining information regarding the health impacts of air pollutants, and identifying potential mitigation measures, BAAQMD has been ordered to set aside the thresholds, and is no longer recommending that these thresholds be used as a general measure of a project's significant air quality impacts. Lead agencies may continue to rely on the Air District's 1999 Thresholds of Significance, and they may continue to make determinations regarding the significance of an individual project's air quality impacts based on the substantial evidence in the record for that project (BAAQMD, 2012b). However, as discussed in more detail below, in Section 3.5.3, Methodology and Thresholds of Significance, the BAAQMD's significance thresholds and recommended analysis methodologies were used in this analysis. The vacated guidelines included conventional air quality (i.e., criteria pollutants and toxic air contaminants [TACs]), GHG, and odor thresholds. The thresholds include: mass emission thresholds of criteria pollutants, a risk-based threshold for TACs, a mass or efficiency metric for GHGs, and a screening threshold for odors.

### 3.5.2 Environmental Setting

For the purpose of this analysis, the project's study area is the SFBAAB, which encompasses all or portions of the following nine counties: Marin, Sonoma, Napa, Solano, Contra Costa, Alameda, Santa Clara, San Mateo, and San Francisco. The study area is within the jurisdiction of the BAAQMD. BAAQMD is the primary agency responsible for air quality regulation in the nine-county SFBAAB. While the Long Term Management Strategy program planning area included small portions of Sacramento and San Joaquin counties, the study area is limited to the SFBAAB because almost all project activities would occur within the SFBAAB. Sherman Island, which is in San Joaquin County and outside the SFBAAB, could be used by USACE as a placement site in the future. However, USACE would not use Sherman Island or the other future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation of air quality and GHG impacts. Therefore, this assessment does not include the potential use of Sherman Island and other future placement sites identified in Section 1.5.4.

This section describes the air quality setting in the study area. Meteorological data are discussed, including temperature and precipitation; and ambient concentrations for the appropriate criteria pollutants are summarized. TACs are also discussed.

The environmental setting constitutes the baseline physical conditions used to determine whether implementation of the proposed project would cause changes in air pollutant emissions that would result in significant air quality impacts according to applicable thresholds. It is important to note that because the project alternatives involve continuation of an existing operation, the projected impacts are compared to the impacts that have occurred under the existing dredging program, which are the same as the No Action/No Project Alternative, as further described in Section 3.5.5.

## **Air Quality Setting in the Study Area**

### ***Climate and Meteorology***

The SFBAAB is characterized by complex terrain consisting of coastal mountain ranges, inland valleys, and bays, which distort normal wind flow patterns. The Coast Range splits wind flows, resulting in a western coast gap (Golden Gate) and an eastern coast gap (Carquinez Strait), which allows air to flow in and out of the SFBAAB and the Central Valley.

The air flowing in from the coast to the Central Valley, called the sea breeze, begins developing at or near ground level along the coast in late morning or early afternoon. As the day progresses, the sea breeze layer deepens and increases in velocity while spreading inland. The depth of the sea breeze depends in large part upon the height and strength of the inversion. If the inversion is low and strong (and hence stable), the flow of the sea breeze will be inhibited, and stagnant conditions are likely to result.

The climate is dominated by the strength and location of a semi-permanent, subtropical high-pressure cell. During the summer, the Pacific high-pressure cell is centered over the northeastern Pacific Ocean, resulting in stable meteorological conditions and a steady northwesterly wind flow. In the winter, the Pacific high-pressure cell weakens and shifts southward, resulting in wind flow offshore, curtailing upwelling, and causing storms. Weak inversions, coupled with moderate winds, result in low air pollution potential.

The SFBAAB is characterized by moderately wet winters and dry summers. Winter rains account for about 75 percent of the average annual rainfall. The amount of annual precipitation can vary greatly from one part of the SFBAAB to another, even within short distances. In general, total annual rainfall can reach 40 inches in the mountains, but it is often less than 16 inches in sheltered valleys (BAAQMD, 2012a).

### ***Ambient Air Quality – Criteria Air Pollutants***

Table 3.5-1 lists the state and federal ambient air quality standards. Table 3.5-2 shows the current attainment status for each criteria air pollutant. A description of each criteria pollutant is provided below.

#### **Ozone**

Ozone, or smog, is not emitted directly into the environment, but is formed in the atmosphere by complex chemical reactions between reactive organic gases (ROG) and nitrogen oxides (NO<sub>x</sub>) in the presence of sunlight. Ozone formation is greatest on warm, windless, sunny days. The main sources of NO<sub>x</sub> and ROG, often referred to as ozone precursors, are combustion processes (including motor vehicle engines); the evaporation of solvents, paints, and fuels; and biogenic sources. Automobiles are the single largest source of ozone precursors in the SFBAAB. For ozone, the SFBAAB is classified as a nonattainment area for the state and federal standards.

Pollutant	Averaging Time	California Standards <sup>1</sup>	Federal Standards <sup>2</sup>	
		Concentration <sup>3</sup>	Primary <sup>3,4</sup>	Secondary <sup>3,5</sup>
Ozone	1-Hour	0.09 ppm (180 µg/m <sup>3</sup> )	—	Same as Primary Standard
	8-Hour	0.070 ppm (137 µg/m <sup>3</sup> )	0.075 ppm (147 µg/m <sup>3</sup> )	
Respirable Particulate Matter (PM <sub>10</sub> ) <sup>6</sup>	24-Hour	50 µg/m <sup>3</sup>	150 µg/m <sup>3</sup>	Same as Primary Standard
	Annual Arithmetic Mean	20 µg/m <sup>3</sup>	—	
Fine Particulate Matter (PM <sub>2.5</sub> ) <sup>6</sup>	24-Hour	No Separate State Standard	35 µg/m <sup>3</sup>	Same as Primary Standard
	Annual Arithmetic Mean	12 µg/m <sup>3</sup>	12 µg/m <sup>3</sup>	15 µg/m <sup>3</sup>
Carbon Monoxide	8-Hour	9.0 ppm (10 mg/m <sup>3</sup> )	9 ppm (10 mg/m <sup>3</sup> )	—
	1-Hour	20 ppm (23 mg/m <sup>3</sup> )	35 ppm (40 mg/m <sup>3</sup> )	
Nitrogen Dioxide	Annual Arithmetic Mean	0.030 ppm (57 µg/m <sup>3</sup> )	53 ppb (100 µg/m <sup>3</sup> ) <sup>7</sup>	Same as Primary Standard
	1-Hour	0.18 ppm (339 µg/m <sup>3</sup> )	100 ppb (188 µg/m <sup>3</sup> ) <sup>7</sup>	—
Sulfur Dioxide	24-Hour	0.04 ppm (105 µg/m <sup>3</sup> )	—	—
	3-Hour	—	—	0.5 ppm (1,300 µg/m <sup>3</sup> ) <sup>8</sup>
	1-Hour	0.25 ppm (655 µg/m <sup>3</sup> )	75 ppb (196 µg/m <sup>3</sup> ) (see footnote 8)	—
Lead <sup>9</sup>	30-Day Average	1.5 µg/m <sup>3</sup>	—	Same as Primary Standard
	Calendar Quarter	—	1.5 µg/m <sup>3</sup>	
	Rolling 3-Month Average <sup>9</sup>	—	0.15 µg/m <sup>3</sup>	
Visibility-Reducing Particles	8-Hour	Extinction coefficient of 0.23 per kilometer — visibility of 10 miles or more (0.07 — 30 miles or more for Lake Tahoe). Method: Beta Attenuation and Transmittance through Filter Tape.	No Federal Standards	
Sulfates	24-Hour	25 µg/m <sup>3</sup>		
Hydrogen Sulfide	1-Hour	0.03 ppm (42 µg/m <sup>3</sup> )		
Vinyl Chloride <sup>8</sup>	24-Hour	0.01 ppm (26 µg/m <sup>3</sup> )

Relevant Federal and California Ambient Air Quality Standards (Continued)**

Pollutant	Averaging Time	California Standards <sup>1</sup>	Federal Standards <sup>2</sup>	
		Concentration <sup>3</sup>	Primary <sup>3,4</sup>	Secondary <sup>3,5</sup>
Source: CARB, 2013a.				
Notes:				
<sup>1</sup> California standards for ozone, carbon monoxide (except Lake Tahoe), sulfur dioxide (1-hour and 24-hour), nitrogen dioxide, suspended particulate matter—PM <sub>10</sub> , PM <sub>2.5</sub> , and visibility-reducing particles—are values that are not to be exceeded. All others are not to be equaled or exceeded. California ambient air quality standards are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations.				
<sup>2</sup> National standards (other than ozone, particulate matter (PM <sub>10</sub> and PM <sub>2.5</sub> ), and those based on annual averages or annual arithmetic mean) are not to be exceeded more than once a year. The ozone standard is attained when the fourth-highest 8-hour concentration in a year, averaged over 3 years, is equal to or less than the standard. For PM <sub>10</sub> , the 24-hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 µg/m <sup>3</sup> is equal to or less than 1. For PM <sub>2.5</sub> , the 24-hour standard is attained when 98 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. Contact USEPA for further clarification and current federal policies.				
<sup>3</sup> Concentration expressed first in units in which it was promulgated. Equivalent units given in parentheses are based upon a reference temperature of 25 °C and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25 °C and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.				
<sup>4</sup> National Primary Standards: The levels of air quality necessary, with an adequate margin of safety to protect the public health.				
<sup>5</sup> National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.				
<sup>6</sup> On December 14, 2012, the national annual PM <sub>2.5</sub> primary standard was lowered from 15 µg/m <sup>3</sup> to 12.0 µg/m <sup>3</sup> . The existing national 24-hour PM <sub>2.5</sub> standards (primary and secondary) were retained at 35 µg/m <sup>3</sup> , as was the annual secondary standard of 15 µg/m <sup>3</sup> . The existing 24-hour PM <sub>10</sub> standards (primary and secondary) of 150 µg/m <sup>3</sup> also were retained. The form of the annual primary and secondary standards is the annual mean, averaged over 3 years.				
<sup>7</sup> To attain this standard, the 3-year average of the 98th percentile of the daily maximum 1-hour average at each monitor within an area must not exceed 0.100 ppm (effective January 22, 2010). Note that the USEPA standards are in ppb. California standards are in ppm. To directly compare the national standards to the California standards, the units can be converted from ppb to ppm. In this case, the national standards of 53 ppb and 100 ppb are identical to 0.053 ppm and 0.100 ppm, respectively.				
<sup>8</sup> On June 2, 2010, a new 1-hour SO <sub>2</sub> standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour national standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb. The 1971 SO <sub>2</sub> national standards (24-hour and annual) remain in effect until 1 year after an area is designated for the 2010 standard, except that in areas designated nonattainment for the 1971 standards, the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved. Note that the 1-hour national standard is in units of ppb. California standards are in units of ppm. To directly compare the 1-hour national standard to the California standard, the units can be converted to ppm. In this case, the national standard of 75 ppb is identical to 0.075 ppm.				
<sup>9</sup> The California Air Resources Board has identified lead and vinyl chloride as “toxic air contaminants,” with no threshold level of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.				
<sup>10</sup> The national standard for lead was revised on October 15, 2008 to a rolling 3-month average. The 1978 lead standard (1.5 µg/m <sup>3</sup> as a quarterly average) remains in effect until 1 year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.				
°C = degrees Celsius µg/m <sup>3</sup> = micrograms per cubic meter mg/m <sup>3</sup> = milligrams per cubic meter PM <sub>2.5</sub> = particulate matter equal to or less than 2.5 micrometers in diameter PM <sub>10</sub> = particulate matter equal to or less than 10 micrometers in diameter ppb = parts per billion ppm = parts per million SO <sub>2</sub> = sulfur dioxide USEPA= United States Environmental Protection Agency				

**Table 3.5-2  
Federal and State Attainment Status for the San Francisco Bay Area**

<b>Pollutant</b>	<b>Averaging Time</b>	<b>California Attainment Status<sup>1</sup></b>	<b>Federal Attainment Status<sup>2,3</sup></b>

Source: CARB, 2013a.

Notes:

- <sup>1</sup> California standards for ozone, carbon monoxide (except Lake Tahoe), sulfur dioxide (1-hour and 24-hour), nitrogen dioxide, suspended particulate matter – PM<sub>10</sub>, and visibility reducing particles are values that are not to be exceeded. The standards for sulfates, Lake Tahoe carbon monoxide, lead, hydrogen sulfide, and vinyl chloride are not to be equaled or exceeded. If the standard is for a 1-hour, 8-hour, or 24-hour average (i.e., all standards except for lead and the PM<sub>10</sub> annual standard), then some measurements may be excluded. In particular, measurements are excluded that CARB determines would occur less than once per year on the average.
- <sup>2</sup> National standards shown are the "primary standards" designed to protect public health. National standards other than for ozone, particulates, and those based on annual averages are not to be exceeded more than once a year. The 1-hour ozone standard is attained if, during the most recent 3-year period, the average number of days per year with maximum hourly concentrations above the standard is equal to or less than one. The 8-hour ozone standard is attained when the 3-year average of the fourth highest daily concentrations is 0.075 ppm (75 ppb) or less. The 24-hour PM<sub>10</sub> standard is attained when the 3-year average of the 99th percentile of monitored concentrations is less than 150 µg/m<sup>3</sup>. The 24-hour PM<sub>2.5</sub> standard is attained when the 3-year average of 98th percentiles is less than 35 µg/m<sup>3</sup>.

**Table 3.5-2  
Federal and State Attainment Status for the San Francisco Bay Area (Continued)**

Notes: (Continued)

Except for the national particulate standards, annual standards are met if the annual average falls below the standard at every site. The national annual particulate standard for PM<sub>10</sub> is met if the 3-year average falls below the standard at every site. The annual PM<sub>2.5</sub> standard is met if the 3-year average of annual averages, spatially averaged across officially designed clusters of sites, falls below the standard.

<sup>3</sup> National air quality standards are set by USEPA at levels determined to be protective of public health, with an adequate margin of safety.

<sup>4</sup> Final designations effective July 20, 2012.

<sup>5</sup> The national 1-hour ozone standard was revoked by USEPA on June 15, 2005.

<sup>6</sup> In April 1998, the San Francisco Bay Area was redesignated to attainment for the national 8-hour carbon monoxide standard.

<sup>7</sup> In June 2002, CARB established new annual standards for PM<sub>2.5</sub> and PM<sub>10</sub>.

<sup>8</sup> Statewide VRP Standard (except Lake Tahoe Air Basin): Particles in sufficient amount to produce an extinction coefficient of 0.23 per kilometer when the relative humidity is less than 70 percent. This standard is intended to limit the frequency and severity of visibility impairment due to regional haze, and is equivalent to a 10-mile nominal visual range.

<sup>9</sup> The 8-hour California ozone standard was approved by the CARB on April 28, 2005 and became effective on May 17, 2006.

<sup>10</sup> USEPA lowered the 24-hour PM<sub>2.5</sub> standard from 65 µg/m<sup>3</sup> to 35 µg/m<sup>3</sup> in 2006. The USEPA designated the San Francisco Bay Area as nonattainment of the PM<sub>2.5</sub> standard on October 8, 2009. The effective date of the designation is December 14, 2009, and the Air District has 3 years to develop a plan, the SIP, that demonstrates the San Francisco Bay Area will achieve the revised standard by December 14, 2014. The SIP for the new PM<sub>2.5</sub> standard must be submitted to the USEPA by December 14, 2012.

<sup>11</sup> To attain this standard, the 3-year average of the 98th percentile of the daily maximum 1-hour average at each monitor within an area must not exceed 0.100 ppm (effective January 22, 2010).

<sup>12</sup> On June 2, 2010, the USEPA established a new 1-hour SO<sub>2</sub> standard, effective August 23, 2010, which is based on the 3-year average of the annual 99th percentile of 1-hour daily maximum concentrations. The existing 0.030 ppm annual and 0.14 ppm 24-hour SO<sub>2</sub> NAAQS must continue to be used until 1 year following USEPA initial designations of the new 1-hour SO<sub>2</sub> NAAQS. The USEPA expects to designate areas by June 2012.

<sup>13</sup> CARB has identified lead and vinyl chloride as 'toxic air contaminants' with no threshold level of exposure below which there are no adverse health effects determined.

<sup>14</sup> National lead standard, rolling 3-month average: final rule signed October 15, 2008. Final designations effective December 31, 2011.

CARB = California Air Resources Board

µg/m<sup>3</sup> = micrograms per cubic meter

N/A = not applicable

NAAQS = National Ambient Air Quality Standards

PM<sub>2.5</sub> = particulate matter equal to or less than 2.5 micrometers in diameter

PM<sub>10</sub> = particulate matter equal to or less than 10 micrometers in diameter

ppb = parts per billion

ppm = parts per million

PST = Pacific Standard Time

SIP = State Implementation Plan

SO<sub>2</sub> = sulfur dioxide

USEPA = U.S. Environmental Protection Agency

VRP = visibility-reducing particle

### **Particulate Matter**

Particulate matter (PM) refers to a wide range of solid or liquid particles in the atmosphere, including smoke, dust, aerosols, and metallic oxides. Respirable PM with an aerodynamic diameter of 10 micrometers or less is referred to as PM<sub>10</sub>. PM<sub>2.5</sub> includes a subgroup of finer particles that have an aerodynamic diameter of 2.5 micrometers or less. Some PM, such as pollen, are naturally occurring. In the SFBAAB, most PM is caused by combustion, factories, construction, grading, demolition, agricultural activities, and motor vehicles. Motor vehicles are currently responsible for about half of particulates in the SFBAAB. Wood burning in fireplaces and stoves is another large source of fine particulates (BAAQMD, 2012a). As indicated in Table 3.5-2, the SFBAAB is classified as a nonattainment area for the state and federal PM<sub>10</sub> and PM<sub>2.5</sub> standards.

### **Carbon Monoxide**

Carbon monoxide (CO) is an odorless, colorless gas. It is formed by the incomplete combustion of fuels. The single largest source of CO in the SFBAAB is motor vehicles. The SFBAAB is classified as an attainment area for the state and federal CO standards.

### **Nitrogen Dioxide**

Nitrogen dioxide (NO<sub>2</sub>) is a reddish-brown gas that is a byproduct of combustion processes. Automobiles and industrial operations are the main sources of NO<sub>2</sub>. NO<sub>2</sub> may be visible as a coloring component of a brown cloud on high pollution days, especially in conjunction with high ozone levels (BAAQMD, 2012a). In 2010, the USEPA implemented a new 1-hour NO<sub>2</sub> standard, which is presented in Table 3.5-1. The SFBAAB has been designated as an unclassified area<sup>1</sup> for the new federal NO<sub>2</sub> standard (BAAQMD, 2013).

### **Sulfur Dioxide**

Sulfur dioxide (SO<sub>2</sub>) is a colorless acid gas with a pungent odor. It is produced by the combustion of sulfur-containing fuels, such as oil, coal, and diesel. As indicated in Table 3.5-2, the SFBAAB is classified as an attainment area for the state and federal SO<sub>2</sub> standards.

### **Lead**

Lead is a metal found naturally in the environment, as well as in manufactured products. The major sources of lead emissions have historically been mobile and industrial sources. As a result of the phase-out of leaded gasoline, metal processing is currently the primary source of lead emissions. The highest levels of lead in air are generally found near lead smelters. Other stationary sources are waste incinerators, utilities, and lead-acid battery manufacturers. As indicated in Table 3.5-2, the SFBAAB is classified as an attainment area for the federal lead standards. There is no additional state standard.

### **Hydrogen Sulfide, Vinyl Chloride (chloroethene), and Visibility-Reducing particles**

As indicated in Table 3.5-2, the SFBAAB is either unclassified, or there is no information available for ambient levels of these three pollutants. There are no federal attainment standards associated with these three pollutants.

### **Toxic Air Contaminants**

In addition to the criteria air pollutants listed above, another group of pollutants, commonly referred to as TACs or hazardous air pollutants, can result in health effects that can be quite severe.

---

<sup>1</sup> An unclassified area is an area in which compliance with the NAAQS cannot be determined with current information.

Industrial facilities and mobile sources are significant sources of TACs. Various common urban facilities produce TAC emissions, such as gasoline stations (benzene), hospitals (ethylene oxide), and dry cleaners (perchloroethylene). Automobile exhaust also contains TACs such as benzene and 1,3-butadiene. Most recently, diesel particulate matter (DPM) was identified as a TAC by CARB. DPM differs from other TACs in that it is not a single substance, but rather a complex mixture of hundreds of substances. BAAQMD research indicates that mobile-source emissions of DPM, benzene, and 1,3-butadiene represent a substantial portion of the ambient background risk from TACs in the SFBAAB.

Ambient standards have not been developed for TACs. Instead, the BAAQMD uses a risk-based approach to regulate TACs. In addition to monitoring criteria pollutants, both the BAAQMD and CARB operate TAC monitoring networks in the SFBAAB.

### **Sensitive Receptors**

Sensitive receptors refer to those segments of the population most susceptible to poor air quality: children, the elderly, and those with pre-existing serious health problems affected by air quality. Examples of receptors include people at residences, schools and school yards, parks and playgrounds, daycare centers, nursing homes, and medical facilities.

A majority of the federal navigation channels and existing placement sites are not located near sensitive receptors. The USACE would not use any of the future placement sites identified in Section 1.5.4 until appropriate environmental review is completed. Commercial and recreational ship traffic is an ambient air emissions source at the federal navigation channels and throughout the study area. Several of the channels (e.g., Richmond Harbor, Oakland Harbor) are also located in areas with surrounding commercial and industrial operations, which are additional sources of ambient emissions. There are sensitive receptors in close proximity (i.e., within 1,000 feet) to portions of some of the federal channels, including San Rafael Creek, Napa River, Petaluma River, Oakland Harbor, and Richmond Inner Harbor.

### **Global Climate Change Setting**

This section describes the causes and consequences of global climate change.

#### **Causes of Climate Change**

Global climate change is caused by anthropogenic emissions of GHGs released into the atmosphere through combustion of fossil fuels, and other GHG-producing activities such as deforestation and land use change.

GHGs play a critical role in the Earth's radiation budget by trapping infrared radiation emitted from the Earth's surface and which could have otherwise escaped to space. The "greenhouse effect" keeps the Earth's atmosphere near the surface warmer than it would be otherwise, and allows for successful habitation by humans and other forms of life.

Prominent GHGs contributing to this process include CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, and fluorocarbons. Emissions of CO<sub>2</sub> and N<sub>2</sub>O are byproducts of fossil fuel combustion, among other sources. CH<sub>4</sub>, a highly potent GHG, results from off-gassing associated with agricultural practices and landfills. Fluorocarbons are commonly used in refrigeration systems.

GWP is a measure of the estimated contribution to global warming of a given mass of GHG. It is a relative scale that compares the gas in question to that of the same mass of CO<sub>2</sub> (whose GWP is by definition 1). For example, emitting 1 ton of CH<sub>4</sub> causes the same amount of global warming as emitting 25 tons of CO<sub>2</sub>; therefore the CH<sub>4</sub> GWP is 25. To account for the GWP of GHGs, GHG emissions are often required to be multiplied by their GWP and then reported as CO<sub>2</sub>e. As such, emissions of CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O are typically converted into CO<sub>2</sub>e by multiplying their emissions by their respective GWP.

### **Effects of Climate Change**

The combustion of fossil fuels releases carbon that has been stored underground into the active carbon cycle, thus increasing concentrations of GHGs in the atmosphere. Emissions of GHGs in excess of natural ambient concentrations are theorized to be responsible for the enhancement of the greenhouse effect, and contribute to what is termed “global warming,” a trend of unnatural warming of the Earth’s natural climate. Increases in these gases lead to more absorption of radiation, and warm the lower atmosphere further, thereby increasing evaporation rates and temperatures near the surface. Climate change is a global problem, and GHGs are global pollutants, unlike criteria pollutants (such as ozone, CO, and PM) and TACs, which are pollutants of regional and local concern.

Climate change could affect California’s natural environment in the following ways (CEC, 2005):

- Rising sea levels along the California coastline, particularly in San Francisco and the Sacramento-San Joaquin River Delta, due to ocean expansion;
- Extreme heat conditions, such as heat waves and very high temperatures, which could last longer and become more frequent;
- An increase in heat-related human deaths and infectious diseases, and a higher risk of respiratory problems caused by deteriorating air quality;
- Reduced snow pack and stream flow in the Sierra Nevada mountains, affecting winter recreation and water supplies;
- Potential increase in the severity of winter storms, affecting peak stream flows and flooding;
- Changes in growing season conditions that could affect California agriculture, causing variations in crop quality and yield; and
- Changes in distribution of plant and wildlife species due to changes in temperature, competition of colonizing species, changes in hydrologic cycles, changes in sea levels, and other climate-related effects.

These changes in California’s climate and ecosystems could occur at a time when California’s population is expected to increase from approximately 37 million in 2010 to 50 million by the year 2050 (California Department of Finance, 2012).

Transportation generates 38 percent of California’s GHG emissions, followed by the industrial sector (21 percent), in-state electricity generation (12 percent), imported electricity generation (11 percent), residential (7 percent), agriculture and forestry (7 percent), commercial (3 percent), and other sources (3 percent) (CARB, 2013b). Sinks of CO<sub>2</sub> include uptake by vegetation, and dissolution into the ocean. In 2010, California generated 451 million metric tons of GHG, measured as CO<sub>2</sub>e emissions (CARB, 2013c).

#### **3.5.3 Thresholds of Significance**

Maintenance dredging under any alternative would be conducted with mechanical dredges, hopper dredges, and cutterhead-pipeline dredges. Methods used to transport dredged materials would include pipelines, hopper dredges, barges, and scows. The analysis considered CEQA Appendix G thresholds, as well as the BAAQMD thresholds, when evaluating significance. Based on these thresholds, the impacts would be significant if the project would:

- Conflict with or obstruct implementation of the applicable air quality plan;
- Violate any air quality standard or contribute substantially to an existing or projected air quality violation;

- Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is in nonattainment under an applicable federal or state ambient air quality standard (including releasing emissions that exceed quantitative thresholds for ozone precursors);
- Expose sensitive receptors to substantial pollutant concentrations; or
- Create objectionable odors affecting a substantial number of people.

In addition, a project would have a potentially significant GHG or global climate change impact if it:

- Generates GHG emissions, either directly or indirectly, that may have a significant impact on the environment; or
- Conflicts with an agency's applicable plan, policy, or regulation designed to reduce GHG emissions.

The BAAQMD's Air Quality CEQA Thresholds of Significance provide reference thresholds for considering whether a project would have an air quality impact, and recommend procedures for evaluating potential air quality impacts. The issues identified in the BAAQMD *CEQA Air Quality Guidelines* court case are not considered relevant to the scientific soundness of the BAAQMD's analysis of the level at which a pollutant would potentially significantly affect air quality or human health. Therefore, even though the guidelines have been suspended by the BAAQMD until the issues identified in the case are resolved, the analysis in this Environmental Assessment/Environmental Impact Report was conducted in accordance with the BAAQMD *CEQA Air Quality Guidelines*. The lead agencies have reviewed and agree with BAAQMD's criteria pollutant and GHG thresholds and are using them for this Environmental Assessment/Environmental Impact Report analysis.

A project's emissions would constitute a less-than-significant air quality impact if they meet the mass thresholds of criteria pollutants. The BAAQMD thresholds for criteria pollutants emissions from construction and operation of projects are summarized in Table 3.5-3.

<b>Table 3.5-3 Mass Thresholds of Criteria Pollutants</b>				
	<b>ROG</b>	<b>NO<sub>x</sub></b>	<b>PM<sub>10</sub></b>	<b>PM<sub>2.5</sub></b>
Average Daily Emissions (lbs/day)	54	54	82	54
Maximum Annual Emissions (tpy)	10	10	15	10
Notes: lbs/day = pounds per day NO <sub>x</sub> = nitrogen oxides PM <sub>10</sub> = particulate matter less than or equal to 10 microns in diameter PM <sub>2.5</sub> = particulate matter less than or equal to 2.5 microns in diameter ROG = reactive organic gas tpy = tons per year				

The BAAQMD has also adopted CEQA thresholds for GHGs. A project's GHG emissions would constitute a less-than-significant GHG impact if they meet any one of these criteria:

- Complies with a qualified GHG Reduction Strategy;
- For stationary source projects, has operational emissions of less than 10,000 metric tons CO<sub>2</sub>e units per year;
- For land-use projects, has operational emissions of less than 1,100 metric tons CO<sub>2</sub>e units per year; or

- For land-use projects, has average emission of less than 4.6 metric tons per service population per year (where service population refers to the total number of residents and employees for the project).

The lead agencies agree with BAAQMD's guidance regarding treatment of existing emissions; therefore, if a proposed project involves the removal of existing emission sources, the existing emissions levels are subtracted from the emissions levels estimated for the new proposed land use. This net calculation is permissible only if the existing emission sources were operational at the time that the Notice of Preparation (NOP) for the CEQA project was circulated, or in the absence of an NOP when environmental analysis begins, and would continue if the proposed redevelopment project is not approved. This net calculation is not permitted for emission sources that ceased to operate, or where the land uses were vacated and/or demolished, prior to circulation of the NOP or the commencement of environmental analysis. This approach is consistent with the definition of baseline conditions pursuant to CEQA (BAAQMD, 2012a).

Per the requirements of NEPA and CEQA, the proposed project is compared to baseline conditions, which is equivalent to the conditions under the No Action/No Project Alternative. The federal standard placement site and amount dredged for each navigation channel would remain the same under all alternatives. Additionally, the type of dredge equipment that would be used to dredge each navigation channel would be the same under the No Action/No Project Alternative and Proposed Action/Project. Therefore, the difference in dredge equipment type (i.e., replacement of hopper dredges with mechanical dredges and tugs under the Reduced Hopper Dredge Use Alternatives) was the basis for evaluating differences in emissions among the action alternatives. The analysis included calculations to determine the change in total air pollutant emissions resulting from dredging material and transporting the dredged material, using a mechanical dredge compared to using a hopper dredge in certain channels in the San Francisco Bay Area. The difference in emissions between the two proposed methods was estimated, and was compared to CEQA thresholds to determine level of significance. Because the type of dredge equipment for each channel would be the same under the No Action/No Project Alternative and Proposed Action/Project, the difference in emissions between these alternatives would be zero. The use of alternative placement sites could affect the distances traveled by vessels, and therefore result in differing emission amounts. The use of these sites is not expected to result in a substantial net change in air emissions because some of the sites are closer to the areas dredged, while others are farther away. Under USACE's operations and maintenance program, USACE regulations require dredged materials to be placed at the federal standard site, which is defined as the least-costly dredged material disposal or placement alternative consistent with sound engineering practices, and meeting the environmental standards established by the Clean Water Act Section 404(b)(1) evaluation process or ocean dumping criteria (33 C.F.R. § 335.7). Transport costs factor largely into determining the federal standard; therefore, generally placement sites closest to the dredge site are the federal standard unless environmental considerations dictate selection of another location. The USACE would make every effort to use the federal standard disposal locations, but may be forced by logistical constraints to use the alternate locations. However, because deviation from the federal standard placement sites are expected to be infrequent, and cost, and therefore transport distance, would factor into the selection of an alternate placement site, the use of alternate placement sites would not result in substantial differences in transport emissions. The USACE would continue to generally minimize distances traveled in an effort to minimize operational costs; therefore, emissions are not expected to increase or decrease because the same cost and distance minimizing drivers would still be in place.

### 3.5.4 Methodology

Because the lead agencies are using BAAQMD guidance, this analysis addressed project emissions of the following air pollutants: ROG, NO<sub>x</sub>, PM, and CO<sub>2</sub>. To quantify the difference in emissions under the two Reduced Hopper Dredge Use Alternatives, the analysis quantitatively assessed emissions from dredging and transit operations associated with hopper and mechanical dredge equipment.

The analysis converted calculations for emissions per unit of material dredged for each dredge equipment type to total annual pollutant emissions from dredging activities and compared them to local and federal annual air quality pollutant thresholds (i.e., the BAAQMD's air quality pollutant thresholds).

### Data Sources

The analysis identified potential air pollutant emission sources (engines/pumps) for each dredge type (hopper and mechanical). Because comparative data for USACE's hopper dredge *Essayons* and a representative mechanical dredge (i.e., the *Paula Lee*) were available, the analysis was performed using specifications and data from those two ships.

The *Essayons* has two main engines, three ship service engines, and two pump engines (USACE, n.d.). The analysis used the *Paula Lee* mechanical barge as a representative model for mechanical barge specifications; the *Paula Lee* has two different main engines, one deck engine, and four deck winch engines (USACE, n.d.). In addition, mechanical dredging operations are supported by a tug boat that has one main engine. Emissions from the tug boat that is used to position the barge were also included in this analysis. The dredge-specific inputs used to calculate each dredge type's emissions include engine horsepower, engine load, and barge dredging rate (i.e., amount of material dredged per pumping hour). Engine load varies depending on the activity being performed, such as pumping versus transport of pumped material. Therefore, equipment specifications and calculations are shown for both the pumping portion of dredging activities as well as the transit portion. Table 3.5-4 provides the mechanical and hopper dredges' specifications.

<b>Dredge Type</b>	<b>Engine</b>	<b>Horsepower<sup>1</sup></b>	<b>Number of Engines Per Barge<sup>1</sup></b>	<b>Dredge Rate (Cubic Yards / Hour)<sup>2</sup></b>	<b>Load<sup>3</sup></b>	<b>Year<sup>1</sup></b>
Hopper ( <i>Essayons</i> ) – Pumping	Main engine	4,640	2	2,657	0.1	2007
	Ship service	1,207	3	2,657	0.6	2007
	Pump	4,640	2	2,657	0.8	2007
Mechanical ( <i>Paula Lee</i> ) – Pumping	Tug – main engine <sup>3</sup>	1,800	1	257	0.1	1970
	Main	1,200	1	257	0.1	2007
	Main	895	1	257	0.1	2002
	Deck	300	1	257	0.8	2004
	Deck Winch	300	4	257	0.8	2007

Sources: USACE, n.d.; USACE, 2013d.

Notes:

- The horsepower, year, and quantity of each hopper dredge engine were obtained from the specifications sheet for the *Essayons*. The horsepower, year and quantity of each mechanical dredge engine, except for the tug boat, were obtained from the specifications sheet for the *Paula Lee*. Both specification sheets were provided by USACE.
- Cubic yards dredged per hour (dredging rate) is an average rate that was calculated from data provided in a mechanical versus hydraulic dredge study provided by USACE.
- Load of all engines and all tug boat specifications were provided by USACE. Zero load indicates that the activity is not part of the corresponding phase (e.g., pumping is not used in transport of material).

Emission factors of ROG, NO<sub>x</sub>, PM, and CO<sub>2</sub> were other inputs used in the calculations of the total annual emissions for each engine. Emission factors associated with a piece of equipment could vary depending on the model year assumed. The emission factors of ROG, NO<sub>x</sub>, PM and CO<sub>2</sub> used in calculations are included in Appendix B; the calculations are further explained below.

### Calculation Methodology

Under the action alternatives, the maximum amount of material to be dredged by a mechanical dredge, as opposed to the currently operated hopper barge, is 575,000 cubic yards per year.<sup>2</sup> Under Reduced Hopper Dredge Use Alternative 1, Suisun Bay Channel and New York Slough, plus either Richmond Outer Harbor or Pinole Shoal Channel, would be dredged with a mechanical dredge as opposed to the currently operated hopper dredge, which would be used under the No Action/No Project Alternative and Proposed Action/Project; therefore, approximately 375,000 cubic yards per year would be dredged with a mechanical dredge instead of a hopper dredge under Reduced Hopper Dredge Alternative 1. Under Reduced Hopper Dredge Use Alternative 2, Richmond Outer Harbor, Pinole Shoal Channel, Suisun Bay Channel and New York Slough would be all dredged with a mechanical dredge as opposed to the currently operated hopper dredge; therefore, approximately 575,000 cubic yards per year would be dredged with a mechanical dredge instead of a hopper dredge under Reduced Hopper Dredge Alternative 2. These alternatives are summarized in Table 3.5-5.

<b>Alternative</b>	<b>Dredging Area</b>	<b>Dredging Method</b>	<b>Volume of Material Dredged (Cubic Yards per Year)</b>
No Action and Proposed Action	Suisun Bay Channel and New York Slough; Richmond Outer Harbor; Pinole Shoal Channel	Hopper	575,000
Reduced Hopper Dredge Use Alternative 1	Suisun Bay Channel and New York Slough; plus either Richmond Outer Harbor or Pinole Shoal Channel	Mechanical	375,000
	Richmond Outer Harbor or Pinole Shoal Channel	Hopper	200,000
Reduced Hopper Dredge Use Alternative 2	Suisun Bay Channel and New York Slough; Richmond Outer Harbor; Pinole Shoal Channel	Mechanical	575,000

Using the engine specification inputs and emission factors described above, maximum pollutant emissions during annual dredging activities were calculated for No Action and Proposed Action, and for Reduced Hopper Alternative 2 because this alternative represents the maximum replacement of hopper dredges with mechanical dredges. The average dredging rate for pumping activities of each barge was calculated using data from a recent study in the Richmond Harbor, in which the average amount of material dredged per pumping hour was recorded daily. The *Essayons* pumped, on average, 2,657 cubic yards per hour, and the *Paula Lee* dredged, on average, 257 cubic yards per hour (USACE, 2013d). The transit activities of each barge were based on the standard capacity of dredges with comparable engine sizes, and an estimated average speed (10 miles per hour) and transport distance (4.5 miles one-way).

<sup>2</sup> Based on estimated volumes for the federal navigation channels that are typically dredged annually.

Based on these assumptions, the *Essayons* and the scow that accompanies the *Paula Lee* are each able to transport, on average, 5,000 cubic yards per hour (USACE, n.d.).

To calculate emissions from dredging a specified amount of material, emission factors were converted to the units of pounds per cubic yard of dredged material. First, as shown in Table 3.5-6, engine specifications, along with the average dredging rate of each barge type, were used to convert engine power to the units of horsepower-hour/cubic yard.

<b>Dredge Type</b>	<b>Engine</b>	<b>hp</b>	<b>Number of Engines Per Barge</b>	<b>Load<sup>1</sup></b>	<b>Dredge Rate<sup>2</sup> (Cubic yards/hour)</b>	<b>Horsepower-Hour/ Cubic Yard)<sup>1,3</sup></b>
Hopper ( <i>Essayons</i> ) – Pumping	Main engine	4,640	2	0.1	2,657	0.35
	Ship service	1,207	3	0.6	2,657	0.82
	Pump	4,640	2	0.8	2,657	2.79
Mechanical ( <i>Paula Lee</i> ) - Pumping	Tug – main engine	1,800	1	0.1	257	0.70
	Main	1,200	1	0.1	257	0.47
	Main	895	1	0.1	257	0.35
	Deck	300	1	0.8	257	0.93
	Deck Winch	300	4	0.8	257	3.74
Hopper ( <i>Essayons</i> ) – Transit	Main engine	4,640	2	0.8	5,000	1.48
	Ship service	1,207	3	0.5	5,000	0.36
	Pump	4,640	2	0	5,000	0
Mechanical ( <i>Paula Lee</i> ) - Transit	Tug – main engine	1,800	1	0.8	5,000	0.29
	Main	1,200	1	0.2	5,000	0.05
	Main	895	1	0.2	5,000	0.04
	Deck	300	1	0	5,000	0
	Deck Winch	300	4	0	5,000	0
Notes:						
<sup>1</sup> Zero value indicates that the activity is not part of the corresponding phase.						
<sup>2</sup> Cubic yards per hour for pumping specifications (dredging rate) is an average rate that was calculated from data provided in a mechanical versus hydraulic dredge study provided by USACE. Cubic yards per hour for transit specifications, is an average rate based on 5,000-cubic-yard capacity for either the <i>Essayons</i> or the scow that accompanies the <i>Paula Lee</i> filled to 90 percent and a 0.9-hour round trip time.						
<sup>3</sup> Calculation: [(hp) * (number of engines per barge) * (load)]/(cubic yards/hour)						
hp = horsepower						

Subsequently, pounds of emissions per cubic yard of dredged material were calculated by multiplying the emission factors [grams per horsepower-hour] by [horsepower-hour/cubic yard]. Appendix B includes the conversion of emission factors from the units provided in the specification sheets to the units of pounds per cubic yard dredged material.

Finally, total emissions of each pollutant from each dredge were calculated by multiplying the emissions per cubic yard dredged by the 575,000 cubic yards of material per year, as shown in Table 3.5-7 below.

	<b>ROG</b>	<b>NO<sub>x</sub></b>	<b>PM<sub>10</sub></b>	<b>CO<sub>2</sub><sup>1</sup></b>
Hopper ( <i>Essayons</i> ) – Pumping	0.8	15	0.5	1,296
Mechanical ( <i>Paula Lee</i> ) – Pumping	1.3	23	0.9	2,024
Hopper ( <i>Essayons</i> ) – Transit	0.4	7	0.2	604
Mechanical ( <i>Paula Lee</i> ) – Transit	0.3	3	0.1	122
Hopper ( <i>Essayons</i> ) – Total	1.2	22	0.7	1,900
Mechanical ( <i>Paula Lee</i> ) – Total	1.6	26	1	2,146
Difference in Emissions Between Hopper and Mechanical Dredging Methods <sup>2</sup>	0.4	4	0.3	246
Significance Threshold (BAAQMD)	10	10	15	1,100 (N/A – land use) 10,000 (N/A – stationary)
Exceeds Thresholds?	No	No	No	No
Notes: BAAQMD = Bay Area Air Quality Management District CO <sub>2</sub> = carbon dioxide N/A = not applicable NO <sub>x</sub> = nitrogen oxides PM <sub>10</sub> = particulate matter equal to or less than 10 micrometers in diameter ROG = reactive organic gas <sup>1</sup> . CO <sub>2</sub> emissions and thresholds are presented in metric tons per year. <sup>2</sup> . This is the difference in emissions between the Proposed Action (equivalent to No Action) and the Reduced Hopper Alternative 2 (equivalent to the maximum impact), and indicates that emissions would increase slightly with the increased use of mechanical dredges.				

Analysis for SO<sub>2</sub> was not included because the area is in attainment for federal and state ambient air quality standards (i.e., NAAQS and CAAQS) for SO<sub>2</sub> and therefore, BAAQMD does not have any mass emissions significance thresholds for SO<sub>2</sub>. Furthermore, the use of ultra-low sulfur diesel fuel requirement makes SO<sub>2</sub> emissions adequately low to be considered negligible for impact analyses.

The major sources of lead emissions have historically been from fuels in on-road motor vehicles (such as cars and trucks) and industrial sources. The major sources of lead emissions to the air today are ore and metals processing and piston-engine aircraft operating on leaded aviation gasoline. The project area is in attainment for lead based on the NAAQS and CAAQS, and BAAQMD does not have any mass emissions significance thresholds for lead. The proposed project alternatives do not include any major sources of airborne lead, and lead emissions from diesel fuel combustion are considered to be negligible.

Because SO<sub>2</sub> and lead emissions would be negligible, they are not further discussed in the analysis.

### 3.5.5 Impacts and Mitigation Measures

#### ***Impact 3.5-1: Conflict with or Obstruct BAAQMD Air Quality Plan Implementation, Exceed Applicable Air Quality Standards, or Contribute Substantially to an Air Quality Violation***

##### **No Action/No Project Alternative**

Dredging and the associated transport and placement activities have occurred in the waters of San Francisco Bay for decades, and the No Action/No Project Alternative would involve continuation of USACE's current maintenance dredging program for the federal navigation channels in San Francisco Bay. Although dredge equipment and vessel use produce ROG, NO<sub>x</sub>, PM, and CO<sub>2</sub> emissions, these activities would only occur for short durations. The No Action/No Project Alternative would allow for the same level of dredging and vessel traffic in the San Francisco Bay that currently occurs. There are no construction activities associated with the No Action/No Project Alternative. Thus, there are no expected increases in annual emissions due to the No Action/No Project Alternative.

Project-level emission increases above the BAAQMD mass significance thresholds would potentially conflict with or obstruct the BAAQMD Air Quality Plan Implementation. Because there are no expected increases in annual emissions due to the No Action/No Project Alternative, the emissions level increase is less than the BAAQMD mass significance thresholds. Therefore, the project would not conflict with or obstruct BAAQMD Air Quality Plan Implementation, exceed applicable air quality standards, or contribute substantially to an air quality violation.

**NEPA Determination.** The No Action Alternative's potential to conflict with or obstruct BAAQMD Air Quality Plan Implementation, exceed applicable air quality standards, or contribute substantially to an air quality violation would be less than significant.

**CEQA Determination.** The No Project Alternative's potential to conflict with or obstruct BAAQMD Air Quality Plan Implementation, exceed applicable air quality standards, or contribute substantially to an air quality violation would be less than significant.

##### **Proposed Action/Project**

Implementation of the Proposed Action/Project would be very similar to the No Action/No Project Alternative; it would involve use of the same type of dredge equipment for each channel, the same volume of dredged material, and the same dredging frequency and durations. Further, there are no construction activities associated with the Proposed Action/Project. However, the use of alternative placement sites could affect the distances traveled by vessels, and thus result in differing emissions amounts. The use of these sites is not expected to result in a substantial net change in air emissions because some of the sites are closer to the areas dredged, while others are further away. As described above (Section 3.5.3), USACE would continue to generally minimize distances traveled in an effort to minimize operational costs; therefore, emissions are not expected to increase or decrease because the same cost and distance minimizing drivers would still be in place.

**NEPA Determination.** The Proposed Action's potential to conflict with or obstruct BAAQMD Air Quality Plan Implementation, exceed applicable air quality standards, or contribute substantially to an air quality violation would be less than significant.

**CEQA Determination.** The proposed project's potential to conflict with or obstruct BAAQMD Air Quality Plan Implementation, exceed applicable air quality standards, or contribute substantially to an air quality violation would be less than significant.

## Reduced Hopper Dredge Use Alternatives 1 and 2

Under Reduced Hopper Dredge Use Alternatives 1 and 2, certain channels would be dredged with a mechanical dredge instead of a hopper dredge, but the overall volume of dredging would not change, and the increase of emissions from reduced hopper/increased mechanical dredge equipment use is not expected to exceed the BAAQMD significance thresholds, as shown in Table 3.5-7. There are no construction activities associated with Reduced Hopper Dredge Use Alternatives 1 and 2.

**NEPA Determination.** The Reduced Hopper Dredge Use Alternatives 1 and 2 potential to conflict with or obstruct BAAQMD Air Quality Plan Implementation, exceed applicable air quality standards, or contribute substantially to an air quality violation would be less than significant.

**CEQA Determination.** The Reduced Hopper Dredge Use Alternatives 1 and 2 potential to conflict with or obstruct BAAQMD Air Quality Plan Implementation, exceed applicable air quality standards, or contribute substantially to an air quality violation would be less than significant.

### ***Impact 3.5-2: Expose Sensitive Receptors to Substantial Pollutant Concentrations***

#### **No Action/No Project Alternative**

Dredging and the associated transport and placement activities have occurred in the waters of San Francisco Bay for decades, and the No Action/No Project Alternative would involve continuation of USACE's current maintenance dredging program.

As stated above, most of the federal navigation channels and existing placement sites are not located near sensitive receptors. The in-Bay and offshore placement sites are located over open waters, and there are no sensitive receivers in close proximity to these sites. Placement would also occur at existing upland at beneficial re-use sites. However, the placement of dredged materials has occurred regularly in the past at these locations, and ongoing emission from placement activities is part of the existing condition. In this context, emissions increases specific to placement of dredged materials from the federal navigation channels compared to baseline conditions would be negligible. There are sensitive receptors in close proximity to portions of some of the federal channels, including San Rafael Creek, Napa River, Petaluma River, Oakland Harbor, and Richmond Inner Harbor. Because dredges move along a channel, the duration a dredge would be operating in close proximity to any one sensitive receptor would be limited. There are no construction activities associated with the No Action/No Project Alternative. Therefore, the impacts of short-term intermittent emissions on sensitive receptors would be minimal.

**NEPA Determination.** The No Action Alternative's potential to expose sensitive receptors to substantial pollutant concentrations would be less than significant.

**CEQA Determination.** The No Project Alternative's potential to expose sensitive receptors to substantial pollutant concentrations would be less than significant.

#### **Proposed Action/Project**

Implementation of the Proposed Action/Project would be very similar to the No Action/No Project Alternative; it would involve use of the same type of dredge equipment for each channel, the same volume of dredged material, and the same dredging frequency and durations. The USACE would not use any of the future placement sites identified in Section 1.5.4 until appropriate environmental review and permitting is completed. There are no construction activities associated with the Proposed Action/Project. Therefore, the potential to expose sensitive receptors to substantial pollutant concentrations would be the same as described above for the No Action/No Project Alternative.

**NEPA Determination.** The Proposed Action's potential to expose sensitive receptors to substantial pollutant concentrations would be less than significant.

**CEQA Determination.** The Project's potential to expose sensitive receptors to substantial pollutant concentrations would be less than significant.

### **Reduced Hopper Dredge Use Alternatives 1 and 2**

Under Reduced Hopper Dredge Use Alternatives 1 and 2, certain channels would be dredged with a mechanical dredge instead of a hopper dredge, but the overall volume of dredging would not change, and the amount of emissions produced by different dredge equipment types is not expected to differ substantially from those under the No Action/No Project Alternative and Proposed Action/Project, as summarized in Table 3.5-7. There are no construction activities associated with the Reduced Hopper Dredge Use Alternative. Therefore, the potential to expose sensitive receptors to substantial pollutant concentrations would be minimal.

**NEPA Determination.** The Reduced Hopper Dredge Use Alternatives 1 and 2 potential to expose sensitive receptors to substantial pollutant concentrations would be less than significant.

**CEQA Determination.** The Reduced Hopper Dredge Use Alternatives 1 and 2 potential to expose sensitive receptors to substantial pollutant concentrations would be less than significant.

### **Impact 3.5-3: Create Objectionable Odors**

#### **No Action/No Project Alternative, Proposed Action, and Reduced Hopper Dredge Use Alternatives 1 and 2**

Dredging and the associated transport and placement activities have occurred in the waters of San Francisco Bay for decades. These past activities are not known to have had any confirmed odor complaints. Additionally, the activities are not listed as BAAQMD source types that are likely to have odor impacts.

**NEPA Determination.** The potential for the No Action Alternative Action, the Proposed Action, or the Reduced Hopper Dredge Use Alternatives to create objectionable odors affecting a substantial number of people would be less than significant.

**CEQA Determination.** The potential for the No Project Alternative, Project, or the Reduced Hopper Dredge Use Alternatives to create objectionable odors affecting a substantial number of people would be less than significant.

### **Impact 3.5-4: Result in Cumulatively Considerable Air Quality Impacts**

The cumulative air quality impacts considered are:

- A net increase of any criteria pollutant for which the project region is in nonattainment under an applicable federal or state ambient air quality standard (including releasing emissions that exceed quantitative thresholds for ozone precursors);
- Expose sensitive receptors to cumulatively substantial pollutant concentrations;
- Create cumulatively considerable objectionable odors.

In developing thresholds of significance for air pollutants, BAAQMD has established limits for pollutant emission levels, above which a project's individual emissions would be cumulatively considerable.

Based on BAAQMD guidance, if a project exceeds the identified significance thresholds, its emissions would be cumulatively considerable, resulting in significant adverse air quality impacts to the region's existing air quality conditions.

As described under Impacts 3.5-1 through 3.5-3, the emissions from dredge equipment and vessel use under all alternatives would have minimal adverse impacts on air quality. The reasonably foreseeable actions in Table 3.1-1 include activities that would produce construction and/or operational emissions that could overlap with USACE's maintenance dredging activities and contribute to cumulative air quality impacts in the study area. Under any of the alternatives, emissions from USACE's dredging, transport, and placement activities would not cause mass emission increases above the BAAQMD significance thresholds (see Table 3.5-7) from those that resulted from past operations and contributed to baseline conditions, and significance thresholds would not be exceeded. Therefore, the project alternatives' emissions would not be cumulatively considerable, and would not result in significant cumulative air quality impacts.

**NEPA Determination.** Under the project alternatives, cumulative air quality impacts would be less than significant.

**CEQA Determination.** The potential for the project alternatives to result in cumulatively considerable impacts would be less than significant.

***Impact 3.5-5: Generate Greenhouse Gas Emissions, Either Directly or Indirectly, that May Have a Significant Impact on the Environment or Conflict with an Applicable Plan, Policy, or Regulation Adopted for the Purpose of Reducing the Emissions of Greenhouse Gases***

**No Action/No Project Alternative**

Dredging and the associated transport and placement activities have occurred in the waters of San Francisco Bay for decades, and the No Action/No Project Alternative would involve continuation of USACE's current maintenance dredging program. Although dredge equipment and vessel use produce emissions, these activities would only occur for short durations. The No Action/No Project Alternative would allow for the same level of dredging and vessel traffic in the San Francisco Bay that currently occurs. There are no construction activities associated with the No Action/No Project Alternative. Thus, there are no expected increases in annual emissions due to the No Action/No Project Alternative.

**NEPA Determination.** The No Action Alternative's GHG emissions impacts would be less than significant.

**CEQA Determination.** The No Project Alternative's GHG emissions impacts would be less than significant.

**Proposed Action/Project**

Implementation of the Proposed Action/Project would be very similar to the No Action/No Project Alternative; it would involve use of the same type of dredge equipment for each channel, the same volume of dredged material, and the same dredging frequency and durations. However, the use of alternative placement sites could affect the distances traveled by vessels, and therefore emissions amounts.

The use of these sites is not expected to result in a substantial net change in air emissions because some of the sites are closer to the areas dredged, while others are further away. Generally, USACE would minimize distances traveled in an effort to minimize operational costs; therefore, any increases in

emissions would be expected to be minimal. There are no construction activities associated with the Proposed Action/Project.

**NEPA Determination.** The Proposed Action's GHG emissions impacts would be less than significant.

**CEQA Determination.** The Project's GHG emissions impacts would be less than significant.

### **Reduced Hopper Dredge Use Alternatives 1 and 2**

Under Reduced Hopper Dredge Use Alternatives 1 and 2, certain channels would be dredged with a mechanical dredge instead of a hopper dredge, but the overall volume of dredging would not change, and increase of emissions from reduced hopper/increased mechanical dredge equipment is not expected to exceed the BAAQMD significance thresholds, as shown in Table 3.5-7. There are no construction activities associated with Reduced Hopper Dredge Use Alternatives 1 and 2.

**NEPA Determination.** The Reduced Hopper Dredge Use Alternatives 1 and 2 GHG emissions impacts would be less than significant.

**CEQA Determination.** The Reduced Hopper Dredge Use Alternatives 1 and 2 GHG emissions impacts would be less than significant.

## 3.6 BIOLOGICAL RESOURCES

This section describes the existing regulatory and environmental setting in the study area for biological resources. Existing species, including special-status species, and habitats, including designated critical habitat, are described. The potential impacts of the project alternatives on these resources are analyzed.

### 3.6.1 Regulatory Setting

#### Federal

##### *Endangered Species Act*

Under the Endangered Species Act (ESA) (16 U.S.C. §§ 1531-1544), all federal agencies shall, in consultation with the Secretary of the Interior, use their authority to ensure that any action authorized, funded, or carried out by such agency is not likely to jeopardize the continued existence of any endangered or threatened species, or result in the destruction or adverse modification of habitat determined under the ESA to be critical. The ESA provides a program for conserving threatened and endangered plants and animals, and the habitats in which they are found. It is designed to protect critically imperiled species from extinction. The ESA is administered by the United States Fish and Wildlife Service (USFWS) and the National Marine Fisheries Service (NMFS). In general, NMFS is responsible for protection of ESA-listed marine species and anadromous fishes, while other species are under USFWS jurisdiction.

The ESA provides protection for federally listed special-status species, and requires conservation of the critical habitat for those species. An “endangered” species is a species in danger of extinction throughout all or a significant portion of its range. A “threatened” species is one that is likely to become “endangered” in the foreseeable future without further protection. Other federally listed special-status species include “proposed” and “candidate” species. Proposed species are those that have been officially proposed (in the Federal Register) for listing as threatened or endangered. Candidate species are those for which enough information is on file to propose listing as endangered or threatened. A “delisted” species is one whose population has reached its recovery goal and is no longer in jeopardy.

Areas of habitat considered essential to the conservation of a listed endangered or threatened species may be designated as critical habitat (referred to above), which is protected under the ESA. Critical habitat designations are the USFWS and NMFS method of identifying, for federal agencies, those physical or biological features believed to be essential to the conservation of the species (such as space, food, cover, and protected habitat), focusing on the principal biological or physical constituent elements in an area considered essential (such as roost sites, nesting grounds, seasonal wetlands, water quality, tide, and soil type). Primary constituent elements are the elements of physical or biological features that—when laid out in the appropriate quantity and spatial arrangement to provide for a species’ life-history processes—are considered to be essential to the conservation of the species. Critical habitat designations are intended as a tool to be used by the USFWS and NMFS in helping federal agencies comply with their obligations under Section 7 of the ESA.

Section 9 of the ESA prohibits the “take” of federally listed endangered or threatened species. Section 7 of this act requires federal agencies to formally consult with USFWS or NMFS for projects that may affect those species that are either listed as or proposed for listing as endangered or threatened, to ensure that the proposed action will not jeopardize the continued existence of federally listed species or destroy or adversely modify designated critical habitat. The Section 7 consultation process provides a means of authorizing the “take” of federally listed special-status species. Taking is defined by the ESA (Section 3[19]) to mean “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct.”

As part of the implementation of the Long-Term Management Strategy (LTMS), the LTMS agencies initiated ESA consultation with NMFS and USFWS for maintenance dredging and disposal projects. These consultations reduced the need for individual consultation for maintenance dredging projects through the establishment of programmatic work windows (refer to Figure 2-6 in Chapter 2). These programmatic work windows are based on presence/absence information for various sensitive species, and establish times and locations wherein dredging and disposal activities may take place without further (formal or informal) consultation.

Pursuant to the ESA, any projects proposing deviation from the work windows for federally listed species are required to undergo consultation with NMFS and/or USFWS, as appropriate. The outcome of the individual consultation would determine whether any additional dredging period for that project is appropriate; and if necessary, provide a “take authorization.”

In addition, the programmatic biological opinions issued by NMFS and USFWS provide federal endangered or threatened species “incidental take” authorization for projects operating within the environmental work window for their area. This “take authorization” protects the dredger from enforcement action in the event of accidental harm to a listed species as a result of the dredging project.

Since 2011, the United States Army Corps of Engineers (USACE) has been required to consult on impacts to delta smelt during dredging of Suisun Bay Channel and New York Slough because of documented occurrences of entrainment during monitoring of hopper dredge use. Since 2011, USACE has received non-jeopardy opinions from USFWS to maintain Suisun Bay Channel with a hopper or clamshell dredge. The USACE will continue to complete annual consultations for hopper dredging of Suisun Bay Channel and New Slough, as required by USFWS.

NMFS is revising the 1998 LTMS programmatic biological opinion; the updated biological opinion (expected 2015) will supersede the 1998 document. USACE would comply with the terms and conditions of the updated biological opinion.

### ***Magnuson-Stevens Fishery Conservation and Management Act***

The Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) establishes a management system for national marine and estuarine fishery resources. This legislation mandates the identification, conservation, and enhancement of essential fish habitat (EFH), which is defined as “waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity,” for all managed species. The Amended Magnuson-Stevens Fishery Conservation and Management Act of 1996, also known as the Sustainable Fisheries Act (Public Law 104-297), requires all federal agencies to consult with the Secretary of Commerce on proposed projects authorized, funded, or undertaken by that agency that may adversely affect EFH. The main purpose of the EFH provisions of the Sustainable Fisheries Act is to avoid loss of fisheries due to disturbance and degradation of the fisheries habitat.

In late 1997, NMFS published regulations requiring consultation for projects or programs that may adversely affect EFH. Consequently, in 2004, the LTMS agencies and NMFS began preparing a programmatic EFH consultation. The programmatic EFH agreement was completed in 2011 (USACE and USEPA, 2011). The EFH agreement includes a number of Conservation Measures that enhance the environmental protectiveness of the LTMS program. No further EFH consultation is required for USACE maintenance dredging in San Francisco Bay performed in accordance with the provisions established through the formal programmatic federal EFH consultations for the LTMS.

### ***Migratory Bird Treaty Act***

The Migratory Bird Treaty Act (16 U.S.C. §§ 703-712) established special protection for migratory birds by regulating hunting or trade in migratory birds. Furthermore, this act prohibits anyone to take, possess,

buy, sell, purchase, or barter any migratory bird listed in 50 C.F.R. pt. 10, including feathers or other parts, nests, eggs, or products, except as allowed by implementing regulations (50 C.F.R. pt. 21). Definition of “take” includes any disturbance that causes nest abandonment and/or loss of reproductive effort (e.g., killing or abandonment of eggs or young), and such activity is potentially punishable by fines and/or imprisonment. As described in Section 3.6.4, the project alternatives are not expected to result in the “take” of migratory birds.

### **Marine Mammal Protection Act**

The Marine Mammal Protection Act (16 U.S.C. §§ 1361-1421h), adopted in 1972, makes it unlawful to take or import any marine mammals and/or their products. Under Section 101(a)(5)(D) of this act, an incidental harassment permit may be issued for activities other than commercial fishing that may impact small numbers of marine mammals. An incidental harassment permit covers activities that extend for periods of not more than 1 year, and that will have a negligible impact on the impacted species. Amendments to this act in 1994 statutorily defined two levels of harassment. Level A harassment is defined as any act of pursuit, torment, or annoyance that has the potential to injure a marine mammal in the wild. Level B harassment is defined as harassment having potential to disturb marine mammals by causing disruption of behavioral patterns including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering. As described in Section 3.6.4, the project alternatives are not expected to result in impacts to marine mammals that would require an incidental harassment permit.

### **Clean Water Act Section 404**

Under Section 404 of the Clean Water Act (CWA), USACE regulates the discharge of dredged and fill materials into “waters of the United States,” which include intrastate lakes, rivers, streams (including intermittent streams), bayflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, and wetlands adjacent to any water of the United States [33 C.F.R. pt. 328]. In areas subject to tidal influence, Section 404 jurisdiction extends to the high tide line or boundary of any adjacent wetlands.

The USACE implements Section 404 of the CWA, and the U.S. Environmental Protection Agency (USEPA) has oversight authority. Section 404(b)(1) of the CWA establishes procedures for the evaluation of permits for discharge of dredged or fill material into waters of the United States. The 1980 USEPA Guidelines (40 C.F.R. pt. 230) were promulgated specifically pursuant to Section 404(b)(1) of the CWA. The Section 404(b)(1) Guidelines govern, in part, the issuance of permits by USACE. The USACE’s 1986 Regulation 33 C.F.R. § 320.4(a)(1) states, “[F]or activities involving 404 discharges, a permit will be denied if the discharge that would be authorized by such permit would not comply with [USEPA’s] 404(b)(1) Guidelines.” In situations where USACE is proposing work that involves discharge of dredged or fill material into waters of the United States, USACE must comply with the requirements of the Section 404(b)(1) Guidelines, although it does not issue itself permits.

Subpart B of the Section 404(b)(1) Guidelines (40 C.F.R. § 230.10) establishes the Alternatives Analysis requirements that must be met. In particular, 40 C.F.R. § 230.10(a) states in relevant part that “[N]o discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences.”

### **Clean Water Act Section 401**

Under Section 401 of the CWA, water quality certification (WQC) is required for any activity which requires a federal permit or license that may result in discharge into navigable waters. To receive certification under Section 401, an application must demonstrate that activities or discharges into waters are consistent with state effluent limitations (CWA Section 301), water quality effluent limitations (CWA

Section 302), water quality standards and implementation plans (CWA Section 303), national standards of performance (CWA Section 306), toxic and pretreatment effluent standards (CWA Section 307), and “any other appropriate requirements of State law set forth in such certification” (CWA Section 401), including protection of the beneficial use of state waters for uses such as special status species habitat and fish migration. In California, the authority to grant WQCs is delegated to the State Water Resources Control Board, and in the San Francisco Bay Area, applications for certification under CWA Section 401 are processed by the San Francisco Bay Regional Water Quality Control Board (Regional Water Board). The CWA and USACE regulations (33 C.F.R. § 336.1[a][1]) require USACE to seek a state WQC for discharges of dredged or fill material into waters of the United States.

The Regional Water Board reviews a proposed project before granting or denying certification. Pursuant to 33 C.F.R. § 337.8(a)(4), action is required by the USACE Division Engineer or Chief of Engineers when “...the state denies or unreasonably delays a WQC or issues the certification with conditions or controls not related to maintenance or enforcement of state water quality standards or significantly exceeding the federal standard.” Based on a report prepared by the District, the Chief of Engineers would make a determination as to whether to defer the dredging and seek Congressional appropriations for the added expense. Alternatively, the issue could be referred to the Secretary of the Army to determine whether it is appropriate to maintain navigation, as provided by sections 511(a) and 404(t) of the CWA.

#### ***Executive Order 11990: Protection of Wetlands***

This order (42 Federal Register [FR] 26961, May 25, 1977) requires federal agencies to minimize destruction of wetlands when managing lands, when administering federal programs, or when undertaking construction. Agencies are also required to consider the effects of federal actions on the health and quality of wetlands. As described in Section 3.6.4, the project alternatives are not expected to result in adverse impacts on wetlands.

#### ***Executive Order 13112: Invasive Species***

The purpose of this order is to prevent the introduction of invasive species, and to provide control for the spread of invasive species that have already been introduced. This order states that the federal government “shall, to the extent practicable and permitted by law, not authorize, fund, or carry out actions that it believes are likely to cause or promote the introduction or spread of invasive species in the United States or elsewhere unless, pursuant to guidelines that it has prescribed, the agency has determined and made public its determination that the benefits of such actions clearly outweigh the potential harm caused by invasive species; and that all feasible and prudent measures to minimize risk of harm will be taken in conjunction with the actions.” As described in Section 3.6.4, the project alternatives are not expected to cause the introduction or substantial spread of invasive nonnative plants or wildlife.

### **State**

#### ***California Endangered Species Act***

Similar to the federal ESA, the California Endangered Species Act (CESA) (California Fish and Game Code 2050-2116), along with the Native Plant Protection Act, authorizes the California Department of Fish and Wildlife (CDFW) to designate, protect, and regulate the taking of special-status species in the state of California. CESA defines “endangered” species as those whose continued existence in California is jeopardized. State-listed “threatened” species are those not currently threatened with extinction, but which may become endangered if their environments change or deteriorate. Any proposed projects that may adversely impact state-listed threatened or endangered species must formally consult with CDFW as a trustee agency.

Section 2080 of the California Fish and Game Code prohibits the taking of state-listed plants and animals. The CDFW also designates “fully protected” or “protected” species as those that may not be taken or possessed. Species designated as fully protected or protected may or may not be listed as endangered or threatened.

In addition to state-listed special-status species, CDFW also maintains a list of “Species of Special Concern,” most of which are species whose breeding populations in California may face extirpation. To avoid the future need to list these species as endangered or threatened, CDFW recommends consideration of these species, which do not as yet have any legal status, during analysis of the impacts of proposed projects.

The programmatic biological opinions issued by NMFS and USFWS for the LTMS Program do not address incidental take of state-listed species. There has been no clear and explicit waiver of federal sovereignty with respect to CESA. Accordingly, as a federal agency, USACE is not required to seek incidental take authorization or other authorization under CESA. In issuing a WQC, however, the Regional Water Board must comply with CESA.

### **3.6.2 Environmental Setting**

For the purpose of this analysis, the project’s study area in San Francisco Bay encompasses the shoreline and in-water areas in the following 11 counties: Marin, Sonoma, Napa, Solano, Sacramento, San Joaquin, Contra Costa, Alameda, Santa Clara, San Mateo, and San Francisco. The geographic scope of the study area includes the estuarine waters of the San Francisco Bay region (including the tidally influenced portion of tributaries of San Francisco Bay), portions of the Sacramento-San Joaquin River Delta (Delta) west of Sherman Island, and the western portion of the Sacramento River Deep Water Ship Channel and Stockton Deep Water Ship Channel. Outside of the Golden Gate, the study area includes the San Francisco Deep Ocean Disposal Site (SF-DODS), the San Francisco Main Ship Channel (MSC), San Francisco Bar Channel Disposal Site (SF-8), and the nearshore zone off Ocean Beach, as well as the waters that are used by vessels en route to these sites.

The following sections describe habitat types, fauna, and special-status species for both the San Francisco Bay Estuary and the offshore portions of the study area.

#### **Habitat Types**

##### ***San Francisco Bay Estuary***

Estuarine habitats around San Francisco Bay include the tidally influenced fringe of San Francisco Bay, such as mud flats, rocky shores, tidal marshes, and subtidal mud, sand, and cobble, as well as the open Bay itself. For the purposes of this discussion, the San Francisco Bay Estuary (the Estuary) includes the tidally influenced portions of its tributaries, such as the Petaluma and Napa rivers. The habitat types around the Estuary often blend with one another and with nearby upland habitats in transition zones called ecotones. Species found in these areas often occur in more than one habitat type.

**Mud Flats, Sand Flats, and Beaches.** Mud flats and sand flats are sparsely vegetated intertidal areas that occur from approximately mean lower low water (MLLW) to mean tide level. Beaches occur where sand flats extend above the mean tide level. In the Estuary, mud flats are far more common than sand flats or beaches. They provide banks and upland shoreline with protection from wave energy and capture suspended sediment. Mud flats, sand flats, and beaches around the Estuary provide habitat for many types of invertebrates, including diatoms (microscopic algae), polychaetes (marine bristleworms), oligochaetes (earthworms and relatives), amphipods (shrimp-like organisms), isopods (sow bugs and relatives), and crustaceans (shrimps, crabs, barnacles, etc.).

During low tide, mud flats, sand flats, and beaches provide crucial foraging and roosting areas for almost one million shorebirds that use the Estuary during the spring migration. Shorebirds frequently found on mud flats, sand flats, and beaches in the Estuary include western sandpiper (*Calidris mauri*), least sandpiper (*Calidris minutilla*), dunlin (*Calidris alpina*), long- and short-billed dowitcher (*Limnodromus griseus*, and *L. scolopaceus*, respectively), long-billed curlews (*Numenius americanus*), whimbrels (*Numenius phaeopus*), and American avocet (*Recurvirostra americana*). During high tide, mud flats, sand flats, and beaches provide foraging habitat for fish, including longfin smelt (*Spirinchus thaleichthys*), staghorn sculpin (*Leptocottus armatus*), starry flounder (*Platichthys stellatus*), and leopard shark (*Triakis semifasciata*). One of the few mammals occasionally present on mudflats, sand flats, and beaches is the Pacific harbor seal (*Phoca vitulina*).

**Rocky Intertidal and Subtidal Habitat.** The rock intertidal and subtidal habitat in the Estuary occurs around the margins of Central and San Pablo bays, and is primarily found around Yerba Buena, Angel, and Alcatraz islands, and the shoreline of the Tiburon peninsula and the Golden Gate. Rocky intertidal and subtidal habitat supports a wide diversity of wildlife, which varies with depth and the intensity of wave action and tidal currents. Invertebrates such as bryozoans, tunicates, anemones, and sponges, as well as algae, colonize these habitats in high densities. Mussels and many species of gastropods (snails and limpets) are common in these rocky habitats.

Rocky habitat is used as foraging and shelter habitat by rockfish (*Sebastes* sp.), surfperch (*Embiotocidae*), and other fishes. Pacific herring (*Clupea harengus*) spawn on rocky habitat and the algae attached to rocky substrates (SCC, 2010). Other wildlife species that use these habitats include shorebirds, brown pelican (*Pelecanus occidentalis*), double-crested cormorants (*Phalacrocorax auritus*), gulls (*Larus* sp.), and harbor seals, which often haul out on rock shores.

**Subtidal Mud, Sand, and Cobble.** The majority of the subtidal habitat in the Estuary is associated with mobile sediments, which range in size from clay (0.001 to 0.0039 millimeters [mm]) to silt (0.0039 to 0.0625 mm) to sand (0.0625 to 2 mm) to gravel (2 to 64 mm) and cobble (64 to 256 mm), and also includes deposits of shell fragments. “Mud” refers to clay and silt dominated substrate. All of these substrates can be moved and are sorted by tidal currents as they move through the estuary, as it takes more tidal current to move larger particles. Sandy subtidal habitat is generally limited to the deepwater channels of San Francisco Bay, and around the Golden Gate Bridge where current velocities are higher (SCC, 2010). Sandy subtidal habitat is generally limited to the deepwater channels of San Francisco Bay, and around the Golden Gate Bridge where current velocities are higher (SCC, 2010). Mud (including silt and clay) deposits make up the majority of the subtidal habitat in the Estuary. Shell deposits are mostly limited to a few areas in the south-central bay, and gravel and cobble deposits are found in the vicinity of Angel Island and the Golden Gate Bridge (SCC, 2010). The size, depth, and position of subtidal substrate in the Estuary determine the community of organisms present (SCC, 2010), which may include a variety of marine worms, amphipods, mollusks, crustaceans, and fish. Recreationally important species that use these habitats include halibut (*Paralichthys californicus*), white sturgeon (*Acipenser transmontanus*), striped bass (*Morone saxatilis*), and leopard shark. These habitats are also used as foraging areas for marine mammals such as harbor seal and California sea lion (*Zalophus californianus*), and fish such as green sturgeon (*Acipenser medirostris*) and bat ray (*Myliobatis californica*). Many of the invertebrate species that use subtidal mud, sand, and gravel are species that have been introduced to the Estuary (SCC, 2010).

**Tidal Marshes.** Tidal marshes are extremely productive and diverse ecological communities that provide important habitat and resources, both to organisms that live solely in the marsh and to species more commonly found in upland and aquatic areas. Tidal marshes occur at scattered locations along the margins of the South Bay, along the waterways of the delta, at the mouths of the Petaluma and Napa rivers, at the margins of San Pablo Bay, and in Suisun Marsh. These marshes can be segregated into salt, brackish, and freshwater types based on water and soil salinity. The vegetative cover in tidal marshes is

largely controlled by salinity. Saltwater tidal marshes are dominated by saltgrass (*Distichlis spicata*) and pickleweed (*Salicornia virginica*), while freshwater tidal marshes are dominated by cattails (*Typha* sp.) and tules (*Schoenoplectus acutus*).

The composition of the invertebrate community in tidal marsh habitats is primarily influenced by salinity, the frequency and duration of tidal inundation, and the type and density of emergent vegetation. Common invertebrate species in tidal marsh habitats include the ribbed horse mussel (*Geukensia demissa*); clams (including Baltic clams [*Macoma balthica*], *Tapes japonica*, *Potamocorbula amurensis*, and soft-shelled clams [*Mya arenaria*]); isopods such as (*Sphaeroma quoyana*); amphipods such as (*Corophium spinicorne* and *Grandidierella japonica*); snails (such as California hornsnailed [*Cerithidea californica*], *Assiminea californica*, and *Ovatella myosotis*); polychaete worms; and the yellow shore crab (*Hemigrapsus oregonensis*). Of these species, only Baltic clams, the yellow shore crab, and the three snail species are native (LTMS, 1998).

The sloughs and tidal channels in tidal marshes provide critical cover, forage, and nursery areas for adults and juveniles of a number of sportfish and special-status fishes. The distribution of fish communities in tidal marsh habitats is influenced by the same factors that influence the composition of invertebrate communities. Common fishes include native species such as arrow goby (*Clevelandia ios*), topsmelt (*Atherinops affinis*), staghorn sculpin, and tule perch (*Hysterothorax traskii*); and introduced species such as yellowfin goby (*Acanthogobius flavimanus*), inland silverside (*Menidia beryllina*), and mosquitofish (*Gambusia affinis*). Commercially important species that rear and forage in these habitats include native Chinook salmon (*Oncorhynchus tshawytscha*) and the introduced striped bass. Certain life stages of special-status species that use tidal marshes include winter-run Chinook salmon, steelhead (*Oncorhynchus mykiss*), delta smelt (*Hypomesus transpacificus*), longfin smelt, Sacramento splittail (*Pogonichthys macrolepidotus*), and green sturgeon.

Tidal marshes also provide a variety of resources for birds and other terrestrial wildlife, including resting, nesting, escape cover, and—most importantly—foraging habitat. A diversity of wildlife, including reptile, bird, and mammal species use tidal marshes. In addition to other habitat types, tidal marshes in the study area are very important for migratory birds, providing foraging habitat and roosting sites. Special-status birds and mammals that use tidal marshes include Ridgway's rail (*Rallus longirostris obsoletus*), black rail (*Laterallus jamaicensis*), and salt marsh harvest mouse (*Reithrodontomys raviventris*).

**Open Bay.** The Goals Report (Goals Project, 1999) subdivides the open bay habitats into two habitat subunits: deep bay and shallow bay. Deep bay habitat is defined as those portions of San Francisco Bay deeper than 18 feet below MLLW, including the deepest portions of San Francisco Bay and the largest tidally influenced channels. Shallow bay, which includes the vast majority of San Francisco Bay, is defined as that portion of San Francisco Bay between 18 feet below MLLW and MLLW.

Species that use the deep bay habitat include several species of free-swimming invertebrates such as California Bay shrimp (*Crangon franciscorum*), and fishes such as brown rockfish (*Sebastes auriculatus*), halibut, and sturgeon (*Asipenser* sp.), delta smelt, and longfin smelt. This habitat provides important roosting and “loafing” habitat for waterbirds, especially in areas protected from intense wind fetch or wave action. Waterbirds, such as surf scoter (*Melanitta perspicillata*), scaups (*Aythya* spp.), brown pelican, and terns (*Sterna* spp.), and marine mammals, such as Pacific harbor seal and California sea lion, can be found using this habitat type. Anadromous fish, such as Chinook salmon and steelhead, use the deep bay habitat as a migratory pathway to and from upstream spawning areas.

The shallow bay habitat is a feeding area for Pacific herring, northern anchovy (*Engraulis mordax*), bat ray, and jacksmelt (*Atherinopsis californiensis*), as well as at least 40 other species of fish, crabs, and shrimp. Pacific herring spawn on hard substrates and eelgrass (*Zostera marina*) along the shallow margins of the Central Bay. Shallow bay habitat is also a nursery area for juvenile halibut and sanddabs

(*Citharichthys stigmaeus*), shiner perch (*Cymatogaster aggregata*), herring, and other fishes. Anadromous fish use the shallow bay area as migratory pathways to and from upstream spawning areas. This habitat is in the depth range of many diving birds, and therefore provides important avian foraging habitat. Marine mammals such as Pacific harbor seals also forage in this habitat type. Eelgrass, San Francisco Bay's only rooted seagrass, is present in some areas of this habitat type. Eelgrass is particularly important to many species of fish such as Pacific herring, which deposit eggs on the blades of this plant; and to the endangered least tern (*Sterna antillarum browni*), which can forage on small fishes associated with the eelgrass. It is also considered an EFH habitat area of particular concern.

### **Ocean Environment**

The MSC is west of Golden Gate in deep subtidal waters (greater than 50 feet MLLW) of the Pacific Ocean. The MSC comprises subtidal habitats of the open coastal waters off the San Francisco coast. The Ocean Beach nearshore placement site (SF-17) and SF-8 also consist of subtidal habitats of the Pacific Ocean, with depths ranging from 20 to 50 feet MLLW. The habitat of the beach nourishment site, along beaches of Ocean Beach, consists of both terrestrial and aquatic environments (i.e., sandy beach and cliff, as well as intertidal habitat). The subtidal habitat of the MSC, SF-17, and SF-8, as well as the intertidal and beach habitat of Ocean Beach support communities of benthic (bottom-dwelling) invertebrates, plankton (drifting organisms in the water column), fish, birds, and marine mammals.

The SF-DODS is in the open ocean on the lower continental slope, approximately 55 miles (48 nautical miles) west of San Francisco; approximately 6 nautical miles west of the outer boundary of the Gulf of Farallones National Marine Sanctuary; and approximately 25 nautical miles west of the Farallon Islands. Water depth at the site ranges between approximately 2,500 meters and 3,000 meters (LTMS, 1998). Biological resources in the SF-DODS can be separated into three basic communities: the shallow pelagic community, the deep water pelagic community, and the continental slope benthic community. Each community contains numerous species with different life history strategies, and each community is interlinked with the others in the overall food web. The shallow pelagic community includes various sea birds that forage in the open waters of the ocean, as well as marine mammals, migratory fish, and pelagic invertebrates. The deepwater pelagic community includes fish and invertebrates such as squid that are adapted to deepwater conditions, as well as some marine mammals that dive to great depths while foraging. The continental slope benthic community is sparsely populated by fish and invertebrates that are adapted to the harsh conditions of the deep sea.

### **Fauna**

#### **Plankton**

Representing the lower levels of the food chain, plankton is important to many marine community members, including benthic organisms, fish, and mammals. As described below, there are three major groups of plankton: phytoplankton, zooplankton, and ichthyoplankton.

**San Francisco Bay.** Phytoplankton are simple, often microscopic, plants or algae suspended in the water column that represent the base of the marine food web. The dominant species found in San Francisco Bay are diatoms, dinoflagellates, and cryptophytes (Cloern and Dufford, 2005). Studies have shown that plankton growth and distribution in San Francisco Bay can be attributed to the amount of sunlight, turbidity, and influx of fresh water (Cloern et al., 1985; Alpine and Cloern, 1988; Cloern, 1999; Jassby et al., 2002; May et al., 2003; NOAA, 2007). The productivity of other organisms, including clams, worms, mussels, and zooplankton, depends on the growth of phytoplankton (SFEP, 1992). Phytoplankton, which rely on photosynthesis for energy generation, are vulnerable to light attenuation caused by turbidity plumes.

Zooplankton consist of microscopic and macroscopic animals that either free-float or feebly swim in open water. Their distribution is controlled largely by tides, current, and wind. Common zooplankton found in San Francisco Bay include species of copepods, rotifers, tintinnids, and meroplankton (larval forms of gastropods, bivalves, barnacles, polychaetes, and crustaceans such as the Dungeness crab [*Cancer magister*]) (Ambler et al., 1985; NOAA, 2007). Zooplankton also provide an ecologically important food source for many types of fish, such as anchovies, smelt, and striped bass.

Ichthyoplankton are the eggs and larval forms of marine fishes, such as Pacific herring, northern anchovy, goby (family *Gobiidae*), white sea bass (*Cynoscion nobilis*), staghorn sculpin, and diamond turbot (*Hypsopsetta guttulata*). Seasonal abundance and distribution of individual ichthyoplankton species are dependent on the reproductive cycles of the adult fish species and their circulation in San Francisco Bay.

**Ocean Environment.** During the upwelling season in March through August, phytoplankton abundance increases dramatically in the ocean in response to higher nutrient levels. Nutrient input from San Francisco Bay also leads to high primary production in the area. The phytoplankton community in the open ocean primarily comprises diatoms, silicoflagellates, coccolithophores (*Chrysophyta*), and dinoflagellates. Zooplankton are an extremely important component of the food web in the epipelagic zone. More than 1,000 species of ichthyoplankton are known to occur in the California current systems. The abundance of larval fish changes substantially on a seasonal and annual basis. However, in general, higher densities of larval fish are found in shallower water than occurs at the SF-DODS (LTMS, 1998).

### **Benthic Communities**

Benthic communities are largely composed of macro-invertebrates, such as mollusks and crustaceans. These organisms inhabit the bottom substrates of aquatic habitats, and play a vital role in maintaining sediment and water quality. They are also an important food source for bottom-feeding fish, invertebrates, and birds. Communities of benthic organisms are important indicators of environmental stress because they are particularly sensitive to pollutant exposure. This sensitivity arises from the close relationship between benthic organisms and sediments that accumulate contaminants over time, and the fact that these organisms receive prolonged exposure to contaminants because they live in the sediment and filter sediment-laden water.

**San Francisco Bay Estuary.** Three major benthic species assemblages (groups of organisms that inhabit a location or locations at a certain time or over a period of time) are present in the Estuary: fresh-brackish, estuarine, and marine assemblages. Assemblage characteristics, such as species composition and abundance, are affected by many physical factors, including salinity and sediment grain size, or by biological factors such as competition and predation (Thompson et al., 2000). In general, diversity is lowest in the delta (LTMS, 1998). In Suisun Bay and the western part of the delta, the benthos found are mostly fresh-brackish assemblages, with a transition assemblage extending into Suisun Bay. Fresh-brackish water species include oligochaetes, chironomids (midges), soft-shelled clams, so-called Asian clam species in the genus *Corbicula*, and amphipods (SFEP, 1992; Thompson et al., 2000). Farther west into San Pablo Bay, more estuarine conditions exist, and intertidal mud flats and marshes are extensive. Here, estuarine assemblages are prevalent. Common benthic species include ribbed mussels, Baltic clams, the introduced clam *Potamocorbula amurensis*, California hornsnaills, yellow shore crabs, amphipods, polychaete worms, and Bay mussels (*Mytilus* spp.). In the Central Bay marine conditions exist. Benthic species common in these areas consist of clams (including the overbite clam, *C. Amurensis* or *Corbula*), amphipods such as *Monocorophium* and *Ampelisca*, polychaete worms, and Bay mussels (SFEP, 1992). *Corbula* has a higher salinity tolerance, and is found throughout the Bay. The less saline-tolerant Asian clam, *Corbicula*, is often the most abundant, and often dominant in the eastern and fresher water areas of the Delta and Suisun Bay. In the South Bay, where there are several substrate types, diversity is even greater. Mollusks comprise the greatest biomass of larger benthic species in the Bay (LTMS, 1998).

Some benthic invertebrates also live on hard substrates, which are much less common in the Estuary compared to sedimentary habitats. Structures such as piers, breakwaters, rip rap, and other hard substrates function as habitat for colonization of benthic invertebrates. These artificial intertidal habitats are populated by algae, barnacles (*Balanus glandula* and *Chthamalus fissus*), mussels, tunicates, bryozoans, cnidarians, and crabs. Additionally, these structures can serve as habitat for invasive species such as the alga (*Undaria pinnatifida*) (California Coastal Conservancy, 2010).

Several of the more common benthic species in the Estuary today were accidentally or intentionally introduced species (SFEP, 1992). Some of these nonindigenous species serve ecological functions similar to those of the native species that they have displaced. Examples of these include the eastern oyster (*Crassostrea virginica*), the Japanese littleneck clam (*Tapes philippinarum*), and the soft-shelled clam, all of which have supported commercial or sport fisheries. However, other species, such as the introduced clam *C. amurensis*, have reduced phytoplankton populations, and have consequently impacted the zooplankton populations and organisms that depend on them. The benthos also provide an important food source for many species of fish, birds, and mammals in the marine environment.

**Ocean Environment.** In the shallower sand and mud bottom, the benthic fauna includes various assemblages of polychaete worms, crustaceans (amphipods, crabs, and ostracods), molluscs (pelecypods, gastropods, and scaphopods); echinoderms (starfish, brittle stars, heart urchins, sea cucumber, and sea pens). Other phyla that may be present include nematodes, coelenterates, echiuridans, and rhychoceols. Overall, the benthic community in the ocean portion of the study area is similar to those typically found in high-energy environments along the coast of Northern California.

Seasonal epibenthic surveys conducted in late winter and fall off Ocean Beach showed arthropods, such as crabs, dominated the intertidal and subtidal habitat, while echinoderms, mainly sand dollar (*Dendraster exentricus*), were the dominant species in the benthic surveys (USACE, 2013a). The surveys found the most characteristic infaunal species of the beach and intertidal habitat are great beach hopper (*Orchistoidea corniculata*), mole crab (*Emerita analoga*), Pismo clam (*Tivela stultorum*), razor clam (*Siliqua patula*), short-spined starfish, a nephtyid polychaete worm (*Nephtys californensis*), and various species of jellyfish (USACE, 2013a).

The benthic community in the SF-DODS is composed of invertebrates that burrow in the substrate (benthic infauna), invertebrates that live on the surface of the substrate (epifauna), and fish that are closely associated with the substrate (demersal fish). The benthic community in the SF-DODS is found in depths ranging between 2,500 meters and 3,000 meters, where environmental conditions are relatively harsh due to low oxygen, low food abundance, no light, high pressure, and low temperature. As a result, the number of species and overall abundance of organisms in this area is relatively low compared to shallower areas on the continental shelf (LTMS, 1998). Benthic infauna at SF-DODS is dominated by polychaete worms and crustaceans such as amphipods. The epibenthic community is predominately composed of sea cucumbers, brittlestars, seastars (*echinoderms*), and sea pens (*cnidarians*). Fifteen species of demersal fish have been collected in the SF-DODS region (LTMS, 1998). The most common species are rattails (*Macrouridae*), thornyheads (*Sebastolobus* sp.), finescale codling (*Antimora microlepis*), and eelpouts (*Zoarcidae*). Monitoring of stations within the SF-DODS boundary that are affected by large volumes of dredged material has shown that these areas are recolonized rapidly, and by the same taxa that are normally found in the adjacent ambient sediments (Germano and Associates, 2008).

### **Shrimp and Crabs**

**San Francisco Bay Estuary.** The Estuary is home to many species of shrimp and crab that are important for their recreational fishery and ecological values. The California bay shrimp is the most common shrimp reported by CDFW in San Francisco Bay (Baxter et al., 1999). Shrimp species are an important food source for virtually all species of fish, marine mammals, and water birds.

Although distributed widely throughout the Estuary, the various species of shrimp have differing centers of distribution. For example, *C. franciscorum* are more commonly collected in the northern reach of the Estuary (San Pablo to the west Delta) than in the Central or South bays, while *C. nigromaculata* are usually found in the Central and South bays (Baxter et al., 1999).

Crabs are both recreationally and ecologically important in the Estuary. The most common species is the Dungeness crab, which supports an important commercial fishery. Other commonly found species include the red rock crab (*C. productus*), Pacific rock crab (*C. antennarius*), and the graceful rock crab (*C. gracilis*). These species are typically abundant in the more marine waters of the Central Bay, but are also found in the South Bay and San Pablo Bay (Baxter et al., 1999).

**Ocean Environment.** SF-DODS does not support populations of commercially important crabs or shrimp, such as Dungeness crab. Deep water species of crab and shrimp are expected to be present in low numbers.

## **Fish**

**San Francisco Bay Estuary.** More than 100 species of fish inhabit the Estuary. The majority of species are native, but there are also many introduced species. Many complete all stages of life in the Estuary; a smaller portion, anadromous fish, migrate from ocean waters, through the Estuary, and into a series of freshwater streams where they spawn. As adults or young-of-the-year, they migrate back to the ocean. Most of the anadromous species spend 4 to 8 months in San Francisco Bay before entering the ocean. Four anadromous species—steelhead, Chinook salmon, striped bass, and green sturgeon—are known to occur in San Francisco Bay. Other common fish species include the Pacific sardine (*Sardinops sagax*), northern anchovy, topsmelt, jacksmelt, striped bass, white croaker (*Genyonemus lineatus*), and Pacific herring (NOAA, 2007). Some of these species spawn offshore and are carried into San Francisco Bay by currents (i.e., Pacific sardine), or spawn directly in San Francisco Bay (i.e., Pacific herring).

Pacific herring are of note, because they are an important component of the San Francisco Bay ecosystem, and support one of the few remaining urban fisheries on the Pacific Coast. Although the Pacific herring is neither a protected species under the ESA or CESA nor a managed fish species under the Magnuson-Stevens Act, as a state fishery it is regulated under Sections 8550-8559 of the California Fish and Game Code. Pacific herring spawn in San Francisco Bay, broadcasting their adhesive eggs over kelp, rocks, or other structures. In past years, peak spawning has occurred along the San Francisco shore from December to March (USFWS, 1988).

Fish species typically found in Suisun and San Pablo bays include sharks, rays, white sturgeon, halibut, longfin smelt, staghorn sculpin, starry flounder, topsmelt, arrow goby, yellowfin goby, stickleback (*Gasterosteus* sp.), mosquitofish, green sunfish (*Lepomis cyanellus*), Pacific herring, Chinook salmon, and steelhead. Typical fish species occurring in the Central Bay include Chinook salmon, striped bass, white croaker, Pacific herring, and northern anchovy (Baxter et al., 1999; SFEP, 1992). Typical fish species occurring in the South Bay include staghorn sculpin, arrow goby, yellowfin goby, stickleback, Pacific herring, jacksmelt, topsmelt, and northern anchovy (Hobbs et al., 2012).

A discussion of fish species with either federal or state protection status is provided below under Special-Status Species.

**Ocean Environment.** The ocean area off the coast at Ocean Beach provides habitat to 50 to 100 species of fish in a given period. Fish sampling conducted 3 to 4 miles offshore of Ocean Beach show species of sharks, skates, ratfish, midshipman (*Porichthys* sp.), pipefish (*Syngnathidae*), poachers, sculpins, surfperch, goby, ling cod (*Ophiodon elongates*), snailfish (*Liparis* sp.), rockfish, halibut, sole, flounder, and turbot (*Scophthalmus maximus*) (USACE, 2013a). Other surveys have found demersal fish species such as speckled sanddab (*Citharichthys stigmaeus*), redbait surfperch (*Amphistichus rhodoterus*), English

sole (*Parophrys vetulus*), shiner surfperch (*Cymatogaster aggregate*), and Pacific sanddab (*Citharichthys sordidus*) (USACE, 2013a).

Some of the planktivorous pelagic fish that may occur in the vicinity of the SF-DODS include Pacific herring, Northern anchovy, Pacific sardine, pacific mackerel (*Scomber australasicus*), market squid (*Doryteuthis opalescens*), and juvenile rockfish. Migratory pelagic species such as anchovy and sardine spawn in Southern California Bight and migrate into waters off Central and Northern California. Predatory fish moving into the area to feed on schools of planktivorous fish include tuna, mackerel, and salmon. Members of the family of deep-sea smelt (*Bathylagidae*), lanternfish (*Myctophidae*), and viperfishes (*Stomiidae*) commonly migrate into the upper surface waters at night to feed on plankton and planktivorous fish (LTMS, 1998).

## **Birds**

**San Francisco Bay Estuary.** Roughly 120 waterbird species from 16 families occur in the Estuary. Of these birds, approximately two-thirds are represented by three families: *Anatidae* (waterfowl), *Laridae* (gulls and terns), and *Scolopacidae* (sandpipers and phalaropes).

The Estuary serves as an important staging and wintering ground on the Pacific Flyway for numerous species of waterbirds, both common and uncommon. The Pacific Flyway is a bird migration corridor along the Pacific Coast that stretches as far north as northern Canada and Alaska, and as far south as the southern tip of South America (SFEP, 1992). In San Francisco Bay region, the greatest waterbird abundance and species diversity is seen in winter, as birds migrate along the flyway. Each year, nearly one million waterfowl and more than one million shorebirds pass through this area.

Some of the most common birds in the open waters of the Estuary are diving ducks, including canvasback (*Aythya valisineria*), scoters, and scaup. The Estuary supports the largest population of canvasback along the Pacific coast; 46 percent of the midwinter population in the Pacific Flyway (Goals Project, 2000). Additionally, the Estuary provides crucial wintering habitat for surf scoter (Goals Project, 2000). Any of these species has the potential to occasionally be found in the project area. The project area could also be used for foraging by brown pelicans, double-crested cormorant, and Forester's tern (*Sterna forsteri*); and other fish-eating birds, such as osprey (*Pandion haliaetus*) and belted kingfisher (*Megaceryle alcyon*).

Tidal flats are a primary foraging habitat for shorebirds in the Estuary. The North Bay supports approximately 20 percent of the shorebirds in the Estuary, while the South Bay supports the majority of shorebirds because of its extensive tidal flats and salt ponds (SFEP, 1992). Western sandpipers and dunlins comprise the majority of shorebirds in the Estuary, but dowitchers, marbled godwits (*Limosa fedoa*), willets (*Tringa semipalmata*), and American avocets also occur in large numbers.

**Ocean Environment.** Waterbird species in the vicinity of Ocean Beach and the MSC include many of the species present in the open San Francisco Bay, such as brown pelican, western gulls (*Larus occidentalis*), surf scooters, and cormorants.

The Farallon Islands are the most important marine bird breeding site on the west coast of the continental United States. There are 16 species of marine birds known to breed along the Pacific coast. Twelve of these species, including the American black oystercatcher (*Haematopus bachmani*), ashy storm-petrel (*Oceanodroma homochroa*), Brandt's cormorant (*Phalacrocorax penicillatus*), Cassin's auklet (*Ptychoramphus aleuticus*), common murre (*Uria aalge*), double-crested cormorant, Leach's storm-petrel (*Oceanodroma leucorhoa*), pelagic cormorant (*Phalacrocorax pelagicus*), pigeon guillemot (*Cephus columba*), rhinoceros auklet (*Cerorhinca monocerata*), tufted puffin (*Fratercula cirrhata*), and western gull, have colonies on the Farallon Islands. The Farallon Islands serve as the nesting grounds for a significant portion (up to 85 percent) of the world populations of ashy storm-petrels, Brandt's cormorants, and western gulls, as well as 80 percent of California's nesting Cassin's auklets. In addition, large

numbers of California brown pelicans roost on the Farallon Islands regularly during summer and autumn. Endangered peregrine falcons (*Falco peregrinus*) also winter on the islands. Aquatic birds also are found in the Sanctuary's lagoon, coastal bay, and four estuaries. Breeding species include the American coot (*Fulica americana*), cinnamon teal (*Anas cyanoptera*), gadwall (*Anas strepera*), great blue heron (*Ardea herodias*), great egret (*Ardea alba*), killdeer (*Charadrius vociferus*), mallard (*Anas platyrhynchos*), pied-billed grebe (*Podilymbus podiceps*), and snowy plover (*Charadrius nivosus*). An additional 20 aquatic bird species summer in the region, and seven species occur as spring and fall migrants (LTMS, 1998). The majority of these bird species feed in the coastal and open waters of the Pacific Ocean, including SF-DODS. They forage for a variety of prey in near surface waters.

### **Marine Mammals**

**San Francisco Bay Estuary.** The most common marine mammals in the Estuary are the Pacific harbor seal, harbor porpoise (*Phocoena phocoena*), and the California sea lion. Other marine mammal species that have been seen occasionally in San Francisco Bay include the gray whale (*Eschrichtius robustus*), northern elephant seal (*Mirounga angustirostris*), Steller sea lion (*Eumetopias jubatus*), northern fur seal (*Callorhinus ursinus*), and, less frequently, the southern sea otter (*Enhydra lutris*). On rare occasions, individual humpback whales (*Megaptera novaeangliae*) have entered San Francisco Bay.

Pacific harbor seals are nonmigratory and use the Estuary year-round, where they engage in limited seasonal movements associated with foraging and breeding activities (Kopec and Harvey, 1995). Harbor seals haul out (come ashore) in groups ranging in size from a few individuals to several hundred. Habitats used as haul-out sites include tidal rocks, bayflats, sandbars, and sandy beaches (Zeiner et al., 1990). No haul-out sites are located in the federal navigation channels or placement sites.

Pacific harbor porpoises have been regularly sighted in San Francisco Bay in recent years, indicating that the species has likely recolonized the area after a long absence. Studies are currently underway to determine the size and status of this population. The majority of the sightings have occurred near the Golden Gate, with some sightings occurring in the vicinity of Angel Island and Alcatraz (Keener, 2011). Harbor porpoises feed on fishes such as herring, sardines, and whiting, and on squid.

California sea lions breed in Southern California and along the Channel Islands. After the breeding season, males migrate up the Pacific Coast and enter the Estuary. In San Francisco Bay, sea lions are known to haul out at Pier 39 in the Fisherman's Wharf area. During anchovy and herring runs, approximately 400 to 500 sea lions (mostly immature males) feed almost exclusively in the North and Central bays (USFWS, 1992).

**Offshore Ocean Environment.** Species of marine mammals such as Pacific harbor seals, northern elephant seals, California sea lions, Pacific white-sided dolphins (*Lagenorhynchus obliquidens*), and harbor porpoise are present offshore Ocean Beach and in the vicinity of the MSC. Blue whales (*Balaenoptera musculus*), humpback whales, and gray whales have been observed offshore Ocean Beach in their migration route through the Gulf of the Farallones.

Seventeen species of cetaceans (whales, dolphins, and porpoises) are frequently observed near the SF-DODS in the Gulf of the Farallones. Of these, Dall's porpoise (*Phocoenoides dalli*), harbor porpoise, and Pacific white-sided dolphin are considered common resident species. In general, the highest densities of cetaceans occur in the continental slope waters at depths between 200 meters and 2,000 meters, whereas the depth at the SF-DODS ranges from 2,500 meters to 3,000 meters. The highest densities of cetaceans in the vicinity of SF-DODS occur from March through May. This time period corresponds to the period of upwelling in the overall region when high phytoplankton and zooplankton production attracts many fish (LTMS, 1998).

## Sea Turtles

Sea turtles are pelagic species but may forage in coastal waters. The Loggerhead turtle (*Carretta caretta*) and green sea turtle (*Chelonia mydas*) have the potential to occur in the study area; however, they are generally found in warmer waters. The leatherback turtle (*Dermochelys coriacea*) has the potential to occur near the Gulf of Farallones; though its occurrence is typically in deep waters (greater than 55 feet MLLW). The nesting of these species occurs in temperate waters; therefore, juveniles and eggs would not occur in the study area. Adult leatherback sea turtles occurrence in the study area is rare.

## Aquatic Plants

**San Francisco Bay Estuary.** Substrate in much of San Francisco Bay consists of soft mud, making it difficult for many macroalgal species to colonize. Some types can initially attach to a hard substrate such as a small rock or piece of shell, and, as they become larger, move with the small attachment (Josselyn and West, 1985). Common plant species of the Estuary include the green algae *Enteromorpha clathrata*, *E. intestinalis*, *U. lactuca*, and *Cladophora sericea*, and the aquatic plant eelgrass.

Eelgrass is a native marine vascular plant indigenous to the soft-bottom bays and estuaries of the Northern Hemisphere. The species is found from middle Baja California and the Sea of Cortez to northern Alaska along the west coast of North America and is common in healthy shallow bays and estuaries. Eelgrass serves as a food source for a number of invertebrates, fish, and some migratory birds. It also provides habitat for many commercially and recreationally important finfish and shellfish species. Pacific herring regularly spawn on eelgrass leaves, and juvenile salmonid and smelt often spend extensive amounts of time in eelgrass habitats prior to heading for the open ocean (Wyllie-Echeverria and Rutten, 1989).

Distribution of eelgrass in the Estuary is limited by sediment in the water (turbidity) and the depth to which light can penetrate at levels high enough to sustain eelgrass growth. In San Francisco Bay, eelgrass is limited to depths of about 10 feet or less along the shoreline.

Eelgrass is protected under the CWA Section 404(b) (1) "Guidelines for Specification of Disposal Sites for Dredged or Fill Material," Subpart E, "Potential Impacts on Special Aquatic Sites."

Eelgrass has also been identified as EFH for various life stages of fish species managed by fisheries management plans (FMPs) under the Magnuson-Stevens Act, as established by NMFS.

Although eelgrass does exist near the Richmond Inner Harbor Channel and Oakland Inner Harbor, there is no known eelgrass in any of the channel boundaries.

The Richmond Inner Harbor channels are 38 feet deep and protected by a training wall. There is eelgrass adjacent to the channel along the training wall. In 2010, 2011, and 2012, USACE conducted three sets of eelgrass surveys both before and after maintenance dredging. A reduction in the density of turions (i.e., new shoots) in eelgrass along the channel margin near the training wall was detected; the survey crews, however, did not find excessive sedimentation or any other evidence that it was the dredging that had caused loss of eelgrass. Losses during winter months, known as seasonal diebacks, are, in fact, common in eelgrass meadows. Examination of surveys done over the last 15 years indicates that eelgrass has persisted in essentially the same locations and densities around Richmond Harbor (USACE, 2012c).

Pre-dredge eelgrass surveys conducted in 2009 for Oakland Harbor revealed several patches of eelgrass along the channel of the Inner Harbor within the 200-foot zone of the federal channel. The USACE did not dredge the Inner Harbor in 2009, and therefore did not conduct post-dredge surveys (USACE, 2010). Pre- and post-dredge surveys of eelgrass were conducted at Oakland Harbor in 2010 and 2011. The pre- and post-dredge surveys found an increase in eelgrass habitat area and in the density of existing beds, in comparison with several reference sites (USACE, 2012b).

**Ocean Environment.** The depth of SF-DODS (2,500 to 3,000 meters) precludes the establishment of any aquatic plants or kelp, because the benthic environment is in complete darkness.

The substrate at the MSC consists of shifting sands, which largely prohibit the establishment of aquatic plants. Cyanobacteria or blue-green algae may be rarely present where rocks or debris provide an attachment site.

### **Terrestrial Habitat and Organisms**

The upland and non-tidal environment in the study area includes beneficial reuse and other upland dredged material placement sites. This section describes the habitats and resources in these upland and non-tidal aquatic areas.

**San Francisco Bay Region.** Upland and non-tidal aquatic environments in the San Francisco Bay portion of the study area include managed wetlands, sand dunes at the Antioch Dunes National Wildlife Refuge, and delta levees. Like tidal marshes described earlier in this section, managed wetlands provide an important habitat for wildlife, particularly migratory birds, but receive no tidal influence from the Estuary. In the delta levees, wildlife species and population differ by location and from island to island, varying with the extent of remnant natural habitat and extent and type of past agricultural cultivation. The sand dunes at the Antioch Dunes National Wildlife Refuge provide habitat for endangered plants and insects, including the Lange's metalmark butterfly (*Apodemia mormo langei*) and Antioch Dunes Evening Primrose (*Oenothera deltoides* spp. *howellii*), and Contra Costa wallflower (*Erysimum capitatum*) (USFWS, 2013).

**Outside of the Bay.** Shoreward of SF-17 is the thin strand of Ocean Beach with steep cliffs leading to the fully urbanized City of San Francisco. The sandy beach consists of rocky or sandy shores above the intertidal zone. The sandy beaches of the Ocean Beach in the project area are immediately abutted by steep sandy cliffs or dunes. Portions of the beach are covered by rock or rubble mounds placed mainly for protection of the cliffs and the infrastructure. Because of these human and natural disturbances, the majority of the dunes are sparsely vegetated and degraded. Vegetation on the dunes mainly consists of the introduced European beach grass (*Ammophila arenaria*); however, native dune vegetation may also be found on this portion of the dunes. Despite the disturbed nature of this area, Ocean Beach provides habitat to a number of terrestrial and avian species. Terrestrial mammals in the proposed dune nourishment area of Ocean Beach are not diverse or abundant. The most common of these species include California ground squirrel (*Otospermophilus beecheyi*), western gray squirrel (*Sciurus griseus*), and house mouse (*Mus musculus*). Reptiles and amphibians such as western toad (*Anaxyrus boreas*), western fence lizard (*Sceloporus occidentalis*), gopher snake (*Pituophis catenifer*), and common garter snake (*Thamnophis sirtalis*) may also inhabit the dune area. Both the open coastal waters of the Pacific Coast and the intertidal habitat along the beach serve as foraging habitat for shorebirds and waterbirds.

An important component of biological resources in the SF-DODS and in adjacent areas are marine mammals and birds whose activities are centered around the Farallon Islands. The Farallon Islands are commonly used for nesting or resting habitat. In years when juvenile rockfish are highly abundant, most foraging activity of marine birds is concentrated around breeding and resting sites on the Farallon Islands, far from the SF-DODS. In years when juvenile rockfish are less abundant, marine birds are more widely scattered throughout the gulf. The Farallon Islands are important haul-out areas for many species of pinnipeds (sea lions and seals); these species have rarely been observed in the vicinity of the SF-DODS (LTMS, 1998).

### **Special-Status Species, Critical Habitat, and Essential Fish Habitat**

Special-status species, designated critical habitat, and EFH with the potential to occur in the areas where dredging and placement activities would occur are described below. Because of the large geographic

extent of the study area, only species that likely inhabit areas in or adjacent to the federal navigations channels or placement sites (and which therefore would be potentially impacted by the project alternatives) are discussed, rather than all special-status species that may occur in the greater San Francisco Bay area.

There are no state-listed or federally listed benthic epifauna and infauna<sup>1</sup> likely to occur in the federal navigation channels and in-water placement sites.

Special-status reptiles and amphibians (e.g., Alameda whipsnake (*Masticophis lateralis*) and California red-legged frog (*Rana draytonii*)) could inhabit certain land-based placement sites. These species are not expected to be impacted by placement activities because dredged materials would be placed in a sterile area scraped clean of all growth and possible habitat. In accordance with their permits for receiving dredged materials, site operators are responsible for coordinating protected species issues with resources agencies, and managing the placement of dredged materials at the placement sites in accordance with conditions of their permits and other regulatory approval. For these reasons, these species are not further discussed in this section.

As described in earlier sections, marine mammals may occasionally be found in the vicinity of project dredging and placement areas. Marine mammals are frequently exposed to vessel traffic, are highly mobile, and can easily avoid dredging and placement activities. As discussed in Section 3.6.4, no impact is expected to these species; therefore, profiles for federally listed and state-listed marine mammals are not presented in this section. The impact analysis in Section 3.6.4 addresses marine mammals in general terms as a group (i.e., not on an individual species-specific basis).

## **Fish**

**Central California Coast Steelhead Distinct Population Segment (DPS) and Central Valley Steelhead DPS.** Central California Coast steelhead was federally listed as threatened on August 18, 1997, and is a CDFW species of concern. The Central Valley steelhead was initially listed as threatened under the ESA by National Oceanic and Atmospheric Administration (NOAA) Fisheries on March 19, 1998 (63 Fed. Reg. 13,347); this listing was reaffirmed on January 5, 2006 (71 Fed. Reg. 834).

Steelhead historically ranged throughout the northern Pacific Ocean, from Baja California to Kamchatka Peninsula. Currently, their range extends from Malibu Creek in southern California to Kamchatka Peninsula (Busby et al., 1996). San Francisco Bay and its tributary streams support migrating steelhead populations. *O. mykiss* can be either anadromous or can complete their entire life cycle in fresh water. Those fish that remain in fresh water are referred to as rainbow trout. Steelhead, the anadromous form of *O. mykiss*, can spend several years in fresh water prior to smoltification, and can spawn more than once before dying, unlike most other salmonids (Busby et al., 1996). Adult steelhead typically migrate from the ocean to fresh water between December and April, peaking in January and February (Fukushima and Lesh, 1998). Juvenile steelhead migrate as smolts to the ocean from January through May, with peak migration occurring in April and May (Fukushima and Lesh, 1998). Central California Coast Steelhead DPS spawns in tributaries of San Francisco Bay, including the watersheds of the Petaluma and Napa rivers, and several tributaries of the South Bay. Central Valley steelhead DPS spawn in the Sacramento and San Joaquin watersheds.

**Sacramento Winter-Run, Central Valley Spring-Run, and Central Valley Fall/Late-Fall-Run Chinook Salmon Evolutionarily Significant Units (ESUs).** Three Chinook salmon ESUs migrate through San Francisco Bay: Sacramento River winter-run, Central Valley spring-run, and Central Valley fall/late-fall-run. The Sacramento River winter-run Chinook salmon was initially listed as endangered under the ESA on January 4, 1994 (59 Fed. Reg. 440); this listing was reaffirmed on June 28, 2005

---

<sup>1</sup> Epifauna live attached on a surface and infauna live in the substrate.

(70 Fed. Reg. 37,160). The CDFW listed the Sacramento River winter-run Chinook salmon as endangered under CESA on September 22. The Central Valley spring-run Chinook salmon ESU was initially listed as threatened under the ESA by NOAA Fisheries on September 16, 1999 (64 Fed. Reg. 50,394) and re-listed as threatened on June 28, 2005 (70 Fed. Reg. 37,160). The CDFW designated the Central Valley spring-run Chinook salmon as threatened under CESA on February 5, 1999. The fall/late-fall-run is a state-listed and federally listed species of special concern.

The species historically ranged from the Ventura River in California to Point Hope, Alaska, on the eastern edge of the Pacific; and in the western portion of the Pacific Ocean from Hokkaido, Japan, to the Anadyr River in Russia (Healey, 1991). Factors used in determining ESUs include spatial, temporal, and genetic isolation, maturation rates, and other life history traits. Chinook salmon have been categorized into 17 ESUs. Each ESU is considered a distinct race and has been given its own management status.

Both winter-run and spring-run Chinook salmon tend to enter freshwater as immature fish, migrate far upriver, and delay spawning for weeks or months. For comparison, fall-run Chinook salmon enter fresh water at an advanced stage of maturity, move rapidly to their spawning areas on the main stem or lower tributaries of rivers, and spawn within a few days or weeks of freshwater entry (Healey, 1991).

The winter-run enter San Francisco Bay from November through June and spawn in the spring and summer, primarily in the Sacramento River. The fall/late-fall-run spawns in the Sacramento and San Joaquin River basins (Myers et al., 1998). Central Valley spring-run Chinook salmon spawn in the Sacramento River Basin. All three runs are most commonly found migrating through the northern and central portions of San Francisco Bay (CDFG, 1987).

**Central California Coast Coho Salmon ESU.** Central California Coast coho salmon (*Oncorhynchus kisutch*) are listed as endangered under the ESA and endangered under the CESA. This species ranges from Baja California, Mexico, north to Alaska, and southwest to Japan (McGinnis, 1984). This species exhibits a simple 3-year anadromous life cycle (Federal Register, 1999), rearing in fresh water for up to 15 months before migrating to the ocean. Coho salmon typically spend two growing seasons in the ocean before returning to their natal streams to spawn (Federal Register, 1996). The Central California Coast coho salmon ESU occurs from Punta Gorda in Northern California south to, and including, the San Lorenzo River in central California (Weitkamp et al., 1995). Coho generally return to their natal streams between November and December. This species has been extirpated from tributaries of San Francisco Bay; therefore, coho are rare in San Francisco Bay.

**North American Green Sturgeon Southern DPS.** On April 7, 2006, the Southern DPS of the North American green sturgeon was listed as threatened under the ESA by NOAA Fisheries (71 Fed. Reg. 17,757). Green sturgeon is also considered a species of special concern by CDFW. Green sturgeon are not abundant along the Pacific Coast, but are known to exist in the Estuary (Pycha, 1956; Skinner, 1962; Moyle, 2002). Green sturgeon are anadromous fish that spend most of their lives in estuarine or marine waters, and return to natal rivers to spawn. Adult southern DPS green sturgeon spawn in the reaches of the Sacramento River watershed with swift currents and large cobble. Adult green sturgeon enter San Francisco Bay between late February and early May, as they migrate to spawning grounds in the Sacramento River (Heublein et al., 2009). Post-spawning adults may be present in San Francisco Bay Estuary during the spring and early summer for months prior to migrating to the ocean. Green sturgeon larvae begin feeding approximately 10 to 15 days after hatching, and approximately 35 days later metamorphose into juveniles. After hatching, young-of-the-year (i.e., first-year juvenile) green sturgeon move into the Delta and Estuary where they may remain for 2 to 3 years before migrating to the ocean (Allen and Cech, Jr., 2007; Kelly et al., 2007). Sub-adult and nonspawning adult green sturgeon use both ocean and estuarine environments for rearing, foraging, and feeding on benthic invertebrates, crustaceans, and fish (Moyle, 2002).

**Longfin Smelt.** Longfin smelt are listed as threatened under the CESA, and a candidate species under the ESA. The longfin smelt is a relatively small plantivorous fish in the family Osmeridae, with adults measuring 3.5 to 5.9 inches long. It is adapted to a wide range of salinities, and travels from fresh to marine waters over its life cycle (i.e., anadromous). The geographic range of the species extends from Alaska to California, with longfin smelt in the Estuary representing the southernmost spawning population in the species range (Robinson and Greenfield, 2011).

Longfin smelt usually live for 2 years, spawn, and then die, although some individuals may spawn as 1- or 3-year-old fish before dying (Moyle, 2002). In the Bay-Delta, longfin smelt are believed to spawn primarily in freshwater in the lower reaches of the Sacramento and San Joaquin rivers (USFWS, 2012b). Longfin smelt in the Bay-Delta may spawn as early as November and as late as June, although spawning typically occurs from January to April (USFWS, 2012b).

Larval longfin smelt less than 12 mm (0.5 inch) in length are buoyant because they have not yet developed an air bladder; as a result, they occupy the upper one-third of the water column (USFWS, 2012b). Longfin smelt develop an air bladder at approximately 12 to 15 mm (0.5 to 0.6 inch) in length, and are able to migrate vertically in the water column. At this time, they shift habitat and begin living in the bottom two-thirds of the water column (CDFG, 2009a).

Water quality must support longfin smelt growth, maturity, and successful reproduction. Water quality in the Sacramento-San Joaquin Delta and Suisun Bay is most critical for the San Francisco Estuary population, because those are longfin smelt incubation and early nursery areas. Longfin smelt larvae and small juveniles are rarely found in water warmer than 22 degrees Celsius (°C). Competent-swimming young juveniles disperse toward more-saline and deeper-water habitats. Mature longfin smelt require cool-to-cold (less than 16°C) freshwater habitats for spawning (CDFG, 2009b).

In the Bay-Delta, most young-of-the-year longfin smelt are in Suisun Bay and Marsh, although surveys conducted by the City of San Francisco collected some young-of-the-year longfin in coastal waters (USFWS, 2012b). Because of their anadromous life cycle, the distribution and abundance of the species in the Estuary varies seasonally. During the winter and spring months (December through May), larval longfin smelt are concentrated in Suisun and San Pablo bays, but are present in the Central and South bays in lower densities. Second-year juveniles and adults are present throughout the Estuary at all times of year, but the majority is concentrated in the Suisun, San Pablo, and Central bays, as well as nearshore waters outside of the Golden Gate during the summer months (June through August) (Robinson and Greenfield, 2011). In the autumn months (September through November), sexually mature adults head up into the Delta to spawn (Robinson and Greenfield, 2011). As a result, the densities of longfin smelt in the Estuary are lowest in the autumn, when spawning adults have moved upstream and before larval smelt have moved down into the Estuary.

The longfin smelt has experienced significant declines in abundance in the Estuary and throughout California in the past two decades (CDFG, 2009a). Population estimates for this species are generally measured in terms of an abundance index as measured by yearly fish sampling studies (e.g., CDFW Bay Study Midwater and Otter Trawl surveys). Actual population size for this species naturally fluctuates widely from year to year, with freshwater outflow through the delta being an important factor in abundance (USFWS, 2012b). Determining the numeric size of the population is an inexact process, but the population been estimated to be around 3 million adults on average in San Francisco Bay (ERDC, 2013). Based on data from 1975 through 2004 from the fall midwater trawl survey, the abundance of juvenile longfin smelt declined by 90 percent during that time period (USFWS, 2012b). In addition to other factors, the introduction of the overbite clam (*C. amurensis*) in 1987 is considered to have negatively influenced abundance of the species (USFWS, 2012b). The most recent abundance index (for the 2012 sampling year) found the abundance index of longfin smelt to be at a near-record low (CDFW, 2014a). Water export facilities in the delta may also be partially responsible for decline of this species. These facilities entrain 5,000 to 150,000 longfin smelt when delta outflow is low (approximately 1 out of

3 years), but do not entrain many longfin smelt on years with high delta outflow (Rosenfield, 2010). The majority of the entrained longfin smelt are young-of-the-year, but some of the entrained fish are adults, which reduces not only fecundity but survivorship of all age classes.

On March 4, 2009, longfin smelt was listed as threatened under the CESA (CESA; Fish and Game Code §§ 2050 et seq.). Under the CESA listing, the species is protected throughout its range in California. In response to the state listing of this species, CDFW has stated that longfin smelt “take” assessments must be conducted for dredging projects in San Francisco Bay.

Previously the USFWS declined to list the Estuary population of the longfin smelt, citing a lack of evidence demonstrating the population’s genetic distinction from other populations within the species range (USFWS, 2012b). In November 2009, a suit was filed by the Center for Biological Diversity, The Bay Institute, and the Natural Resources Defense Council to challenge the federal decision not to list the longfin smelt (Robinson and Greenfield, 2011).

In February 2011, USFWS agreed to conduct a range-wide 12-month review of the longfin smelt status, to determine if the population met the criteria of a DPS under the ESA, and if listing of the population is warranted under the ESA.

On April 2, 2012, the USFWS released the 12-month review of longfin smelt, determining that the San Francisco Bay-Delta Population meets the requirements of a DPS. The USFWS found that the limited swimming capabilities of the longfin smelt, existing ocean current patterns, and the great distances between the Bay-Delta and other known breeding populations, make it unlikely that regular interchange occurs between the Bay-Delta and other longfin smelt breeding populations (USFWS, 2012b).

Additionally, the USFWS determined that the population meets the criterion of significance because it resides in a unique environment and the loss of the population would result in a significant gap in the range of the species. The temperature and geography associated with the San Francisco Bay-Delta are unique to estuaries where the longfin smelt resides, and the loss of the San Francisco Bay-Delta longfin smelt would result in a loss of the southernmost population of the species (USFWS, 2012b).

In the 12-month review findings, the USFWS concluded that the listing of the longfin smelt as a threatened species is warranted, but is currently precluded by other higher priority listing actions. As a result, the longfin smelt is currently a candidate species (USFWS, 2012b).

**Delta Smelt.** The planktivorous delta smelt occurs only in the upper portion of the San Francisco Bay Estuary. This species is listed as threatened under the ESA and endangered under the CESA. This euryhaline species primarily inhabits the open surface waters of the Delta and Suisun Bay (USFWS, 1995). The delta smelt population is centered in Suisun Bay, Grizzly Bay, Suisun Marsh, and the Sacramento River, but delta smelt also occur in lower numbers in San Pablo Bay and the Lower Napa River (Merz et al., 2011). The species is found in the highest concentrations near the fresh and salt water-mixing zone. Abundance is generally higher on the freshwater side of the mixing zone, in salinity of less than 2 parts per thousand. The position of the mixing zone changes seasonally and annually, depending on outflow through the Delta. In dry years, the mixing zone can be found near the confluence of the Sacramento and San Joaquin Rivers; in wet years, the mixing zone usually is in Suisun Bay, but it can occur as far downstream as San Pablo Bay. Although delta smelt tolerate a wide range of temperatures (8 to 25°C), warmer water temperatures restrict their distribution more than colder water temperatures (USFWS, 2004b).

Delta smelt have an unusual life history pattern relative to other fishes because they have a small geographic range compared with other smelt, generally live only one year, have relatively low fecundity, and have pelagic larvae (Moyle, 2002). Their short life span and low reproductive output makes them especially sensitive to inter-annual perturbation (i.e., variability).

Adult delta smelt migrate upstream in the fall to spawn in the upper Delta. Spawning takes place between February and July, peaking in early April through May. Most spawning occurs at temperatures between 12 and 18°C (USFWS, 2014). Delta smelt spawn in sloughs and shallow edge water habitat in channels in the upper Delta and in the Sacramento River above Rio Vista (Moyle, 2002). Spawning has also been recorded in Montezuma Slough and Suisun Slough in Suisun Bay, as well as in the Napa River estuary. Spawning takes place primarily at night during a full or new moon, presumably at low tide (Moyle, 2002). Females lay 1,200 to 2,600 eggs, which are broadcast over the substrate in a single spawning event. The eggs are laid near the bottom and are adhesive, using a stalk to attach to hard substrates (Moyle, 2002). The majority of delta smelt die after spawning. However, a small number of adults survive and continue to grow, reaching lengths of 90 to 120 mm. These second year adults then die after spawning the following year.

Newly hatched larvae are semi-buoyant, allowing them to remain just off the bottom until their swim bladder and fins are fully developed. Within a few weeks, the swim bladder and fins develop; the smelt are able to move up into the water column, and are then washed downstream into the freshwater/saltwater mixing zone or the area immediately above it. They remain in the general vicinity of the mixing zone, migrating vertically in the water column in response to day/night cycles along with their zooplankton prey (Moyle, 2002). The location of this mixing zone varies depending on the volume of freshwater output from the Sacramento and San Joaquin Rivers, as well as the volume of freshwater exports from the Delta.

The USFWS listed the delta smelt as threatened on March 5, 1993 (58 Fed. Reg. 12,863) and designated critical habitat for this species on December 19, 1994 (59 Fed. Reg. 65,256). On April 7, 2010, the USFWS submitted a 12-month petition finding to reclassify the delta smelt as endangered. They found that reclassification is warranted, but precluded by other higher priority listing actions (75 Fed. Reg. 17,667). The CDFW listed the delta smelt as threatened under CESA on December 9, 1993, and reclassified it as endangered on January 20, 2010. Although research interest has increased substantially since the species was listed, many aspects of delta smelt biology are still not well understood. The threats or combinations of threats that are directly responsible for the decrease in abundance and possible danger of extinction are still yet to be determined.

Information on the current status of delta smelt abundance is limited; however, the short form 5-Year Review released on March 25, 2009, stated that delta smelt abundance indices decreased since 2002 (USFWS, 2009). Like the longfin smelt, population estimates for this species are generally measured in terms of an abundance index as measured by yearly fish sampling, which varies widely from year to year. The 2009 fall midwater trawl abundance index was less than one-tenth the level of the 2003 fall midwater trawl, making the 2009 index the lowest ever recorded (USFWS, 2009). Determining the numeric size of the population is an inexact process, but the population has been estimated to be around 400,000 adults on average (Bennett, 2005). The population had not recovered greatly as of 2011, and continues to be well below recovery goal levels set by USFWS (Adib-Samii, 2011). The most recent abundance index (for the 2012 sampling year) found the abundance index to be at a near-record low (CDFW, 2014b). Water export facilities in the delta are likely contributing to the decline of this species. These facilities entrain, on average, 2,500 to 10,000 delta smelt, depending on delta outflow and time of spawning (Bennett, 2005; Kimmerer, 2008). For delta smelt, adult losses due to entrainment in water export facilities have been estimated at 4 to 50 percent of the population (Kimmerer, 2008). As a result of these entrainment rates, water export facilities have been identified as “the most conspicuous and controversial factor contributing to mortality in delta smelt” (Bennett, 2005).

**Sacramento Splittail.** The Sacramento splittail is a large, endemic minnow found in the San Joaquin Valley River system that is a California species of special concern, but is not listed as under the ESA or CESA. The species is tolerant of brackish water and can be found in Suisun Bay, San Pablo Bay, the Napa River, and the Carquinez Strait following high fresh water outflows from the Delta Region. The Sacramento splittail was formerly widespread in the Sacramento-San Joaquin river system, and occurred in various parts of San Francisco Bay as well. At present, its range includes the main channel of the

Sacramento River, the lower part of the Delta, the Napa and Petaluma Rivers, and sloughs adjoining Suisun Bay and San Pablo Bay (USFWS, 2010).

Sacramento splittail are benthic foragers that mainly feed in the daytime. Composition of gut contents has revealed that they feed almost exclusively on aquatic invertebrates. Since the introduction of the Asian overbite clam into the Estuary, Sacramento splittail have shifted their diet from prey items such as mysid shrimp to a diet increasingly focused on bi-valves, in particular the overbite clam. Sacramento splittail spawn over submerged vegetation in flooded areas, typically where the water depth is at least 3 feet. Spawning habitat includes the natural and newly restored floodplains of the Cosumnes River, managed floodplains such as the Yolo and Sutter bypasses, and disjunct segments of floodplain adjacent to the Sacramento and San Joaquin rivers and tributaries (USFWS, 2010).

In October of 2010, the USFWS issued a 12-month finding, determining that listing of the Sacramento splittail under the ESA was not warranted at the time (USFWS, 2010).

### **Mammals**

**Salt Marsh Harvest Mouse.** The salt marsh harvest mouse was listed by the federal government as endangered on October 13, 1970 (35 Fed. Reg. 16,047). The CDFG listed the salt marsh harvest mouse as endangered under CESA on June 27, 1971. In addition, the state considers the salt marsh harvest mouse a fully protected species. Two subspecies of the harvest mouse are endemic to the salt and brackish marshes bordering San Francisco Bay. The northern subspecies (*R. r. halicoetes*) inhabits saline emergent wetlands bordering Suisun and San Pablo bays, while the southern subspecies (*R. r. raviventris*) occurs in central and south San Francisco Bay.

Trapping efforts in 1997, 1998, and 1999 verified the presence of the salt marsh harvest mouse in the San Leandro Shoreline Marshlands, immediately south and southeast and adjacent to the San Leandro Dredged Materials Management Site. Although a lack of nesting and foraging habitat (in particular, a lack of pickleweed) makes the disposal site unsuitable for this species, individual harvest mice may occasionally stray into the Dredged Materials Management Site (USACE, 2009).

Extensive salt marsh harvest mouse habitat exists in Phases II through IV of the Montezuma Wetlands Restoration Project (MWRP), and surveys conducted between 2000 and 2009 have confirmed the presence of salt marsh harvest mouse habitat in these areas (Acta Environmental, 2011). Salt marsh harvest mouse may also be present at Cullinan Ranch, because this placement site is adjacent to a known source population (i.e., the Guadalcanal Village Marsh Restoration).

### **Birds**

**California Least Tern.** The California least tern (*Sterna antillium*) is a federally listed and state-listed endangered species. This species feeds primarily in shallow estuaries or lagoons where small fish are abundant. The least tern breeds in California from mid-May to August. Nesting sites for least terns exist along the runway apron at the former Naval Air Station Alameda in the city and county of Alameda. Least terns have been observed to forage primarily along the breakwaters and shallows of the southern shoreline of Naval Air Station Alameda and in Ballena Bay during May through August. Least terns are known to use a restoration site (i.e., the Middle Harbor Enhancement Area [MHEA]) in the middle harbor area of Oakland Harbor for foraging and roosting. The least tern generally migrates from the San Francisco Bay Area in August and winters south of the United States.

Documented sightings of the tern in the Suisun Bay area are relatively recent. In 2005, least terns were observed at MWRP site for the first time. Since this sighting, Montezuma Wetlands, LLC, has been working with CDFW and USFWS staff to create suitable nesting habitat for the tern outside of areas of the site that would be impacted by planned restoration activities (USACE, 2012b). It is the sole

responsibility of Montezuma Wetlands, LLC, to coordinate with CDFW and USFWS on least tern issues for MWRP. Proposed dredged material placement actions for the site must first be in compliance with the ESA, and with other federal, state, and local wildlife protection laws, before USACE can use MWRP as a beneficial use site for dredged material.

**Western Snowy Plover.** The western snowy plover (*Charadrius alexandrinus nivosus*) is listed as threatened under the ESA. Western snowy plovers are one of two recognized subspecies of snowy plovers in North America. The coastal population, about 2,000 birds, breeds along the Pacific coast from southern Washington to southern Baja California, Mexico. Plovers forage for invertebrates on wet sand areas of intertidal zones, in dry, sandy areas above high tide lines, on salt pans and along the edges of salt marshes and salt ponds. They nest on coastal sand spits, dune-packed beaches, gravel bars, beach strands with little or no vegetation, open areas around estuaries, and on beaches at river mouths and gravel bars from early March to the third week in July. Both eggs and nests are extremely difficult to see even at close range. Chicks leave the nest within hours of hatching, but cannot fly for about a month. Western snowy plovers are site-faithful nesters, returning to successful nesting sites year after year.

Habitat for the western snowy plover is found on Ocean Beach, but it is not designated critical habitat. In 2008, the National Park Service, through formal rulemaking, established a Snowy Plover Protection Area on Ocean Beach, providing a protection zone for western snowy plovers overwintering on Ocean Beach (no known nesting of snowy plover occurs on Ocean Beach) (SFPUC, 2012).

**Ridgway's Rail.** Ridgway's rail (previously known as the California Clapper rail) was listed as endangered under the ESA by the USFWS on October 13, 1970 (35 Fed. Reg. 16047). Ridgway's rail is also listed as endangered under CESA by CDFW, and is considered a fully-protected species. The species formerly occurred in salt marshes along the California coast from Humboldt Bay to San Luis Obispo County, but at present it is only found in salt marshes around San Francisco, San Pablo, and Suisun bays. Ridgway's rail inhabits tidal salt marshes, especially where they include tidal channel, which are preferred foraging habitat during low tides. This species feeds mainly on invertebrates. Breeding occurs from March to August.

Ridgway's rail is a permanent resident of salt and brackish marshes around San Francisco Bay. The only remaining populations occur in San Francisco Bay. Since the mid-1800s, about 80 percent of San Francisco Bay's marshlands have been eliminated through filling, diking, or conversion to salt evaporation ponds. As a result, Ridgway's rail lost most of its former habitat, and the population declined severely. These birds also require shallow areas or mudflats for foraging, particularly channels with overhanging banks and vegetation (Goals Project, 2000). Ridgway's rails forage on crabs, mussels, clams, snails, insects, spiders, worms, and occasionally mice and dead fish. As a refuge from extreme high tides and as a supplementary foraging area, rails move to the upper marsh vegetation where it intergrades with upland vegetation. These birds have no requirement for fresh water. Ridgway's rails nest from early March through August in the tallest vegetation along tidal sloughs, particularly in California cordgrass and marsh gumplant. They are nonmigratory, although juveniles disperse during late summer and autumn.

Individual Ridgway's rails may nest near the San Leandro Marina, in the adjacent salt marsh, and wander into or along Estudillo Canal immediately north of the Dredged Materials Management Site (USACE, 2009). In addition, Ridgway's rails are known to be present within a tidal marsh near the San Rafael Creek Inner Canal Channel (USACE, 2011a). The USFWS has indicated that Ridgway's rail may be sensitive to loud noise while it is nesting if the noise intensity is unusually high. For this reason, the USFWS Biological Opinion for the LTMS program specifies that dredging shall not occur within 250 feet of potential habitat for this species from February 1 through August 31. The USFWS considers all potential habitat to actually be occupied by this species unless surveys that year document its absence.

**Bank Swallow.** The CDFG listed the bank swallow (*Riparia riparia*) as threatened under CESA on June 11, 1989. The bank swallow occurs as a breeding species in California in a hundred or so widely

distributed nesting colonies in alluvial soils along rivers, streams, lakes, and ocean coasts. There are nesting colonies in vertical banks or bluffs in friable soils, and these colonies can support dozens to thousands of nesting birds. Nesting habitat is particularly prone to erosion. Bank swallows arrive on their breeding grounds in California beginning in late March and early April, and the bulk of breeding birds arrive in late April and early May. Birds vacate their breeding grounds as soon as juveniles begin dispersing from the colonies around late June and early July. The bank swallow forages predominantly on flying or jumping insects that it captures almost exclusively on the wing (Garrison, 1998).

Bank swallows are known to breed on the sandy bluffs in the southern portion of the beach nourishment site at Ocean Beach; the Fort Funston colony of bank swallows is in this area. A survey conducted in 2010 showed the southernmost 1,000 feet of the proposed beach nourishment area coinciding with this colony (USACE, 2013a). In 2009, the City and County of San Francisco constructed a revetment to protect its infrastructure from the imminent storm damage. The 2010 survey showed the bank swallow colony residing on top half of this revetment in the sandy areas of the cliff.

### ***Invertebrates***

**Monarch Butterfly.** The monarch butterfly (*Danaus plexippus*) is not a federal or state protected species; however, overwintering grounds are considered significant and unique by the State of California, and the City of San Leandro Municipal Code prohibits interference with these butterflies during the entire time they remain in the areas of the San Leandro Marina, Tony Lema Golf Course, and Marina Golf Course, in whatever spot therein they may choose to stop. There is a monarch overwintering site at the eastern end of the Monarch Bay Golf complex, west of the San Leandro Dredged Material Management site, where they congregate in large numbers from October through January (USACE, 2009).

### ***Critical Habitat***

**Steelhead.** Critical habitat was established for the Central California Coast steelhead DPS on September 2, 2005 (70 C.F.R. pt. 52488-52626). Designated critical habitat for this species includes all portions of San Francisco Bay below the ordinary high water line. The designation includes natal spawning and rearing waters, migration corridors, and estuarine areas that serve as rearing areas. In tidally influenced waters, the lateral extent of this critical habitat is defined by the mean higher high water line (NOAA, 2005).

**Chinook Salmon.** Critical habitat for the Sacramento River winter-run Chinook salmon was designated by the NMFS (50 C.F.R. pt. 226) in 2005. The designation includes natal spawning and rearing waters, migration corridors, and estuarine areas that serve as rearing areas. Designated critical habitat for this species includes the waters of San Francisco Bay north of the San Francisco – Oakland Bay Bridge. The lateral extent of this critical habitat is defined by the mean higher high water line (NOAA, 2005).

**Delta Smelt.** Critical habitat was established for the delta smelt on January 18, 1995 (50 C.F.R. pt. 65256-65279). Designated critical habitat for this species includes all water and submerged lands below ordinary high water, and the entire water column bounded by and contained in Suisun Bay (including the contiguous Grizzly and Honker bays); the length of Goodyear, Suisun, Cutoff, First Mallard (Spring Branch), and Montezuma sloughs; and the existing contiguous waters contained in the Delta, as defined in Section 12220 of the California Water Code. The downstream limit of critical habitat for delta smelt is the Carquinez Bridge.

**Green Sturgeon.** On October 9, 2009, the NMFS issued a final designation of critical habitat for green sturgeon (74 C.F.R. pt. 52300-52351). This includes the designation of specific rivers, estuaries, and coastal areas as critical habitat for this species. Under this ruling, the entire San Francisco Bay below mean higher high water is designated as critical habitat, which includes the portion of San Francisco Bay in the project area (NMFS, 2009).

**Leatherback Turtle.** In 1979, NMFS designated critical habitat for leatherback turtles to include the coastal waters adjacent to Sandy Point, St. Croix, U.S. Virgin Islands. In January 2012, NMFS designated additional critical habitat to provide protection for endangered leatherback sea turtles along the west coast of the United States (77 FR 4170). This designation includes approximately 16,910 square miles (43,798 square kilometers) stretching along the California coast from Point Arena to Point Arguello, east of the 3,000-meter depth contour. A portion of this critical habitat lies in the ocean portion of the study area.

### **Essential Fish Habitat**

San Francisco Bay and the portions of the project area in the Pacific Ocean (including SF-DODS) are classified as EFH under the Magnuson-Stevens Act. The project area serves as habitat for species of commercially important fish and sharks that are federally managed under three FMPs: the Pacific Groundfish FMP, the Coastal Pelagic FMP, and the Pacific Coast Salmonid FMP.

The Pacific Groundfish FMP is designed to protect habitat for more than 90 species of fish, including rockfish, flatfish, groundfish, some sharks and skates, and other species that associate with the underwater substrate. This includes both rocky and soft substrates.

The Coastal Pelagic FMP is designed to protect habitat for a variety of fish species that are associated with open coastal waters. Fish managed under this plan include planktivores and their predators.

The Pacific Salmon FMP is designed to protect habitat for commercially important salmonid species, including Chinook salmon, and coho salmon.

The Estuary, including any eelgrass beds contained within, is identified as a “habitat of particular concern” under these FMPs. These habitats are of particular importance to certain life stages of species managed under the FMPs, and are more sensitive to degradation.

Although they are not a state-listed or federally listed species, native oysters (*Ostrea conchaphila*) are considered a historical keystone species for San Francisco Bay, and contribute to EFH where oyster beds occur. A century ago, native oysters were a highly visible component of San Francisco Bay ecosystems, supporting industries from cement-making to gourmet dining. Oysters require hard substrate for larval settlement, preferably other oyster shells, and this settling habit led to the formation of oyster reefs, the nooks and crannies of which support communities of fish, crab, and other invertebrates. By the early 1900s, however, overfishing, habitat degradation, and the introduction of nonnative shellfish led to the decline of native oysters. Oyster beds are not known to occur in the federal navigation channels or in-water placement sites.

### **Other Special Designated Habitat Areas**

There are two approved regional conservation plans that apply to locations of dredging and placement activities: the Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and the Bay Delta Conservation Plan (BDCP).

The Suisun Marsh Habitat Management, Preservation, and Restoration Plan (Bureau of Reclamation et al., 2011) is being implemented by the Suisun Principal Agencies, a group of agencies with primary responsibility for Suisun Marsh management. The 30-year plan is intended to balance the benefits of tidal wetland restoration with other habitat uses in Suisun Marsh by achieving certain specific changes in marsh-wide land uses affecting values such as salt marsh harvest mouse habitat, managed wetlands, public use, and upland habitat. This involves implementing a broad array of activities covering ESA and CESA compliance, managed wetland activities, restoration activities, and maintenance activities related to certain State Water Project and Central Valley Project mitigation commitments. The central component of the plan is the restoration of 7,000 acres of tidal salt marsh in Suisun Bay.

The BDCP sets out a comprehensive conservation strategy for the Delta, designed to restore and protect ecosystem health, water supply, and water quality within a stable regulatory framework. The BDCP reflects the outcome of a multiyear collaboration between public water agencies; state and federal fish and wildlife agencies; nongovernment organizations; agricultural interests; and the general public. The BDCP is intended to result in a permit decision concerning long-term regulatory authorizations under state and federal endangered species laws for the operations of the State Water Project and the Central Valley Project. The BDCP will further provide the basis for durable regulatory assurances. Specifically, the BDCP serves as a natural community conservation plan under the state's Natural Community Conservation Planning Act, and a habitat conservation plan under Section 10 of the ESA. The BDCP will support the issuance of permits from CDFW under Section 2835 of the Natural Community Conservation Planning Act, and permits from the USFWS and the NMFS pursuant to Section 10 of the ESA. The BDCP will also provide the basis for a biological assessment that supports new ESA Section 7 consultations between the U.S. Department of the Interior, Bureau of Reclamation, USFWS, and NMFS.

### 3.6.3 Methodology and Thresholds of Significance

Under the National Environmental Policy Act (NEPA), the analysis of potential impacts considered whether the project alternatives would have a substantial adverse effect on any species identified as a proposed, threatened, or endangered species under the ESA. The Council on Environmental Quality's NEPA Regulations, 40 C.F.R. § 1508.27(b)(9), generally equate whether an action significantly affects the quality of the human environment with "the degree to which the action may adversely affect an endangered or threatened species." Therefore, an alternative may result in a significant impact if it would directly or indirectly (e.g., through habitat modification) result in a substantial population decline of any proposed, threatened, or endangered species protected under the ESA. Furthermore, a project impact may be significant if it would result in the decline of a non-federally listed species such that populations would fall below self-sustaining levels.

Under the California Environmental Quality Act (CEQA), the analysis of potential impacts of the proposed project considered whether the project alternatives would have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, proposed, or listed species under, or otherwise protected by, the ESA or the CESA, or where they would otherwise meet the CEQA Guidelines' definition of "endangered or threatened" (14 California Code of Regulations 15380). In addition, Section 15065 of the CEQA Guidelines states that a project would have a significant effect if it has the potential to "substantially reduce the habitat of a fish or wildlife species," "cause a fish or wildlife population to drop below self-sustaining levels," "threaten to eliminate a plant or animal community," or "substantially reduce the number or restrict the range of an endangered, rare or threatened species."

In addition, under both NEPA and CEQA, the analysis of the potential effects of the proposed project on biological resources considered whether the project alternatives would:

- Alter or diminish critical habitat, EFH, or a special aquatic site, including eelgrass beds, mudflats, and wetlands;
- Interfere substantially with the movement of resident or migratory fish or wildlife species;
- Cause the introduction or substantial spread of invasive nonnative plants or wildlife; or
- Cause substantial or sustained impact to spawning habitat of commercially important species (e.g., Pacific herring);

Discussions are provided below for direct impacts (e.g., entrainment) and indirect impacts (e.g., turbidity and other water quality effects). These impacts are evaluated by comparing proposed project methods with impacts observed and reported in scientific literature.

Because of the nature of the proposed project, there would be no project impacts that would:

- Result in the reduction of protected wetland habitat as defined in Section 404 of the CWA, or result in alteration of desirable functions and values through direct removal, filling, hydrological interruption, or other means. Maintenance dredging of the federal channels would not result in a reduction of protected wetland habitat or alteration of desirable functions. Placement of dredged material at wetland restoration beneficial reuse sites (e.g., Cullinan Ranch, MWRP) would provide beneficial impacts by increasing wetlands in the study area, creating additional habitat for fish and wildlife, including special-status species and migratory birds, that depend on wetlands.
- Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other applicable Habitat Conservation Plan. The project alternatives only include dredging within the established federal shipping channels, and placement at permitted placement sites. Additionally, the LTMS strategy for dredged material management, which would be used under all project alternatives, includes the beneficial reuse of dredged materials for restoration and conservation projects such as those included in the above plans. Therefore, no conflicts with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other applicable Habitat Conservation Plan would occur.

Potential impacts associated with California Coastal Act and Bay Plan policies protecting biological resources are addressed in Section 3.8, Land Use.

#### **3.6.4 Impacts and Mitigation Measures**

Maintenance dredging would disturb bottom sediments, which would temporarily increase turbidity; disturb benthic habitat and associated communities of organisms living in or on the mud bottom; and generate underwater noise. This disturbance could result in the temporary loss or reduction of habitat suitable for fish foraging for sensitive species such as steelhead, Chinook salmon, green sturgeon, delta smelt, and longfin smelt, as well as fish managed under the Magnuson-Stevens Act. In addition, entrainment of fish in dredging equipment could occur. Pacific herring, a commercially important species, could also be affected if spawning had occurred in the area just before or during maintenance dredging activities. The behavior of marine mammals, such as harbor seals and sea lions, is not likely to be affected by dredging activities. Dredged material placement also would result in temporary increases in turbidity, which could result in similar effects on habitat, benthic habitat, and wildlife behavior. These effects are discussed in more detail below.

Because sediment resuspension from dredging vessel movement would be limited, the movement of vessels for transport of dredged material would not be expected to increase turbidity above ambient ranges generated by natural hydrologic processes, weather, and existing vessel traffic. Vessel traffic for transport of dredged material would be similar to that which has occurred during USACE's past maintenance dredging operations, would occur in areas with frequent vessel movement, and would be negligible considering the existing volume of vessel movement in the study area. Therefore, the transport of dredged material is not expected to impact biological resources.

##### ***Impact 3.6-1: Potential Adverse Effects of Increased Turbidity Resulting from Maintenance Dredging and Dredged Material Placement on Special-Status Species, Critical Habitat, and Commercially Valuable Marine Species***

During any type of dredging operations, the interaction of the dredge equipment with the dredged material resuspends sediment into the water column. The placement of dredged material in the aquatic environment also creates a plume of turbidity as the material travels downward. The turbidity resulting from dredging and the placement of dredged material may affect marine organisms and aquatic wildlife during various life stages by affecting respiration (clogging gills); reducing visibility and the ability to forage or avoid predators; and altering movement patterns (due to avoidance of turbid waters). Suspended sediments have

been shown to affect fish behavior, including avoidance responses, territoriality, feeding, and homing behavior. Wilber and Clarke found that suspended sediments result in cough reflexes, changes in swimming activity, and gill flaring. Suspended sediments can have other impacts, including abrasion to the body and gill clogging (Wilber and Clarke, 2001). Generally, bottom-dwelling fish species are the most tolerant of suspended solids, and filter feeders are the most sensitive. The effect of dredging on fish can vary with life stage; early life stages tend to be more sensitive than adults. For example, pelagic eggs and larvae of fishes and shellfishes depend on local hydrodynamic conditions for transport into and out of dredging activity areas, and have limited avoidance capabilities. Demersal eggs (eggs sinking to the bottom) and sessile, or nonmotile life history stages, are perceived as particularly susceptible because of their longer exposure to elevated suspended sediments or due to smothering by increased sedimentation. Motile organisms can generally avoid unsuitable conditions in the field (Clarke and Wilber, 2000).

Pacific herring, a commercially important species, could be affected if spawning occurred in the area just before or during maintenance dredging activities. Exposure of Pacific herring eggs to suspended San Francisco Bay dredged sediments at ecologically relevant concentrations of 250 or 500 milligrams per liter (mg/L) within their first 2 hours of contact with water has been documented to result in higher percentages of abnormal larvae, as well as an increase in larval mortality (Griffin et al., 2009).

It should be noted that the eggs or larval life stages of steelhead, Chinook salmon, or green sturgeon are not expected to be present in any of the federal navigation channel or placement locations. Large adult and juvenile fish (including steelhead, Chinook, and green sturgeon) as well as marine mammals would be motile enough to avoid areas of high turbidity plumes caused by dredging. The USACE Waterways Experiment Station Technical Report DS-78-5 (Effects of Dredging on Aquatic Organisms) reports that: “Most organisms tested are very resistant to the effects of sediment suspensions in the water, and aside from natural systems requiring clear water such as coral reefs and some aquatic plant beds, dredging induced turbidity is not a major ecological concern” (Hirsch et al., 1978).

Brief plumes caused by in-water placement has the potential to reduce food availability and foraging success for fish and marine mammals that might be in the vicinity of the placement sites. It is expected that these species will avoid the plumes, which are ephemeral in nature (LTMS, 1998). Species that might be affected can forage in the unaffected areas surrounding the placement site, so any temporary reduction in food supply and foraging success would be minor. No significant long-term effects to pelagic-based food resources are expected, because of the fairly rapid recovery expected in these communities and the small area affected.

Increased turbidity and activity during dredging may disturb marine mammal foraging activities by temporarily decreasing visibility or causing the relocation of mobile prey from the area affected by the sediment plume. Marine mammals would not be substantially affected by dredging operations because they forage over large areas of San Francisco Bay and the ocean, and can avoid areas of temporarily increased turbidity and dredging disturbance.

Total suspended solids levels in the Estuary vary greatly, ranging from 10 mg/L to more than 100 mg/L (SFEI, 2011). In general, higher total suspended solids result in more turbid water. Waters in the study area are naturally turbid because of the resuspension of sediments from wind, waves, and tides. Light penetration is generally limited to a few feet from the surface, which in turn limits phytoplankton productivity. Increased sediment concentrations in the upper water column can reduce sunlight penetration, and therefore reduce phytoplankton productivity. Turbid plumes from dredging that could limit productivity would be localized, and would be small in relation to surrounding areas of similar habitat, as well as short in duration. The impact of turbidity on phytoplankton productivity due to decreased light transmission would depend largely on the difference between background turbidity and increased turbidity from dredged material when dredging takes place. Increased turbidity effects from dredging are short term, minor, and greatly diminished with distance from the activity. In San Francisco Bay, turbidity plumes would be quickly diluted to near or within background particulate concentrations.

Generally, hydraulic dredging (i.e., hopper and cutterhead-pipeline dredges) reduces disturbance and resuspension of sediments at a dredging site compared to mechanical dredges. The USACE studies show that turbidity plumes at placement sites last only 20 minutes, and plume duration is even less during placement of sandy material, because their coarse sediments settle out of the water column more quickly than fine sediments (USACE 1976a; LTMS, 1998; Anchor, 2003). Increased turbidity from dredging and placement activities is expected to have a negligible effect on plankton productivity.

Although leatherback turtle designated critical habitat along the west coast of the United States also coincides with part of the ocean portion of the study area, occurrence of leatherback turtle in the study area is rare. For this reason, impacts to this species and its critical habitat are not expected.

### **No Action/No Project Alternative, Proposed Action/Proposed Project**

Under the No Action/No Project Alternative and Proposed Action/Project, the amount and effects of increased turbidity as a result of dredging and placement would be similar because the dredge equipment type, frequency of dredging, volumes dredged, and federal standard placement site would be the same. As described in Chapter 2, USACE would continue to implement standard practices intended to minimize increases in turbidity from dredging and placement activities. Dredging and placement would continue to be limited to the work windows for the LTMS program, including the work window for Pacific herring. In the past, dredging schedules have occasionally slipped for logistical or financial reasons, and dredging occurred outside of the LTMS work window for one or more species. In the event that this should occur in any year covered by this Environmental Assessment (EA)/Environmental Impact Report (EIR), USACE would initiate an additional consultation process with the appropriate agencies to obtain written authorization to work outside these windows, and implement consultation recommendations as necessary.

Dredging would result in localized and temporary increases in turbidity at both the dredge locations and placement sites. As described above, this is not expected to have substantial effects on special-status species, their critical habitat, or EFH.

**NEPA Determination.** Under the No Action Alternative and Proposed Action, impacts on special-status species, critical habitat, and commercially valuable marine species from localized and temporary increases in turbidity would be less than significant.

**CEQA Determination.** Under the No Project Alternative and Project, impacts on special-status species, critical habitat, and commercially valuable marine species from localized and temporary increases in turbidity would be less than significant.

### **Reduced Hopper Dredge Use Alternatives 1 and 2**

Impacts to marine organisms and aquatic wildlife resulting from increased turbidity during dredging would be slightly greater under Reduced Hopper Dredge Use Alternatives 1 and 2 in comparison with the No Action/No Project Alternative and Proposed Action/Project, because there would be increased use of mechanical dredges. Impacts from the placement of dredged material would be similar to those under the No Action/No Project Alternative and Proposed Action/Project. Under Reduced Hopper Dredge Use Alternative 1, Suisun Bay Channel/New York Slough and either Pinole Shoal or Richmond Outer Harbor would be dredged with clamshell-bucket equipment instead of a hopper dredge. Under Reduced Hopper Dredge Use Alternative 2, Suisun Bay Channel/New York Slough, Pinole Shoal, and Richmond Outer Harbor would all be dredged with clamshell-bucket equipment instead of a hopper dredge. Under both alternatives, San Bruno Channel in Redwood City Harbor would also be dredged with clamshell-bucket equipment instead of a hopper dredge.<sup>2</sup> Short-term increases in turbidity at Pinole Shoal, Richmond Outer Harbor, and San Bruno Channel would be higher when they are dredged with a clamshell-bucket dredge

<sup>2</sup> San Bruno Channel is dredged at intervals of 10 years or longer.

instead of a hopper dredge, because mechanical dredging generates more turbidity than hopper dredging, as described in Section 3.3, Hydrology and Water Quality, and can take up to ten times longer than hopper dredging (USACE, 2013d). Nonetheless, as described above, impacts from increased turbidity during dredging and placement would be temporary and minor. Dredging Suisun Bay Channel/New York Slough with a mechanical dredge instead of a hopper dredge would not be expected to result in a noticeable increase in turbidity, because sandy material settles out of the water column quickly (Anchor, 2003).

These alternatives would reduce hopper dredge use for maintenance dredging compared to the No Action/No Project Alternative and Proposed Action/Project, but it would not change the volume of material dredged, standard placement sites used, or standard operating procedures. As noted above under the No Action/No Project Alternative and Proposed Action/Project, in the event USACE should need to dredge outside the LTMS work windows, USACE would initiate an additional consultation process with the appropriate agencies to obtain written authorization to work outside these windows, and implement consultation recommendations as necessary.

**NEPA Determination.** Under Reduced Hopper Dredge Use Alternatives 1 and 2, turbidity increases during dredging are expected to be greater than under the No Action Alternative and Proposed Action; however, impacts on special-status species, critical habitat, and commercially valuable marine species from localized and temporary increases in turbidity would still be considered less than significant.

**CEQA Determination.** Under Reduced Hopper Dredge Use Alternatives 1 and 2, turbidity increases during dredging are expected to be greater than under the No Project Alternative and Project; however, impacts on special-status species, critical habitat, and commercially valuable marine species from localized and temporary increases in turbidity would still be considered less than significant.

### ***Impact 3.6-2: Potential Adverse Effects of Maintenance Dredging Resulting from the Disturbance of Benthic Habitat on Special-Status Species, Critical Habitat, and Commercially Valuable Marine Species***

Dredging would directly impact benthic communities through physical disruption and direct removal of benthic organisms, resulting in the potential loss of most, if not all, organisms in the dredged area. Generally, benthic habitat within the federal channels is highly disturbed because of regular maintenance dredging and the propeller wash of ship traffic. Organisms immediately adjacent to the dredged channels may be also be lost because of smothering or burial from sediments resuspended in the water column during the dredging. Similarly, organisms in or immediately adjacent to the placement sites may be also be lost because of smothering or burial from sediments during dredged material placement.

As described in Section 3.6.2, critical habitat for steelhead, Chinook salmon, delta smelt, green sturgeon, and leatherback turtle overlaps with some or all of the estuarine/marine portions of the project areas. Benthic habitat can be an important part of critical habitat for some species by providing foraging areas, especially for steelhead, Chinook salmon, and green sturgeon. Because delta smelt feed in the water column, benthic habitat provides less of a function. Similarly, leatherback turtles forage in open waters and do not rely on benthic habitat. The loss of benthic invertebrates during dredging activities may decrease the forage value of critical habitat at the dredge location. There are no state listed or federally listed benthic epifauna and infauna likely to occur in the federal navigation channels and in-water placement sites.

The proposed activities may impact two primary constituent elements<sup>3</sup> of delta smelt critical habitat: rearing habitat and adult migration. Rearing habitat includes shallow water river and tributary habitat

<sup>3</sup> A physical or biological feature essential to the conservation of a species for which its designated or proposed critical habitat is based on, such as space for individual and population growth, and for normal behavior; food, water, air, light, minerals, or other nutritional or physiological requirements; cover or shelter; sites for breeding, reproduction, rearing of offspring, germination, or seed dispersal; and habitats that are protected from disturbance or are representative of the species historic geographic and ecological distribution.

extending eastward from Carquinez Strait, including Suisun Bay, Grizzly Bay, Honker Bay, Montezuma Slough and its tributary sloughs, up the Sacramento River to its confluence with Three Mile Slough, and south along the San Joaquin River including Big Break. Protection of this habitat is most important from February through the summer. The entire action area is within the rearing habitat primary constituent element. With the exception of August, the work window (August 1 through November 30) is mostly protective of the delta smelt rearing life stage. However, rearing delta smelt may be affected by the proposed action. With respect to adult migration, adults must be provided unrestricted access to suitable spawning habitat from December through July. Spawning areas include areas of the Sacramento and San Joaquin Rivers and tributaries, Cache Slough, Montezuma Slough, and tributaries. Although spawning habitat is not found in the action area, adult delta smelt begin migrating from the action area to spawning grounds September and October. The proposed action may affect adults migrating from the action area to spawning grounds during this timeframe; however, the affected area would be limited to the immediate dredging or placement zone, and would not substantially limit the available habitat or movement of fish (see also Impact 3.6-8).

Following sediment-disturbing activities such as dredging or the placement of dredged materials, disturbed areas are usually recolonized quickly by benthic organisms (Newell et al., 1998). The species that recolonize first are usually characterized by rapid growth and reproduction rates. Marine benthic invertebrates often colonize disturbed sedimentary habitats via pelagic larvae that settle from the water column. Crustaceans, such as amphipods that are abundant in San Francisco Bay, brood young to much more advanced stages than pelagic larvae, releasing what are essentially miniature adults into the sediment, and can rapidly colonize adjacent disturbed areas. Recovery may be slower in deep water channels; therefore, there is potential for some loss of habitat and forage to organisms that use deep water channels. This potential is minimal, because the federal deep-draft navigation channels are in a constant state of disturbance by deep-draft vessels that travel through the channels at a maximum of 15 knots under their own power. At a minimum, oil tankers can be as close as 3 feet to the channel bottom, and other vessels as close as 2 feet. Annually, approximately 3,800 vessel trips occur on Oakland Harbor channels; 2,300 vessel trips occur on Richmond Harbor channels; 2,300 to 4,000 vessel trips occur on Pinole Shoal Channel; 800 vessel trips occur on Suisun Bay and New York Slough channels; and 250 vessel trips occur on Redwood City Harbor channels. Under these conditions, the benthos of these highly-used channels, which are dredged annually, is in a constant state of disruption. The potential for habitat loss in channels that are dredged less frequently would be slightly greater, but still small due to disruption of benthos from frequent vessel traffic.

Studies have indicated that even relatively large areas disturbed by dredging activities are usually recolonized by benthic invertebrates within 1 month to 1 year, with original levels of biomass and abundance developing within a few months to between 1 and 3 years (Newell et al., 1998). Following dredging, disturbed areas are recolonized, beginning with mobile and opportunistic species (Oliver et al., 1977; Lenihan and Oliver, 1995). These species, characterized by rapid growth and reproduction, may or may not be the same species that were present in the area prior to the disturbance. San Francisco Bay harbors more nonindigenous benthic invertebrate species than any other aquatic ecosystem in North America (Cohen and Carlton, 1995). The introduced species range from approximately 20 to 80 percent of all species present (Lee et al., 1999), depending on the area of San Francisco Bay; recolonization would likely include nonindigenous species already present in the area.

During in-water placement in San Francisco Bay, benthic organisms would suffer burial followed by prolonged exposure to anaerobic conditions after the dumping has ceased. This would result in mortality of most of the organisms in the burial footprint; however, this would be a short-term effect because benthic habitat is quickly recolonized. The existing benthic communities at the in-Bay disposal sites have, over the years, reached an equilibrium that adjusts to the periodic disposal of dredged material.

Similarly, placement of dredged material (i.e., sand) at SF-17, SF-8, and along beach and intertidal habitat of Ocean Beach would cause temporary disturbance to benthic organisms; however, both the nearshore and the

shore environment along the coast of Ocean Beach are dynamic and high-energy environments that experience rapid sediment flux. Organisms that inhabit sandy intertidal and subtidal habitat have adaptations for surviving in areas of high sediment flux. Although placement operations would cause burial of the less mobile benthic community, the impact of those operations will be episodic and short term. Since 1972, similar types of impacts to the benthic community and other communities have been regularly occurring at SF-8; and at the Ocean Beach Disposal Sites since 2005. Studies on impacts of beach nourishment activities on the invertebrate community have shown that recovery of the benthic community at the beach and intertidal habitat generally takes place in on the order of a few weeks to months (USACE, 2013a).

At SF-DODS, physical alterations to benthic habitat at the disposal site could result from deposition of dredged sediments whose grain size and other physical characteristics differ from the native sediments at the site. These physical changes ultimately alter the community of benthic infaunal species at the site. However, these changes would not affect any unique or limiting habitats, would only occur within the boundaries of SF-DODS, and would affect only a very small proportion of the extensive, similar habitat throughout the region (LTMS, 1998). Therefore, benthic habitat effects at SF-DODS are considered to be negligible and would be similar to those that have occurred historically. Annual monitoring by USACE has confirmed that this disposal has occurred without causing significant impacts to the ocean and the marine biology in and around SF-DODS.

### **No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

Under all alternatives, USACE would continue maintenance dredging and dredged material placement for the projects it maintains in San Francisco Bay, and the frequency of dredging, volumes dredged, and federal standard placement site would be the same. Regardless of the dredging methods used, similar amounts of benthic habitat would be disturbed by dredging and dredged material placement. The USACE would continue to implement standard practices described in Chapter 2 that are intended to minimize the impacts of dredging and placement on the marine environment. As described above, the potential effects of benthic habitat disturbance would be short term and localized.

**NEPA Determination.** Under all alternatives, impacts on special-status species, critical habitat, and commercially valuable marine species from localized and temporary disturbances of benthic habitat would be less than significant.

**CEQA Determination.** Under all alternatives, impacts on special-status species, critical habitat, and commercially valuable marine species from localized and temporary disturbances of benthic habitat would be less than significant.

### **Impact 3.6-3: Potential Adverse Effects of Underwater Noise Generated During Maintenance Dredging on Special-Status Fish and Marine Mammals**

Mechanical and hydraulic dredges produce a complex combination of repetitive sounds that may be intense enough to cause adverse effects on fish and marine mammals, though the intensity, periodicity, and spectra of emitted sounds differ among the dredge types and the substrate being dredged. Clamshell dredges have a repetitive sequence of sounds generated by the winches, bucket impact with the substrate, closing and opening the bucket, and sounds associated with dumping the dredged material into the barge. The most intense sound impacts are produced during the bucket's impact with the substrate, with peak sound pressure levels (SPL) of 124 decibels (dB) measured 150 meters from the bucket strike location (Reine et al., 2002; Dickerson et al., 2001). Underwater noise is generated by hydraulic dredging equipment, including rotating cutter heads, pumps, propellers, suction pipes, and the drag head contacting the channel bottom. Noise produced by hopper dredges fluctuates; the most intense sounds are produced during loading or unloading. While underway, continuous noise from hopper dredges operating in a variety of environments has been measured to range from 125 to 150 dB (Reine et al., 2012). A hydraulic

cutterhead dredge can produce continuous noise in the range of 150 to 170 dB when measured 10 meters from the cutterhead (California Department of Water Resources, 2013), with noise levels varying with dredge size and sediment type. This is comparable to underwater noise levels of 160 to 180 dB root mean square (RMS)<sup>4</sup> produced by small boats and ships (MALSF, 2009).

The scientific knowledge of the effects of dredge-generated noise and sound waves on fishes is limited, and varies depending on the species. Effects may include behavioral changes, neurological stress, and temporary shifts in hearing thresholds. Studies on the effects of noise on anadromous Pacific coast fishes are primarily related to pile-driving activities. The interagency Fisheries Hydraulic Working Group has established interim criteria for noise impacts from pile driving on fishes. A peak SPL of 206 dB is considered injurious to fishes. Accumulated SPLs of 187 dB for fishes that are greater than 2 grams, and 183 dB for fishes below that weight, are considered to cause temporary shifts in hearing, resulting in temporarily decreased fitness (i.e., reduced foraging success, reduced ability to detect and avoid predators). The NMFS uses 150 dB as the threshold for adverse behavioral effects.

For marine mammals, NMFS criteria define exposure to underwater noises from impulse sounds at or above 160 dB RMS and continuous sounds at or above 120 dB as constituting harassment to marine mammals. NMFS has also determined that noises with SPLs above 180 dB RMS can cause injury to cetaceans (whales, dolphins, and porpoises), and SPLs above 190 dB RMS can cause injury to pinnipeds (seals and sea lions).

Injury to fish from peak noise (e.g., rupture of swim bladder) is not expected to occur, but behavioral effects (e.g., changes in feeding behavior, fleeing, startle responses) could occur. All fish, listed or otherwise, would experience the same effects. In comparison, commercial shipping vessels can produce continuous noise in the range of 180 to 189 dB (Reine and Dickerson, 2013). Although dredging could produce underwater noise that is considered to be harassment for marine mammals, it is comparable to that produced by commercial shipping vessels, which are common in the study area. Marine mammals are highly motile and would likely avoid areas of noise and disturbance from dredging operations.

The project alternatives' potential impact on the movement or migration of fish or wildlife species is addressed under Impact 3.6-7.

### **No Action/No Project Alternative and Proposed Action/Project**

As discussed above, underwater noise produced during dredging may have temporary adverse effects on fish and marine mammals, but would not be expected to cause injury to fish and marine mammals. These effects include fleeing, the cessation of feeding, or other behavioral changes. Additionally, fish exposed to underwater noise above the NMFS sound exposure level thresholds may experience temporary hearing threshold shifts. All dredging activities would take place in the federal navigation channels, which receive regular boat traffic, and therefore have high background levels of underwater noise.

**NEPA Determination.** Under the No Action Alternative and Proposed Action, temporary adverse effects to special-status fish and marine mammals from underwater noise would be less than significant.

**CEQA Determination.** Under the No Project Alternative and Project, temporary adverse effects to special-status fish and marine mammals from underwater noise would be less than significant.

### **Reduced Hopper Dredge Use Alternatives 1 and 2**

Impacts on fish and marine mammals from underwater noise during dredging would be lower in intensity but longer in duration under Reduced Hopper Dredge Use Alternatives 1 and 2, in comparison with the

---

<sup>4</sup> Root-mean-square measures the average noise energy measured over a 35-millisecond period. Note that this is a different type of measurement than the peak sound or sound exposure level used to measure impacts to fish (NOAA, 2012).

No Action/No Project Alternative and Proposed Action/Project, because there would be increased use of mechanical dredges. As discussed above, mechanical dredges usually generate lower levels of underwater noise than hydraulic dredges; however, because dredging with a mechanical dredge and can take up to ten times longer than dredging with a hopper dredge, impacts would be longer in duration (USACE, 2013d). Under Reduced Hopper Dredge Use Alternative 1, Suisun Bay Channel/New York Slough and either Pinole Shoal or Richmond Outer Harbor would be dredged with clamshell-bucket equipment instead of a hopper dredge. Under Reduced Hopper Dredge Use Alternative 2, Suisun Bay Channel/New York Slough, Pinole Shoal, and Richmond Outer Harbor would all be dredged with clamshell-bucket equipment instead of a hopper dredge. Under both alternatives, San Bruno Channel in Redwood City Harbor would also be dredged with clamshell-bucket equipment instead of a hopper dredge.<sup>5</sup> All dredging activities would take place in the federal navigation channels, which receive regular boat traffic, and therefore have high background levels of underwater noise.

**NEPA Determination.** Under Reduced Hopper Dredge Use Alternatives 1 and 2, temporary adverse effects to fish and marine mammals from underwater noise would be less than significant.

**CEQA Determination.** Under Reduced Hopper Dredge Use Alternatives 1 and 2, temporary adverse effects to fish and marine mammals from underwater noise would be less than significant.

***Impact 3.6-4: Potential Adverse Effects from Entrainment on Special-Status or Commercially and Recreationally Important Marine Species, Not Including Delta Smelt and Longfin Smelt***

All forms of dredging have the potential to incidentally remove organisms from the environment with the dredged material, a process referred to as entrainment. Organisms on the dredged material may be entrained, in addition to organisms in the water column near the dredging apparatus. In general, smaller organisms with limited or no swimming capabilities are more susceptible to dredge entrainment. Mechanical dredging is generally accepted to entrain far fewer fish than hydraulic dredging, because little water is removed along with the sediment; but it still may remove demersal fish and crustaceans that live in or on the sediment. Entrained fish are likely to suffer mechanical injury or suffocation during dredging, resulting in mortality. Organisms that can survive entrainment, such as small crustaceans, would be transported and released with the dredged material, which may be at an upland location or in habitat unsuitable for the species.

**No Action/No Project Alternative and Proposed Action/Project**

Under the No Action/No Project Alternative, dredging and placement would continue to be limited to the work windows set out by NMFS, USFWS, and CDFW for the LTMS program—unless, through an additional consultation process, the appropriate agencies provide written authorization to work outside these windows. The agreed-upon LTMS work windows include seasonal avoidance of Dungeness crab, Pacific herring, delta smelt, steelhead, coho salmon, and Chinook salmon for dredging conducted in various portions of San Francisco Bay (Figure 2-6). The work windows have been established to avoid sensitive periods for these species (i.e., migration periods, spawning periods). In the past, dredging schedules have occasionally slipped for logistical or financial reasons, and dredging occurred outside of the LTMS work window for one or more species. In the event that this should occur in any year covered by this EA/EIR, USACE would initiate an additional consultation process with the appropriate agencies to obtain written authorization to work outside these windows.

Dredging would be conducted in accordance with the standard practices described in Section 2.3.2, which include measures to reduce the potential for entrainment. The USACE would also implement appropriate measures to minimize impacts to EFH, as detailed in the *Agreement on Programmatic EFH Conservation Measures for Maintenance Dredging Conducted Under the LTMS Program* (USACE and USEPA, 2011).

<sup>5</sup> San Bruno Channel is dredged at intervals of 10 years or greater.

There is currently no work window approved for green sturgeon; this species is presumed present throughout the Estuary year-round. Green sturgeon spawn in the Sacramento River, which is outside the study area. Although juvenile and adult green sturgeon are expected to be present in the Estuary during dredging, it is generally believed they would be motile enough to avoid entrainment. The LTMS agencies are in the process of updating the LTMS Programmatic ESA consultation with NMFS to include green sturgeon. The updated consultation would satisfy ESA compliance for green sturgeon for USACE future maintenance dredging under the LTMS program.

Demersal fish species (e.g., Pacific staghorn sculpin, Pacific sanddab), which live and feed on and near the bottom, have a higher potential to be entrained with the sediment. Although some of these fish may be entrained, these are not special-status species. The minimum mortality to these bottom species, if any, would have no significant effect on their population numbers or species survival.

Under the Proposed Action/Project, USACE would dredge a ½-mile portion of Bulls Head Reach (just east of the Benicia-Martinez Bridge in Suisun Bay Channel) outside the LTMS work window, as warranted by conditions, to remove the hazardous shoal that can form quickly at this location. Removal of the shoal would likely involve 1 to 5 days of dredging to clear the hazard area to the authorized depth (35 feet MLLW), plus 2 feet of overdepth. The dredge equipment used would be based on availability, and dredging could be completed by either mechanical or hopper equipment. Dredging that occurs outside of the LTMS windows is more likely to result in entrainment, or to have other adverse effects on special-status or commercially important species. The potential for entrainment would be reduced with the use of a mechanical dredge. All other maintenance dredging under the Proposed Action would be scheduled to occur during the LTMS work windows.

**NEPA Determination.** With implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment, effects to special-status and commercially important species resulting from entrainment would be less than significant under the No Action Alternative and Proposed Action.

**CEQA Determination.** Effects to special-status and commercially important species resulting from entrainment would be significant under the No Project Alternative and Project, but would be reduced to less than significant with implementation of the LTMS work windows, and other standard practices intended to reduce the potential for entrainment.

### **Reduced Hopper Dredge Use Alternatives 1 and 2**

Impacts to special-status and commercially valuable marine species resulting from entrainment during dredging would be slightly lower under Reduced Hopper Dredge Use Alternatives 1 and 2, in comparison with the No Action/No Project Alternative and Proposed Action/Project, because there would be a decreased use of hopper dredges. Mechanical dredges are less likely to entrain fish and other animals when compared to hopper dredges. Under Reduced Hopper Dredge Use Alternative 1, Suisun Bay Channel/New York Slough and either Pinole Shoal or Richmond Outer Harbor would be dredged with clamshell-bucket equipment instead of a hopper dredge. Under Reduced Hopper Dredge Use Alternative 2, Suisun Bay Channel/New York Slough, Pinole Shoal, and Richmond Outer Harbor would all be dredged with clamshell-bucket equipment instead of a hopper dredge. Under both alternatives, San Bruno Channel in Redwood City Harbor would also be dredged with clamshell-bucket equipment instead of a hopper dredge.<sup>6</sup>

As described under the No Action/No Project Alternative and Proposed Action/Project, impacts to special-status and commercially valuable marine species from entrainment during dredging would be

---

<sup>6</sup> San Bruno Channel is dredged at intervals of 10 years or longer.

minor with implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment.

**NEPA Determination.** With implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment, effects to special-status and commercially important species resulting from entrainment would be less than significant under Reduced Hopper Dredge Use Alternatives 1 and 2. The potential for impacts would be reduced compared to the No Action Alternative and Proposed Action.

**CEQA Determination.** Effects to special-status and commercially important species resulting from entrainment would be significant under Reduced Hopper Dredge Use Alternatives 1 and 2, but would be reduced to less than significant with implementation of reduced hopper dredge use, the LTMS work windows, and other standard practices intended to reduce the potential for entrainment. Impacts would be less than under the No Project Alternative and Project.

### ***Impact 3.6-5: Potential Substantial Adverse Effects and Cumulative Impacts to Delta Smelt from Entrainment***

Delta smelt are not strong swimmers, and are presumed susceptible to entrainment in the flow fields created around drag heads of trailing suction dredges. There is also a potential for entrainment during water intake for flushing of hopper dredges. Although entrainment may impact the numbers of delta smelt, because entrainment does not permanently impact or remove habitat, dredging is not likely to impact the species' range. All dredge areas that are part of the proposed project are currently maintained for boat traffic, have been maintained for several decades, and therefore are regularly disturbed. For this reason, continued dredging is not expected to further reduce habitat quality for the species.

As described in Section 3.6.2, delta smelt have potential to occur in the portions of the Estuary that include the Napa River Channel, San Pablo Bay/Mare Island Strait, and Suisun Bay Channel dredge areas during certain seasons. Delta smelt occur in San Pablo Bay in lower numbers than in the Napa River or Suisun Bay; however, they may be present in San Pablo Bay in increased numbers during high water outflow years. Delta smelt are not expected to occur in the other federal channels. Entrained fish would likely be killed either through physical injury during entrainment or suffocation in the collected dredged material. Because delta smelt typically occur in the upper portion of the water column, entrainment is more likely when dredging in shallow waters or when the drag head is lifted from the bottom (Sweetnam and Stevens, 1993). To reduce delta smelt entrainment, LTMS uses a depth of 10 feet to distinguish between "shallow" and deeper waters when implementing work windows for delta smelt.

Overall abundances of delta and longfin smelt in the environment were analyzed for spatial and temporal patterns using CDFW monitoring database from 2002 to 2011. CDFW conducts monthly otter trawls (San Francisco Bay Study) and midwater trawl (San Francisco Bay Study and Fall Midwater Trawl Study) surveys at both channel and shoal stations throughout San Francisco Estuary. This trawl data is used to build yearly abundance indices for delta smelt. Delta smelt abundance in San Francisco Bay was relatively high in 2011 when the smelt entrainment study, discussed below, was conducted,<sup>7</sup> compared to data from recent years (ERDC, 2013). The delta smelt abundance index for 2011 was 234, more than ten times higher than the preceding 6 years (CDFW 2014b). The 2012 monitoring data indicated a population drop, with an abundance index of 42 (CDFW 2014b). The 2011 entrainment levels could be

<sup>7</sup> The ERDC study was based on entrainment data collected during a year (i.e., 2011) with higher than normal outflow, pushing the low salinity zone further downstream into the Suisun Bay region. Between January and March 2011, the mean water outflow was approximately 57,200 cubic feet per second, which was significantly higher than previous years, except 2006 (ERDC, 2013). The mean outflow during September and October was also high, averaging 12,200 cubic feet per second. The high outflows resulted in approximately 8,366 hectares of low salinity zone habitat and an increased habitat suitability index (USGS, 2014), compared to typical years with less outflow.

correlated to the higher overall abundance of delta smelt in Suisun Bay. In years with normal or below average outflow, delta smelt entrainment could be lower.

**Entrainment Estimates.** An entrainment modeling study of delta and longfin smelt in San Francisco Bay by hydraulic dredges was prepared by the United States Army Engineer Research and Development Center (ERDC) (ERDC, 2013). In the study, the risk of smelt entrainment was assessed by comparing fish abundances in the environment (CDFW monthly trawls described above) to fish collections in entrainment monitoring samples (screened sub-samples of dredged material). Fish entrainment samples were collected during dredging in San Francisco Bay in 2010 and 2011. In June 2010, 62 samples were collected from 32 hopper loads during dredging of Pinole Shoal in San Pablo Bay by the hopper dredge *Essayons* (McGowan, 2010). In 2011, 228 samples were collected during dredging by the hopper dredge *Essayons* in the Central Bay (Richmond Harbor), San Pablo Bay (Pinole Shoal), and Suisun Bay (Suisun Bay Channel and New York Slough) (Gold et al., 2011).

Four delta smelt were collected in entrainment samples (each consisting of less than one percent of the total sediment in a load) from four hopper loads in 2011, all of which occurred in Suisun Bay. No delta smelt were collected during the 2010 entrainment sampling. There were no obvious associations between the collection of delta smelt in entrainment samples and environmental parameters; as noted in the study, a larger sample size of dredged sediment, including any entrained fish, may allow clearer associations between environmental factors and entrainment susceptibility (ERDC, 2013).

As part of the entrainment modeling study, the number of delta smelt entrained in 2011 was extrapolated using a variety of analytical techniques<sup>8</sup> based on the number of smelt collected in the 2011 entrainment samples and the percentage of hopper loads that were monitored; the 2010 monitoring results were not used in the modeling study.

Although the numbers of fish collected in the entrainment monitoring are fixed values, the appropriate volume of dredged material used to extrapolate the entrainment rate estimate varies depending on what dredging and environmental scenarios are considered relevant. For this reason, a range of entrainment rate estimates (low, moderate, and high entrainment scenarios) were calculated using the 2011 entrainment monitoring data. Low, moderate, and high entrainment rate estimate calculations are defined as:

- Low – number of smelt collected divided by the total volume of all entrainment samples (includes zero catches) in each embayment for the month of sampling
- Moderate (i.e., Medium) – number of smelt collected divided by the total volume sampled on days delta smelt were entrained (includes zero catches) for each embayment.
- High – number of smelt collected divided by the volume of that sample.

Many factors are associated with the accuracy of these projections. The small sample size of entrained fish (18 longfin smelt and 4 delta smelt), combined with the overall low percentage of dredge material sampled result in uncertainty as to the accuracy of the entrainment estimates. In addition, there may be unidentified factors that influence entrainment. Modeled estimates of delta smelt entrainment during hydraulic dredging in 2011 based on 2011 abundance indices are 394 for the low entrainment scenario, 1,444 for the medium entrainment scenario, and 3,694 for the high entrainment scenario.

---

<sup>8</sup> The ERDC's study assesses entrainment risk using three methods: 1) dredged material volume extrapolation based on the number of fish entrained during the 2011 entrainment monitoring and percentage of material sampled; 2) flow-field models using hopper suction velocities at varying distances from the drag head and smelt swimming performance; and 3) a Poisson distribution analysis.

**Population-Level Effects.** As part of the entrainment modeling study, the impact of the low, medium, and high levels of entrainment on the future of the delta smelt population was further modeled using Population Viability Analysis (PVA). This technique is often used to forecast the probability of future declines in population size, taking into consideration the significant variability of natural processes and substantial knowledge gaps. Case histories show that PVA-predicted results do not differ significantly from observed trends in population trajectories (Brook et al., 2000). Because dredging of the federal channels has been ongoing for many years, population projections with losses due to dredging entrainment are considered to be the baseline. The baseline is compared to projections with reduced losses due to dredge entrainment, either through the cessation of dredging or successful implementation of entrainment reduction measures. The difference between these projections provides an estimate of the population level effects of dredging over the next 30 years. With baseline conditions (dredging continues as it has in the past), the modeling predicts a 50 percent chance that delta smelt populations will be reduced by more than 60 percent in 30 years. If a high level of current entrainment (3,694 delta smelt) is assumed, and entrainment was completely eliminated in future dredging, the modeling predicts a 38 percent chance that delta smelt populations will still be reduced by more than 60 percent in 30 years (ERDC, 2013).

For delta smelt, dredging impacted abundance and probability of decline under the medium and high estimates of entrainment. For low estimates of entrainment, reductions in population numbers were less than 2 percent, and there was no increase in the probability of a population decline. For medium and high estimates of entrainment, dredging resulted in a 9 to 29 percent reduction in median population abundance and increased the probability of observed decline (greater than 60 percent over 30 years) by 3 to 12 percent. However, for medium and high estimates of entrainment, the proposed entrainment reduction measures reduced impacts to abundance by approximately one third, and probability of decline by approximately half; additional entrainment reduction measures have been included under the action alternatives.

Because inter-annual variation in population size is high, in both nature and in the model simulations, and is highly correlated with freshwater flow, changes in median abundance less than 60 percent may not be functionally significant because abundance naturally fluctuates more than an order of magnitude (ERDC, 2013). Importantly, the results of the entrainment study highlight that the risk of populations decline is due to factors other than dredging-related entrainment. For delta smelt, under any estimate of entrainment, abundance declines greater than 75 percent are attributable to factors other than dredging.

In its 2014 biological opinion for maintenance dredging the Suisun Bay Channel using a hopper dredge, the USFWS analyzed the ERDC entrainment risk assessment and concluded that the high entrainment levels are potentially overstated because delta smelt are patchily distributed in the Estuary, which would limit their exposure. The risk assessment assumed fish are uniformly distributed in the dredged material and process water. Furthermore, the risk assessment used all 2011 dredge samples to extrapolate the number of entrained delta smelt, rather than only the Suisun Bay Channel samples where the fish are most likely to be present. The USFWS concluded that the 2014 dredging of the Suisun Bay Channel would not jeopardize the continued existence of delta smelt and provided measures to further minimize potential entrainment, including:

- Lowering the drag head to at least 3 feet from the bottom of the channel prior to turning on pumps (which is included as a best management practice [BMP] under all alternatives), and
- Keeping the drag head water intake doors closed to the maximum extent practicable (this measure is included under the action alternatives) (USFWS, 2014).

**Potential Impacts from Cutterhead Dredging.** Cutterhead dredges would be used to dredge the Napa River Channel, Petaluma River Channel, and San Leandro Marina. Cutterheads used to dredge the federal navigation channels in San Francisco Bay are small—with a pipe diameter of only 10 inches

(ERDC, 2013). The entrainment study assumed, because the volume of entraining flow generated by a cutterhead dredge is 1 to 2 orders of magnitude lower than that generated by a hopper dredge, that entrainment of smelt by cutterhead is inconsequential (ERDC, 2013). This contention is supported by a 2006 monitoring study conducted in a smaller body of water (i.e., Port Sonoma Marina), in which smelt were present and rate of entrainment by a 10-inch cutterhead dredge was negligible (ERDC, 2013). During that study, entrainment of a single longfin smelt was documented in 2006, and no longfin smelt were entrained in 2007, during a fourfold increase in the sampling effort. The conclusion by the researchers was that “risk of longfin smelt entrainment is very low” from cutterhead dredging. In addition, entrainment impacts from cutterhead dredging in the Napa and Petaluma rivers and San Leandro Marina would be avoided by conducting hydraulic dredging in these locations when water temperatures are above 22 degrees Celsius, in accordance with the existing avoidance measure identified in coordination with CDFW, to the extent feasible. Therefore, potential entrainment during cutterhead dredging operations is not further analyzed in this EA/EIR.

### **No Action/No Project Alternative**

Under the No Action/No Project Alternative, USACE would continue current maintenance dredging practices for the projects it maintains in San Francisco Bay, as described in Section 2.3.2. These practices include the following measures to reduce the potential for entrainment of delta smelt from hydraulic dredging:

- Dredging may proceed anywhere when water temperature exceeds 22.0°C;<sup>9</sup>
- No dredging would occur in water ranging from 0 to 5 parts per thousand salinity between December 1 and June 30;
- At the beginning and end of each hopper load, pump priming, drag head clearing, and suction of water would be conducted within 3 feet of the seafloor;
- Hopper drag head suction pumps would be turned off when raising and lowering the drag arms from the seafloor when turning the dredge vessel; and
- The USACE would implement a worker education program for listed fish species that could be adversely impacted by dredging. The program would include a presentation to all workers on biology, general behavior, distribution and habitat needs, sensitivity to human activities, legal protection status, and project-specific protective measures. Workers would also be provided with written materials containing this information.<sup>10</sup>

These measures reduce the likelihood of delta smelt being present during dredging, and reduce the potential for delta smelt to become entrained through the drag heads.

The USACE would undertake mitigation, as appropriate, in meeting its compliance requirements. In the past, USACE purchased a total of 1.4 mitigation credits at the Liberty Island Conservation Bank for potential impacts to listed species for 2011 and 2012 maintenance dredging activities in San Francisco Bay.

---

<sup>9</sup> If hydraulic maintenance dredging occurs when water temperatures are less than 22 degrees Celsius, USACE would coordinate mitigation, as appropriate, with USFWS, NMFS, and CDFW at the times such dredging episodes occur.

<sup>10</sup> The USACE has implemented this program in compliance with a condition in the San Francisco Bay Conservation and Development Commission’s Letter of Agreement for USACE’s coastal zone consistency determination for maintenance dredging in San Francisco Bay. Although the condition in the Letter of Agreement was specific to longfin smelt, USACE’s worker education program, overseen by a USACE regional fisheries biologist, also includes information on other special-status fish species that could be impacted by dredging activities (i.e., those fish species considered in the LTMS work windows).

Dredging and placement would continue to be limited to the work windows set out by NMFS, USFWS, and CDFW for the LTMS program—unless, through an additional consultation process, the appropriate agencies provide written authorization to work outside these windows. The agreed-upon LTMS work windows include seasonal avoidance of delta smelt for dredging conducted between the Carquinez Bridge and Collinsville and in the Napa River (Figure 2-6). Although USACE would dredge Suisun Bay Channel and New York Slough during the LTMS work window for delta smelt in this area (August 1 through November 30), because entrainment of delta smelt has been documented during past USACE maintenance dredging, USACE would consult annually with USFWS to address incidental take of delta smelt during dredging of Suisun Bay Channel and New York Slough.

**NEPA Determination.** Under the No Action Alternative, hopper dredging would continue in Richmond Outer Harbor, Pinole Shoal, and Suisun Bay Channel and New York Slough using BMPs and mitigation identified above.<sup>11</sup> ERDC's entrainment study was modeled on the No Action Alternative, which concludes that entrainment impacts to the population would not be significant. The ERDC study was based on entrainment data collected during a year with higher-than-normal outflow, pushing the low-salinity zone further downstream into the Suisun Bay region, and delta smelt abundances were also higher in Suisun Bay during the entrainment monitoring. It is likely that during typical outflow years, delta smelt entrainment risk would be reduced because fish are likely to be congregating further upstream. The entrainment study also likely overstates the levels of entrainment, because delta smelt are patchily distributed in the Estuary, which would limit their exposure; and because the risk assessment uses all 2011 dredge samples to extrapolate the number of entrained delta smelt, rather than only the Suisun Bay Channel samples where the fish are most likely to be present.

In addition to continuing to employ BMPs to reduce entrainment risk, the USACE proposes to continue purchasing compensatory mitigation credits at the Liberty Island Conservation Bank, or other approved site, to mitigate for fish entrainment. As noted above, USACE purchased a total of 1.4 mitigation credits at the Liberty Island Conservation Bank for potential impacts to listed species for 2011 and 2012 maintenance dredging activities in San Francisco Bay.

Based on ERDC's conclusion that entrainment impacts under the No Action Alternative would result in negligible impacts to delta smelt populations, and with the continued purchase of compensatory mitigation credits, the potential entrainment impacts on delta smelt are expected to be less than significant. Although the project could contribute to cumulative impacts on delta smelt, the project's contribution, compared to that from water export facilities and other factors, to cumulative impacts would not be significant.

**CEQA Determination.** The ERDC entrainment modeling study, using 2011 entrainment monitoring data, estimated the annual range of entrainment due to hopper dredging to be 394 to 3,694 delta smelt, or up to approximately 29 percent of the median annual population abundance. The study also concluded that the medium and high estimates of dredging entrainment increased the probability of observed population decline by 3 to 12 percent. Over the past decade, abundance indices for various life stages of delta smelt have hit record lows as indicated by CDFW survey data.<sup>12</sup> Based on this survey data indicating that the species is in imminent danger of extinction, the state elevated its listing status from threatened to endangered in 2010.

Based on the administrative record and the discussion above, there is a significant impact to delta smelt under CEQA. In addition, the No Project Alternative includes 10 years of dredging operations, which, as proposed, and as summarized above, are likely to substantially reduce the number of delta smelt. In

<sup>11</sup> Although San Bruno Channel in Redwood City Harbor would also be dredged with a hopper dredge under the No Action Alternative, this channel is outside the range of delta smelt.

<sup>12</sup> Annual abundance indices of delta smelt from 20 mm survey (larvae and juveniles, 1995-2012); summer townet survey (juveniles; 1959-2012); and fall midwater trawl survey (subadults; 1967-2012).

addition to the project's impacts being individually significant, other activities are also causing significant take of delta smelt, as described above. Therefore, the cumulative impacts of this project, considered with the impacts of other projects causing related impacts, are significant.

### Proposed Action/Project

Under the Proposed Action/Project, the dredge equipment type, frequency of dredging, and volumes dredged would be the same as under the No Action/No Project Alternative. Over the next 10 years, dredging and placement of dredged materials would be conducted in accordance with the conditions described under the No Action/Project Alternative to protect delta smelt, as well as the following additional conditions identified in Section 2.3.3:

- Completing hydraulic dredging in Suisun Bay between August 1 and September 30, to the extent feasible, to avoid impacts to spawning adult longfin and delta smelt;
- Maintaining contact of drag head, cutterheads, and pipeline intakes with the seafloor during suction dredging;<sup>13</sup> and
- Closing the drag head water intake doors in locations most vulnerable to entraining or entrapping smelt. In circumstances when the doors need to be opened to alleviate clogging, the doors would be opened incrementally (i.e., the doors would be opened in small increments and tested to see if the clog is removed) to ensure that doors are not fully opened unnecessarily. It may take multiple iterations to fine tune the exact intake door opening necessary to prevent clogging. For each project, the intake door opening will be different because the sediment in each location is different. The sediment physical characteristics (e.g., sand versus mud) determine how much water is needed to slurry the sediment adequately. Typically, the drag arms do not clog when dredging areas composed mostly of sand.

These measures would further reduce the likelihood of delta smelt being present during dredging, and the potential for delta smelt to become entrained compared to the No Action/No Project Alternative.

The USACE would purchase 0.92 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species. The 0.92 acre mitigation credit was calculated from CDFW formula (3.0 million acre-feet/800 acres = volume dredged\*/X acres of mitigation habitat) used by the Central Valley Water Project and State Water Project to determine the mitigation requirements for hydraulically pumping water from the Delta, which is considered adequate mitigation for the water projects. For volume dredged, available government-hopper-dredge-pumped water volumes for 2006 through 2012 were reviewed. The highest volume for each of the in-Bay channels (Pinole Shoal, Richmond Outer Harbor, and Suisun Bay Channel/New York Slough) from this period was used in the calculation. Of the 0.92 acre mitigation credit, 0.19 acre mitigation credit would be for Pinole Shoal, 0.34 acre mitigation credit would be for Richmond Outer Harbor, and 0.39 acre mitigation credit would be for Suisun Bay Channel and New York Slough. The 0.92 acre mitigation credit per year is expected to be more than the credit needed based on actual future annual maintenance dredging volumes.

The Bulls Head Reach is located in critical habitat for the delta smelt, and delta smelt are expected to occur in that location, at least seasonally. Because urgent action dredging of the Bulls Head Reach may occur at any time of year and would not conform to the LTMS work windows for delta smelt, it is likely that some delta smelt would be entrained during some dredging episodes when a hopper dredge is used. The potential for entrainment would be reduced with the use of a mechanical dredge. Because the extent

<sup>13</sup> The seafloor surface is not uniform and is undulating, which could cause the drag head to lose contact with the seafloor. The hopper dredge also has to contend with sea state (i.e., swells and wave action) in the bay which also affects the drag heads contact with the channel bottom. The dredge's swell compensator provides an opposing force to maintain contact with the seafloor when the bottom is uneven or there is wave/swell action.

and frequency of critical dredging episodes cannot be predicted, appropriate mitigation for these episodes, if warranted based on expected impacts, would be determined in coordination with regulatory agencies at time they occur.

**NEPA Determination.** Although delta smelt could be entrained by hopper dredging, the anticipated entrainment is not expected to result in substantial declines in populations. Impacts would be reduced, compared to the No Action Alternative, by the additional minimization measures and compensatory mitigation under the Proposed Action. The entrainment study was based on existing hopper dredging practices in San Francisco Bay (i.e., not the Proposed Action); therefore, it does not account for the avoidance and minimization measures identified by USFWS, or for additional minimization measures identified in the ERDC report to further reduce the risk of entrainment. The Proposed Action includes these avoidance and minimization measures to reduce the risk of delta smelt entrainment. The ERDC study also does not account for compensatory mitigation proposed in the Draft EA/EIR. In its March 14, 2014, letter to the Regional Water Board, CDFW indicated that the proposed 0.92 acre mitigation credit of restored and managed tidal wetlands per year as compensatory mitigation to reduce impacts to fish is generally consistent with mitigation to other projects that cause take of delta smelt associated with water diversions or extractions. Therefore, with the proposed minimization measures and compensatory mitigation, it is expected that the Proposed Action would result in a less-than-significant impact on delta smelt. Although the project could contribute to cumulative impacts on delta smelt, the project's contribution, compared to that from water export facilities and other factors, to cumulative impacts would not be significant.

**CEQA Determination.** The ERDC entrainment modeling study, using 2011 entrainment monitoring data, estimated the annual range of entrainment due to hopper dredging to be 394 to 3,694 delta smelt, or up to approximately 29 percent of the median annual population abundance. The study also concluded that the medium and high estimates of dredging entrainment increased the probability of observed population decline by 3 to 12 percent. Over the past decade, abundance indices for various life stages of delta smelt have hit record lows, as indicated by CDFW survey data.<sup>14</sup> Based on survey data indicating that the species is in imminent danger of extinction, the state elevated its listing status from threatened to endangered in 2010. In a letter to the Regional Water Board dated March 14, 2014, the CDFW noted the above figures concerning entrainment, and stated that "the Project, as proposed, would substantially reduce the number of an endangered, rare, or threatened species."

Based on the administrative record and the discussion above, there is a significant impact to delta smelt under CEQA. In addition, the Proposed Action/Project includes 10 years of dredging operations, which, as proposed, and as summarized above, are likely to substantially reduce the number of delta smelt. In addition to the project's impacts being individually significant, other activities are also causing significant take of delta smelt, as described above. Therefore, the cumulative impacts of this project, considered with the impacts of other projects causing related impacts, are significant.

### **Reduced Hopper Dredge Use Alternative 1**

Under this alternative, use of a hopper dredge for maintenance dredging of the federal navigation channels would be reduced, compared to the No Action/No Project Alternative and Proposed Action/Project. Under Reduced Hopper Dredge Use Alternative 1, a hopper dredge would only be used to dredge the MSC, and either the Richmond Outer Harbor or the Pinole Shoal Channel, annually. Dredging of the in-Bay channel would occur within the LTMS work window (Figure 2-6), or after an individual consultation is conducted with the appropriate regulatory agencies to allow dredging to be performed outside the work window.

---

<sup>14</sup> Annual abundance indices of delta smelt from 20 mm survey (larvae and juveniles, 1995-2012); summer townet survey (juveniles; 1959-2012); and fall midwater trawl survey (subadults; 1967-2012).

The channel not selected as the additional hopper dredge channel (i.e., either Pinole Shoal or Richmond Outer Harbor) would be dredged with a mechanical dredge. Because Richmond Outer Harbor is outside the range of delta smelt, the potential for impacts would be less when this channel is dredged with hopper dredge than when Pinole Shoal is dredged with a hopper dredge, especially during high outflow years when delta smelt may be present in San Pablo Bay in increased numbers. In addition, Suisun Bay Channel and New York Slough Channel would be dredged with a mechanical dredge under this alternative, instead of a hopper dredge; the potential exception being urgent action dredging of the Bulls Head Reach, which could be conducted with either a mechanical or hopper dredge. All other dredging, placement activities, and minimization measures would be as described for the Proposed Action/Project.

Because reduced hopper use would not be implemented until fiscal year 2017, as described in Section 2.3.4, USACE would purchase 0.92 acre mitigation credit at Liberty Island Conservation Bank for potential impacts to listed species in fiscal years 2015 and 2016. Beginning in fiscal year 2017, the USACE would purchase 0.19 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species if Pinole Shoal is dredged with a hopper. If Richmond Outer Harbor is dredged with a hopper, USACE would purchase 0.34 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species. This is expected to be more than the credit needed based on actual future annual maintenance dredging volumes.

As discussed above, mechanical dredges are unlikely to cause entrainment of delta smelt, and hopper dredges are expected to entrain delta smelt. A reduction in the use of hopper dredges in the Suisun Bay Channel/New York Slough, which is within the range of delta smelt, would further reduce the effects to delta smelt resulting from dredge entrainment compared to the Proposed Action/Project. Because the MSC, Pinole Shoal Channel, and Richmond Outer Harbor are not within the typical range of the delta smelt, the potential adverse effects to delta smelt resulting from dredge entrainment would be largely eliminated under this alternative. Because urgent action dredging of the Bulls Head Reach may occur at any time of year and would not conform to the LTMS work windows for delta smelt, it is likely that some delta smelt would be entrained during some dredging episodes when a hopper dredge is used. The potential for entrainment would be reduced with the use of a mechanical dredge. Because the extent and frequency of critical dredging episodes at Bulls Head Reach cannot be predicted, appropriate mitigation for these episodes, if warranted based on expected impacts, would be determined in coordination with regulatory agencies at time they occur.

**NEPA Determination.** Although delta smelt could be entrained by hopper dredging, the anticipated entrainment is not expected to result in substantial declines in populations. In its March 14, 2014, letter to the Regional Water Board, CDFW indicated that USACE's proposed compensatory mitigation is generally consistent with mitigation to other projects that cause take of delta smelt. Therefore, with the proposed minimization measures and compensatory mitigation, it is expected that the Proposed Action would result in a less-than-significant impact on delta smelt. Although the project could contribute to cumulative impacts on delta smelt, the project's contribution, compared to that from water export facilities and other factors, would not be significant. Under Reduced Hopper Dredge Use Alternative 1, any project and cumulative impacts would be reduced compared to the No Action Alternative and Proposed Action.

**CEQA Determination.** This Alternative reduces hopper dredging to one in-Bay channel per year, implements specific minimization measures, and provides compensatory mitigation for the one channel that is hopper-dredged. Hopper dredging of Richmond Outer Harbor as the sole in-Bay channel, which is outside the normal range of delta smelt, would result in greater impact reduction than hopper dredging in Pinole Shoal Channel, which is near the western extent of their range. Hopper dredging in Pinole Shoal could result in a significant and unavoidable impact to delta smelt, both individually and cumulatively with other activities causing take of delta smelt over the 10-year life of the Project. This impact, however, would be mitigated to a less-than-significant level with minimization of hopper dredge use, as

contemplated by this alternative, and successful implementation of the proposed minimization measures and compensatory mitigation described above.

### **Reduced Hopper Dredge Use Alternative 2**

Under Reduced Hopper Dredge Use Alternative 2, a hopper dredge would only be used to dredge the MSC. Pinole Shoal, Richmond Outer Harbor, Suisun Bay Channel, and New York Slough would be dredged with a mechanical dredge under this alternative, instead of a hopper dredge; the potential exception being urgent action dredging of the Bulls Head Reach in Suisun Bay Channel, which could be conducted with either a mechanical or hopper dredge. All other dredging, placement activities, and minimization measures would be as described for the Proposed Action/Project. Because reduced hopper use would not be implemented until fiscal year 2017, as described in Section 2.3.4, USACE would purchase 0.92 acre mitigation credit at Liberty Island Conservation Bank for potential impacts to listed species in fiscal years 2015 and 2016.

As discussed above, mechanical dredges are unlikely to cause entrainment of delta smelt, although hopper dredges are expected to entrain delta smelt. Because the MSC is not within the range of the delta smelt, the potential adverse effects to delta smelt resulting from dredge entrainment would be largely eliminated under this alternative. Therefore, no compensatory mitigation is proposed for fiscal years 2017 through 2024.

Because urgent action dredging of the Bulls Head Reach may occur at any time of year and would not conform to the LTMS work windows for delta smelt, it is likely that some delta smelt would be entrained during some dredging episodes when a hopper dredge is used. The potential for entrainment would be reduced with the use of a mechanical dredge. Because the extent and frequency of critical dredging episodes at Bulls Head Reach cannot be predicted, appropriate mitigation for these episodes, if warranted based on expected impacts, would be determined in coordination with regulatory agencies at time they occur.

**NEPA Determination.** With the elimination of hopper dredging inside San Francisco Bay, the potential for entrainment of delta smelt would be largely eliminated under Reduced Hopper Dredge Use Alternative 2. Project and cumulative impacts would be less than significant.

**CEQA Determination.** This alternative eliminates hopper dredging inside San Francisco Bay, thus largely eliminating the potential for entrainment of delta smelt. Project and cumulative impacts would be less than significant.

### **Impact 3.6-6: Potential Substantial Adverse Effects and Cumulative Impacts to Longfin Smelt from Entrainment**

Smelt are not strong swimmers, and longfin smelt in particular are known to occur near the bottom of the water column (CDFG, 2009a). As a result, they are presumed susceptible to entrainment in the flow fields created around drag heads of trailing suction dredges. Longfin smelt have potential to occur, at least in low numbers, in any of the project dredge areas during any season. Although entrainment may impact the numbers of longfin smelt, because entrainment does not permanently impact or remove habitat, dredging is not likely to impact the species' range.

As described in Section 3.6.2, longfin smelt have potential to occur throughout much of the San Francisco Bay Estuary, and populations are seasonally concentrated in certain portions of the estuary. The densities of longfin smelt in Estuary are lowest in the autumn, when spawning adults have moved upstream and before larval smelt have moved down into the Estuary. During the winter and spring months, larval longfin smelt are concentrated in Suisun and San Pablo bays, but are present in the Central and South bays in lower densities. Juveniles and adults are present throughout the Estuary at all times of year, but

the majority of the population is concentrated in the Suisun, San Pablo, and Central bays, as well as nearshore waters during the summer months. As described under Impact 3.6-5, a study of entrainment of delta and longfin smelt in San Francisco Bay by hydraulic dredges was prepared by the ERDC (ERDC, 2013).

As described under Impact 3.6-5, abundances of delta and longfin smelt in the environment were analyzed for spatial and temporal patterns using CDFW monitoring trawl data from 2002 to 2011. This trawl data is used to build yearly abundance indices for longfin smelt. Longfin smelt abundances in San Francisco Bay were relatively high in 2011 and low in 2010 when the smelt monitoring study was conducted (ERDC, 2013), which is consistent with the corresponding high and low delta outflows for the respective years.

**Entrainment Estimates.** As described under Impact 3.6-5, an entrainment modeling study of delta and longfin smelt in San Francisco Bay by hydraulic dredges was prepared by the ERDC (ERDC, 2013). Entrainment sampling was conducted in 2010 and 2011, though no smelt were collected in the 2010 sampling. During the 2011 entrainment sampling, 228 hopper loads were sampled. Eighteen longfin smelt were collected from 12 hopper loads. For the each load sampled, including the 12 hopper loads where smelt were entrained, less than 1 percent of the total load was sampled. Entrainment of approximately one-third of the individuals during the 2011 monitoring occurred when the pumps were running with the drag heads at mid water column; typically, the dredge is only suctioning when the drag heads are just above (within 3 feet) of the bottom or on the bottom. Longfin smelt were collected in the 2011 entrainment samples in the Central Bay, San Pablo Bay, and Suisun Bay, but only during the portion of the tidal cycle when tidal currents are strongest. The majority were entrained in the Central Bay (12 fish), while three fish were entrained in San Pablo Bay, and three fish in Suisun Bay. No correlations were found between tidal direction (ingoing or outgoing) or time of day (day versus night) and the incidence of longfin smelt entrainment. The percentages of samples with entrained fish of any species were positively correlated with daily tidal range in Central Bay, with more fish being entrained on days where the tidal range is greatest (i.e., spring tides) and tidal currents strongest; it should be noted that this result is based on only one sampling year(2011). Fish may respond to stronger tidal currents by orienting to bottom habitat, therefore becoming more susceptible to entrainment. Alternatively, more fish may be carried into channels from shallow water habitat during outgoing spring tides.

As part of the entrainment study, the projected number of longfin smelt entrained was extrapolated using a variety of analytical techniques based on the number of smelt collected in the 2011 entrainment samples and the percentage of hopper loads that monitored; the 2010 monitoring results were not used in the modeling study. Although the numbers of fish collected in the entrainment monitoring are fixed values, the appropriate volume of dredged material used to extrapolate the entrainment rate estimate varies depending on what dredging and environmental scenarios are considered relevant. For this reason, a range of entrainment rate estimates (low, moderate, and high entrainment scenarios) were calculated using 2011 entrainment monitoring data. Low, moderate, and high entrainment rate estimate calculations are defined as:

- Low – number of smelt collected divided by the total volume of all entrainment samples (includes zero catches) in each embayment for the month of sampling
- Moderate (i.e., Medium) - number of smelt collected divided by the total volume sampled on days longfin smelt were entrained (includes zero catches) for each embayment.
- High – number of smelt collected divided by the volume of that sample.

As with the modeling for delta smelt entrainment, many factors are associated with the accuracy of these projections. The small sample size of entrained fish (18 longfin smelt and 4 delta smelt), combined with the overall low percentage of dredge material sampled result in uncertainty as to the accuracy of the

entrainment estimates. Additionally, there may be yet unidentified factors that influence entrainment. Modeled estimates of longfin smelt entrainment during hydraulic dredging in 2011 based on 2011 abundance indices are 3,848 for the low entrainment scenario, 6,528 for the medium entrainment scenario, and 10,260 for the high entrainment scenario.

**Population-Level Effects.** As with delta smelt, the implications of the low, medium, and high levels of entrainment on the future of the longfin smelt population was further modeled using PVA. As the dredging of the federal channels has been ongoing for many years, population projections with losses due to dredging entrainment are considered to be the baseline. The baseline is compared to projections with reduced losses due to dredge entrainment, either through the cessation of dredging or successful implementation of entrainment reduction measures. The difference between these two projections provides an estimate of the population-level effects of dredging over the next 22 years. Low and medium estimates of entrainment resulted in less than 5 percent reduction in median population abundance. The high estimate of entrainment indicated greater reductions of median population abundance, but this was still less than 9 percent. For low, medium, and high estimates of entrainment, the study found that successful implementation of entrainment reduction measures would reduce impacts to abundance by approximately one third (ERDC, 2013); additional entrainment reduction measures have been included under the action alternatives. With baseline conditions (dredging continues as it has in the past), the modeling predicts a 50 percent chance that longfin smelt populations will be reduced by more than 90 percent in 22 years. Even if a high current level of entrainment (10,260 longfin smelt) is assumed, and entrainment were completely eliminated in future dredging, the probability that longfin smelt populations would be reduced by 90 percent in 22 years remains the same; therefore, the study concluded that future dredging would have no effect on the probability of longfin smelt population decline (ERDC, 2013).

Because inter-annual variation in population size is high, in both nature and in the model simulations and highly correlated with freshwater flow, changes in median abundance less than 30 percent may not be functionally significant because abundance naturally fluctuates more than an order of magnitude (ERDC, 2013). Importantly, the results of the entrainment study highlight that the risk of population decline risk is largely due to factors other than dredging-related entrainment. Under any estimate of entrainment, decline in abundance of longfin smelt is more than 90 percent attributable to factors other than dredging.

### **No Action/No Project Alternative**

Under the No Action/No Project Alternative, USACE would continue current maintenance dredging practices for the projects it maintains in San Francisco Bay as described in Section 2.3.2, which include the following measures to reduce the potential for entrainment of longfin smelt from hydraulic dredging:

- Dredging may proceed anywhere when water temperature exceeds 22.0°C;<sup>15</sup>
- No dredging would occur in water ranging from 0 to 5 parts per thousand salinity between December 1 and June 30;
- At the beginning and end of each hopper load, pump priming, drag head clearing, and suction of water would be conducted within 3 feet of the seafloor;
- Hopper drag head suction pumps would be turned off when raising and lowering the drag arms from the seafloor when turning the dredge vessel; and

---

<sup>15</sup> To the extent feasible, hydraulic dredging in the Napa and Petaluma rivers and San Leandro Marina would only occur when water temperatures are above 22 degrees Celsius. If hydraulic maintenance dredging occurs when water temperatures are less than 22 degrees Celsius, USACE would coordinate mitigation, as appropriate, with USFWS, NMFS, and CDFW at the times such dredging episodes occur.

- The USACE would implement a worker education program for listed fish species that could be adversely impacted by dredging. The program would include a presentation to all workers on biology, general behavior, distribution and habitat needs, sensitivity to human activities, legal protection status, and project-specific protective measures. Workers would also be provided with written materials containing this information.<sup>16</sup>

These measures reduce the likelihood of longfin smelt being present during dredging, and reduce the potential for longfin smelt to become entrained through the drag heads.

The USACE would undertake mitigation, as appropriate, in meeting its compliance requirements. In the past, USACE purchased a total of 1.4 mitigation credits at the Liberty Island Conservation Bank for potential impacts to listed species for 2011 and 2012 maintenance dredging activities in San Francisco Bay.

The LTMS work windows do not currently include seasonal avoidance measures for longfin smelt.

**NEPA Determination.** Under the No Action Alternative, hopper dredging would continue in Richmond Outer Harbor, Pinole Shoal, and Suisun Bay Channel and New York Slough using BMPs identified above.<sup>17</sup> ERDC's entrainment study was modeled on the No Action Alternative, which concludes that entrainment impacts to the population would not be significant.

ERDC concluded that longfin smelt entrainment impacts occurred only at the highest estimated level of entrainment, yet the impacts are still negligible, and that the probability of population declines resulting from dredging is not anticipated.

ERDC noted that longfin smelt abundances in the Central Bay (where most longfin smelt were entrained in 2011) were relatively high, which was consistent with the corresponding high delta outflows. Therefore, ERDC determined that the level of entrainment estimated is a very conservative estimate and is likely higher than during typical outflows.

Based on ERDC's conclusion that entrainment impacts under the No Action Alternative would result in negligible impacts to delta smelt populations and with the continued purchase of compensatory mitigation credits, the potential entrainment impacts on longfin smelt are expected to be less than significant. Although the project could contribute to cumulative impacts on longfin smelt, the project's contribution, compared to that from water export facilities and other factors, to cumulative impacts would not be significant.

**CEQA Determination.** The ERDC entrainment modeling study, using 2011 entrainment monitoring data, estimated the annual range of entrainment due to hydraulic hopper dredging to be 3,848 to 10,260 longfin smelt, or approximately 3 to 8 percent of the median annual population abundance. In a letter to the Regional Water Board dated March 14, 2014, CDFW found this take to be a significant impact to a special-status species. According to CDFW annual abundance indices from the fall midwater trawl surveys from 1967 to 2013, the population of longfin smelt has declined 99 percent or more in the last 45 years, with record lows in the past decade.

---

<sup>16</sup> The USACE has implemented this program in compliance with a condition in the San Francisco Bay Conservation and Development Commission's Letter of Agreement for USACE's coastal zone consistency determination for maintenance dredging in San Francisco Bay. Although the condition in the Letter of Agreement was specific to longfin smelt, USACE's worker education program, overseen by a USACE regional fisheries biologist, also includes information on other special-status fish species that could be impacted by dredging activities (i.e., those fish species considered in the LTMS work windows).

<sup>17</sup> Under the No Action/No Project Alternative and Proposed Action/Project, San Bruno Channel in Redwood City Harbor would also be dredged with a hopper dredge; however, this channel is dredged at intervals of 10 years or greater and is in South San Francisco Bay, where longfin smelt occur in lower densities. The analysis focuses on the federal navigation channels that are dredged annually and where longfin smelt are more likely to occur.

Based on the administrative record and the discussion above, there is a significant impact to longfin smelt under CEQA. In addition, the Project includes 10 years of dredging operations, which, as proposed, and as summarized above, are likely to substantially reduce the number of longfin smelt. In addition to the project's impacts being individually significant, other activities are also causing significant take of longfin smelt, as described above. Therefore, the cumulative impacts of the No Project Alternative, considered with the impacts of other projects causing related impacts, are significant.

### Proposed Action/Project

Under the Proposed Action/Project, the dredge equipment type, frequency of dredging, and volumes dredged would be the same as under the No Action/No Project Alternative. Over the next 10 years, dredging and placement of dredged materials would be conducted in accordance with the conditions described under the No Action/Project Alternative to protect longfin smelt, as well as the following additional conditions identified in Section 2.3.3:

- Completing hydraulic dredging in the Central Bay later in the year (from August 1 to November 30) during the June-to-November environmental dredging window, to the extent feasible, to allow young-of-the-year longfin smelt to grow large and spawning adults to return upstream;
- Completing hydraulic dredging in Suisun Bay between August 1 and September 30, to the extent feasible, to avoid impacts to spawning adult longfin and delta smelt;
- Maintaining contact of drag head, cutterheads, and pipeline intakes with the seafloor during suction dredging;<sup>18</sup> and
- Closing the drag head water intake doors in locations most vulnerable to entraining or entrapping smelt. In circumstances when the doors need to be opened to alleviate clogging, the doors would be opened incrementally (i.e., the doors would be opened in small increments and tested to see if the clog is removed) to ensure that doors are not fully opened unnecessarily. It may take multiple iterations to fine tune the exact intake door opening necessary to prevent clogging. For each project, the intake door opening will be different because the sediment in each location is different. The sediment physical characteristics (e.g., sand versus mud) determine how much water is needed to slurry the sediment adequately. Typically, the drag arms do not clog when dredging areas composed mostly of sand.

These measures would reduce the likelihood of longfin smelt being present during dredging, and the potential for longfin smelt to become entrained compared to the No Action/No Project Alternative.

The USACE would purchase 0.92 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species. The 0.92 acre mitigation credit was calculated from CDFW formula ( $3.0 \text{ million acre-feet} / 800 \text{ acres} = \text{volume dredged} * X \text{ acres of mitigation habitat}$ ) used by the Central Valley Water Project and State Water Project to determine the mitigation requirements for hydraulically pumping water from the Delta, which is considered adequate mitigation for the water projects. For volume dredged, available government-hopper-dredge-pumped water volumes for 2006 through 2012 were reviewed. The highest volume for each of the in-Bay channels (Pinole Shoal, Richmond Outer Harbor, and Suisun Bay Channel/New York Slough) from this period was used in the calculation. Of the 0.92 acre mitigation credit, 0.19 acre mitigation credit would be for Pinole Shoal, 0.34 acre mitigation credit would be for Richmond Outer Harbor, and 0.39 acre mitigation credit would

<sup>18</sup> The seafloor surface is not uniform and is undulating, which could cause the drag head to loose contact with the seafloor. The hopper dredge also has to contend with sea state (i.e., swells and wave action) in the bay which also affects the drag heads contact with the channel bottom. The dredge's swell compensator provides an opposing force to maintain contact with the seafloor when the bottom is uneven or there is wave/swell action.

be for Suisun Bay Channel and New York Slough. The 0.92 acre mitigation credit per year is expected to be more than the credit needed based on actual future annual maintenance dredging volumes.

The LTMS work windows do not currently include seasonal avoidance measures for longfin smelt. Longfin smelt is not a federally listed species under the ESA.

Because dredging of the Bulls Head Reach may occur at any time of year, longfin smelt would likely be entrained during some dredging episodes when a hopper dredge is used. The potential for entrainment would be reduced with the use of a mechanical dredge. Because the extent and frequency of critical dredging episodes cannot be predicted, appropriate mitigation for these episodes, if warranted based on expected impacts, would be determined in coordination with regulatory agencies at time they occur.

**NEPA Determination.** Although longfin smelt could be entrained by hopper dredging, the anticipated entrainment is not expected to result in substantial declines in longfin smelt populations. Impacts would be reduced, compared to the No Action Alternative, by the additional minimization measures and compensatory mitigation under the Proposed Action. In its March 14, 2014, letter to the Regional Water Board, CDFW indicated that the proposed 0.92 acre mitigation credit of restored and managed tidal wetlands per year as compensatory mitigation to reduce impacts to fish is generally consistent with mitigation to other projects that cause take of longfin smelt associated with water diversions and extraction. Therefore, with the proposed minimization measures and compensatory mitigation, it is expected that the Proposed Action would result in a less-than-significant impact on longfin smelt. Although the project could contribute to cumulative impacts on longfin smelt, the project's contribution, compared to that from water export facilities and other factors, to cumulative impacts would not be significant.

**CEQA Determination.** The ERDC entrainment modeling study, using 2011 entrainment monitoring data, estimated the annual range of entrainment due to hydraulic hopper dredging to be 3,848 to 10,260 longfin smelt, or approximately 3 to 8 percent of the median annual population abundance. According to CDFW annual abundance indices from the fall mid-water trawl surveys from 1967 to 2013, the population of longfin smelt has declined 99 percent or more in the last 45 years, with record lows in the past decade. In a letter to the Regional Water Board dated March 14, 2014, the CDFW noted the above figures concerning entrainment, and stated that "the Project, as proposed, would substantially reduce the number of an endangered, rare, or threatened species."

Based on the administrative record and the discussion above, there is a significant impact to longfin smelt under CEQA. In addition, the Proposed Action includes ten years of dredging operations, which, as proposed, and as summarized above, are likely to substantially reduce the number of longfin smelt. In addition to the project's impacts being individually significant, other activities are also causing significant take of longfin smelt, as described above. Therefore, the cumulative impacts of this project, considered with the impacts of other projects causing related impacts, are significant.

### **Reduced Hopper Dredge Use Alternative 1**

Under this alternative, use of a hopper dredge for maintenance dredging of the federal navigation channels would be reduced, compared to the No Action/No Project Alternative and Proposed Action/Project. Under Reduced Hopper Dredge Use Alternative 1, a hopper dredge would only be used to dredge the MSC, and either the Richmond Outer Harbor or the Pinole Shoal Channel, annually.

The channel not selected as the additional hopper dredge channel (i.e., either Pinole Shoal or Richmond Outer Harbor) would be dredged with a mechanical dredge. Additionally, Suisun Bay Channel and New York Slough Channel would be dredged with a mechanical dredge under this alternative, instead of a hopper dredge; the potential exception being urgent action dredging of the Bulls Head Reach, which

could be conducted with either a mechanical or hopper dredge. All other dredging, placement activities, and minimization measures would be as described for the Proposed Action/Project.

Because reduced hopper use would not be implemented until fiscal year 2017, as described in Section 2.3.4, USACE would purchase 0.92 acre mitigation credit at Liberty Island Conservation Bank for potential impacts to listed species in fiscal years 2015 and 2016. Beginning in fiscal year 2017, the USACE would purchase 0.19 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species if Pinole Shoal is dredged with a hopper. If Richmond Outer Harbor is dredged with a hopper, USACE would purchase 0.34 acre mitigation credit at the Liberty Island Conservation Bank annually for potential impacts to listed species. This is expected to be more than the credit needed based on actual future annual maintenance dredging volumes.

As discussed above, mechanical dredges are unlikely to cause entrainment of longfin smelt, although hopper dredges are expected to entrain longfin smelt. A reduction in the use of hopper dredges in the Estuary under this alternative would reduce the effects to longfin smelt resulting from dredge entrainment. Because dredging of the Bulls Head Reach may occur at any time of year, longfin smelt would likely be entrained during some dredging episodes when a hopper dredge is used. The potential for entrainment would be reduced with the use of a mechanical dredge. Because the extent and frequency of critical dredging episodes cannot be predicted, appropriate mitigation for these episodes, if warranted based on expected impacts, would be determined in coordination with regulatory agencies at time they occur.

**NEPA Determination.** Although longfin smelt could be entrained by hopper dredging, the anticipated entrainment is not expected to result in substantial declines in populations. In its March 14, 2014, letter to the Regional Water Board, CDFW indicated that USACE's proposed compensatory mitigation is generally consistent with mitigation to other projects that cause take of longfin smelt. Therefore, with the proposed minimization measures and compensatory mitigation, it is expected that the proposed project would result in a less-than-significant impact on longfin smelt. Although the project could contribute to cumulative impacts on longfin smelt, the project's contribution, compared to that from water export facilities and other factors, to cumulative impacts would not be significant. Under Reduced Hopper Dredge Use Alternative 1, any project and cumulative impacts could be reduced compared to the No Action Alternative and Proposed Action, depending upon where longfin smelt are congregating when dredging occurs.

**CEQA Determination.** This Alternative reduces hopper dredging to one in-Bay channel per year, implements specific minimization measures, and provides compensatory mitigation for the one channel that is hopper-dredged. Hopper dredging of either Richmond Outer Harbor or Pinole Shoal as the sole in-Bay channel could result in a significant and unavoidable impact to longfin smelt, both individually and cumulatively with other activities causing take of longfin smelt over the 10-year life of the Project. This impact, however, would be mitigated to a less-than-significant level with minimizing hopper dredge use, as contemplated by this alternative, and with successful implementation of the proposed minimization measures and compensatory mitigation described above.

### **Reduced Hopper Dredge Use Alternative 2**

Under Reduced Hopper Dredge Use Alternative 2, a hopper dredge would only be used to dredge the MSC. Pinole Shoal, Richmond Outer Harbor, Suisun Bay Channel, and New York Slough Channel would be dredged with a mechanical dredge under this alternative, instead of a hopper dredge; the potential exception being urgent action dredging of the Bulls Head Reach in Suisun Bay Channel, which could be conducted with either a mechanical or hopper dredge. All other dredging, placement activities, and minimization measures would be as described for the Proposed Action/Project. Because reduced hopper use would not be implemented until fiscal year 2017, as described in Section 2.3.4, USACE would

purchase 0.92 acre mitigation credit at Liberty Island Conservation Bank for potential impacts to listed species in fiscal years 2015 and 2016.

As discussed above, mechanical dredges are unlikely to cause entrainment of longfin smelt, although hopper dredges are expected to entrain longfin smelt. Limiting the use of hopper dredges to the MSC would largely eliminate the potential adverse effects to longfin smelt resulting from dredge entrainment. Therefore, no compensatory mitigation is proposed for fiscal years 2017 through 2024.

Because urgent action dredging of the Bulls Head Reach may occur at any time of year, it is likely that some longfin smelt would be entrained during some dredging episodes when a hopper dredge is used. The potential for entrainment would be reduced with the use of a mechanical dredge. Because the extent and frequency of critical dredging episodes cannot be predicted, appropriate mitigation for these episodes, if warranted based on expected impacts, would be determined in coordination with regulatory agencies at time they occur.

**NEPA Determination.** With the elimination of hopper dredging inside San Francisco Bay, the potential for entrainment of longfin smelt would be largely eliminated under Reduced Hopper Dredge Use Alternative 2. Project and cumulative impacts would be less than significant.

**CEQA Determination.** This alternative eliminates hopper dredging inside San Francisco Bay, thus largely eliminating the potential for entrainment of longfin smelt. Project and cumulative impacts would be less than significant.

***Impact 3.6-7: Dredging and Placement Activities Could Result in the Disturbance of Essential Fish Habitat and "Special Aquatic Sites," Including Eelgrass Beds and Mudflats.***

**No Action/No Project Alternative, Proposed Action/Project, Reduced Hopper Dredge Use Alternatives 1 and 2**

All portions of the project area in the Estuary or Pacific Ocean are designated as EFH under one or more FMPs. The programmatic EFH agreement completed in 2011 includes a number of Conservation Measures that enhance the environmental protectiveness of the LTMS program. No further EFH consultation is required for USACE maintenance dredging in San Francisco Bay performed in accordance with the provisions established through the formal programmatic federal EFH consultations for the LTMS.

Eelgrass beds and mudflats are considered special aquatic sites, and are subject to jurisdiction under Section 404 of the CWA, and San Francisco Bay Conservation and Development Commission (BCDC) jurisdiction under Section 66605 of the McAttee-Petris Act. Additionally, eelgrass beds and estuarine areas such as San Francisco Bay are considered "habitat areas of particular concern" with regard to EFH designations.

Mudflats serve as important foraging areas for shorebirds species, and provide shallow water habitat for juvenile fish. No loss of mudflat acreage would occur as a result of maintenance dredging and placement activities. Sensitive habitats (such as marshes and mud flats) that occur in the vicinity of some of the federal navigation channels (e.g., Napa River) would not be disturbed.

Eelgrass in San Francisco Bay provides spawning habitat for herring, and serves as a nursery ground and shelter for juvenile fish, among other functions. Eelgrass has been identified as EFH for various life stages of fish species managed by FMPs under the Magnuson-Stevens Act, as established by NMFS. Although eelgrass does exist near the Richmond Inner Harbor Channel and Oakland Inner Harbor, there is no known eelgrass in any of the channel boundaries. Because these two locations would be dredged mechanically under all alternatives, there would be no difference in the turbidity generated by dredging, and impacts under all alternatives would be the same.

Eelgrass may be indirectly impacted by turbidity and increased sedimentation in areas adjacent to, or down current from, dredging operations. Turbidity plumes from dredging operations may temporarily reduce light penetration in waters adjacent to the plumes. Sediment near areas of dredging may settle on eelgrass blades and affect the viability of the eelgrass in beds adjacent to dredging operations. Eelgrass beds are easily affected by changes in water quality and turbidity, because their growth and survival is a direct function of light penetration in the water column. However, as discussed under Impact 3.6-1, turbidity effects from dredging are expected to be localized and short-term.

Examination of surveys done over the last 15 years indicates that eelgrass has persisted in essentially the same locations and densities around Richmond Harbor (USACE, 2012c). Pre- and post-surveys of eelgrass conducted at Oakland Harbor in 2010 and 2011 found an increase in eelgrass habitat area and in the density of existing beds, in comparison with several reference sites (Merkel & Associates, 2011 and 2012). These results indicate that there does not appear to be any adverse effect to, or decline in, eelgrass habitat as a result of annual maintenance dredging activities Richmond Harbor and Oakland Harbor.

Placement of dredged materials would not impact the Gulf of Farallones National Marine Sanctuary if placement takes place at SF-DODS; the barge route is south of the Sanctuary boundary to preclude scow spillage in the special aquatic site.

**NEPA Determination.** The project alternatives' potential impact on EFH or special aquatic sites, including eelgrass beds and mudflats, would be less than significant.

**CEQA Determination.** The project alternatives' potential impact on EFH or special aquatic sites, including eelgrass beds and mudflats, would be less than significant.

### ***Impact 3.6-8: Interference with the Movement of Resident or Migratory Fish or Wildlife Species During Dredging and Placement Activities***

#### **No Action/No Project Alternative, Proposed Action/Project, Reduced Hopper Dredge Use Alternatives 1 and 2**

No solid structures, such as breakwaters, are proposed; therefore, the project would not permanently interfere with the movement of resident or migratory fish or other wildlife species. To the extent that dredging activities impede migration because of entrainment, those impacts are discussed above in Impacts 3.6-4 through 3.6-6.

The noise and in-water disturbance associated with dredging and placement activities could cause fish and wildlife species to temporarily avoid the immediate dredging or placement area when work is being conducted. Placement activities can cause temporary displacement of fish from the vicinity of the placement site, especially during high-frequency placement activity (whether due to cumulative water quality effects or due to the physical disturbance of placement). Fish tend to exhibit avoidance behavior for about 2 to 3 hours after dredged material placement, and fish community densities generally return to pre-disposal levels after about 3 hours (ECORP, 2009). Localized effects of this type have been documented around the Alcatraz Island placement site (SF-11), where behavioral avoidance of the area by some fish species was seen to last from 2 to 3 hours following dredged material placement events (LTMS, 1998). Portions of the study area are major corridors used by fish and marine mammals as they move between different habitats in the open ocean, San Francisco Bay, and upstream tributaries. However, the affected area would be limited to the immediate dredging or placement zone, and would not substantially limit the available habitat or movement of fish, seabirds, or marine mammals. Impacts would be slightly greater, but still less than significant, under the reduced hopper dredge use alternatives, because mechanical dredges would be present up to ten times longer in areas previously typically dredged with a hopper, potentially causing migrating species to avoid the areas of dredging and the associated turbidity plumes for a longer period of time.

Salt marsh harvest mouse has been documented at MWRP and may be present at Cullinan Ranch. This species is not expected to be impacted by placement activities at these sites because dredged materials would be placed in a sterile area scraped clean of all growth and possible habitat. In accordance with their permits for receiving dredged materials, site operators for MWRP and Cullinan Ranch are responsible for coordinating protected species issues with resources agencies, and managing the placement of dredged materials at the placement sites in accordance with conditions of their permits and other regulatory approval.

Also, although it is highly unlikely that any salt marsh harvest mice occur at the upland Dredged Material Management Site near the San Leandro Marina, the dredge contractor would be trained to identify salt marsh harvest mice, and to do a spot check for these endangered mice when beginning each day's work; before moving or repositioning any materials or machinery; and before beginning to pipe the slurry into a settling pond. In the unlikely event that a salt marsh harvest mouse is found at the Dredged Material Management Site, work would be stopped until authorized personnel has removed the mouse from the project area. These are standard practices that USACE has implemented at the Dredged Material Management Site. No impacts are anticipated.

The City of San Leandro Municipal Code prohibits interference with monarch butterflies during the entire time they remain in the areas of the San Leandro Marina, Tony Lema Golf Course, and Marina Golf Course, in whatever spot therein they may choose to stop. There is a monarch overwintering site at the eastern end of the Monarch Bay Golf complex, where they congregate in large numbers from October through January. Project activities would not occur at the time of butterfly migration, or at the time of overwintering. However, consistent with USACE standard practices, the contractor would be instructed to ensure that dredging and disposal operations do not interfere with the monarch butterflies. Therefore, no impacts are anticipated.

**NEPA Determination.** The project alternatives' potential impact on the movement or migration of fish or wildlife species would be less than significant.

**CEQA Determination.** The project alternatives' potential impact on the movement or migration of fish or wildlife species would be less than significant.

### ***Impact 3.6-9: Dredging and Placement Activities Could Disturb Roosting and Foraging by Avian Species***

#### **No Action/No Project Alternative, Proposed Action/Project, Reduced Hopper Dredge Use Alternatives 1 and 2**

San Francisco Bay is an important stopover for many species of migratory waterfowl in the Pacific Flyway. Several of the federal navigation channels and existing placement sites are in areas where human activity is consistent and ongoing. Birds in these areas are accustomed to human activity and noise, including that from vessel traffic. Dredging temporarily may disturb foraging and resting behaviors, decrease time available for foraging, and increase energetic costs as a result of increased flight times and startling responses. Birds that might be found in or near the federal navigation channels or placement sites are highly mobile and can avoid the open water project activity. Indirect effects on waterbirds and shorebirds would occur from the temporary loss of intertidal community from dredged material placement in the nearshore zone at Ocean Beach, where temporary disruption to foraging patterns could occur. Any impact on food availability and foraging success as a result of increased turbidity in the water column and burial of the benthic community caused from placement will be short term and localized. Sediment placement (both in SF-8 and the Ocean Beach Disposal Site) has been a regular occurrence in the past four decades, and there has been very minimal disturbance to avian species recorded in this time period (USACE, 2013a). Additionally, it is expected that waterbirds and shorebirds would be able find other forage resources nearby. Therefore, birds are not expected to be adversely affected by dredging and placement activities.

**Least Tern.** There is insufficient monitoring data of California least tern use in Oakland Outer Harbor. It is known, however, that terns use a restoration site (i.e., the MHEA) in the middle harbor area of Oakland Harbor for foraging and roosting. Dredging the Oakland Entrance Channel and Outer Harbor shipping channels is not expected to impact tern activity in MHEA, but may temporarily deter terns from foraging in the Outer Harbor and Entrance Channel. The noise associated with the dredging would not be expected to substantially impact least terns, due to the ambient noise levels associated with the activity at the Port of Oakland (H.T. Harvey and Associates, 2012). Interviews with Alameda tern colony site biologists and researchers revealed that, based on observations, least tern adults and fledglings use MHEA in July annually for foraging and roosting (USACE, 2010). The LTMS work window for California least tern from within 1 mile of the coastline from the Berkeley Marina south to San Lorenzo Creek is August 1 through March 15 each year. In the event that USACE should need to dredge outside the LTMS work window for least tern in any year covered by this EA/EIR, USACE would initiate additional consultation with USFWS to obtain written authorization to work outside this window.

Because Montezuma Wetlands, LLC, is managing potential nesting habitat for the least tern outside of areas of MWRP that would be impacted by planned restoration activities, placement of dredged material at MWRP would not be expected to impact least tern. As stated in Section 3.6.2, it is the sole responsibility of Montezuma Wetlands, LLC, to coordinate with CDFW and USFWS on least tern issues for MWRP. Proposed dredged material placement actions for the site must first be in compliance with the ESA, and with other federal, state, and local wildlife protection laws before USACE can use MWRP as a beneficial use site for dredged material.

**Western Snowy Plover.** Beach nourishment at Ocean Beach would be designed not to interfere with the Snowy Plover Protection Area. If placement activities were to occur during the snowy plover season (July 1 through May 15), haul activities would be limited to a narrow corridor along the eastern edge of the Snowy Plover Protection Area—within 50 feet of the O’Shaughnessy Seawall between Stairwells 21 and 28. This travel corridor was determined by National Park Service biologist and Golden Gate Audubon Society representative Dan Murphy to be the best location for truck haul traffic to minimize interaction with snowy plovers (and other shorebirds), based on historical monitoring information and habitat preferences (SFPUC, 2012).

**Ridgway’s Rail.** Individual Ridgway’s rails may nest near the San Leandro Marina, in the adjacent salt marsh, and wander into or along Estudillo Canal immediately north of the Dredged Materials Management Site. In addition, Ridgway’s rails are known to be present within a tidal marsh near the San Rafael Creek Inner Canal Channel. The USFWS has indicated Ridgway’s rail may be sensitive to loud noise while it is nesting if the noise intensity is unusually high. For this reason, the USFWS Biological Opinion the LTMS Program specifies that dredging shall not occur within 250 feet of potential habitat for this species from February 1 through August 31. The USFWS considers all potential habitat to actually be occupied by this species unless surveys that year document its absence.

The proposed upland placement at the Dredged Materials Management Site would require laying pipe across an area that has the potential to house Ridgway’s rail nesting sites. Prior to dredging and placement activities, consistent with USACE standard practices, USACE will contract with ornithologists to conduct a survey for Ridgway’s rail nests. The survey would begin in February and be completed by mid-March, and would determine the best route for the pipe to go over the levee into the containment and overflow ponds without impacting any Ridgway’s -rail nesting sites. Installation of the dredged material pipeline would take place prior to the dredging episode. The pipe would be submerged, except for the portion that will cross the marsh into the containment pond. The contractor will adhere to all applicable environmental laws, regulations, and procedures specified in the contract with USACE. Therefore, no impacts to Ridgway’s rail are expected.

**Bank Swallow.** Beach nourishment at Ocean Beach would be designed not to interfere with nesting of the bank swallow. For instance, the sand would be placed to cover the existing revetment, and not extend to the

top of this bluff where the bank swallow nests may occur. In general, placement of dredged material at SF-17 is not expected to have differing effects from those annually occurring at SF-8 or the Ocean Beach Demonstration Site. Although the bankswallow colony overlaps with the southern 1,000 feet segment of the beach nourishment site, no sand is expected to be placed above the revetment area where the bank swallows nest. According to the National Park Service, bank swallows forage for invertebrates mainly over Lake Merced; therefore, no impacts to this species' foraging is expected (USACE, 2013a).

**NEPA Determination.** The project alternatives' impacts on avian roosting and foraging would be less than significant.

**CEQA Determination.** The project alternatives' impacts on avian roosting and foraging would be less than significant.

***Impact 3.6-10: Contaminated Sediments Could Become Resuspended During Dredging and Placement Activities, and Could Be Toxic to Aquatic Organisms, Including Plankton, Benthos, Fish, Birds, and Marine Mammals***

**No Action/No Project Alternative, Proposed Action/Project, Reduced Hopper Dredge Use Alternatives 1 and 2**

Dredging can disturb aquatic habitats by resuspending bottom sediments, thereby recirculating toxic metals, hydrocarbons, pesticides, pathogens, and nutrients into the water column. Any toxic metals and organics, pathogens, and viruses, absorbed or adsorbed to fine-grained particulates in the sediment may become biologically available to organisms either in the water column or through food chain processes. However, most contaminants are tightly bound in the sediments, and are not easily released during short-term resuspension. Most available studies suggest that there is no significant transfer of metal concentrations into the dissolved phase during dredging, even though release of total metals associated with the suspended matter may be large (Jabusch et al., 2008). Organic contaminants such as pesticides, polychlorinated biphenyls, and polyaromatic hydrocarbons are generally not very soluble in water, and direct toxicity by exposure to dissolved concentrations in the water column is not very likely (Jabusch et al., 2008).

Sediments are tested prior to dredging, and the results are reviewed by the Dredged Material Management Office (DMMO) prior to dredging and placement, including evaluation of the potential for impact to aquatic organisms. As described in Section 3.3.2, sediment testing results for previous USACE maintenance dredging episodes indicate that, in general, dredged materials from the subject federal navigation channels have been suitable for unconfined aquatic disposal. Over time, some isolated areas in or adjacent to the channels have been identified as containing sediment that is not suitable for unconfined aquatic disposal (NUAD); USACE would continue to avoid dredging areas (e.g., portions of the Richmond Harbor federal channel adjacent to the United Heckathorn site) that it has been able to avoid dredging in the past. If future testing identifies NUAD material that must be dredged, USACE would place all NUAD material at upland sites, and in some cases MWRP, as determined during DMMO review. The USACE would also implement sediment bioaccumulation testing, as detailed in the *Agreement on Programmatic EFH Conservation Measures for Maintenance Dredging Conducted Under the LTMS Program* (USACE and USEPA, 2011). Therefore, dredging and placement activities would not be expected to increase contaminant concentrations in the environment above baseline conditions.

As directed by the LTMS agencies, a study on the short-term water quality impacts of dredging and dredged material placement on sensitive fish species in San Francisco Bay was completed by the San Francisco Estuary Institute (Jabusch et al., 2008). The review considered five fish species: Chinook salmon, coho salmon, delta smelt, steelhead trout, and green sturgeon. Water quality impacts of concern include dissolved oxygen reduction, pH decrease, and releases of toxic components such as heavy metals, hydrogen sulfide, ammonia, and organic contaminants (including polyaromatic hydrocarbons, polychlorinated biphenyls, and pesticides). Potential short-term effects include acute toxicity, subacute toxicity, and biological and other

indirect effects, such as avoidance. The study concluded that direct short-term effects on sensitive fish by contaminants associated with dredging plumes are minor. The study identified a need to better study the potential of ammonia releases during dredging in San Francisco Bay.

Ammonia toxicity studies have been done in freshwater, but none have been done replicating estuarine conditions. Under freshwater conditions, swimming performance was adversely affected. Slower swimming speeds and reaction times would make fish more vulnerable to predation. Saltwater-adapted species are believed to be more susceptible to ammonia, because their gills are more permeable to ammonia (Jabusch et al., 2008). Ammonia found in sediments is mostly attributable to bacterial action on decaying organic matter. Aside from the natural production of ammonia by decomposition of organic material, there are other contributors, such as waste water treatment facilities, fertilizers, and livestock wastes, that enter into San Francisco Bay. Since 1968, the United States Geological Survey (USGS) has been studying ammonia concentrations in San Francisco Bay. The results of these studies show ammonia concentrations declining dramatically after implementation of improved wastewater-treatment methods mandated by state and federal legislation. One result of the implementation of these improved methods has been a large reduction in the input of ammonia-nitrogen from some municipal wastewater-treatment facilities. According to the USGS, advanced wastewater treatment in 1979 immediately reduced the input of ammonia-nitrogen to South San Francisco Bay (USGS, 1997). In prior decades, the South San Francisco Bay had repeated episodes of oxygen depletion and animal die-offs. USGS measurements have shown a complete cessation of these episodes since 1980 (USGS, 1997). Yearly dredging activities have likely limited the accumulation of organic material in the federal navigation channels, therefore limiting the amount of ammonia produced by the decomposition actions of microorganisms. Considering the facts that San Francisco Bay no longer suffers from the condition of elevated background levels of ammonia; most aqueous ammonia is metabolized to nitrates and used by microorganisms; and the federal channels are regularly dredged, limiting the accumulation of organic material, the amount of ammonia released by maintenance dredging is expected to be minimal and the consequent effects short term and minor.

Dredging, transport, and placement of dredged material would be conducted in cooperation with the DMMO. This process would identify contaminated sediments and appropriate placement site options for dredged materials, based on the characteristics of the sediment and criteria for each placement site. Additionally, USACE would implement BMPs and comply with water quality protection measures included as conditions to the Water Quality Certification issued by the Regional Water Board and the letter of agreement issued by the BCDC for USACE's consistency determination. The USACE would also implement sediment bioaccumulation testing in accordance with the LTMS Programmatic EFH agreement. Adherence to these measures and BMPs would minimize the potential for water quality degradation that could impact aquatic organisms.

**NEPA Determination.** The project alternatives' potential impacts would be less than significant.

**CEQA Determination.** The project alternatives' potential impacts would be less than significant.

### ***Impact 3.6-11: Dredging and Placement Could Substantially Increase the Spread of Invasive Nonnative Species***

#### **No Action/No Project Alternative, Proposed Action/Project, Reduced Hopper Dredge Use Alternatives 1 and 2**

Under all alternatives, dredging vessels would come from areas outside of the study area. There is the potential that nonnative species could be introduced to San Francisco Bay. Larval forms of nonnative species can be carried in the ballast water of vessels, and if ballast water is released in San Francisco Bay, larvae can be introduced into the San Francisco Bay ecosystem. The United States Coast Guard has mandatory regulations in effect that require ships carrying ballast water to have a ballast water management and reporting program in place and, without jeopardizing the safety of the crew, exchange ballast water with

mid-ocean water or use an approved form of ballast water treatment, prior to releasing any ballast water in a port in the United States. Dredge equipment would comply with these regulations, as applicable.

Beneficial reuse and upland placement site operators are responsible for managing the placement of dredged materials at the placement sites in accordance with conditions of their permits and other regulatory approval, which include measures to minimize the spread of invasive nonnative species.

Therefore, project activities would not be expected to substantially increase the spread of invasive nonnative species.

**NEPA Determination.** The project alternatives' potential to substantially increase the spread of invasive nonnative species would be less than significant.

**CEQA Determination.** The project alternatives' potential to substantially increase the spread of invasive nonnative would be less than significant.

### Cumulative Impacts

#### ***Impact 3.6-12: Potential to Result in Cumulative Impacts on Biological Resources, Not Including Entrainment Impacts on Delta Smelt and Longfin Smelt<sup>19</sup>***

Under all alternatives, maintenance dredging and placement of dredged materials would have adverse effects on biological resources, including temporary impacts to foraging and species health due to temporary increases in turbidity; disturbance of benthic habitat; temporary loss or reduction of habitat suitable for sensitive fish species; alteration of behavior of marine mammals and birds; and potential exposure to contaminants in resuspended sediments. Other dredging projects and waterfront construction projects listed in Table 3.1-1 would also involve activities that could result in similar impacts. These activities could cumulatively impact biological resources by impacting water quality and habitat. The USACE would comply with existing regulations, requirements, and conditions in permits approvals from NMFS, USFWS, the Regional Water Board, and BCDC for dredging, which would minimize and/or avoid adverse impacts associated with dredging. Additionally, other projects involving dredging and construction in the marine environment would be subject to permitting/regulatory approval processes similar to those for the proposed project, and would be required to implement similar measures to minimize water quality and biological impacts.

**NEPA Determination.** The proposed project would not contribute to significant cumulative impacts on biological resources.

**CEQA Determination.** The proposed project would not contribute to significant cumulative impacts on biological resources.

---

<sup>19</sup> Cumulative impacts related to entrainment of delta smelt and longfin smelt are discussed under Impacts 3.6-5 and 3.6-6, respectively.

### **3.7 CULTURAL AND PALEONTOLOGICAL RESOURCES**

This section describes existing conditions for cultural and paleontological resources, including applicable plans and policies, and evaluates the potential impacts to these resources from implementation of the alternatives. Because the project alternatives neither propose demolition of existing structures nor introduce elements that could affect the historic setting of the built environment, only the potential effects of project implementation to archaeological and paleontological resources are considered in this analysis.

#### **3.7.1 Regulatory Setting**

##### **Federal**

##### **National Historic Preservation Act, as Amended**

The National Historic Preservation Act (NHPA) declares federal policy to protect historic sites and values, in cooperation with other nations, states, and local governments. Subsequent amendments designated the State Historic Preservation Officer as the individual responsible for administering state-level programs. The act also created the President's Advisory Council on Historic Preservation (ACHP). Federal agencies are required to consider the effects of their undertakings on historic resources, and to give the ACHP a reasonable opportunity to comment on those undertakings. Federal agencies are required by statute to "take into account" the effects of their actions and undertakings on "historic properties." A historic property is the federal term that refers to cultural resources (e.g., prehistoric or historical archaeological sites, maritime historical resources including shipwrecks, buildings and structures on the shore or in the water, and cultural artifacts) that are 50 or more years old, possess integrity, and meet the criteria of the National Register of Historic Places (NRHP). The NRHP eligibility criteria are found at 36 C.F.R. § 60.4. A lead federal agency is responsible for project compliance with Section 106 of the NHPA and its implementing regulations, set forth by the ACHP at 36 C.F.R. pt. 800. As detailed further in this section, because there are no known historical resources at the federal navigation channels or existing placement sites that could be impacted by the project alternatives, the United States Army Corps of Engineers (USACE) has no further obligations under Section 106 of the NHPA.

##### **National Environmental Policy Act**

Under the National Environmental Policy Act, 42 U.S.C. §§ 4321-4327, federal agencies are required to consider potential environmental impacts—including those to cultural resources—and appropriate mitigation measures for projects with federal involvement. This document has been prepared in compliance with National Environmental Policy Act (NEPA) and Council on Environmental Quality regulations.

##### **Submerged Lands Act**

The Submerged Lands Act established state jurisdiction over offshore lands within 3 miles of shore (or 3 marine leagues for Texas and the Gulf Coast of Florida). The act did reaffirm the federal claim to the Outer Continental Shelf, which consists of those submerged lands seaward of state jurisdiction. However, the act limited states' claims to the submerged lands inside the landward boundary of the Outer Continental Shelf. Several federal courts rejected, for various reasons, state positions on historic preservation laws that pertained to shipwrecks within this 3-mile zone. Judicial conclusions from cases involving the Submerged Lands Act were inconsistent, yet shipwrecks in state waters were still at risk from damage and destruction. These circumstances provided the momentum for the passage of the Abandoned Shipwreck Act, which largely superseded the Submerged Lands Act. In compliance with this act, the California State Land Commission (CSLC) will receive a copy of this Environmental Assessment/

Environmental Impact Report and will have the opportunity to comment on its potential impacts to submerged lands.

### **Abandoned Shipwreck Act**

The Abandoned Shipwreck Act, 43 U.S.C. §§ 2101–2106, is a federal legislative act, but does protect shipwrecks found in state waters. The Abandoned Shipwreck Act also states that the laws of salvage and finds do not apply to abandoned shipwrecks protected by the act. Under the Abandoned Shipwreck Act, the United States asserts title to abandoned shipwrecks in state waters that are either:

- Embedded in state-submerged lands;
- Embedded in the coralline formations protected by a state on submerged lands; or
- Resting on state-submerged lands and are either included in or determined eligible for the NRHP.

The Abandoned Shipwreck Act also has a provision for the simultaneous transfer, by the federal government, of title for those abandoned shipwrecks to the state(s) in whose waters the wrecks are located. As detailed further in this section, because there are no known shipwrecks within the federal navigation channels or existing placement sites, no impacts are expected to result from the project alternatives.

## **State**

### **California Environmental Quality Act**

In California, cultural resources include archaeological and historical objects, sites and districts, historic buildings and structures, cultural landscapes, and sites and resources of concern to local Native American and other ethnic groups. Compliance procedures are set forth in California Environmental Quality Act (CEQA) Sections 15064.5 and 15126.4.

Section 15064.5 of CEQA also assigns special importance to human remains, and specifies procedures to be used when Native American remains are discovered. These procedures are detailed under California Public Resources Code (PRC) Section 5097.98.

CEQA also requires evaluation if a project will directly or indirectly destroy a unique paleontological resource, site, or unique geological feature. This document is intended to fulfill the requirements set forth in the CEQA Guidelines.

### **California Public Resources Code, Section 5097.9**

PRC Section 5097.9 details procedures to be followed for whenever Native American remains are discovered. It states that no public agency, and no private party using or occupying public property, or operating on public property, under a public license, permit, grant, lease, or contract made on or after July 1, 1977, shall interfere with the free expression or exercise of Native American religion as provided in the United States Constitution and the California Constitution. It further states that no such agency or party shall cause severe or irreparable damage to any Native American sanctified cemetery, place of worship, religious or ceremonial site, or sacred shrine on public property, except on a clear and convincing showing that the public interest and necessity so require. This document recognizes the potential for inadvertent discovery of such resources, and proposes mitigation for the treatment of human remains and associated or unassociated funerary objects discovered during any soil-disturbing activity.

### **California Public Resources Code, Section 7050.5**

Every person who knowingly mutilates or disinters, wantonly disturbs, or willfully removes any human remains in or from any location other than a dedicated cemetery without authority of law is guilty of a

misdeemeanor, except as provided in Section 5097.99 of the PRC. In the event of discovery or recognition of any human remains in any location other than a dedicated cemetery, the PRC states that there shall be no further excavation or disturbance of the site, or any nearby area reasonably suspected to overlie adjacent remains, until the coroner of the county in which the human remains are discovered has determined the remains to be archaeological. If the coroner determines that the remains are not subject to his or her authority, and if the coroner recognizes the human remains to be those of a Native American or has reason to believe that they are those of a Native American, he or she shall contact the Native American Heritage Commission by telephone within 24 hours. This document recognizes the potential for inadvertent discovery of human remains, and proposes mitigation for the treatment of human remains discovered during any soil-disturbing activity.

### **California Public Resources Code, Section 7051**

PRC Section 7051 states that it is a public offense to remove any part of any human remains from any place where it has been interred, or from any place where it is deposited while awaiting interment or cremation, with intent to sell it or to dissect it, without authority of law, or written permission of the person or persons having the right to control the remains under Section 7100, or with malice or wantonness. This document recognizes the potential for inadvertent discovery of human remains, and proposes mitigation for the treatment of human remains discovered during any soil-disturbing activity.

### **Administrative Code, Title 14, Section 4307**

Under this state preservation law, no person shall remove, injure, deface, or destroy any object of paleontological, archaeological, or historical interest or value. As detailed further in this section, because there are no known paleontological, archaeological, or historical resources within the federal navigation channels or existing placement sites, no impacts are expected to result from the project alternatives.

## **3.7.2 Environmental Setting**

The USACE has established policy and procedures for conducting underwater surveys for maintenance dredging and disposal activities (Dredging Guidance Letter No. 89-01, USACE, March 13, 1989). The USACE is directed to make a reasonable and good faith effort to identify submerged cultural resources that may be affected by project implementation. Typically, the review of project documents and research of historical records and other sources is sufficient to determine what the potential is for submerged sites to be present and whether there would be an effect. The policy states that underwater surveys to identify archaeological sites are not required within the boundaries of previously dredged channels or previously used disposal areas unless USACE determines that there is a good reason to believe that such resources exist, and that they would be altered or destroyed as a result of project implementation.

There are two types of cultural resources of interest for the project: (a) archaeological sites from Native American settlement that may be situated on the shoreline or submerged beneath the waters of San Francisco Bay, or on the continental shelf as a result of post-Ice Age rise in sea levels, and (b) vessels that have sunk offshore, and shoreline structures associated with the historic-era maritime industry. The investigation for this project consisted of reviewing the environmental documents from previous dredging projects, reviewing archaeological literature and survey reports, and reviewing information on shipwrecks produced by the CSLC.

### **Historic Maritime Background**

In San Francisco Bay, the study area spans the shoreline and marine areas of the following 11 counties: Marin, Sonoma, Napa, Solano, Sacramento, San Joaquin, Contra Costa, Alameda, Santa Clara, San Mateo, and San Francisco. It does not include the landside areas far removed from navigable waters. The geographic scope of the study area comprises the estuarine waters of the San Francisco Bay region,

portions of the Sacramento-San Joaquin Delta west of Sherman Island, and the western portion of the Sacramento River Deep Water Ship Channel and Stockton Deep Water Ship Channel. Outside the Golden Gate, the study area includes the San Francisco Deep Ocean Disposal Site (SF-DODS), the San Francisco Bar Channel Disposal Site (SF-8), and the nearshore zone off Ocean Beach, as well as the waters that are used by vessels en route to these sites. As such, the cultural setting is presented with a maritime focus. Although it is well-documented that aboriginal inhabitants of the region used watercraft constructed of tule (Levy, 1978:406), given the poor preservation qualities of this material, it is not anticipated that such craft remain preserved in the submarine environment. As such, only a discussion of historic-period maritime activities that could manifest in the archaeological record is provided.

**The Hispanic Period.** Jose de Ortega may have observed the entrance to San Francisco Bay in 1769; however, the first undisputed identification of the entrance by nonnative peoples occurred on November 28, 1770, by the expedition of Pedro Fages. Entry into San Francisco Bay from the sea first occurred in August of 1775, when Juan Manuel de Ayala began his 2-month-long nautical survey of San Francisco Bay aboard the San Carlos (Beck and Haase, 1974:17).

With Mexico's independence from Spain in 1821, previous trade restrictions enforced by the Spanish were relaxed. Merchant vessels from the United States and Europe began freely entering San Francisco Bay. In addition to the merchant vessels, an occasional whaler or man-of-war would enter San Francisco Bay to restock provisions, including wood, food, and water (Kemble, 1957:1).

**American Period.** With the discovery of gold at Sutter's Mill in 1848, ship traffic into San Francisco Bay increased dramatically. By July 1850, more vessels entered San Francisco Bay than departed. Some 500 ships, inside and outside the anchorage, lay abandoned by their crews, who had deserted them in hopes of finding a better life, mostly in the gold fields.

San Francisco became a major city and port almost overnight, and grew at a phenomenal rate, replacing Monterey as the coast's principal port. Maritime traffic arrived through three major shipping channels approaching San Francisco. These lanes converge outside the Golden Gate to form the single channel entering San Francisco Bay. Through this channel came lumber schooners from the Mendocino coast, along with sealers, whalers, fishermen, traders, and passenger ferries. Large docks were built so that cargo could be discharged directly onto the wharves instead of being ferried to shore by rowboats. From those docks, the cargo was distributed and sometimes reloaded onto smaller vessels to transport to various settlements.

In the 1850s, commercial fishing in San Francisco Bay began with whaling and salmon fishing. Throughout California's coastal waters, shrimp were harvested and sold. After 1870, shrimp fishing evolved into a major industry along the shores of San Pablo and San Francisco bays. Approximately 26 fishing camps or villages have been recorded in this region. During the 1870s, a significant expansion of the fishing industry occurred due to the increased immigration of fisherman from Italy, Greece, China, and Portugal (Hart, 1978).

Ferry enterprises traveling to Oakland, San Pablo Bay, and San Francisco flourished during the late nineteenth century and the first half of the twentieth century. San Francisco Bay was a transportation corridor for both local and international traffic. During the early part of the American period, the ferries united the sparsely populated rural communities and ranches with San Francisco. By the early 1870s, the railroad companies owned the ferries operating on San Francisco Bay. As communities in the area grew larger, local trade produced a demand for more frequent ferry schedules and for inter-urban lines to feed the ferry terminals. Despite all this success, the needs of the San Francisco Bay Area were rapidly changing. Most ferry service ceased in 1939 with the completion of several bridges spanning San Francisco Bay, and the opening of the Bay Bridge to electric trains.

## Shipwrecks

The title to all abandoned shipwrecks, archaeological sites, and historic or cultural resources on or in the tide and submerged lands of California is vested in the State and under the jurisdiction of the CSLC. The online CSLC Shipwreck Database is a list of shipwrecks by county, and is based primarily on historical accounts of these incidents. It should be noted that most of the location data thus refer to where the ship went down, and not necessarily where it came to rest on the sea floor, which may be in a different location. These data are therefore not to be interpreted as definitive resource locations, only potential resource locations in the vicinity of various project components. The database indicates 43 shipwrecks in the vicinity of several of the project components (Table 3.7-1). Figure 3.7-1 depicts the location of the reported shipwrecks.

It should be noted that the CSLC database does not indicate whether the wrecked vessel was ultimately salvaged. Vessels close to the shoreline would likely have been salvaged or demolished, to minimize navigational hazards to the ship traffic. Furthermore, repeated dredging has historically taken place in the study area to accommodate facilities and historic ship traffic; this dredging would have likely dislodged any remnants of these vessels.

## Paleontological Setting

Paleontological resources are fossils (the remains of ancient plants and animals) and trace fossils (such as burrows or tracks) that can provide scientifically significant information on the history of life on earth. Assessments of the scientific significance of these remains are based on whether they can provide data on the taxonomy and phylogeny of ancient organisms, the paleoecology and nature of paleoenvironments in the geologic past, or the stratigraphy and age of geologic units.

The San Francisco Bay region contains a diverse record of geologic and biologic history, which spans more than 100 million years, dating from the Upper Cretaceous period. Under the combined influences of regional tectonic events ranging from creation of the Sacramento Basin to uplift of the Coast Range foothill region, deposition of sedimentary sequences and fluctuating worldwide sea level changes, fossils of marine and terrestrial organisms have accumulated to produce a significant record of prehistoric life.

Much of the paleontological interest in San Francisco Bay stems from the well-known discoveries of Pleistocene age (10,000 to 1 million years ago) fossil vertebrate faunas derived from Quaternary age units (present to 1 million years ago) in other parts of the San Francisco Bay region. Identification and scientific description of both of these diverse fossil vertebrate assemblages provides one of the best-known records of Pleistocene faunas in California (Stirton, 1939, 1951; Savage, 1951; Wolf, 1971; and Jefferson, 1991). Preservation of specimens buried by estuarine and river sediments and other continental volcanoclastic deposits provided favorable conditions for preserving vertebrate fossil remains in these geologic units.

### 3.7.3 Methodology and Thresholds of Significance

This section presents federal and state criteria used to determine the significance of cultural resources; federal and state criteria used to evaluate impacts to cultural resources; and criteria for evaluating impacts to paleontological resources.

## Significance Criteria for Evaluation of Cultural Resources

### Federal Significance Criteria

The four evaluation criteria to determine a resource's eligibility to the NRHP, in accordance with the regulations outlined in 36 C.F.R. pt. 800, are identified at 36 C.F.R. § 60.4. These evaluation criteria, listed below, are used to determine what properties should be considered for protection from destruction or impairment resulting from project-related activities (36 C.F.R. § 60.2).

**Table 3.7-1  
Shipwreck Data from the State Lands Commission Database**

<b>Channel/ Placement Site</b>	<b>Ship Name</b>	<b>Year Sunk</b>	<b>County</b>	<b>Latitude</b>	<b>Longitude</b>
Oakland Harbor	<i>Whitesboro</i>	NA	Alameda	37deg 47'20"N	122deg 15'40"W

**URS**

**FIGURE 3.7-1**

The quality of significance in American history, architecture, archaeology, engineering, and culture is present in districts, sites, buildings, structures, and objects that possess integrity of location, design, setting, materials, workmanship, feeling, and association, and:

- a. Resources that are associated with events that have made a significant contribution to the broad patterns of our history; or
- b. Resources that are associated with the lives of persons significant in our past; or
- c. Resources that embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction; or
- d. Resources that have yielded, or may be likely to yield, information important in prehistory or history (36 C.F.R. § 60.4).

### **State Significance Criteria**

At the state level, consideration of significance as a “historical resource” is measured by cultural resource provisions considered under CEQA Sections 15064.5 and 15126.4, and the criteria regarding resource eligibility to the California Register of Historical Resources (CRHR).

Generally under CEQA, a historical resource (these include built-environment historic and prehistoric archaeological resources) is considered significant if it meets the criteria for listing on the CRHR. These criteria are set forth in CEQA Section 15064.5 and defined as any resource that:

- a. Is associated with events that have made a significant contribution to the broad patterns of California’s history and cultural heritage;
- b. Is associated with lives of persons important in our past;
- c. Embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of an important creative individual, or possesses high artistic values; or
- d. Has yielded, or may be likely to yield, information important in prehistory or history.

Section 15064.5 of CEQA also assigns special importance to human remains and specifies procedures to be used when Native American remains are discovered. These procedures are detailed under California PRC Section 5097.98.

“Unique” archaeological resources are also considered under CEQA, as described under PRC 21083.2. A unique archaeological resource implies an archaeological artifact, object, or site about which it can be clearly demonstrated that—without merely adding to the current body of knowledge—there is a high probability that it meets one of the following criteria:

- a. The archaeological artifact, object, or site contains information needed to answer important scientific questions, and there is a demonstrable public interest in that information;
- b. The archaeological artifact, object, or site has a special and particular quality, such as being the oldest of its type or the best available example of its type; or
- c. The archaeological artifact, object, or site is directly associated with a scientifically recognized important prehistoric or historic event or person.

A nonunique archaeological resource indicates an archaeological artifact, object, or site that does not meet the above criteria. Impacts to nonunique archaeological resources and resources that do not qualify for listing on the CRHR receive no further consideration under CEQA.

### Conformity of Federal and State Evaluation Criteria

The criteria for eligibility for the CRHR are very similar to those that qualify a property for the NRHP. A property that is eligible for the NRHP is also eligible for the CRHR. All potential impacts to significant resources under a federal agency must be assessed and addressed under the procedures of Section 106 of the NHPA, set forth at 36 C.F.R. pt. 800.

### Criteria for Evaluation of Cultural Resource Impacts

The criteria for determining an adverse effect under Section 106 of the NHPA are applied to assess what impacts a federal undertaking (i.e., federal action) would have on the historic integrity of a historic property, and how the undertaking would affect those features of a historic property that contribute to its eligibility for listing in the NRHP. Similarly, the criteria of significant impacts to historic resources under CEQA are applied to assess a project's impacts on the historic integrity of a historical resource, and whether the project impacts would materially impair the historical significance of the resource.

The federal definition of effect is contained in 36 C.F.R. pt. 800: “*Effect* means alteration to the characteristics of a historic property qualifying it for inclusion in or eligibility for the National Register.” An *adverse effect* occurs “when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property’s location, design, setting, materials, workmanship, feeling, or association . . . Adverse effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance, or be cumulative.”<sup>1</sup>

The California Code of Regulations, beginning with 15064.5(b), defines significant impacts for historical resources as: “[S]ubstantial adverse change in the significance of a historical resource means physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of a historical resource would be materially impaired.”

In addition to those cultural resources determined eligible for listing to the NRHP and/or CRHR, CEQA (Section 15064.5) also contains provisions for the treatment of human remains (PRC Section 5097.98) and “unique” archaeological resources (PRC Section 21083.2).

Therefore, the analysis of impacts to cultural resources considers whether the project would:

- Result in a substantial adverse change in the significance of a historical resource (NRHP and/or CRHR Listed, or Eligible to be Listed), or a unique archaeological resource as defined under California PRC Section 21083.2; or
- Result in disturbance of any human remains, including those interred outside of formal cemeteries as considered under PRC Section 5097.9.

As stated at the beginning of this section, the project alternatives neither propose demolition of existing structures nor introduce elements that could affect the historic setting of the built environment. Therefore, there would be no potential for impacts to historic architectural resources, and such impacts are not further addressed in this analysis.

---

<sup>1</sup> 36 C.F.R. § 800.5(a)(1).

## Criteria for Evaluation of Paleontological Resource Impacts

Assessments of the scientific significance of paleontological remains are based on whether they can provide data on the taxonomy and phylogeny of ancient organisms, the paleoecology and nature of paleoenvironments in the geologic past, or the stratigraphy and age of geologic units. Significant paleontological resources are defined in this analysis to include the interpretation outlined by the Society of Vertebrate Paleontology (SVP) (SVP, 1994), wherein vertebrate fossils are considered significant.

The evaluation of impacts on paleontological resource is conducted consistent with the standards and guidelines recommended for the assessment and mitigation of impacts to paleontological resources recommended by the SVP (SVP, 1995). Therefore, the analysis of impacts to paleontological resources considers whether the project would result in disturbance or destruction of a sensitive and/or unique paleontological resource or site.

### 3.7.4 Impacts and Mitigation Measures

Under all alternatives, USACE would continue to conduct maintenance dredging, transport of dredged materials, and placement of dredged materials. Dredged material transport would not involve sediment disturbance, and would therefore not be expected to disturb archaeological or paleontological resources. Therefore, the area of potential effects is limited to the federal navigation channels and placement sites.

#### ***Impact 3.7-1: Substantial Adverse Change to a Historical Resource or Disturb Unique Archaeological Resources***

#### **No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

It has been generally accepted that the initial construction of shipping lanes and maneuvering areas and the repeated maintenance dredging of these areas alter the seafloor to a point that submerged cultural resources, if present prior to the work, would be severely damaged or destroyed. Maintenance dredging that would occur under all alternatives would be confined to the removal of sediments accumulated since the last dredging effort. Sediments deposited since the previous dredging activities would not contain *in situ* archaeological resources. Furthermore, given the extent of past dredging in the channels, the likelihood of any intact remains in these areas is negligible.

The dredged material would be placed at existing placement sites on previously placed dredged material. Therefore, placement activities would not result in impacts to historical resources or unique archaeological resources, because the underlying native deposits would not be disturbed. The USACE would not use future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation and mitigation of archaeological impacts.

Per 36 C.F.R. pt. 800.3(1), because there are no known historical resources at the federal navigation channels or existing placement sites that could be impacted by the project alternatives, USACE has no further obligations under Section 106 of the NHPA.

Although unlikely, given the repeated dredging and dredged material placement activities that have historically occurred at the federal navigation channels and existing placement sites, there remains the potential that archaeological materials could be inadvertently uncovered by project activities. Such inadvertently discovered archaeological materials could represent historical resources or unique archaeological resources, and their disturbance could adversely change their condition. As such, the inadvertent discovery of archaeological materials represents a potential project impact. Implementation of Mitigation Measure CUL-1, Inadvertent Archaeological Discovery Measures, would reduce potential

impacts to archaeological material by identifying the procedures to be followed by USACE in the event archaeological resources are inadvertently exposed during project activities.

**Mitigation Measure CUL-1: Inadvertent Archaeological Discovery Measures**

To avoid potential adverse effects on inadvertently discovered NRHP- and/or CRHR-eligible or unique archaeological resources, should any indication of an archeological resource, including—but not limited to—encountering fragments of bone, stone tools, structural remains, ship remnants, or historic refuse during any soil-disturbing activity of the project, USACE will immediately suspend any soils-disturbing activities in the vicinity of the discovery.

In the event of such a discovery, USACE will consult a qualified archaeologist. The archaeologist will advise USACE as to whether the discovery is an archaeological resource that retains sufficient integrity and is of potential scientific/historical/cultural significance. If an archaeological resource is present, the archaeologist will identify and evaluate the archaeological resource. The archaeologist will make a recommendation to USACE as to what action or additional measures, if any, are warranted.

Measures might include: an archaeological monitoring program, or an archaeological evaluation program. If an archaeological resource cannot be avoided by project activities, the archaeologist will prepare an Archaeological Evaluation Plan (AEP). The AEP will create a program to determine the potential of the expected resource to meet the NRHP and CRHR criteria, and the archaeologist will submit this plan to USACE for approval. The archaeologist will then conduct an evaluation consistent with the USACE-approved AEP. The methods and findings of the evaluation will be presented in an Archaeological Evaluation and Effects Report, which will be submitted to USACE for review upon completion.

**NEPA Determination:** Under all alternatives, the inadvertent discovery of archaeological materials during project activities represents a potential impact; however, implementation of Mitigation Measure CUL-1 would reduce the potential to result in impacts to archaeological resources to a less-than-significant level.

**CEQA Determination:** Under all alternatives, the inadvertent discovery of archaeological materials during project activities represents a potential impact; however, implementation of Mitigation Measure CUL-1 would reduce the potential to result in impacts to archaeological resources to a less-than-significant level.

***Impact 3.7-2: Disturb Human Remains, including those Interred Outside of Formal Cemeteries***

**No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

There are no known cemeteries, formal or otherwise, or other evidence of human internment in the federal navigation channels or existing placement sites. Furthermore, USACE would not use the future placement sites identified in Section 1.5.4 until appropriate environmental review and permitting are completed. Although unlikely, given the repeated dredging and dredged material placement activities that have historically occurred at the federal navigation channels and existing placement sites, there remains the potential that previously unidentified human remains could be inadvertently uncovered with project implementation. Such disturbance of human remains represents a potential project impact. Implementation of Mitigation Measure CUL-1, Inadvertent Archaeological Discovery Measures (above) and Mitigation Measure CUL-2, Treatment of Human Remains, would reduce potential impacts by identifying the procedures to be followed by the applicant in the event human remains are inadvertently exposed during project implementation.

**Mitigation Measure CUL-2: Treatment of Human Remains**

The treatment of human remains and associated or unassociated funerary objects discovered during any soil-disturbing activity will comply with applicable state laws. In the event the discovery is composed entirely of—or includes—human skeletal remains, construction activities will immediately cease and USACE’s project representative will immediately contact the local coroner (county in which discovery is made) to evaluate the remains, and follow the procedures and protocols set forth in Section 15064.5 (e)(1) of the CEQA Guidelines. If the coroner determines that the remains are Native American, USACE will contact the Native American Heritage Commission, who will appoint a Most Likely Descendant (MLD), in accordance with Health and Safety Code Section 7050.5, subdivision (c), and PRC 5097.98 (as amended by AB 2641). In accordance with PRC 5097.98, USACE shall ensure that, according to generally accepted cultural or archaeological standards or practices, the immediate vicinity of the Native American human remains is not damaged or disturbed by further development activity until USACE has discussed and conferred, as prescribed in this section (PRC 5097.98), with the MLD regarding their recommendations, if applicable, taking into account the possibility of multiple human remains. The USACE and the MLD will make all reasonable efforts to develop an agreement for the treatment of, with appropriate dignity, human remains and associated or unassociated funerary objects (CEQA Guidelines Sec. 15064.5[d]). The agreement should take into consideration the appropriate recordation, analysis, custodianship, curation, and final disposition of the human remains and associated or unassociated funerary objects. PRC allows 48 hours to reach agreement on these matters. If the MLD and the other parties do not agree on the reburial method, the project will follow Section 5097.98(b) of the PRC, which states, “the landowner or his or her authorized representative will re-inter the human remains and items associated with Native American burials with appropriate dignity on the property in a location not subject to further subsurface disturbance.”

**NEPA Determination:** Under all alternatives, the inadvertent disturbance of human remains represents a potential impact; however, implementation of Mitigation Measures CUL-1 and CUL-2 would reduce the potential to result in impacts to human remains to a less-than-significant level.

**CEQA Determination:** Under all alternatives, the inadvertent disturbance of human remains represents a potential impact; however, implementation of Mitigation Measures CUL-1 and CUL-2 would reduce the potential to result in impacts to human remains to a less-than-significant level.

**Impact 3.7-3: Disturb Unidentified Significant Paleontological Resources****No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

As described under Impact 3.7-1, maintenance dredging and placement at existing placement sites would not disturb native sediments; therefore, disturbance of paleontological resources would not be expected. The USACE would not use the future placement sites identified in Section 1.5.4 until appropriate environmental review and permitting are completed. Although unlikely, there remains the potential that paleontological materials could be inadvertently uncovered by project activities. Such disturbance of paleontological resources represents a potential project impact. Implementation of Mitigation Measure CUL-3, Inadvertent Paleontological Discovery, would reduce potential impacts due to disturbance of paleontological resources by identifying the procedures to be followed by USACE in the event human remains are inadvertently exposed.

**Mitigation Measure CUL-3: Inadvertent Paleontological Discovery**

In the event that paleontological resources are discovered during sediment-disturbing activities, work will be temporarily halted or diverted. The USACE will consult a qualified paleontologist (in accordance with SVP standards). The paleontologist will document the discovery as needed,

evaluate the potential resource, and assess the significance of the find under the criteria set forth in CEQA Guidelines Section 15064.5. The paleontologist will consult USACE to determine procedures that would be followed before work is allowed to resume at the location of the find. If USACE determines that avoidance is not feasible, the paleontologist will prepare a salvage plan in accordance with the SVP and CEQA Guidelines for mitigating the effect of the project on the qualities that make the resource important. The plan will be submitted to USACE for review and approval prior to implementation.

**NEPA Determination:** Under all alternatives, with implementation of proposed Mitigation Measure CUL-3, the potential to result in impacts to paleontological resources would be reduced to a less-than-significant level.

**CEQA Determination:** Under all alternatives, with implementation of proposed Mitigation Measure CUL-3, the potential to result in impacts to paleontological resources would be reduced to a less-than-significant level.

***Impact 3.7-4: Potential to Result in Cumulative Impacts on Archaeological or Paleontological Resources***

Under all alternatives, project activities would not result in impacts to known historic or unique archaeological resources or to significant paleontological resources, and therefore would not contribute to any cumulative impact to these resources. Dredging and placement activities could result in the inadvertent discovery of a buried archaeological resource, buried human remains, or paleontological resources. The other ongoing and reasonably foreseeable projects shown in Table 3.1-1, which include dredging to deepen channels, would also have the potential to inadvertently uncover previously unidentified buried archaeological resources, buried human remains, or paleontological resources.

If previously undiscovered archaeological resources are inadvertently exposed during construction activities, an incremental effect to archaeological resources may occur. However, other ongoing and reasonably foreseeable future projects would be subject environmental review under NEPA and/or CEQA, and would be required to consider mitigation for impacts to historical or unique archaeological resources and paleontological resources. If these resources are properly evaluated and managed according to mitigation measures, no adverse cumulative impact to archaeological resources is expected to occur.

**NEPA Determination.** Cumulative impacts to archaeological and paleontological resources would be less than significant.

**CEQA Determination.** Cumulative impacts to archaeological and paleontological resources would be less than significant.

### **3.8 LAND USE**

This section describes the land use planning context, including applicable plans and policies, and evaluates the potential land use impacts from implementation of the alternatives. The proposed dredging, transport, and placement activities would not require any new land-based construction or facilities, and would not result in any new residences or infrastructure that could indirectly induce growth or development in the study area. Therefore, this land use evaluation focuses on land use policies that affect shoreline development and the waters in the study area. Habitat conservation plans are addressed in Section 3.6, Biological Resources.

#### **3.8.1 Regulatory Setting**

##### **Federal**

##### **Coastal Zone Management Act**

The Coastal Zone Management Act (CZMA), established in 1972 and administered by the National Oceanic and Atmospheric Administration's Office of Ocean and Coastal Resource Management, provides for management of the nation's coastal resources. The overall purpose is to balance competing land and water issues in the coastal zone. The CZMA encourages states to develop coastal management programs. The federal government certified the California Coastal Management Program (CCMP) in 1977. Under the CZMA, any federal agency conducting or supporting activities directly affecting the coastal zone must proceed in a manner consistent with the federally approved state coastal zone management programs, to the maximum extent practicable. The processes established to implement this requirement are called a consistency determination for federal activities and development projects; and a consistency certification for federal permits and licenses and federal support to state and local agencies (CCC, 2012a). In lieu of a consistency determination, pursuant to 15 C.F.R. § 930.35, a federal agency may submit a negative determination for an activity that "is the same as or is similar to activities for which consistency determinations have been prepared in the past." The enforceable policies of the CCMP are in Chapter 3 of the California Coastal Act of 1976. However, as described below, the California Coastal Act covers a much broader jurisdiction beyond implementation of the federal CZMA.

##### **Commerce Clause of the Constitution**

Navigable servitude is a United States constitutional doctrine that gives the federal government the right to regulate navigable waterways as an extension of the Commerce Clause of the Constitution. The federal navigational servitude entitles the government to exert a dominant servitude in all lands below the ordinary high water mark of navigable waters.

Navigable waters of the United States are those waters that are subject to the ebb and flow of the tide and/or are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce (33 C.F.R. § 329.4). For rivers, lakes and marshlands, federal regulatory jurisdiction and powers of improvement for navigation extend laterally to the entire water surface and bed of a navigable waterbody, which includes all the land and waters below the ordinary high water mark (33 C.F.R. § 329.11).

##### **Submerged Lands Act**

The Submerged Lands Act of 1953 (43 U.S.C. § 1301 et seq.) grants states title to all submerged navigable lands within their boundaries. This includes navigable waterways, such as rivers, as well as marine waters within the state's boundaries, generally three geographical miles from the coastline. Section 1311(d) of the Submerged Lands Act provides that nothing in the act shall affect the use, development, improvement, or control by or under the constitutional authority of the United States for the

purposes of navigation or be construed as the release or relinquishment of any rights of the United States arising under the constitutional authority of Congress to regulate or improve navigation. In compliance with this act, the California State Land Commission will receive a copy of this Environmental Assessment/Environmental Impact Report and will have the opportunity to comment on its potential impacts to submerged lands.

## **State**

### **California Environmental Quality Act**

The California Environmental Quality Act (CEQA) (California Public Resources Code Sections 21000-21178) and the CEQA Guidelines (14 California Code of Regulations 15000-15387) are the primary policies that require projects to analyze potential impacts to land use, as well as to analyze the project's consistency with land use planning policies applicable to the project. This document is intended to fulfill the requirements of CEQA and the CEQA Guidelines.

### **Public Trust Doctrine (California State Lands Commission)**

The California State Lands Commission (CSLC) manages lands in California according to the Public Trust Doctrine. Several of the guiding principles of the Public Trust are:

- I. Lands under the ocean and under navigable streams are owned by the public and held in trust for the people by government. These are referred to as public trust lands, and include filled lands formerly under water. Public trust lands cannot be bought and sold like other state-owned lands. Only in rare cases may the public trust be terminated, and only where consistent with the purposes and needs of the trust.
- II. Uses of trust lands, whether granted to a local agency or administered by the state directly, are generally limited to those that are water dependent or related, and include commerce, fisheries, and navigation, environmental preservation and recreation. Public trust uses include, among others, ports, marinas, docks and wharves, buoys, hunting, commercial and sport fishing, bathing, swimming, and boating. Public trust lands may also be kept in their natural state for habitat, wildlife refuges, scientific study, or open space. Ancillary or incidental uses are also permitted—that is, uses that directly promote trust uses; are directly supportive and necessary for trust uses; or that accommodate the public's enjoyment of trust lands. Although trust lands cannot generally be alienated from public ownership, uses of trust lands can be carried out by public or private entities by lease from the CSLC or a local agency grantee.
- III. Because public trust lands are held in trust for all citizens of California, they must be used to serve statewide, as opposed to purely local, public purposes (CSLC, 2010).

### **California Coastal Act**

The California Coastal Act includes specific policies (Division 20 of the California Public Resources Code) for planning and regulatory decisions made by the California Coastal Commission (CCC) and local governments. The CCC works with coastal cities and counties to regulate the use of land and water in the coastal zone. The California Coastal Act regulates development activities, such as the construction of buildings, divisions of land, and activities that change the intensity of use of land or public access to coastal waters. On land, the coastal zone varies in width from several hundred feet in highly urbanized areas up to 5 miles in certain rural areas; offshore, the coastal zone includes a 3-mile-wide band of ocean. The coastal zone established by the California Coastal Act does not include San Francisco Bay, where development is regulated by the San Francisco Bay Conservation and Development Commission (BCDC) (CCC, 2012a), as further described below.

The CCC developed the CCMP, pursuant to the requirements of the CZMA, described above. If a proposed activity affects water use in the coastal zone (i.e., the territorial sea and inland), the federal agency must determine that its project is consistent—to the maximum extent practicable—with the CCMP. The BCDC, further described below, is the state’s coastal zone management agency responsible for reviewing consistency determinations under the CZMA in San Francisco Bay. For activities outside of the Golden Gate, consistency determinations are reviewed by the CCC.

Article 4 of the California Coastal Act requires that marine resources be maintained, enhanced, and where feasible, restored. The act also requires that special protection be given to areas and species of special biological or economic significance. It further requires that uses of marine environments be such that habitat function, biological productivity, healthy species populations, and fishing and recreational interests of coastal waters are maintained for long-term commercial, recreational, scientific, and educational purposes; and that marine resources are protected against the spillage of crude oil, gas, petroleum products, and hazardous substances.

### **McAteer-Petris Act**

The McAteer-Petris Act (California Government Code Section 66000, et seq.), first enacted in 1965, created the BCDC to prepare a plan to protect the San Francisco Bay and shoreline, and provide for appropriate development and public access. This act directs BCDC to exercise its authority to issue or deny permit applications for placing fill; dredging; or changing the use of any land, water, or structure in the area of its jurisdiction. The BCDC also reviews determinations of consistency with the CZMA for federally sponsored projects. The San Francisco Bay Plan (Bay Plan) is BCDC’s policy document specifying goals, objectives, and policies for BCDC jurisdictional areas. Pursuant to the federal CZMA, USACE is required to be consistent to the maximum extent practicable with the enforceable policies of the Bay Plan.

### **Regional**

#### **San Francisco Bay Conservation and Development Commission San Francisco Bay Plan**

BCDC has permit authority over development of San Francisco Bay and the shoreline pursuant to the McAteer-Petris Act (California Government Code Section 66000 et seq.). The act requires BCDC to prepare a “comprehensive and enforceable plan for the conservation of the water of San Francisco Bay and the development of its shoreline.” BCDC’s jurisdiction includes all tidal areas of San Francisco Bay up to the line of mean high tide; all areas formerly subject to tidal action that have been filled since September 17, 1965; and the “shoreline band,” which extends 100 feet inland from and parallel to the San Francisco Bay shoreline.

BCDC is also the regional coastal zone management agency for San Francisco Bay. Therefore, under the provisions of Section 307 of the federal CZMA, federal agencies must assess whether their actions are consistent with BCDC’s regulations and policies to the maximum extent practicable. BCDC has jurisdiction over all filling, dredging, and changes in use in San Francisco Bay.

The Bay Plan, first adopted in 1969, and last updated in 2011, is BCDC’s policy document specifying goals, objectives, and policies for BCDC jurisdictional areas (BCDC, 2007). Policies in the Bay Plan applicable to the proposed project include those in the following categories: Dredging; Fish, Other Aquatic Organisms, and Wildlife; Water Quality; Tidal Marshes and Tidal Flats; Subtidal Areas; and Navigational Safety and Oil Spill Prevention.

Dredging policies in the Bay Plan relevant to the proposed project are summarized below:

**Dredging Policy 1.** Dredging and dredged material disposal should be conducted in an environmentally and economically sound manner. Dredgers should reduce disposal in San Francisco Bay and certain waterways over time to achieve the Long-Term Management Strategy (LTMS) goal of limiting in-Bay disposal volumes to a maximum of one million cubic yards per year. The LTMS agencies should implement a system of disposal allotments to individual dredgers to achieve this goal only if voluntary efforts are not effective in reaching the LTMS goal. In making its decision regarding disposal allocations, the BCDC should confer with the LTMS agencies and consider the need for the dredging and the dredging projects, environmental impacts, regional economic impacts, efforts by the dredging community to implement and fund alternatives to in-Bay disposal, and other relevant factors.

**Dredging Policy 2.** Dredging should be authorized when the BCDC can find: (a) the applicant has demonstrated that the dredging is needed to serve a water-oriented use or other important public purpose, such as navigational safety; (b) the materials to be dredged meet the water quality requirements of the Regional Water Board; (c) important fisheries and Bay natural resources would be protected through seasonal restrictions established by the California Department of Fish and Wildlife (CDFW), the United States Fish and Wildlife Service (USFWS), and/or the National Marine Fisheries Service (NMFS), or through other appropriate measures; (d) the siting and design of the project will result in the minimum dredging volume necessary for the project; and (e) the materials would be disposed of in accordance with Policy 3.

**Dredging Policy 3.** Dredged materials should, if feasible, be reused or disposed outside San Francisco Bay and certain waterways. Except when reused in an approved fill project, dredged material should not be disposed in San Francisco Bay and certain waterways unless disposal outside these areas is infeasible and the BCDC finds: (a) the volume to be disposed is consistent with applicable dredger disposal allocations and disposal site limits adopted by the BCDC by regulation; (b) disposal would be at a site designated by the BCDC; (c) the quality of the material disposed of is consistent with the advice of the Regional Water Board and the Dredged Material Management Office; and (d) the period of disposal is consistent with the advice of the CDFW, the USFWS, and the NMFS.

**Dredging Policy 4.** If an applicant proposes to dispose dredged material in tidal areas of San Francisco Bay and certain waterways that exceeds either disposal site limits or any disposal allocation that the BCDC has adopted by regulation, the applicant must demonstrate that the potential for adverse environmental impact is insignificant, and that nontidal and ocean disposal is infeasible because there are no alternative sites available or likely to be available in a reasonable period, or because the cost of disposal at alternate sites is prohibitive. In making its decision whether to authorize such in-Bay disposal, the BCDC should confer with the LTMS agencies and consider the factors listed in Policy 1.

**Dredging Policy 5.** To ensure adequate capacity for necessary Bay dredging projects and to protect Bay natural resources, acceptable nontidal disposal sites should be secured and the San Francisco Deep Ocean Disposal Site should be maintained. Furthermore, dredging projects should maximize use of dredged material as a resource consistent with protecting and enhancing Bay natural resources, such as creating, enhancing, or restoring tidal and managed wetlands, creating and maintaining levees and dikes, providing cover and sealing material for sanitary landfills, and filling at approved construction sites.

**Dredging Policy 6.** Dredged materials disposed in San Francisco Bay and certain waterways should be carefully managed to ensure that the specific location, volumes, physical nature of the material, and timing of disposal do not create navigational hazards; adversely affect Bay

sedimentation, currents, or natural resources; or foreclose the use of the site for projects critical to the economy of the San Francisco Bay Area.

Policies in the Bay Plan pertaining to Fish, Other Aquatic Organisms, and Wildlife that are relevant to the proposed project are summarized below:

**Fish, Other Aquatic Organisms, and Wildlife Policy 1.** To assure the benefits of fish, other aquatic organisms, and wildlife for future generations, to the greatest extent feasible, San Francisco Bay's tidal marshes, tidal flats, and subtidal habitat should be conserved, restored, and increased.

**Fish, Other Aquatic Organisms, and Wildlife Policy 2.** Specific habitats that are needed to conserve, increase, or prevent the extinction of any native species, species threatened or endangered, species that the CDFW has determined are candidates for listing as endangered or threatened under the California Endangered Species Act, or any species that provides substantial public benefits, should be protected, whether in San Francisco Bay or behind dikes.

**Fish, Other Aquatic Organisms, and Wildlife Policy 4.** The BCDC should not authorize projects that would result in the "taking" of any plant, fish, other aquatic organism or wildlife species listed as endangered or threatened pursuant to the state or federal endangered species acts, or the federal Marine Mammal Protection Act, or species that are candidates for listing under the California Endangered Species Act, unless the project applicant has obtained the appropriate "take" authorization from the USFWS, NMFS, or CDFW. The BCDC should give appropriate consideration to the recommendations of the CDFW, NMFS, or USFWS to avoid possible adverse effects of a proposed project on fish, other aquatic organisms, and wildlife habitat.

Water Quality policies in the Bay Plan relevant to the proposed project are summarized below:

**Water Quality Policy 1.** Bay water pollution should be prevented to the greatest extent feasible. The Bay's tidal marshes, tidal flats, and water surface area and volume should be conserved, and whenever possible, restored and increased to protect and improve water quality.

**Water Quality Policy 2.** Water quality in San Francisco Bay should be maintained at a level that will support and promote the beneficial uses of San Francisco Bay as identified in the Regional Water Board's Water Quality Control Plan for the San Francisco Bay Basin, and should be protected from all harmful or potentially harmful pollutants. The policies, recommendations, decisions, advice, and authority of the State Water Resources Control Board and the Regional Water Board should be the basis for carrying out the BCDC's water quality responsibilities.

Policies in the Bay Plan pertaining to Tidal Marshes and Tidal Flats relevant to the proposed project are summarized below:

**Tidal Marshes and Tidal Flats Policy 1.** Tidal marshes and tidal flats should be conserved to the fullest possible extent. Filling, diking, and dredging projects that would substantially harm tidal marshes or tidal flats should be allowed only for purposes that provide substantial public benefits, and only if there is no feasible alternative.

**Tidal Marshes and Tidal Flats Policy 2.** Any proposed fill, diking, or dredging project should be thoroughly evaluated to determine the effect of the project on tidal marshes and tidal flats, and designed to minimize—and if feasible—avoid any harmful effects.

Policies for Subtidal Areas in the Bay Plan that are relevant to the proposed project are summarized below:

**Subtidal Areas Policy 1.** Any proposed filling or dredging project in a subtidal area should be thoroughly evaluated to determine the local and Bay-wide effects of the project on: (a) the possible introduction or spread of invasive species; (b) tidal hydrology and sediment movement; (c) fish, other aquatic organisms, and wildlife; (d) aquatic plants; and (e) San Francisco Bay's bathymetry. Projects in subtidal areas should be designed to minimize—and if feasible—avoid any harmful effects.

**Subtidal Areas Policy 2.** Subtidal areas that are scarce in San Francisco Bay or have an abundance and diversity of fish, other aquatic organisms, and wildlife (e.g., eelgrass beds, sandy deep water, underwater pinnacles) should be conserved. Filling, changes in use; and dredging projects in these areas should therefore be allowed only if: (a) there is no feasible alternative; and (b) the project provides substantial public benefits.

Navigational Safety and Oil Spill Prevention policies in the Bay Plan relevant to the proposed project are summarized below:

**Navigational Safety and Oil Spill Prevention Policy 1.** Physical obstructions to safe navigation, as identified by the U.S. Coast Guard and the Harbor Safety Committee of the San Francisco Bay Region, should be removed to the maximum extent feasible when their removal would contribute to navigational safety, and would not create significant adverse environmental impacts. Removal of obstructions should ensure that any detriments arising from a significant alteration of Bay habitats are clearly outweighed by the public and environmental benefits of reducing the risk to human safety; or the risk of spills of hazardous materials, such as oil.

**Navigational Safety and Oil Spill Prevention Policy 3.** To ensure navigational safety and help prevent accidents that could spill hazardous materials, such as oil, the BCDC should encourage major marine facility owners and operators, USACE and the National Oceanic and Atmospheric Administration to conduct frequent, up-to-date surveys of major shipping channels, turning basins, and berths used by deep-draft vessels and oil barges. Additionally, the frequent, up-to-date surveys should be quickly provided to the U.S. Coast Guard Vessel Traffic Service San Francisco, masters and pilots.

### 3.8.2 Environmental Setting

For the purpose of this analysis, the project's study area in San Francisco Bay encompasses the shoreline and in-water areas in the following 11 counties: Marin, Sonoma, Napa, Solano, Sacramento, San Joaquin, Contra Costa, Alameda, Santa Clara, San Mateo, and San Francisco. The geographic scope of the study area includes the estuarine waters of the San Francisco Bay region, portions of the Sacramento-San Joaquin Delta west of Sherman Island, and the western portion of the Sacramento River Deep Water Ship Channel and Stockton Deep Water Ship Channel. Outside of the Golden Gate, the study area includes the San Francisco Deep Ocean Disposal Site, the San Francisco Main Ship Channel (MSC), San Francisco Bar Channel Disposal Site (SF-8) and the nearshore zone off Ocean Beach, as well as the waters that are used by vessels en route to these sites.

BCDC's jurisdiction extends over most of the in-Bay portion of the study area, with the exception of a small portion of the eastern extent of the study area east of Pittsburg. The Winter Island, Antioch Dunes, and Sherman Island placement sites are outside of BCDC's jurisdictional boundary. Outside of San Francisco Bay, the coastal zone extends approximately 3,000 feet into the eastern end of the Main Ship Channel and includes the SF-8 and the Ocean Beach nearshore placement site (SF-17) in-water placement

sites and Ocean Beach onshore beach nourishment placement area; this area of the coastal zone is under the jurisdiction of the CCC.

### 3.8.3 Methodology and Thresholds of Significance

The proposed project would involve the maintenance dredging of existing federal navigation channels and placement of dredged materials at existing placement sites. These activities would have no potential to divide an existing community or substantially affect existing land uses and land use patterns in the study area, because no new land uses, types of activities, or improvements would be implemented. In addition, the use of future placement sites identified in Section 1.5.4 would be unlikely to result in such impacts based on their location and existing surrounding land uses; however, USACE would not use the future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation of impacts on land use.

Therefore, this land use evaluation focuses on consistency with coastal land use policies and plans. The analysis considered whether the project would conflict with applicable land use plans, policies, or regulations that an agency with jurisdiction over the project has adopted to avoid or mitigate environmental effects.

### 3.8.4 Impacts and Mitigation Measures

#### ***Impact 3.8-1 Conflict with Applicable Plans and Policies***

##### **No Action/No Project Alternative**

Under the No Action/No Project Alternative, dredging and placement activities would be similar to numerous USACE annual maintenance dredging operations previously concurred with by the CCC and BCDC. Therefore, for the most part, continuation of these activities would not be expected to conflict with plans, regulations, or policies considered under the CZMA, including the CCMP and the Bay Plan; the exception being policies pertaining to the protection of listed species due to the entrainment of delta smelt and longfin smelt during hopper dredging operations at in-Bay locations. Pursuant to the CZMA, the BCDC and the CCC would review USACE's consistency determination for dredging and placement activities that occur within each agency's jurisdictional boundaries. The No Action/No Project Alternative's consistency with the applicable policies from each plan is evaluated below.

**Bay Plan.** The USACE's dredging, transport, and placement activities would be consistent with Bay Plan Dredging Policies and Water Quality Policies as described below:

- Per Dredging Policy 1, USACE would conduct dredging and dredged material placement in an environmentally and economically sound manner in accordance with LTMS goals, to the extent that funding and authority allows. The USACE, as one of the LTMS managing agencies, is committed to the LTMS goal of reducing the placement of dredged material at in-Bay placement sites. Dredged material placement by USACE would support the goals of the Bay Plan.
- Per Dredging Policy 2 and Water Quality Policies 1 and 2, maintenance dredging is needed for safe navigation; USACE would abide by the conditions of the Water Quality Certification issued by the Regional Water Board; Bay fisheries and natural resources would be protected; only the minimum volumes necessary would be dredged; and the sediment would be disposed of in accordance with the Policy 3 guidelines. The dredging activities would maintain the navigational safety of federal channels for commercial and recreational vessels, all serving valuable water-oriented uses.
- Per Dredging Policy 3, dredged materials placed in BCDC's jurisdiction would be placed in accordance with the Bay Plan guidelines unless it is found infeasible to comply with established

regulations. The volumes proposed for placement at each designated site would be within placement site target values; the material would be determined suitable by the Dredged Material Management Office (which includes the Regional Water Board); and the dredging of sediments would be completed within the LTMS work windows, or USACE would consult with the appropriate resource agencies for work outside the windows. Because the use of in-Bay sites would continue for some projects, site-management strategies and monitoring activities for placement sites would continue to be implemented to lessen the cumulative impacts on San Francisco Bay's aquatic habitats, and to ensure that the dispersion of dredged material is maximized.

- Per Dredging Policy 4, the total volume of dredged material placed at in-Bay sites would fall within the LTMS target limits for in-Bay sites, and would not exceed disposal site limits.
- Per Dredging Policy 5, USACE would maximize, to the extent feasible, the use of dredged sediment as a resource, in accordance with the goals of the LTMS Management Plan. In addition, adequate placement capacity for these dredging projects is continually being researched by USACE. For example, following a pilot project at the Ocean Beach Demonstration Site, SF-17 was proposed as a placement site and is presently undergoing the designation process.
- Per Dredging Policy 6, all in-Bay sites would continue to be carefully managed (by performing regular bathymetric surveys) to ensure that the amount and timing of placement do not create navigational hazards, adversely affect Bay currents or natural resources of San Francisco Bay, or foreclose the use of the sites by projects critical to the economy of the San Francisco Bay Area.

The USACE's dredging, transport, and placement activities would be consistent with Bay Plan Fish, Other Aquatic Organisms, and Wildlife Policies:

- For Fish, Other Aquatic Organisms, and Wildlife Policy 1, USACE would place dredged materials in the most cost-efficient and environmentally responsible fashion. Dredged material would continue to be evaluated for—and used in the restoration of—tidal wetlands, or other habitat types wherever possible.
- For Fish, Other Aquatic Organisms, and Wildlife Policies 2 and 4, the schedule for maintenance dredging projects in San Francisco Bay would be developed and followed in a manner protective of threatened or endangered species and special-status species in accordance with LTMS work windows. The dredging and disposal of sediments would be completed within these work windows, or USACE would consult with the appropriate resource agencies. The USACE would meet all federal environmental compliance requirements (e.g., Clean Water Act Section 404, Endangered Species Act), including those federal requirements implemented by state agencies (e.g., Clean Water Act Section 401). The USACE would undertake mitigation, as appropriate, in meeting its compliance requirements.

The USACE's dredging, transport, and placement activities would be consistent with Bay Plan Tidal Marshes and Tidal Flats Policies:

- Per Tidal Marshes and Tidal Flats Policy 1, USACE maintenance dredging would remove only the minimum volume necessary to ensure safe navigation in San Francisco Bay and the continuance of economic development benefiting the public.
- Per Tidal Marshes and Tidal Flats Policy 2, USACE has and would continue to minimize and avoid to the extent feasible potentially harmful effects on tidal marshes.

For the two projects that are dredged through tidal mudflat—Petaluma River Across the Flats, and San Rafael Across the Flats—only the minimum material necessary to ensure safe navigation would be

dredged. Although these projects cross the tidal mudflats, the channels are not considered to be tidal mudflat because of the channel depths.

No known tidal marsh habitat exists within the current channel boundaries; however, several projects may require work in, or near enough, to potentially impact tidal marsh areas. Projects that may require work in the tidal marsh habitats are Redwood City Harbor, San Leandro Marina, Petaluma River, and the Napa River channels. The dredging of these channels would provide public benefits of navigational safety and economic benefits to the communities who use them, and proposed dredging and placement activities would not substantially harm tidal marshes. These projects have nearby upland placement sites that may require transport of the material through the marsh habitat. This transport is typically accomplished through pipelines temporarily crossing the habitat to place the material. Through coordinated efforts, USACE has avoided impacts to special-status species in these habitats in the past; these efforts have included surveying for the species of concern, and then implementing the project in a manner that does not affect them. The USACE would continue to coordinate with the appropriate resource agencies on any work that may affect the tidal marsh habitat or its species.

Although eelgrass does exist near the Richmond Inner Harbor Channel, there is no known eelgrass within any of the channel boundaries. In 2010, 2011, and 2012 USACE conducted three sets of eelgrass surveys, conducted both before and after maintenance dredging. A reduction in the density in eelgrass along the channel margin was detected; the survey crews, however, did not find excessive sedimentation or any other evidence indicating that dredging had caused loss of eelgrass. Losses during winter months, known as seasonal diebacks, are, in fact, common in eelgrass meadows. Examination of surveys done over the last 15 years indicates that eelgrass has persisted in essentially the same locations and densities around Richmond Harbor. Minimization measures are always included in contract specifications. For Richmond Inner Harbor, a closed or “environmental” clamshell bucket is required, and contractors are prohibited from anchoring or placing any equipment in locations that could possibly disturb eelgrass habitat (USACE, 2012a). The USACE would also comply with the programmatic Essential Fish Habitat conservation measures for the LTMS Program (June 2011).

Therefore, the dredging, transport, and placement activities would be consistent, to the maximum extent feasible, with Tidal Marshes and Tidal Flats Policies 1 and 2.

The USACE’s dredging, transport, and placement activities would be consistent with Bay Plan Subtidal Areas Policies:

- Per Subtidal Areas Policy 1, only short-term impacts result from the maintenance dredging and placement actions. There is no feasible alternative to maintaining the federal navigation channels through dredging and placement. The maintenance of these channels is essential to providing safe navigation and access to the ports and recreational marinas in San Francisco Bay.
- Per Subtidal Areas Policy 2, the federal channels are not considered scarce or unique habitat in San Francisco Bay, and there is no feasible alternative to maintaining them through dredging and placement.

The USACE’s dredging, transport, and placement activities would be consistent with Bay Plan Navigational Safety and Oil Spill Prevention Policies:

- Per Navigational Safety and Oil Spill Prevention Policy 1, USACE’s maintenance dredging program would remove obstructions to safe navigation, thereby ensuring the safe movement of maritime vessels, the protection of the surrounding habitat, and the continuation of the economic well-being and national defense of the nation.

- Per Navigational Safety and Oil Spill Prevention Policy 3, USACE would continue to perform surveys of all maintenance dredging project areas, and make these surveys available for public use.

The BCDC would review USACE's consistency determination for dredging and placement activities that would occur within BCDC's jurisdiction, to verify that the activities would be consistent, to the maximum extent practicable, with the Bay Plan.

**California Coastal Management Plan.** The MSC is the only federal navigation channel addressed in this Environmental Assessment/Environmental Impact Report that is within the jurisdiction of the CCC. Of the placement sites, SF-17 and a portion of SF-8 are within CCC's jurisdiction. In 2012, USACE submitted a negative determination to the CCC for maintenance dredging at the MSC and placement of dredged material at SF-8, SF-17, and onshore at Ocean Beach for a 5-year period from 2012 through 2016. As stated in Section 3.8.1, a federal agency may submit negative determination for an activity that "is the same as or is similar to activities for which consistency determinations have been prepared in the past." The negative determination demonstrated that the proposed dredging and placement activities for the MSC would be consistent—to the maximum extent practicable—with the CCMP and Article 4 of the California Coastal Act; and that the proposed activities were consistent with the annual maintenance dredging program for the MSC implemented by USACE, and previously concurred with by the CCC (USACE, 2012a). The CCC concurred with USACE's negative determination on May 9, 2012. For dredging of the MSC from 2017 through 2024, USACE would request concurrence from the CCC on a negative determination to verify that continuing activities would be consistent, to the maximum extent practicable, with the CCMP and California Coastal Act. The dredging and placement activities under the No Action/No Project Alternative would be the same as those previously proposed by USACE for 2012 through 2016, and therefore would continue to be consistent with the CCMP and Article 4 of the California Coastal Act.

Because the federal navigation channels addressed in this Environmental Assessment/Environmental Impact Report are congressionally authorized navigation projects, dredging and placement activities would not require a lease agreement from the CSLC for use of public trust lands based on the navigational servitude provisions of the Submerged Lands Act. Although the Submerged Land Act grants CSLC title to all submerged navigable lands in the state, the act provides that nothing in the act shall affect the federal government's constitutional authority for the purposes of navigation.

**NEPA Determination:** The No Action Alternative would not conflict with applicable land use plans and policies.

**CEQA Determination:** The No Project Alternative would not conflict with applicable land use plans and policies.

### **Proposed Action/Project**

Implementation of the Proposed Action/Project would be very similar to the No Action/No Project Alternative; it would involve use of the same type of dredge equipment for each channel, the same volume of dredged material, and the same dredging frequency and durations. As described in Section 2.3.3, USACE would implement additional best management practices to minimize impacts to longfin smelt and delta smelt. Dredging and placement activities would not require a lease agreement from the CSLC for use of public trust lands.

**Bay Plan.** Under the Proposed Action/Project, USACE may use alternate placement sites for in-Bay Channels than those identified under the No Action/No Project Alternative; however, placement would still be conducted in support of the goals of the LTMS, and therefore consistent with the Bay Plan. The USACE would not use any of the future placement sites identified in Section 1.5.4 until appropriate environmental review and permitting is completed. Under the Proposed Action/Project, consistency with

Bay Plan Policies would be the same as described for the No Action/No Project Alternative. The USACE would meet all federal environmental compliance requirements (e.g., Clean Water Act Section 404, Endangered Species Act), including those federal requirements implemented by state agencies (e.g., Clean Water Act Section 401). The USACE would purchase 0.92 mitigation credit at the Liberty Island Mitigation Bank annually for potential impacts to listed species. The BCDC would review USACE's consistency determination for dredging and placement activities that would occur within BCDC's jurisdiction, to verify that the activities would be consistent, to the maximum extent practicable, with the Bay Plan.

**California Coastal Management Plan.** Under the Proposed Action/Project, dredging and placement activities for the MSC would be the same as under the No Action/No Project Alternative, and therefore would be consistent with the CCMP and California Coastal Act. Dredging through 2016 would be covered under the existing negative determination and CCC concurrence. For dredging of the MSC from 2017 through 2024, USACE would request concurrence from the CCC on a negative determination to verify that the activities would be consistent, to the maximum extent practicable, with the CCMP and California Coastal Act.

**NEPA Determination.** The Proposed Action would not conflict with applicable land use plans and policies.

**CEQA Determination.** The Project would not conflict with applicable land use plans and policies.

### **Reduced Hopper Dredge Use Alternative 1**

Implementation of the Reduced Hopper Dredge Use Alternative 1 would be very similar to the Proposed Action/Project Alternative, except that Suisun Bay Channel, New York Slough Channel, San Bruno Channel in Redwood City Harbor,<sup>1</sup> and either Pinole Shoal or Richmond Outer Harbor, would be dredged with a mechanical dredge instead of a hopper dredge. Dredging and placement activities would not require a lease agreement from the CSLC for use of public trust lands.

**Bay Plan.** Reducing in-Bay hopper dredge use would likely reduce occurrences of entrainment of longfin smelt and delta smelt, pursuant to Fish, Other Aquatic Organisms, and Wildlife Policy 4. Consistency with Bay Plan Policies would be the same as described for the No Action/No Project Alternative and Proposed Action/Project. The USACE would meet all federal environmental compliance requirements (e.g., Clean Water Act Section 404, Endangered Species Act), including those federal requirements implemented by state agencies (e.g., Clean Water Act Section 401). The USACE would purchase 0.19 mitigation credit at the Liberty Island Mitigation Bank annually for potential impacts to listed species if Pinole Shoal is dredged with a hopper. If Richmond Outer Harbor is dredged with a hopper, USACE would purchase 0.34 mitigation credit at the Liberty Island Mitigation Bank annually for potential impacts to listed species. The BCDC would review USACE's consistency determination for dredging and placement activities that would occur within BCDC's jurisdiction, to verify that the activities would be consistent, to the maximum extent practicable, with the Bay Plan.

**California Coastal Management Plan.** Under Reduced Hopper Dredge Alternative 1, dredging and placement activities for the MSC would be the same as under the No Action/No Project Alternative, and therefore would be consistent with the CCMP and California Coastal Act. Dredging through 2016 would be covered under the existing negative determination and CCC concurrence. For dredging of the MSC from 2017 through 2024, USACE would request concurrence from the CCC on a negative determination to verify that the activities would be consistent, to the maximum extent practicable, with the CCMP and California Coastal Act.

---

<sup>1</sup> San Bruno Channel is dredged at intervals of 10 years or greater.

**NEPA Determination.** Reduced Hopper Dredge Use Alternative 1 would not conflict with applicable land use plans and policies.

**CEQA Determination.** Reduced Hopper Dredge Use Alternative 1 would not conflict with applicable land use plans and policies.

### **Reduced Hopper Dredge Use Alternative 2**

Implementation of the Reduced Hopper Dredge Use Alternative 2 would be very similar to the Proposed Action/Project Alternative, except a hopper dredge would not be used for the regular maintenance dredging of in-Bay channels.

**Bay Plan.** Under this alternative, the potential for hopper dredge entrainment impacts to longfin smelt and delta smelt would be minimized. The USACE would meet all federal environmental compliance requirements (e.g., Clean Water Act Section 404, Endangered Species Act), including those federal requirements implemented by state agencies (e.g., Clean Water Act Section 401). Because no in-Bay channels would be dredged with a hopper dredge, the purchase of mitigation credit at the Liberty Island Mitigation Bank would not be warranted. Consistency with Bay Plan Policies would be the same as described for the No Action/No Project Alternative and Proposed Action/Project. The BCDC would review USACE's consistency determination for dredging and placement activities that would occur within BCDC's jurisdiction, to verify that the activities would be consistent, to the maximum extent practicable, with the Bay Plan.

**California Coastal Management Plan.** Under Reduced Hopper Dredge Alternative 2, dredging and placement activities for the MSC would be the same as under the No Action/No Project Alternative, and would be consistent with the CCMP and California Coastal Act. Dredging through 2016 would be covered under the existing negative determination and CCC concurrence. For dredging of the MSC from 2017 through 2024, USACE would request concurrence from the CCC on a negative determination to verify that the activities would be consistent, to the maximum extent practicable, with the CCMP and California Coastal Act.

**NEPA Determination.** Reduced Hopper Dredge Use Alternative 2 would not conflict with applicable land use plans and policies.

**CEQA Determination.** Reduced Hopper Dredge Use Alternative 2 would not conflict with applicable land use plans and policies.

### **Cumulative Impacts**

Because the project would not result in any land use impacts (i.e., the project would not conflict with applicable land use plans and policies), it would not contribute to cumulative land use impacts.

**NEPA Determination.** The project would not contribute to cumulative land use impacts.

**CEQA Determination.** The project would not contribute to cumulative land use impacts.

### **3.9 HAZARDS AND HAZARDOUS MATERIALS**

This section describes the existing conditions for hazards, including emergency planning, and hazardous materials in the San Francisco Bay Area region, and evaluates the potential hazard and hazardous materials impacts related to human health. Potential hazardous materials impacts on sediments are addressed in Section 3.3, Geology, Soils, and Sediment Quality. Potential hazardous materials impacts on water quality are addressed in Section 3.4.4 under Hydrology and Water Quality. Hazards related to marine navigation are evaluated in Chapter 3.10, Transportation and Circulation.

#### **3.9.1 Regulatory Setting**

##### **Federal**

##### **United States Environmental Protection Agency**

The United States Environmental Protection Agency (USEPA) is the lead agency responsible for enforcing federal laws and regulations governing hazardous materials that affect public health or the environment. The major federal laws and regulations enforced by the USEPA include: the Resource Conservation and Recovery Act; the Toxic Substances Control Act; the Comprehensive Environmental Response, Compensation, and Liability Act; and the Superfund Amendments and Reauthorization Act. In California, the USEPA has granted most enforcement authority over federal hazardous materials regulations to the California Environmental Protection Agency.

##### **United States Army Corps of Engineers**

The United States Army Corps of Engineers (USACE) regulates water quality and potentially hazardous discharges through the Rivers and Harbors Acts of 1890 (superseded) and 1899 (33 U.S.C. § 401, et seq.), and the Clean Water Act (33 U.S.C. § 1257, et seq.). The provisions of each are described in Section 3.4, Hydrology and Water Quality.

##### **Oil Pollution Act**

The Oil Pollution Act, Title 33 U.S.C. § 2701 et seq., establishes a liability system for oil spills into navigable waters or adjacent shorelines that injure or are likely to injure natural resources, and/or the services that those resources provide to the ecosystem or humans. Pursuant to this act, federal and state agencies and Indian tribes may act as Trustees on behalf of the public to assess the injuries, scale restoration to compensate for those injuries, and implement restoration.

##### **U.S. Department of Commerce, National Oceanic and Atmospheric Administration, Office of Response and Restoration**

The National Oceanic and Atmospheric Administration (NOAA) Office of Response and Restoration (OR&R) is charged with responding to oil spills, chemical accidents, and other emergencies in coastal areas. Under the National Contingency Plan, NOAA is responsible for providing scientific support to the Federal On-Scene Coordinator for oil and hazardous material spills. To support this mandate, OR&R provides 24-hour, 7-day-a-week response to spills. During an oil spill in coastal waters, OR&R's role is to provide scientific support to the U.S. Coast Guard officers in charge of response operations. In addition to spill response software and mapping tools, OR&R provides standard techniques and publishes guidelines for observing oil, assessing shoreline impact, and evaluating accepted cleanup technologies (NOAA, 2013a).

## **Transportation of Hazardous Materials and Waste**

Transportation of hazardous materials and hazardous waste is carried out by individuals or entities that move hazardous materials and waste from one site to another by highway, rail, water, or air (refer to 40 C.F.R. § 260.10). This includes transporting hazardous waste from a generator's site to a facility that can recycle, treat, store, or dispose of the waste. It can also include transporting treated hazardous waste to a site for further treatment or disposal. Transportation of hazardous materials is required by law to occur in accordance with the Hazardous Waste Manifest System, which is a set of forms, reports, and procedures that track hazardous waste from the time it leaves the generator facility until it reaches the waste management facility that receives it.

Transportation of hazardous materials by truck and rail is regulated by the United States Department of Transportation). The United States Department of Transportation regulations establish criteria for safe handling procedures.

### **State**

#### **California Environmental Protection Agency**

Under the authority of the California Environmental Protection Agency, the Department of Toxic Substances Control and the San Francisco Bay Regional Water Quality Control Board (Regional Water Board) are responsible for overseeing the cleanup of contaminated sites in the San Francisco Bay Area. The Department of Toxic Substances Control also regulates disposal of hazardous wastes under California's Hazardous Waste Control Law. This law requires the filing of a Hazardous Waste Manifest detailing the hauling and disposal of the hazardous waste materials.

#### **Oil Spill Prevention and Response Programs in California**

In 1990, California passed the Lempert-Keene-Seastrand Oil Spill Prevention and Response Act (California Government Code 8670.1 et seq., California Public Resources Code 8750 et seq.) in response to lessons learned from the 1989 Exxon Valdez oil spill offshore Alaska and the 1990 American Trader oil spill offshore Orange County, California. Pursuant to this act, California has developed a comprehensive oil spill prevention and response program that requires all marine facilities and vessels to comply with an integrated system of statewide regulations, operation manuals, inspections, training and drill programs in order to provide the "best achievable protection" of the state's coastal and marine resources through the use of "best achievable technologies" and practices.

The California Coastal Commission (CCC) staff works in partnership with seven other California state agencies and five federal agencies to ensure that California and federal regulations and programs for safe oil and gas exploration and development operations, and for oil spill prevention and response, are consistent with California Coastal Act policies.

The California Office of Spill Prevention and Response is the state's lead agency for oil spill prevention, preparedness, response, and natural resource damage assessment. The Office of Spill Prevention and Response's responsibilities include development and enforcement of California's regulations and programs for oil spill prevention and response planning requirements for marine facilities; identification of sensitive shoreline areas and response strategies; oil spill drill and training requirements for vessels and marine facilities; and natural resource damage assessment requirements for the restoration of ecological and human use losses caused by an oil spill.

The CCC Oil Spill Program is part of the Energy, Ocean Resources, and Federal Consistency Division of the CCC. Under this program, the CCC reviews regulations for oil spill prevention and response, and provides input on these regulations' consistency with California Coastal Act regulations and policies;

reviews oil spill contingency plans for marine facilities in the coastal zone, and oil spill response plans for facilities on the outer continental shelf; and participates in the State Interagency Oil Spill Committee (CCC, 2012b).

The San Francisco Bay Conservation and Development Commission (BCDC) has responsibilities for oil spill prevention and response in San Francisco Bay. The Lempert-Keene-Seastrand Oil Spill Prevention and Response Act specified that BCDC must carry out certain responsibilities critical to the achievement of the goals of the state oil spill act. BCDC actively participates in planning to reduce the risk of oil spills in California waters through its membership on the San Francisco Bay Harbor Safety Committee (navigation safety), and to better respond if a spill does occur by its participation on the San Francisco Bay Delta Area Committee (contingency planning). Through its statutory permit authority, BCDC can condition a project in its jurisdiction to meet the objectives of the McAteer-Petris Act and policies of the San Francisco Bay Plan equivalent to achieving “best achievable protection” against an oil spill for San Francisco Bay. During a spill event, BCDC assists the response by monitoring activities and providing technical expertise. When required, BCDC can authorize emergency response activities that meet its laws and policies.

### **California Office of Emergency Services**

The California Office of Emergency Services was established as part of the Governor’s Office on January 1, 2009, merging the duties, powers, purposes, and responsibilities of the former Governor’s Office of Emergency Services with those of the Governor’s Office of Homeland Security. The California Office of Emergency Services is responsible for the coordination of overall State agency response to major disasters in support of local government. The Agency is responsible for assuring the State’s readiness to respond to, and recover from, all hazards—natural, man-made, and war-caused emergencies and disasters—and for assisting local governments with emergency preparedness, response, recovery, and hazard mitigation efforts (OES, 2011).

Each county has a local Office of Emergency Services, which coordinates with the State during emergency situations. When local and mutual aid resources are exhausted, the State coordinates its emergency resources through its State Operations Center in Sacramento, and its multiple Emergency Operations Centers throughout the region.

## **Regional**

### **Dredged Material Management Office**

The Long-Term Management Strategy program for San Francisco Bay provides the basis for uniform federal and state dredged material disposal policies and regulations. The Dredged Material Management Office (DMMO) was established as part of the Long-Term Management Strategy program to consolidate the processing of dredging permit applications. The process for obtaining approvals for dredging or dredged material disposal has three phases: (1) suitability determination; (2) permit process; and (3) episode approval. The suitability determination process occurs at the DMMO level.

The applicant must submit results from recent sediment testing, or submit sufficient data to support a finding by the agencies that the sediments are suitable for the proposed disposal environment. The applicant should submit to the DMMO either a sediment Sampling and Analysis Plan and Quality Assurance Project Plan, or a written request (with supporting information) for an exclusion from testing requirements based on factors such as previous testing history and physical characteristics of the material proposed for dredging. The applicant must submit the sampling results to the DMMO for review, and the DMMO will make a determination about where the materials can be disposed.

Although the DMMO provides initial review of permit applications and suitability recommendations, applicants must eventually obtain separate approval from the appropriate DMMO member agencies (such as a Clean Water Act Section 401 Certification from the Regional Water Board); each agency issues permit conditions and specific requirements about how the project is to be performed.

### **San Francisco Bay Area Water Emergency Transportation Authority**

The San Francisco Bay Area Water Emergency Transportation Authority (WETA) was established by Senate Bill 976 in 2007 to replace the San Francisco Bay Water Transit Authority, which was created in 1999. WETA has been authorized by the State of California to oversee and operate a public water transit system in the San Francisco Bay Area. WETA created and adopted an Emergency Water Transportation System Management Plan for the San Francisco Bay Area in 2009. This plan integrates and complements the emergency plans of other agencies, to ensure mobility in the San Francisco Bay Area following a major disaster.

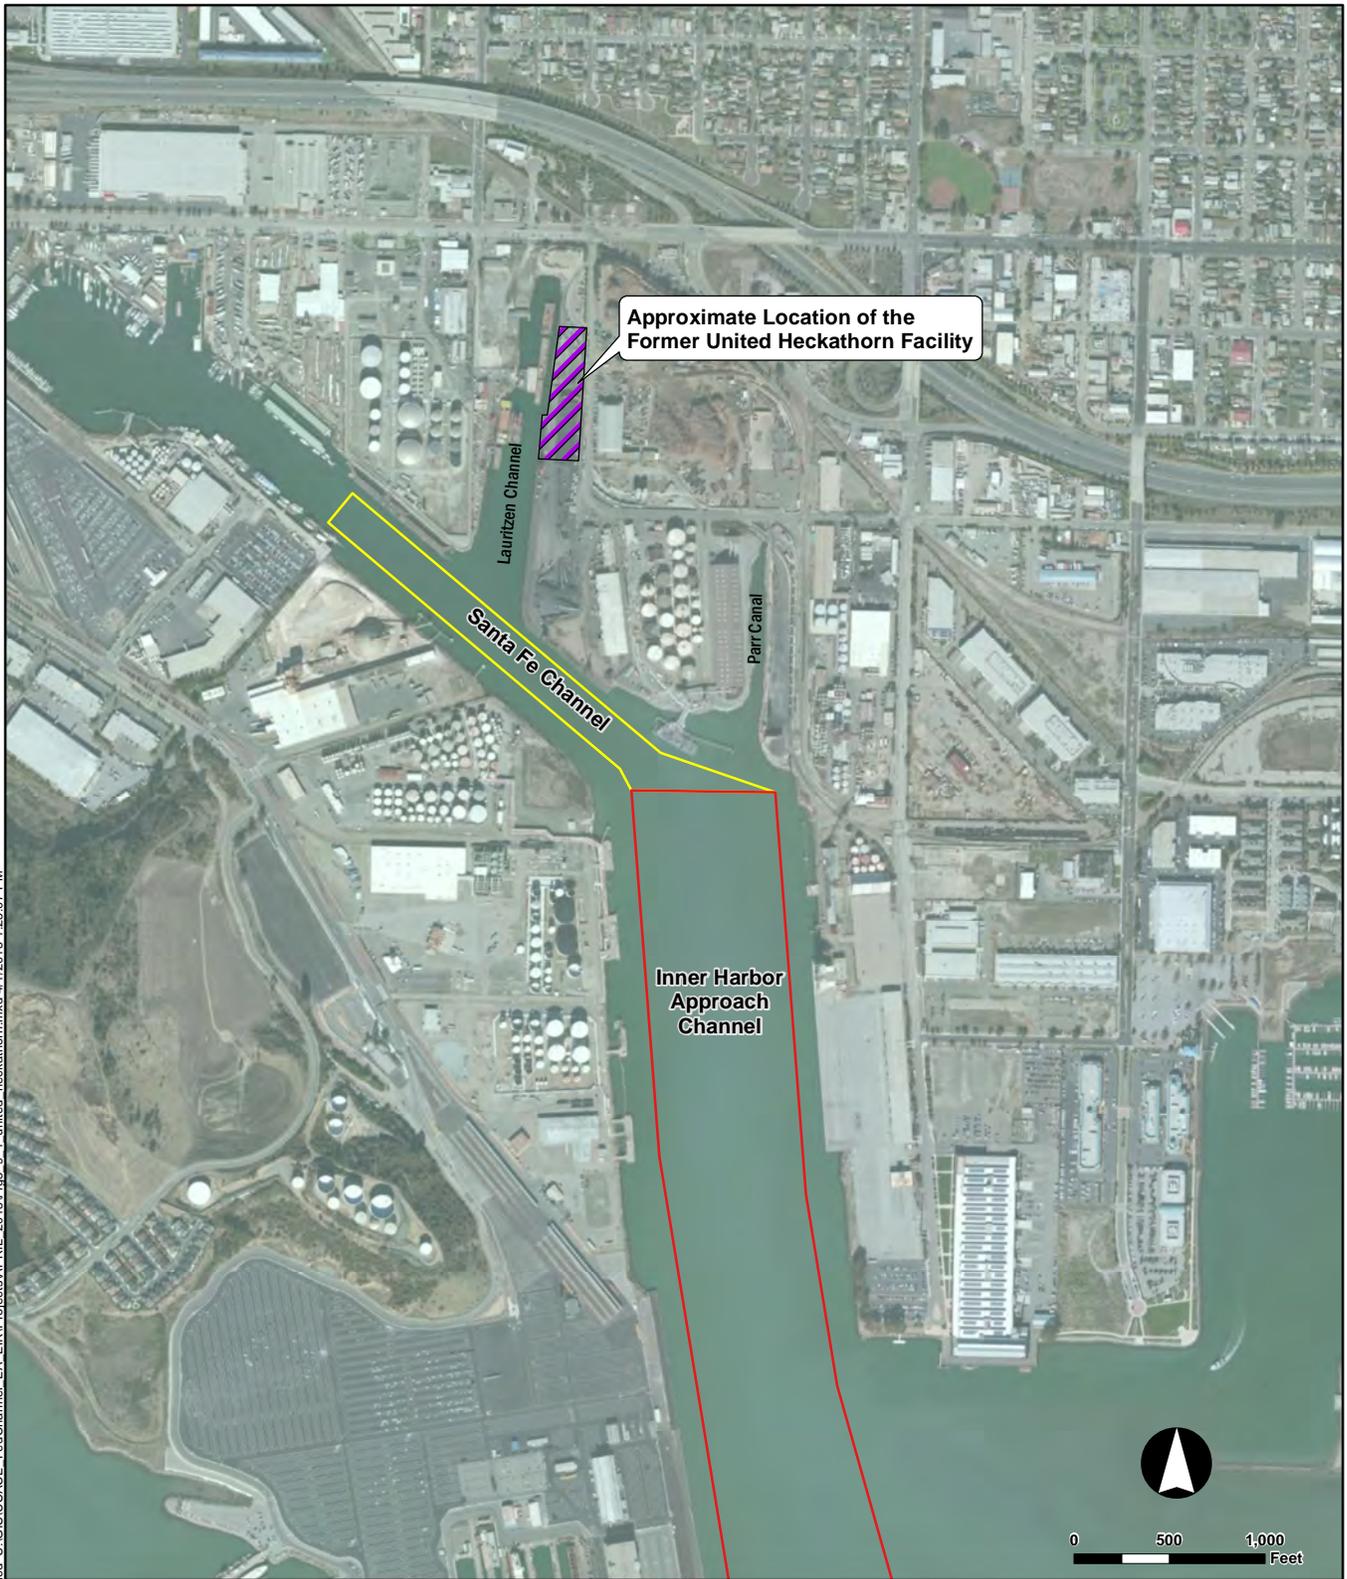

## **3.9.2 Environmental Setting**

### **Study Area**

In San Francisco Bay, the study area spans the shoreline and marine areas of the following 11 counties: Marin, Sonoma, Napa, Solano, Sacramento, San Joaquin, Contra Costa, Alameda, Santa Clara, San Mateo, and San Francisco. The geographic scope of the study area comprises the estuarine waters of the San Francisco Bay region, portions of the Sacramento-San Joaquin Delta west of Sherman Island, and the western portion of the Sacramento River Deep Water Ship Channel and Stockton Deep Water Ship Channel. Outside the Golden Gate, the study area includes the San Francisco Deep Ocean Disposal Site (SF-DODS), the San Francisco Bar Channel Disposal Site (SF-8), and the nearshore zone off Ocean Beach, as well as the waters that are used by vessels en route to these sites.

The NOAA Office of Response and Restoration “At Work Where You Live” database provides information regarding oil spills, chemical spills, ship grounding, hazardous waste sites, and marine debris projects for marine areas in the United States (NOAA, 2013b). The following hazard sites are in the study area:

- **Cosco Busan, CA:** The container ship Cosco Busan struck one of the towers of the San Francisco-Oakland Bay Bridge in San Francisco Bay on November 7, 2007. The impact created a gash in the hull of the vessel, and 53,000 gallons of fuel oil were released into the water. The oil quickly spread to other parts of San Francisco Bay. Wind and currents carried some of the oil contamination outside of the San Francisco Bay, where it impacted the outer coast from approximately Half Moon Bay to Point Reyes. Inside the San Francisco Bay, the oil contamination impacted waters and shoreline in the central portion of San Francisco Bay, from Tiburon to San Francisco on the western side, and from Richmond to Alameda on the eastern side (CDFW et al., 2012). A Final Restoration Plan was approved in 2012, and restoration is under way.
- **United Heckathorn Company:** The United Heckathorn Superfund site (Superfund Site EPA # CAD981436363) is in Richmond Harbor, and includes 5 acres of land and approximately 15 acres of marine sediments in the Parr and Lauritzen channels. The Parr channel is immediately north of the Richmond Inner Harbor dredging channel; and the Lauritzen channel is slightly northwest of the Richmond Inner Harbor dredging channel (Figure 3.9-1). The historical use of the Heckathorn Superfund site was to package and ship pesticides. Since 1997, the removal of contaminated soils and sediments has greatly reduced the potential for exposure to pesticide contaminants from the United Heckathorn site. However, unacceptable levels of dichloro-diphenyl-trichloroethane (DDT) and dieldrin remain in the waters and sediments of the Lauritzen channel. Because these pesticides

**FIGURE 3.9-1**

bio-accumulate in fish, people who fish in the area run the risk of exposure to unacceptably high levels of DDT and dieldrin. As such, the state of California issued an advisory against eating fish from the Lauritzen channel. In October 2012, the USEPA installed a flap gate on the stormwater outfall in the Lauritzen channel to prevent DDT and dieldrin-contaminated sediment from moving in and out of the system during high tide. The USEPA also completed multiple phases of field work in 2013 to further delineate the contamination, investigate sources, and assess sediment movement in the channel. The USEPA is currently preparing a Focused Feasibility Study to evaluate additional cleanup options, and expects to propose a cleanup plan in 2015 (Thompson, 2014).

- **Suisun Bay Reserve Fleet:** The U.S. Maritime Administration historically moored a fleet of vessels north of the Suisun Bay Channel to serve as a reserve of ships for national defense and national emergency purposes (NOAA, 2013b). In response to concerns about heavy metals and anti-fouling agents in paint peeling off the decaying vessels, as well as other hazardous materials that may have been released, NOAA completed a year-long study to characterize contaminant levels in sediments, and in tissues of mussels and clams, near the Reserve Fleet. NOAA's findings concluded that contaminant concentrations in the vicinity of the Reserve Fleet are comparable to those at other locations throughout the greater San Francisco Bay. Consequently, NOAA scientists did not recommend specific cleanup actions (NOAA, 2013c). In 2010, the Maritime Administration conceded to a consent decree with the Regional Water Board and coplaintiffs San Francisco Baykeeper, Natural Resources Defense Council, and ArcEcology, that required a strict schedule for the removal and recycling of the vessels, and the aggressive management of the discharges associated with exfoliating paint containing heavy metals. The Maritime Administration has succeeded in practically eliminating the paint discharges, and has removed and recycled all but five of the 54 polluting vessels. At this rate, they will complete their obligations regarding ship removal years ahead of their 2017 deadline.

### 3.9.3 Methodology and Thresholds of Significance

The following analysis evaluates the proposed project's potential effects related to hazards and hazardous materials. The project alternatives would involve maintenance dredging of federal navigation channels, transport of dredged materials, and placement of dredged materials at permitted placement sites. Based on the nature of these activities and the locations at which they would occur, the following California Environmental Quality Act (CEQA) Appendix G thresholds do not apply to the project alternatives, because there would be no potential for impacts relative to these thresholds:

- Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within 1/4 mile of an existing or proposed school;
- Be on a site that is included on a list of hazardous material sites compiled pursuant to Government Code Section 65962.5; and as a result, create a significant hazard to the public or the environment;
- Result in a safety hazard for people residing and working in the vicinity of a public-use airport;
- Result in a safety hazard for people residing and working in the vicinity of a private airstrip; and
- Expose people or structures to a significant risk of loss, injury, or death involving wildland fires.

The analysis evaluated whether the alternatives would:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials or wastes;

- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment; and
- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.

Placement of dredged material not suitable for unconfined aquatic disposal would only occur at locations permitted to accept such material. Contaminated dredged sediments that do not meet the criteria for placement at permitted beneficial re-use or upland placement sites ultimately would be disposed at a facility approved by the DMMO, and permitted for the receipt of such material (e.g., a landfill); therefore, the potential impacts related to release of hazardous materials to land are anticipated to not be adverse, and are not further evaluated.

Because dredging, transport, and placement activities would take place over open water, releases of hazardous materials could adversely affect water quality in the study area; these potential effects are discussed in Section 3.4.4 under Hydrology and Water Quality. Therefore, impact analysis in this section focuses on potential adverse effects to human health associated with hazardous materials handling.

### 3.9.4 Impacts and Mitigation Measures

#### ***Impact 3.9-1: Potential Public or Environmental Exposure from the Transport, Use, and Disposal of Hazardous Materials***

#### **No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

Under all alternatives, the DMMO would require sediment analysis and approval. Requirements would include development of a sampling plan, sediment characterization, a sediment removal plan, and handling and disposal in accordance with applicable permit conditions. All federal, state, and local regulations regarding the use, transport, and disposal of hazardous materials would be adhered to during project activities. Human health and safety impacts would be avoided through adherence to these procedures, conditions, and regulations.

Although existing hazard sites exist in the study area, these releases or potential releases are considered not adverse because the proposed dredge and placement operations would not interfere with cleanup activities at the Cosco Busan and Heckathorn hazard sites. In addition, the project alternatives do not involve fishing operations or waterborne recreation in contaminated areas; therefore, the project alternatives would not pose a human health risk.

Dredged material is not usually transported by land because this method is more expensive and inefficient compared to in-water transport. Transport of dredged material by truck or train would only occur in rare circumstances, where dredged material that is not suitable for unconfined aquatic disposal is initially placed via dredge or barge at a rehandling site, and requires land-based transport for secondary placement at a land-based facility, such as a landfill, after the material has dried. The transport of dried sediment via truck or train is not expected to result in emissions of hazardous materials that would pose a human health concern, because in a dried state, the sediment would be easily contained, and there be no expected release of contaminants. Therefore, impacts from land transport would be negligible.

**National Environmental Policy Act (NEPA) Determination:** The No Action Alternative, Proposed Action, and Reduced Hopper Dredge Use Alternatives 1 and 2 would have no impact on hazards and hazardous materials.

**CEQA Determination:** The No Project Alternative, Project, and Reduced Hopper Dredge Use Alternatives 1 and 2 would have no impact on hazards and hazardous materials.

**Note Regarding Potential Impacts of the Reduced Hopper Dredge Use Alternatives:** In the event that the budget process does not include a funding request, or Congress does not authorize additional funding or reprogramming of funding for these alternatives, then there is a possibility that certain channels (i.e., Richmond Outer, Pinole Shoal, and Suisun Bay Channel and New York Slough) would not be dredged at all or would not be fully maintained. As discussed in Section 3.10, with the reduced or lack of maintenance of certain channels, there would be an increased risk in groundings, allisions, or collisions of vessels, including those transporting hazardous materials. Navigational regulations and controls would reduce the potential for such incidents, but the agencies acknowledge that there would be an increased risk under this scenario. Because the risk of these incidents is speculative, the agencies do not evaluate it in any detail beyond this qualitative notation.

### ***Impact 3.9-2: Potential Impacts to Implementation of an Adopted Emergency Response Plan***

#### **No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Use Alternatives 1 and 2**

None of the alternatives would be expected to impair implementation of, or interfere with, any emergency operation or evacuation plans in the study area. In the event of an emergency, dredge equipment would be removed from the federal navigation channel(s), or positioned in such a manner as to not impede the navigation of emergency response or evacuation vessels.

Under all alternatives, dredging would have a long-term beneficial impact by removing shoaled sediment and maintaining the navigability of the federal channels for use by vessels during emergency response operations.

**NEPA Determination:** The No Action Alternative, Proposed Action, and Reduced Hopper Dredge Use Alternatives 1 and 2 would have a beneficial impact on emergency operation.

**CEQA Determination:** The No Project Alternative, Project, and Reduced Hopper Dredge Use Alternatives 1 and 2 would have no impact on emergency operation.

**Note Regarding Potential Impacts of the Reduced Hopper Dredge Use Alternatives:** In the event that the budget process does not include a funding request, or Congress does not authorize additional funding or reprogramming of funding for these alternatives, then there is a possibility that certain channels (i.e., Richmond Outer, Pinole Shoal, and Suisun Bay Channel and New York Slough) would not be dredged at all or would not be fully maintained. Because Richmond Outer, Pinole Shoal, and Suisun Bay Channel and New York Slough are deep water channels and have project depths of 35 feet mean low lower water or greater, these channels would likely remain navigable to most emergency response or evacuation vessels, depending on the extent accumulation of sediment, under a deferred dredging scenario. However, there is a possibility that some adverse impacts on emergency response operations, and consequently on public safety, could occur.

### ***Cumulative Impacts***

Because the project would not cause adverse impacts related to hazards and hazardous materials, it would not contribute to cumulative hazards and hazardous materials use impacts.

**NEPA Determination.** The project would not contribute to cumulative hazards and hazardous materials impacts.

**CEQA Determination.** The project would not contribute to cumulative hazards and hazardous materials impacts.

### 3.10 TRANSPORTATION

As described in Chapter 2, Alternatives, the project alternatives would involve maintenance dredging of the federal navigation channels, and transport and placement of the dredged materials, at a combination of in-water and adjacent landward placement sites.

Dredged material is rarely transported by land, because this method is more expensive and inefficient compared to in-water transport. Transport of dredged material by truck or train would only occur in circumstances where dredged material that is not suitable for unconfined aquatic disposal requires secondary placement. For example, not suitable for unconfined aquatic disposal material would be placed initially by way of dredge or barge at a rehandling site, and then transported by truck or train for secondary placement at a land-based facility, such as a landfill, after the material has dried. Based on United States Army Corps of Engineers (USACE) data regarding sediment quality in the federal navigation channels, it is anticipated that occurrences of secondary transport of dredged material by way of truck or train would be rare. As discussed in Section 3.3.2, sediment testing results for previous USACE maintenance dredging episodes indicate that, in general, dredged materials from the subject federal navigation channels have been suitable for unconfined aquatic disposal. Land-based transport of dredged material from USACE's maintenance dredging projects in San Francisco Bay did not occur during the 2000-2012 baseline period. Considering the extensive roadway and railway infrastructure in the study area, and existing levels of vehicle traffic and rail use, the project alternatives would not result in noticeable impacts on vehicle traffic or rail use, especially because occurrences of land-based transport of dredged material would be rare. Additionally, no impacts to pedestrian and bicycle movement would be expected because land-based transport would be infrequent and would not be expected to impact pedestrian and bicycle facilities. Because impacts on land-based transportation and transit would be negligible, these modes of transportation are not further discussed in this section.

Therefore, this section evaluates the potential impact of the project alternatives on marine navigation in the study area.

#### 3.10.1 Regulatory Setting

This section provides a regulatory framework describing the federal, state, and regional policies and plans applicable to navigation in the study area.

##### **Federal**

##### **United States Coast Guard**

Under 14 U.S.C. and 33 U.S.C., and other portions of the Code of Federal Regulations, the United States Coast Guard (USCG) has authority for maritime law enforcement on the navigable waters of the United States, as well as responsibilities for search and rescue. Title 33: Navigation and Navigable Waters, Part 162: Inland Waters Navigation Regulations identifies regulations for navigation by both commercial and noncommercial vessels.

##### **Inland Navigational Rules Act of 1980**

The Inland Navigational Rules Act of 1980 (Public Law 96-591, 94 Stat. 3415, 33 C.F.R. pt. 83), more commonly known as the Inland Rules, governs many rivers, lakes, harbors, and inland waterways. Directly applicable to the proposed project is Rule 27 – Vessels Not Under Command or Restricted in Their Ability to Maneuver, which specifies lighting and safety requirements for vessels engaged in dredging or underwater operations that are restricted in their ability to maneuver (USCG, 1980). In addition, Title 33 C.F.R. § 88.15 contains requirements for lighting on floating or supported dredge pipelines that must be displayed at night and in periods of restricted visibility.

## **Regulated Navigation Areas**

The USCG has established regulated navigation areas (RNAs) in the San Francisco Bay region to reduce vessel congestion where maneuvering room is limited. These RNAs increase navigational safety by organizing traffic flow patterns; reducing meeting, crossing, and overtaking situations between large vessels in constricted channels; and limiting vessel speed (USCG, 2013a). The RNAs apply to all large vessels (defined as any power-driven vessels of 1,600 or more gross tons, or tugs with a tow of 1,600 or more gross tons).

## **Ports and Waterways Safety Act of 1972**

The Ports and Waterways Safety Act of 1972 (Title 33, Chapter 25, Section 1221) authorized the USCG to establish, operate, and maintain vessel traffic services for ports, harbors, and other waters subject to congested vessel traffic. As a result, in 1972, the USCG established the Vessel Traffic Service (VTS) for San Francisco Bay and designated traffic lanes for inbound and outbound vessel traffic, specified separation zones between vessel traffic lanes, and set up rules to govern vessels entering and leaving ports (USCG, 2012b). The VTS, which is on Yerba Buena Island, controls marine traffic throughout the San Francisco Bay Area. Although some small and private vessels are not required to coordinate their movements by contacting the VTS, the USCG monitors all commercial, United States Navy, and private marine traffic in San Francisco Bay and local coastal waters. VTS San Francisco is responsible for the safe movement of approximately 133 miles of waterway from offshore to the ports of Stockton and Sacramento. VTS San Francisco averages 250 vessel movements a day (USCG, 2013b).

## **The International Regulations for Preventing Collision at Sea**

The International Regulations for Preventing Collision at Sea (Public Law 95-75, 91 Stat. 308, 33 U.S.C. §§ 1-8), also known as the Rules of the Road or International Navigation Rules, or 72 COLREGS, govern open bodies of water in which foreign shipping traffic is possible, and are a set of statutory requirements designed to promote navigational safety. The most recently adopted version of these regulations took effect on July 15, 1977. These rules include requirements for navigation lights, dayshapes, and steering, as well as sound signals for both good and restricted visibility. The boundaries between where the Inland Rules and the International Rules apply are displayed as Demarcation Lines on navigational charts.

## **Energy Independence and Security Act of 2007**

The Energy Independence and Security Act of 2007 established The America's Marine Highway Program, which is a Department of Transportation initiative to expand the use of waterborne transportation to relieve landside congestion and to reduce carbon emissions. The Marine Highway Program was fully implemented in April 2010 through publication of a Final Rule in the Federal Register. The Secretary's designations were made pursuant to the Final Rule, as required by the Energy Independence and Security Act of 2007. The Energy Independence and Security Act defines America's Marine Highways as navigable waterways that have demonstrated the ability to provide additional capacity to relieve congested landside routes serving freight and passenger movement (USDOT, 2013a). The study area includes the Marine Highway 580 Connector, which includes the San Joaquin River, Sacramento River, and connecting commercial navigation channels, ports, and harbors in Central California from Sacramento to Oakland. The Marine Highway 580 Connector also connects to the Marine Highway 5 Corridor at Oakland, which spans Washington, Oregon, and California along the West Coast (USDOT, 2013b).

## **America's Marine Highway Program**

The Marine Highway Program was established by Section 1121 of the Energy Independence and Security Act of 2007 to reduce landside congestion through the designation of Marine Highway Routes. Section 405 of the Coast Guard and Maritime Transportation Act of 2012 further expanded the scope of the program beyond reducing landside congestion to efforts that generate public benefits by increasing the use or efficiency of domestic freight or passenger transportation on Marine Highway Routes between ports in the United States. The Marine Highway Program does not develop or operate Marine Highway services. The private sector or state/local governments develop and operate Marine Highway services.

### **State**

#### **California Harbors and Navigation Code**

The California Harbors and Navigation Code vests authority with the Department of Boating and Waterways to regulate matters of navigational safety for the state's boating public. The California Department of Boating and Waterways was formed in 1979 through the consolidation of functions previously held by a number of divisions in the Departments of Natural Resources, Motor Vehicles, and Parks and Recreation. The code established a comprehensive set of state laws and regulations governing the equipment and operation of vessels on all waters of the state.

### **Regional**

#### **The San Francisco Bay Area Seaport Plan**

The San Francisco Bay Area Seaport Plan, first adopted in 1996 and last amended in 2012, is the product of a cooperative planning effort of the Metropolitan Transportation Commission (MTC) and the San Francisco Bay Conservation and Development Commission (BCDC). The Seaport Plan constitutes the maritime element of MTC's Regional Transportation Plan, and is incorporated into BCDC's San Francisco Bay Plan, where it is the basis of the Bay Plan port policies. The MTC uses the Seaport Plan to assist in making project funding decisions and managing the metropolitan transportation system; and BCDC uses the Seaport Plan to help guide its regulatory decisions on permit applications, consistency determinations, and related matters.

#### **San Francisco Bay Area Water Emergency Transportation Authority**

The San Francisco Bay Area Water Emergency Transportation Authority (WETA) was established by Senate Bill 976 in 2007 to replace the San Francisco Bay Water Transit Authority, which was created in 1999. WETA has been authorized by the State of California to oversee and operate a public water transit system in the San Francisco Bay Area. WETA created and adopted an Emergency Water Transportation System Management Plan for the San Francisco Bay Area in 2009. This plan integrates and complements the emergency plans of other agencies, to ensure mobility in the San Francisco Bay Area following a major disaster.

### **3.10.2 Environmental Setting**

#### **Study Area**

In San Francisco Bay, the study area spans the shoreline and marine areas of the following 11 counties: Marin, Sonoma, Napa, Solano, Sacramento, San Joaquin, Contra Costa, Alameda, Santa Clara, San Mateo, and San Francisco. It does not include the landside areas far removed from navigable waters. The geographic scope of the study area comprises the estuarine waters of the San Francisco Bay region, portions of the Sacramento-San Joaquin Delta west of Sherman Island, and the western portion of the

Sacramento River Deep Water Ship Channel and Stockton Deep Water Ship Channel. Outside the Golden Gate, the study area includes the San Francisco Deep Ocean Disposal Site (SF-DODS), the San Francisco Bar Channel Disposal Site (SF-8) and the nearshore zone off Ocean Beach, as well as the waters that are used by vessels en route to these sites.

### Vessel Movement in the Study Area

Vessel traffic in the San Francisco Bay consists of inbound and outbound vessels and wholly in-Bay vessel movements. This vessel traffic includes tugs, government vessels, passenger ferry ships, commercial shipping vessels, recreational boats, commercial and sport fishing boats, board sailors, and personal watercraft.

Water transit is a small but growing part of the San Francisco Bay Area's transportation network. Although it carries only a fraction of the total San Francisco Bay Area travelers, water transit plays a meaningful role in reducing congestion and providing mobility in the key transbay bridge corridors throughout the San Francisco Bay Area. Existing ferry service is summarized in Table 3.10-1. Services to Oakland and Vallejo use the federal navigation channels.

<b>Corridor/Ferry Route</b>	<b>Operator(s)</b>

Note:	
<sup>1</sup> Blue & Gold Fleet operates these services under an Operations and Maintenance contract with WETA.	
WETA = San Francisco Bay Area Water Emergency Transportation Authority	

The Bay Area is served by five seaports. The Port of Oakland, the largest of the five, is the third largest seaport on the West Coast of the United States. Other seaports in the San Francisco Bay Area include the Port of San Francisco, the Port of Richmond, the Port of Benicia, and the Port of Redwood City (MTC and ABAG, 2013). The federal navigation channels are used for commercial traffic, including deep-draft, merchant, and oil tanker vessels. Waterborne transportation through the Petaluma River, Suisun Bay and Redwood City is important for the regional movement of aggregates, gravel, oyster shell and building materials. In addition, the proposed dredging activities would support the continued operation of the Port of Sacramento and the Port of Stockton. Individual barges are able to transport larger quantities of materials than individual tractor trailer trucks; therefore, use of the above seaports avoids a substantial number of truck trips on the regional roadway network.

Regionally, the Marine Highway Initiative is an effort to establish a “container on barge” service stretching from West Sacramento to Oakland, with stops in Stockton, to provide a viable marine highway that facilitates short sea shipping service between regional ports to improve goods movement throughout Northern California. In addition, this initiative will decrease congestion on major roadways, and significantly reduce the number of truck emissions associated with the current distribution system. Service started in July 2013 between the Port of Stockton and the Port of Oakland (Port of Oakland, 2013). The Port of Stockton anticipates six to eight trips per week by the end of 2013 (Wingfield, 2013).

Deep-draft vessels in San Francisco Bay are often constrained to navigate only within the main shipping channels. Groundings have been reported in many areas of the region, in part due to the narrow width of many of the channels. Groundings can result in damage to vessels and property, with the potential for serious environmental consequences. A ship aground in a channel can block the transit of other vessels or create new shoaling, and may cause serious delays to commerce. Maneuvering deep-draft ships in narrow channels with minimal underkeel clearance poses high navigational risks, given the complexities of tides, currents, and weather conditions in the Bay (HSC, 2014).

Critical Maneuvering Areas (CMAs) are areas within the Bay where additional standards of care are required due to the restrictive nature of the channel, proximity of hazards, or the prevalence of adverse currents. Tugs with tows should not transit through CMAs when visibility is less than 0.25 nautical mile. Tugs with tows in petroleum service should not transit through CMAs when visibility is less than 0.5 nautical mile. Locations in the Bay identified as CMAs are Redwood Creek, San Mateo-Hayward Bridge, Oakland Bar Channel, Islais Creek Channel, Richmond Inner Harbor, the east span of Richmond-San Rafael Bridge, Union Pacific Bridge, up-bound New York Slough, and Rio Vista Lift Bridge (HSC, 2014).

### 3.10.3 Methodology and Thresholds of Significance

Maintenance dredging would be conducted with clamshell-bucket dredges, hopper dredges, and cutterhead-pipeline dredges. Methods used to transport dredged materials would include pipelines, hopper dredges, barges, and scows. Because this transportation evaluation focuses on marine navigation, many of the California Environmental Quality Act (CEQA) Appendix G thresholds for transportation/traffic, as written, do not apply to the project alternatives because they are focused on land-based or air transportation. Therefore, the following project-specific thresholds were established to evaluate the potential for navigation impacts under the National Environmental Policy Act (NEPA) and CEQA, considering the topics addressed in the transportation/traffic CEQA thresholds that could be applied to navigation:

- a) Would the project alternatives disrupt or substantially impede marine navigation? For the purposes of this analysis, a marine traffic disruption would occur if dredging or placement activities substantially interfered with vessel navigation, and/or substantially increased the volume of vessel movement in the study area.
- b) Would the project alternatives create substantial navigational safety risks?

### 3.10.4 Impacts and Mitigation Measures

#### ***Impact 3.10-1: Potential to Disrupt or Impede Marine Navigation***

##### **No Action/No Project Alternative**

Dredging—and the associated transport and placement activities—have occurred in the waters of San Francisco Bay for decades; the No Action/No Project Alternative would be a continuation of USACE’s current maintenance dredging program for the federal navigation channels in San Francisco Bay.

Dredging is a temporary activity that varies in duration depending on the amount of shoaled sediment in each channel, the frequency at which a channel is dredged, and the equipment used for dredging and dredged material transport. The typical duration of dredging for each channel varies, and ranges from 5 to 65 days for the federal channels addressed in this Environmental Assessment/Environmental Impact Report; however, because dredges move along a channel, the duration a dredge would be operating in any one specific location would be limited. The federal navigation channels are generally wide enough to accommodate dredge equipment and allow passage of other vessel traffic, and dredges would move out of the way to allow passage of larger vessels. However, the dredging activities may occasionally delay or temporarily impede some vessels. Hopper dredges generally have less impact on navigation because they are continually moving, while clamshell-bucket dredges and cutterhead-pipeline dredges are stationary during operation, and may need to temporarily cease dredging activities to move out of the way of larger passing vessels. Compared to a hopper dredge, which is self-propelled, clamshell-bucket dredge and cutterhead-pipeline dredge operations may occupy more space in a channel, because these methods require the use of support vessels to tow and position the dredge. Cutterhead and clamshell-bucket dredge operations require the use of a dredge plant, on which the dredge equipment is located, plus four to five support vessels in the immediate dredge area for maneuvering the dredge plant and providing equipment support. Clamshell-bucket dredging also involves the use of one or two dredged material transport placement vessel, whereas hopper dredges store and transport the dredged material. Cutterhead dredging does not involve transport of dredged material by vessel. As described above, the USCG is responsible for organizing vessel traffic and maintaining RNAs to reduce vessel congestion where maneuvering room is limited. The dredging and placement activity for this alternative would comply with all applicable vessel traffic and safety requirements, including specifications for dredge pipelines.

Maintenance dredging and placement activities would add to vessel movement in the study area, particularly during transport to placement sites; however, this vessel traffic would be similar to that which has occurred during USACE's past maintenance dredging operations, and would be negligible considering the existing volume of vessel movement in the study area.

Therefore, adverse impacts to navigation under No Action/No Project Alternative would be minimal and short-term.

Dredging would have a long-term beneficial impact by removing shoaled sediment and maintaining the navigability of the federal channels.

**NEPA Determination:** The No Action Alternative would have a short-term, less-than-significant adverse impact and long-term beneficial impact on navigation.

**CEQA Determination:** The No Project Alternative would have a less-than-significant impact on navigation.

### **Proposed Action/Project**

Implementation of the Proposed Action/Project would be very similar to the No Action/No Project Alternative; it would involve use of the same type of dredge equipment for each channel, the same volume of dredged material, and the same dredging frequency and durations. This alternative would also comply with applicable vessel traffic and safety requirements. Therefore, impacts related to disruption of navigation from dredging would be the same as under the No Action/No Project Alternative.

Depending on the placement site selected for each channel, patterns of vessel movement could differ from the No Action/No Project Alternative, but the overall volume of vessel traffic would be similar to that under the No Action/No Project Alternative. Hopper dredging only involves the use of one vessel (i.e., the hopper dredge) to transport dredged material to the placement site. Clamshell-bucket dredging involves the use of one or two scows to transport dredged material from the federal channel to the

placement site. Cutterhead dredging does not involve transport of dredged material by vessel. The effect of this small amount of vessel movement would be negligible, considering the existing volume of vessel movement in the study area, and historic vessel traffic to existing placement sites. The USACE would not use the future placement sites identified in Section 1.5.4 until appropriate environmental review is completed, including evaluation of impacts on navigation.

As under the No Action/No Project Alternative, dredging would have a long-term beneficial impact by removing shoaled sediment and maintaining the navigability of the federal channels.

**NEPA Determination:** The Proposed Action would have a short-term, less-than-significant adverse impact and long-term beneficial impact on navigation.

**CEQA Determination:** The Project would have a less-than-significant impact on navigation.

### **Reduced Hopper Dredge Use Alternative 1**

Implementation of Reduced Hopper Dredge Use Alternative 1 would be very similar to the Proposed Action/Project Alternative, except that either Richmond Outer Harbor or Pinole Shoal and Suisun Bay Channel would be dredged with a clamshell-bucket dredge instead of a hopper dredge. San Bruno Channel in Redwood City Harbor would also be dredged with a clamshell-bucket dredge instead of a hopper dredge; however, this channel is dredged at intervals of 10 years or longer. As noted above, clamshell-bucket dredges have a greater potential to impact navigation compared to hopper dredges because they are stationary while operating. Clamshell-bucket dredge operations also involve the use of multiple vessels in the dredge area, whereas hopper dredge operations only require one vessel, so there would be four to five additional vessels in or near the federal channel during dredging. In addition, dredging a channel with a clamshell bucket dredge can take up to ten times longer than dredging with a hopper dredge (USACE, 2013d). Although clamshell-bucket dredges would stop dredging and move out of the way of larger vessels as necessary, impacts to navigation related to temporary delays of other vessel traffic could be slightly greater than under the No Action/No Project Alternative or the Proposed Action/Project at the channels where a mechanical dredge would be used instead of a hopper dredge. Moving clamshell-bucket dredges out of the way of deep draft vessels would take longer, because the dredges are mounted on barges and secured into the bay floor by spuds; moving mechanical dredges would require removing the spuds and moving the barge buy tugs. Under this alternative, USACE would also comply with all applicable vessel traffic and safety requirements.

As under the other alternatives, dredging would have a long-term beneficial impact by removing shoaled sediment and maintaining the navigability of the federal channels.

**NEPA Determination:** Reduced Hopper Dredge Use Alternative 1 would have a short-term, less-than-significant adverse impact and long-term beneficial impact on navigation.

**CEQA Determination:** Reduced Hopper Dredge Use Alternative 1 would have a less-than-significant impact on navigation.

### **Reduced Hopper Dredge Use Alternative 2**

Under Reduced Hopper Dredge Use Alternative 2, impacts would be very similar to the Proposed Action/Project Alternative, except that Richmond Outer Harbor, Pinole Shoal, and Suisun Bay Channel would be dredged with a clamshell-bucket dredge instead of a hopper dredge. San Bruno Channel in Redwood City Harbor would also be dredged with a clamshell-bucket dredge instead of a hopper dredge; however, this channel is dredged at intervals of 10 years or longer. As noted above, clamshell-bucket dredges have a greater potential to impact navigation compared to hopper dredges, because they are stationary while operating and clamshell-bucket dredges typically take longer than hopper dredges to dredge a particular

channel. Clamshell-bucket dredge operations also involve the use of multiple vessels in the dredge area, whereas hopper dredge operations only require one vessel, so there would be four to five additional vessels in or near the federal channel during dredging. Although mechanical dredges would stop dredging and move out of the way of larger vessels as necessary, temporary impacts to navigation related to temporary delays of other vessel traffic could be slightly greater than under the No Action/No Project Alternative or the Proposed Action/Project at these channels. Impacts could also be greater than under Reduced Hopper Dredge Alternative 1, because both Pinole Shoal and Richmond Outer Harbor would be dredged with a mechanical dredge instead of a hopper dredge. Under this alternative, USACE would also comply with applicable vessel traffic and safety requirements.

As under the other alternatives, dredging would have a long-term beneficial impact by removing shoaled sediment and maintaining the navigability of the federal channels.

**NEPA Determination:** Reduced Hopper Dredge Use Alternative 2 would have a short-term, less-than-significant adverse impact and long-term beneficial impact on navigation.

**CEQA Determination:** The Reduced Hopper Dredge Use Alternative 2 would have a less-than-significant impact on navigation.

**Note Regarding Potential Impacts of the Reduced Hopper Dredge Use Alternatives:** In the event that the budget process does not include a funding request, or Congress does not authorize additional funding or reprogramming of funding for these alternatives, then there is a possibility that certain channels (i.e., Richmond Outer, Pinole Shoal, and Suisun Bay Channel and New York Slough) would not be dredged at all or would not be fully maintained. Cargo ships are loaded to maximize the amount of cargo transported. If the federal channels in San Francisco Bay are not fully maintained and cannot be safely navigated by larger cargo vessels, commercial shippers may have to use more ships with lighter loads. There could be additional deep draft traffic, including tankers, bulk, and containerized vessels, navigating a constrained channel to carry the same amount of cargo. Because it is not expected that traffic would significantly increase above current vessel traffic volumes, the agencies do not evaluate it in any detail beyond this qualitative notation.

CEQA does not require consideration of economic impacts; however, such impacts are considered under NEPA. If commercial shippers have to use more ships with lighter loads, this may increase the cost of transporting cargo. An increase in cargo transportation costs could result in an adverse impact on the regional economy.

### ***Impact 3.10-2: Potential to Create Navigational Safety Risks***

#### **No Action/No Project Alternative, Proposed Action/Project, and Reduced Hopper Dredge Alternatives 1 and 2**

Under all of the alternatives, dredging and placement activities would comply with applicable vessel traffic and safety requirements, including specifications for dredge pipelines. Notes to mariners and navigational warning markers would be used as needed to prevent navigational hazards. Therefore, there would be no impacts related to navigational safety risks.

Dredging would have a long-term beneficial impact by removing shoaled sediment that could pose a navigation hazard, and allowing for safe navigation in the federal channels.

**NEPA Determination:** The No Action Alternative, Proposed Action, and Reduced Hopper Dredge Use Alternatives 1 and 2 would have a beneficial impact on navigational safety.

**CEQA Determination:** The No Project Alternative, Project, and Reduced Hopper Dredge Use Alternatives 1 and 2 would not impact navigational safety.

**Note Regarding Potential Impacts of the Reduced Hopper Dredge Use Alternatives:** In the event that the budget process does not include a funding request, or Congress does not authorize additional funding or reprogramming of funding for these alternatives, then there is a possibility that certain channels (i.e., Richmond Outer, Pinole Shoal, and Suisun Bay Channel and New York Slough) would not be dredged at all or would not be fully maintained. With the reduced or lack of maintenance in these channels, there would be an increased risk of a navigational hazard that could result in vessel groundings, allisions, or collisions. Navigational regulations and controls would reduce the potential for such incidents, but the agencies acknowledge that there would be an increased risk under this scenario. Because the risk of these incidents is speculative, the agencies do not evaluate it in any detail beyond this qualitative notation.

***Impact 3.10-3: Potential to Result in Cumulative Impacts on Navigation***

The project alternatives would have minimal, short-term, adverse impacts on navigation due to the presence of dredge equipment in the federal channels, which may temporarily delay or impede other vessels. Although the reasonably foreseeable actions in Table 3.1-1 may result in vessel use of the federal channels, most of the vessels associated with these actions would be mobile, and therefore would not be expected to result in cumulative impacts related to disruption of navigation. Other activities that are included on the cumulative project list include dredging to deepen channels, including the Redwood City and San Bruno channels. Although deepening of a federal channel would involve the presence of dredge equipment in the channel, maintenance dredging and dredging for deepening of a channel would not be conducted concurrently, and therefore would not result in cumulative impacts to navigation.

**NEPA Determination:** The project alternatives would not result in cumulative impacts on navigation.

**CEQA Determination:** The project alternatives would not result in cumulative impacts on navigation.

## **CHAPTER 4 PUBLIC AND AGENCY INVOLVEMENT**

Since early 2013, public and agency participation has occurred as a part of the environmental review process, pursuant to the requirements of the National Environmental Policy Act and the California Environmental Quality Act (CEQA). Stakeholders and public agencies, including those with permitting authority for the project, have been engaged and involved as described below.

### **4.1 ALTERNATIVES DEVELOPMENT**

On February 20, 2013, the United States Army Corps of Engineers (USACE) and San Francisco Bay Regional Water Quality Control Board (Regional Water Board) conducted an alternatives workshop to provide natural resource agencies with an opportunity to provide input on the alternatives to be analyzed in the Environmental Assessment (EA)/Environmental Impact Report (EIR). Representatives of the United States Environmental Protection Agency, United States Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), and San Francisco Bay Conservation and Development Commission (BCDC) participated in the workshop. Although invited, the National Marine Fisheries Service was unable to participate in the workshop.

### **4.2 SCOPING**

As required by CEQA for the preparation of an EIR, the Regional Water Board submitted a Notice of Preparation to the California State Clearinghouse on February 26, 2013. The purpose of the notice was to alert potentially interested parties of the project, and to invite participation in the environmental review process.

On February 26, 2013, copies of the notice were sent to 63 interested parties, which included agencies, landowners, and residents in the project vicinity; community organizations; public agencies and representatives; and interested parties from a list developed in coordination with the Regional Water Board and USACE. A scoping meeting was held on March 12, 2013, at 1333 Broadway, Suite 800, in Oakland, California. Two members of the public and two agency staff representatives attended the scoping meeting. Comments were received at the meeting and throughout the scoping period, which ended on March 27, 2013.

The USACE and Regional Water Board received four e-mail messages and ten letters during the scoping period. Four correspondents were property owners or businesses in the project vicinity. Eight correspondents were public resource agencies. Two correspondents were nongovernmental organizations. All comments received were considered in the preparation of the EA/EIR. Table 4-1 provides a summary of all comments received, organized by applicable resource area. Although all comments were considered, some comments pertained to items beyond the scope of this EA/EIR, and therefore were not addressed in the content of this document.

### **4.3 SMELT WORKING GROUP**

Agency coordination to minimize impacts to longfin smelt and delta smelt commenced prior to the initiation of this EA/EIR. In an April 2010 letter to USACE, CDFW requested that USACE convene a working group to develop and standardize minimization, mitigation, funding, and effectiveness monitoring measures by July 31, 2010. The measures developed were to minimize and fully mitigate the impacts of the taking of longfin smelt. The mitigation was to be proportional in extent to the impact of the taking, and measures should be capable of successful implementation.

<b>Table 4-1 Summary of Comments Received</b>		
<b>Resource Area</b>	<b>Agency/Nongovernmental Organization Comments</b>	<b>Public Comments</b>
Aesthetics	None	None
Air Quality and Greenhouse Gases	<ul style="list-style-type: none"> <li>• Evaluate the project's contribution to greenhouse gases.</li> <li>• Consider the potential effects on sea level rise.</li> <li>• Consider air quality impacts between tug traffic and the CO<sub>2</sub> sequestered in tidal marshes.</li> <li>• Consider air quality impacts of hydraulic versus mechanical dredging.</li> <li>• Analyze emissions for deep ocean disposal, in-Bay disposal, and transport to restoration sites.</li> <li>• Assess carbon offset programs.</li> </ul>	<ul style="list-style-type: none"> <li>• Analyze emissions for deep ocean disposal, in-Bay disposal, and transport to restoration sites.</li> </ul>
Alternatives	<ul style="list-style-type: none"> <li>• Consider including the Edgerly Island and Imola Avenue placement sites in the EA/EIR.</li> <li>• Reexamine the result of the 1998 LTMS EIR, which picked as a preferred alternative a mix of ocean disposal and beneficial reuse.</li> <li>• Consider a smaller scope other than the no project alternative, which may entail fewer channels.</li> </ul>	<ul style="list-style-type: none"> <li>• Request dredging of Richardson Bay</li> <li>• Consider including the Edgerly Island and Imola Avenue placement sites in the EA/EIR.</li> <li>• Consider the institution of scouring systems to reduce the costs of maintaining the channels.</li> </ul>

Following this request, the USACE convened a longfin smelt and delta smelt working group, consisting of CDFW, USFWS, BCDC, Regional Water Board, and USACE. The group assisted in the development of the hopper dredging entrainment monitoring conducted in 2010 (McGowan, 2010) and 2011 (Gold et al., 2011). They also participated in the development of the Engineer Research and Development Center 2012-2013 entrainment monitoring risk assessment. In addition, the group agreed that hopper dredge smelt fish entrainment would be fully mitigated by using the CDFW-developed fish entrainment mitigation ratio equation, which is used by other projects that entrain fish through pumping of water, including the State Water Project (see Section 2.3.3). Since then, the USACE has continued to provide mitigation based on the previous year's hydraulic pumping ratio.

#### 4.4 REVIEW OF THE DRAFT EA/EIR

The Draft EA/EIR was published on December 5, 2014. On that date, the Notice of Availability (NOA) for the Draft EA/EIR was published in the *Contra Costa Times* and *Oakland Tribune*, mailed to the project mailing list, and emailed to the Long-Term Management Strategy stakeholders email distribution list and the Harbor Safety Committee of the San Francisco Bay Region email distribution list. In addition, the NOA and CEQA Notice of Completion were submitted to the State Clearinghouse on December 5, 2014.

The Draft EA/EIR was made available for download on USACE's website (<http://www.spn.usace.army.mil/Missions/ProjectsandPrograms/Navigation.aspx>) and the Regional Water Board's website ([http://www.waterboards.ca.gov/sanfranciscobay/public\\_notices/](http://www.waterboards.ca.gov/sanfranciscobay/public_notices/)). Printed copies of the Draft EA/EIR were made available for public review at the following locations during normal business hours:

- Regional Water Quality Control Board, San Francisco Region, 1515 Clay Street, Oakland;
- Napa Main Library, 580 Coombs Street, Napa;
- Petaluma Regional Library, 100 Fairgrounds Drive, Petaluma;
- Oakland Public Library, 125 14th Street, Oakland;
- Pittsburg Library, 80 Power Avenue, Pittsburg;
- Redwood City Public Library, 1044 Middlefield Road, Redwood City;
- Richmond Public Library, 325 Civic Center Plaza, Richmond; and
- San Francisco Public Library, 100 Larkin Street, San Francisco.

Agencies and the general public had the opportunity to review and comment on the Draft EA/EIR during a formal 45-day comment period, which ended on January 20, 2015.

A public meeting was held on January 7, 2015, at 1333 Broadway, Suite 800, Oakland, to receive comments on the Draft EA/EIR. The public meeting was announced in the NOA and through the same notifications described above. At the public meeting, an overview of the proposed project and the findings of the Draft EA/EIR were presented and the public was given the opportunity to provide verbal comments or submit written comments on comment cards. Appendix C, Response to Comments, includes a summary of comments provided at the public meeting, written comments received on the Draft EA/EIR, and responses to comments received.

#### 4.5 LIST OF AGENCIES AND ORGANIZATIONS CONTACTED

The following federal, state, and local agencies, and other organization were contacted during the preparation of this EA/EIR.

##### Federal Agencies

- National Marine Fisheries Service
- United States Coast Guard

- United States Environmental Protection Agency
- USFWS
- United States Geological Survey

### **State Agencies**

- California Department of Boating and Waterways
- CDFW
- California Department of Water Resources
- California Coastal Conservancy
- California State Lands Commission
- Central Valley Regional Water Quality Control Board

### **Local Agencies**

- Alameda County
- Association of Bay Area Governments
- BCDC
- City and County of San Francisco Planning Department
- City of Alameda
- City of American Canyon
- City of Antioch
- City of Belvedere
- City of Benicia
- City of Berkeley
- City of Emeryville
- City of Fairfield
- City of Foster City
- City of Larkspur
- City of Martinez
- City of Napa
- City of Oakland
- City of Petaluma
- City of Pittsburg
- City of Redwood City
- City of San Leandro
- City of San Rafael
- City of Sausalito
- City of Suisun City
- City of Tiburon
- City of Vallejo
- Contra Costa County Department of Public Works
- Marin County Department of Public Works
- Napa County
- Napa County Flood Control and Water Conservation District
- Port of Oakland
- Port of Redwood City
- Port of Richmond
- Port of San Francisco
- Port of Stockton
- Sacramento County
- San Francisco Bay Area Water Emergency Transportation Authority

- San Francisco Public Utilities Commission
- San Joaquin County
- San Mateo County
- Santa Clara County Board of Supervisors
- Santa Clara County Planning Office
- Solano County Department of Environmental Management
- Sonoma County Department of Public Works

**Other Organizations**

- Bay Area Council
- Bay Planning Coalition
- Delta Stewardship Council
- Harbor Safety Committee of the San Francisco Bay Region

## CHAPTER 5 SUMMARY OF IMPACTS AND OTHER REQUIRED ANALYSES

This chapter presents a summary of impacts and mitigation measures, and a comparison of the project alternatives. It also includes additional analysis required under the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA).

### 5.1 COMPARISON OF THE ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES

As stated in Section 3.1, the project would have no or negligible impacts on forestry, agriculture, public services, minerals, noise, utilities, energy, recreation, aesthetic and visual resources, population and housing, socioeconomics, environmental justice, and regional growth.

For each resource topic evaluated in detail, Table 5-1 presents a summary of impacts for the action alternatives, mitigation measures, and the NEPA and CEQA impact levels for each alternative after mitigation.

Impacts of the No Action/No Project Alternative are presented in Chapter 3.0 for comparison to those of the action alternatives. Because the No Action/No Project Alternative represents a continuation of the United States Army Corps of Engineers' (USACE) current maintenance dredging practices, adverse impacts of the No Action/No Project Alternative would be similar to those of the Proposed Action/Project, because both alternatives involve use of the same dredge equipment type. However, adverse impacts to longfin smelt and delta smelt would be greater under the No Action/No Project Alternative, because there would be fewer measures implemented to minimize entrainment impacts to these species; these impacts would be significant under CEQA.

Under the action alternatives, no impacts are expected related to land use plans and hazards and hazardous materials.

Under the Proposed Action/Project and both reduced hopper dredge use alternatives, dredging and placement activities would have equivalent minor adverse impacts on sediments. Although not expected, inadvertent discovery of archaeological or paleontological resources could result in adverse cultural resource impacts under all alternatives; with implementation of the identified mitigation measures, these impacts would not be significant.

All action alternatives would have impacts on water quality, primarily from increased turbidity. Impacts would be greater under the reduced hopper dredge use alternatives compared to the Proposed Action/Project, because mechanical dredging, which would be conducted in place of hopper dredging at certain locations, generates more turbidity than hopper dredging over a longer period of time. Nonetheless, under all alternatives, impacts would be short-term and minor.

Under the reduced hopper dredge use alternatives, there would be a minor increase of emissions compared to the Proposed Action/Project from increased mechanical dredge equipment use; however, the increase would not exceed the Bay Area Air Quality Management District significance thresholds.

All action alternatives would have minor adverse impacts on certain biological resources, including: temporary, localized turbidity impacts on aquatic species and habitat; temporary, localized disturbance of benthic habitat; temporary adverse effects on fish and marine mammals from underwater noise; temporary, localized interference with the movement or migration of fish and wildlife species (with the exception of entrainment risks discussed below); and temporary, and localized impacts on avian foraging and roosting. Under all action alternatives, the potential for project activities to result in biotoxicity impacts to aquatic organisms or increase the spread of invasive nonnative species would be minimal. Turbidity impacts on aquatic species from dredging would be longer in duration under the reduced hopper dredge use alternatives than under the Proposed Action/Project, but they would still be less than significant under NEPA and CEQA.

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<b>Geology, Soils, and Sediment Quality</b>				
<p><b>Impact 3.3-1: Potential for Dredging, Transport, and Placement Activities to Result in Substantial Soil Erosion</b></p> <p>Minimal erosion of the channel sides from sloughing could occur after the channels are dredged due to the disturbance of sediments. Placement of dredged material at beneficial reuse sites would have beneficial impacts on soil resources.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.3-2: Potential for Dredging, Transport, and Placement Activities to Substantially Degrade Sediment Quality</b></p> <p>The USACE’s conformance with established sediment testing and analysis protocols for dredged material would ensure that dredged material placement activities would not substantially degrade sediment quality at the placement sites.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.3-3: Potential for Dredging, Transport, and Placement Activities to Result in Cumulative Impacts on Sediments and Soils</b></p> <p>The project would not result in adverse cumulative impacts on sediments and soils.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Project would not contribute to adverse cumulative impacts.</p> <p><b>CEQA Finding:</b> Project would not contribute to adverse cumulative impacts.</p>	<p><b>NEPA Finding:</b> Project would not contribute to adverse cumulative impacts.</p> <p><b>CEQA Finding:</b> Project would not contribute to adverse cumulative impacts.</p>	<p><b>NEPA Finding:</b> Project would not contribute to adverse cumulative impacts.</p> <p><b>CEQA Finding:</b> Project would not contribute to adverse cumulative impacts.</p>
<b>Hydrology and Water Quality</b>				
<p><b>Impact 3.4-1: Potential to Substantially Degrade Water Quality through Alteration of Water Temperature, Salinity, pH, and Dissolved Oxygen</b></p> <p>Impacts to water quality temperature, salinity, pH, and dissolved oxygen from project activities would be minor, short-term, and localized.</p>	No mitigation necessary.	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.4-2: Potential to Substantially Degrade Water Quality Because of Increased Turbidity</b></p> <p>Dredging and placement activities would have minor, short-term, and localized impacts to water quality due to short-term increases in turbidity. Placement of dredged materials at habitat restoration beneficial reuse projects could have long-term beneficial effects on water quality.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.4-3: Potential to Substantially Degrade Water Quality Because of Mobilization of Contaminated Sediments or Release of Hazardous Materials</b></p> <p>Dredging and placement activities would not be expected to increase contaminant concentrations in the water column above baseline conditions, or result in violation of a water quality standard.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.4-4: Potential to Result in Cumulative Impacts to Hydrology or Water Quality</b></p> <p>The project, in combination with other past, present, and reasonably foreseeable future projects, could result in adverse cumulative impacts on water quality; however, the project’s contribution to these cumulative impact would not be cumulatively considerable or significant.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<b>Air Quality and Global Climate Change</b>				
<p><b>Impact 3.5-1: Conflict with or Obstruct BAAQMD Air Quality Plan Implementation, Exceed Applicable Air Quality Standards, or Contribute Substantially to an Air Quality Violation</b></p> <p>The project would not result in emissions level increases that exceed BAAQMD mass significance thresholds. Therefore, the project would not conflict with or obstruct BAAQMD Air Quality Plan Implementation, exceed applicable air quality standards, or contribute substantially to an air quality violation.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.5-2: Expose Sensitive Receptors to Substantial Pollutant Concentrations</b></p> <p>The impacts of short-term intermittent emissions on sensitive receptors from dredging and dredged material placement activities would be minimal.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.5-3: Create Objectionable Odors</b></p> <p>The project would not create objectionable odors affecting a substantial number of people.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.5-4: Result in Cumulatively Considerable Air Quality Impacts</b></p> <p>The project alternatives would not cause mass emission increases above the BAAQMD significance thresholds, would not be cumulatively considerable, and would not result in significant cumulative air quality impacts.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.5-5: Generate Greenhouse Gas Emissions, Either Directly or Indirectly, that May Have a Significant Impact on the Environment or Conflict with an Applicable Plan, Policy, or Regulation Adopted for the Purpose of Reducing the Emissions of Greenhouse Gases</b></p> <p>The project alternatives would not cause greenhouse gas emission increases above the BAAQMD significance thresholds or conflict with an applicable plan, policy, or regulation for reducing the emissions of greenhouse gases.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Biological Resources</b></p>				
<p><b>Impact 3.6-1: Potential Adverse Effects of Increased Turbidity Resulting from Maintenance Dredging and Dredged Material Placement on Special-Status Species, Critical Habitat, and Commercially Valuable Marine Species</b></p> <p>Localized and temporary increases in turbidity resulting from dredging and the placement of dredged material may affect marine organisms and aquatic wildlife during various life stages. Impacts may include impaired respiration; reduced visibility and the ability to forage or avoid predators; and alteration of movement patterns. Increases in turbidity from the project are not expected to have substantial effects on special-status species, their critical habitat, or EFH.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.6-2: Potential Adverse Effects of Maintenance Dredging Resulting from the Disturbance of Benthic Habitat on Special-Status Species, Critical Habitat, and Commercially Valuable Marine Species</b></p> <p>Dredging would have localized, direct impacts on benthic communities through physical disruption and direct removal of benthic organisms. Effects would be temporary because benthic habitat is quickly recolonized.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-3: Potential Adverse Effects of Underwater Noise Generated During Maintenance Dredging on Special-Status Fish and Marine Mammals</b></p> <p>Underwater noise produced during dredging may have temporary adverse effects on fish and marine mammals, include fleeing, the cessation of feeding, or other behavioral changes, but would not be expected to cause injury to fish and marine mammals.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-4: Potential Adverse Effects from Entrainment on Special-Status or Commercially and Recreationally Important Marine Species, Not Including Delta Smelt and Longfin Smelt</b></p> <p>During dredging, organisms on the dredged material may be entrained, in addition to organisms in the water column near the dredging apparatus. With implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment, effects to special-status and commercially important species, not including delta smelt and longfin smelt, would not be significant.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts, reduced to less than significant with implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts, reduced to less than significant with implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts, reduced to less than significant with implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.6-5: Potential Substantial Adverse Effects and Cumulative Impacts to Delta Smelt from Entrainment</b></p> <p>Entrainment of delta smelt could occur during hopper dredging. Under the Proposed Action/Project, a hopper dredge would be used to dredge three in-bay channels and the Main Ship Channel annually; therefore, this alternative would have the greatest potential to result in entrainment impacts. The potential for entrainment impacts would be less under Reduced Hopper Dredge Use Alternative 1 because only one in-Bay channel and the Main Ship Channel would be maintained with a hopper dredge. The potential for entrainment impacts would be largely eliminated under Reduced Hopper Use Dredge Alternative 2 because hopper dredges would not be used for maintaining in-Bay channels.</p>	<p>Minimization measures proposed as part the project description for all action alternatives. Compensatory mitigation (i.e., conservation credit) proposed as part of the project description for the Proposed Action/Project and Reduced Hopper Dredge Use Alternative 1. No additional measures proposed as mitigation.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts, reduced to less than significant with the implementation of reduced hopper dredging.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-6: Potential Substantial Adverse Effects and Cumulative Impacts to Longfin Smelt from Entrainment</b></p> <p>Entrainment of delta smelt could occur during hopper dredging. Under the Proposed Action/Project, a hopper dredge would be used to dredge three in-bay channels and the Main Ship Channel annually; therefore, this alternative would have the greatest potential to result in entrainment impacts. The potential for entrainment impacts would be less under Reduced Hopper Dredge Use Alternative 1 because only one in-Bay channel and the Main Ship Channel would be maintained with a hopper dredge. The potential for entrainment impacts would be largely eliminated under Reduced Hopper Use Dredge Alternative 2 because hopper dredges would not be used for maintaining in-Bay channels.</p>	<p>Minimization measures proposed as part the project description for all action alternatives. No additional measures proposed as mitigation.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Significant adverse impacts, reduced to less than significant with the implementation of reduced hopper dredging.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.6-7: Dredging and Placement Activities Could Result in the Disturbance of Essential Fish Habitat and “Special Aquatic Sites,” Including Eelgrass Beds and Mudflats.</b> Eelgrass near the Richmond Inner Harbor Channel and Oakland Inner Harbor may be indirectly impacted by turbidity and increased sedimentation from dredging operations. Turbidity plumes from dredging operations may temporarily reduce light penetration in waters adjacent to the plumes. Sediment near areas of dredging may settle on eelgrass blades and affect the viability of the eelgrass in beds adjacent to dredging operations.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-8: Interference with the Movement of Resident or Migratory Fish or Wildlife Species During Dredging and Placement Activities</b> The noise and in-water disturbance associated with dredging and placement activities could cause fish and wildlife species to temporarily avoid the immediate dredging or placement area when work is being conducted. However, the affected area would be limited to the immediate dredging or placement zone, and would not substantially limit the available habitat or movement of fish, seabirds, or marine mammals.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-9: Dredging and Placement Activities Could Disturb Roosting and Foraging by Avian Species</b> Dredging may disturb avian foraging and resting behaviors, decrease time available for foraging, and increase energetic costs as a result of increased flight times and startling responses. Impacts would be temporary, localized, and minor.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.6-10: Contaminated Sediments Could Become Resuspended During Dredging and Placement Activities, and Could Be Toxic to Aquatic Organisms, Including Plankton, Benthos, Fish, Birds, and Marine Mammals</b> Sediment testing results for previous USACE maintenance dredging episodes indicate that, in general, dredged materials from the subject federal navigation channels have been suitable for unconfined aquatic disposal. Dredging, transport, and placement of dredged material would be conducted in cooperation with the DMMO. This process would identify contaminated sediments and appropriate placement site options for dredged materials, based on the characteristics of the sediment and criteria for each placement site. Adherence to best management practices and conditions in regulatory approvals would minimize the potential for water quality degradation that could impact aquatic organisms.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.6-11: Dredging and Placement Could Substantially Increase the Spread of Invasive Nonnative Species</b> Dredge equipment would comply with United States Coast Guard regulations for vessels intended to minimize the spread of invasive nonnative species. Beneficial reuse and upland placement site operators are responsible for managing the placement of dredged materials at the placement sites in accordance with conditions of their permits and other regulatory approval, which include measures to minimize the spread of invasive nonnative species. Therefore, project activities would not be expected to substantially increase the spread of invasive nonnative species.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.6-12: Potential to Result in Cumulative Impacts on Biological Resources, Not Including Entrainment Impacts on Delta Smelt and Longfin Smelt</b></p> <p>The project, in combination with other past, present, and reasonably foreseeable future projects, could result in adverse cumulative impacts on biological resources; however, the project’s contribution to these cumulative impacts would not be cumulatively considerable or significant.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Cultural and Paleontological Resources</b></p>				
<p><b>Impact 3.7-1: Substantial Adverse Change to a Historical Resource or Disturb Unique Archaeological Resources</b></p> <p>Although unlikely, given the repeated dredging and dredged material placement activities that have historically occurred at the federal navigation channels and existing placement sites, there remains the potential that archaeological materials could be inadvertently uncovered by project activities. Such inadvertently discovered archaeological materials could represent historical resources or unique archaeological resources, and their disturbance could adversely change their condition. As such, the inadvertent discovery of archaeological materials represents a potential project impact. Implementation of Mitigation Measure CUL-1, Inadvertent Archaeological Discovery Measures, would reduce potential impacts.</p>	<p><b>Mitigation Measure CUL-1: Inadvertent Archaeological Discovery Measures</b></p> <p>Measures will be implemented to avoid potential adverse effects on inadvertently discovered NRHP- and/or CRHR-eligible or unique archaeological resources. Refer to Section 3.7 for complete mitigation measure.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts with mitigation. <b>CEQA Finding:</b> Less-than-significant adverse impacts with mitigation.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts with mitigation. <b>CEQA Finding:</b> Less-than-significant adverse impacts with mitigation.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts with mitigation. <b>CEQA Finding:</b> Less-than-significant adverse impacts with mitigation.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.7-2: Disturb Human Remains, including those Interred Outside of Formal Cemeteries</b></p> <p>There are no known cemeteries, formal or otherwise, or other evidence of human internment in the federal navigation channels or existing placement sites. Although unlikely, given the repeated dredging and dredged material placement activities that have historically occurred at the federal navigation channels and existing placement sites, there remains the potential that previously unidentified human remains could be inadvertently uncovered with project implementation. Such disturbance of human remains represents a potential project impact. Implementation of Mitigation Measure CUL-1, Inadvertent Archaeological Discovery Measures, and Mitigation Measure CUL-2, Treatment of Human Remains, would reduce potential impacts.</p>	<p><b>Mitigation Measure CUL-1: Inadvertent Archaeological Discovery Measures</b> <b>Mitigation Measure CUL-2: Treatment of Human Remains</b></p> <p>The treatment of human remains and associated or unassociated funerary objects discovered during any soil-disturbing activity will comply with applicable state laws. Refer to Section 3.7 for complete mitigation measure.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts with mitigation. <b>CEQA Finding:</b> Less-than-significant adverse impacts with mitigation.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts with mitigation. <b>CEQA Finding:</b> Less-than-significant adverse impacts with mitigation.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts with mitigation. <b>CEQA Finding:</b> Less-than-significant adverse impacts with mitigation.</p>
<p><b>Impact 3.7-3: Disturb Unidentified Significant Paleontological Resources</b></p> <p>Disturbance of paleontological resources would not be expected. Although unlikely, there remains the potential that paleontological materials could be inadvertently uncovered by project activities. Such disturbance of paleontological resources represents a potential project impact. Implementation of Mitigation Measure CUL-3, Inadvertent Paleontological Discovery, would reduce potential impacts.</p>	<p><b>Mitigation Measure CUL-3: Inadvertent Paleontological Discovery</b></p> <p>Measures will be implemented to avoid potential adverse effects on inadvertently discovered paleontological resources. Refer to Section 3.7 for complete mitigation measure.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts with mitigation. <b>CEQA Finding:</b> Less-than-significant adverse impacts with mitigation.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts with mitigation. <b>CEQA Finding:</b> Less-than-significant adverse impacts with mitigation.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts with mitigation. <b>CEQA Finding:</b> Less-than-significant adverse impacts with mitigation.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<p><b>Impact 3.7-4: Potential to Result in Cumulative Impacts on Archaeological or Paleontological Resources</b></p> <p>Project activities would not result in impacts to known historic or unique archaeological resources or to significant paleontological resources, and therefore would not contribute to any cumulative impact to these resources. If previously undiscovered archaeological resources are inadvertently exposed by the project or other reasonably foreseeable projects, an incremental effect to archaeological resources may occur.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts. <b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<b>Land Use</b>				
<p><b>Impact 3.8-1 Conflict with Applicable Plans and Policies</b></p> <p>The project would not conflict with plans, regulations, or policies considered under the Coastal Zone Management Act, including the California Coastal Management Program and the San Francisco Bay Plan. As a result of the California Coastal Commission and the San Francisco Bay Conservation and Development Commission review of USACE’s consistency determination for the project, the project would be implemented in a manner consistent with applicable plans and policies, and would be consistent with the Coastal Zone Management Act to the maximum extent practicable.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> No impact. <b>CEQA Finding:</b> No impact.</p>	<p><b>NEPA Finding:</b> No impact. <b>CEQA Finding:</b> No impact.</p>	<p><b>NEPA Finding:</b> No impact. <b>CEQA Finding:</b> No impact.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<b>Hazards and Hazardous Materials</b>				
<p><b>Impact 3.9-1: Potential Public or Environmental Exposure from the Transport, Use, and Disposal of Hazardous Materials</b></p> <p>All federal, state, and local regulations regarding the use, transport, and disposal of hazardous materials would be adhered to during project activities. Human health and safety impacts would be avoided through adherence to these procedures, conditions, and regulations. Project activities would not interfere with cleanup activities at contaminated sites.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> No impact. <b>CEQA Finding:</b> No impact.</p>	<p><b>NEPA Finding:</b> No impact. <b>CEQA Finding:</b> No impact.</p>	<p><b>NEPA Finding:</b> No impact. <b>CEQA Finding:</b> No impact.</p>
<p><b>Impact 3.9-2: Potential Impacts to Implementation of an Adopted Emergency Response Plan</b></p> <p>The project would not impair implementation of, or interfere with, any emergency operation or evacuation plans in the study area.</p> <p>Dredging would have a long-term beneficial impact by removing shoaled sediment and maintaining the navigability of the federal channels for use by vessels during emergency response operations.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> No adverse impacts; beneficial impacts. <b>CEQA Finding:</b> No impact.</p>	<p><b>NEPA Finding:</b> No adverse impacts; beneficial impacts. <b>CEQA Finding:</b> No impact.</p>	<p><b>NEPA Finding:</b> No adverse impacts; beneficial impacts. <b>CEQA Finding:</b> No impact.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

Impact	Mitigation Measure	Proposed Action	Reduced Hopper Dredge Use Alternative 1	Reduced Hopper Dredge Use Alternative 2
<b>Transportation</b>				
<p><b>Impact 3.10-1: Potential to Disrupt or Impede Marine Navigation</b></p> <p>Maintenance dredging and placement activities would add to vessel movement in the study area; however, this vessel traffic would be similar to that which has occurred during USACE’s past maintenance dredging operations. Dredging activities may occasionally delay or temporarily impede some vessels. Adverse impacts to navigation would be minimal and short-term.</p> <p>Dredging would have long-term beneficial impacts by removing shoaled sediment and maintaining the navigability of the federal channels.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>	<p><b>NEPA Finding:</b> Less-than-significant adverse impacts; beneficial impacts.</p> <p><b>CEQA Finding:</b> Less-than-significant adverse impacts.</p>
<p><b>Impact 3.10-2: Potential to Create Navigational Safety Risks</b></p> <p>Dredging and placement activities would comply with applicable vessel traffic and safety requirements; therefore, there would be no impacts related to navigational safety risks.</p> <p>Dredging would have long-term beneficial impacts by removing shoaled sediment that could pose a navigation hazard, and allowing for safe navigation in the federal channels.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Beneficial impacts.</p> <p><b>CEQA Finding:</b> No impact.</p>	<p><b>NEPA Finding:</b> Beneficial impacts.</p> <p><b>CEQA Finding:</b> No impact.</p>	<p><b>NEPA Finding:</b> Beneficial impacts.</p> <p><b>CEQA Finding:</b> No impact.</p>

**Table 5-1  
Summary of Impacts, Mitigation Measures, and NEPA and CEQA Findings for the Action Alternatives (Continued)**

<b>Impact</b>	<b>Mitigation Measure</b>	<b>Proposed Action</b>	<b>Reduced Hopper Dredge Use Alternative 1</b>	<b>Reduced Hopper Dredge Use Alternative 2</b>
<p><b>Impact 3.10-3: Potential to Result in Cumulative Impacts on Navigation</b> The project would not result in adverse cumulative impacts on navigation.</p>	<p>No mitigation necessary.</p>	<p><b>NEPA Finding:</b> Project would not contribute to adverse cumulative impacts. <b>CEQA Finding:</b> Project would not contribute to adverse cumulative impacts.</p>	<p><b>NEPA Finding:</b> Project would not contribute to adverse cumulative impacts. <b>CEQA Finding:</b> Project would not contribute to adverse cumulative impacts.</p>	<p><b>NEPA Finding:</b> Project would not contribute to adverse cumulative impacts. <b>CEQA Finding:</b> Project would not contribute to adverse cumulative impacts.</p>

Notes:  
 AB = Assembly Bill  
 BAAQMD = Bay Area Air Quality Management District  
 CEQA = California Environmental Quality Act  
 CRHR = California Register of Historical Resources  
 EFH = Essential Fish Habitat  
 LTMS = Long-Term Management Strategy  
 NEPA = National Environmental Policy Act  
 NRHP = National Register of Historic Places  
 USACE = United States Army Corps of Engineers

Entrainment of delta smelt and longfin smelt could occur during hopper dredging. Under the Proposed Action/Project, a hopper dredge would be used to dredge three in-bay channels and the Main Ship Channel annually; therefore, of the action alternatives, the Proposed Action/Project would have the greatest potential to result in entrainment impacts. The potential for entrainment impacts would be less under Reduced Hopper Dredge Use Alternative 1 because only one in-Bay channel and the Main Ship Channel would be maintained with a hopper dredge. The potential for entrainment impacts would be largely eliminated under Reduced Hopper Use Dredge Alternative 2 because hopper dredges would not be used for maintaining in-Bay channels after 2016. Under NEPA, project and cumulative impacts to delta smelt and longfin smelt from entrainment would be less than significant under all action alternatives. Under CEQA, the project and cumulative impacts to delta smelt and longfin smelt from entrainment would be significant under the Proposed Action/Project; significant but reduced to less than significant with reduced hopper dredging and minimization and mitigation measures under Reduced Hopper Dredge Use Alternative 1; and less than significant under Reduced Hopper Dredge Use Alternative 2.

Entrainment of other special-status or commercially and recreationally important marine species also could occur during hopper dredging. Under NEPA, these impacts would be less than significant under all alternatives. Under CEQA, these impacts would be significant under all alternatives, but reduced to less than significant with implementation of the LTMS work windows and other standard practices intended to reduce the potential for entrainment.

Under all action alternatives, dredging activities may occasionally delay or temporarily impede some vessels using the federal navigation channels, resulting in short-term minor impacts on navigation. Mechanical dredges have a greater potential to impact navigation compared to hopper dredges, because they are stationary while operating and involve use of multiple vessels. Therefore, potential navigation impacts would be greatest under Reduced Hopper Dredge Use Alternative 2 because it maximizes use of mechanical dredges, and least under the Proposed Action/Project, but less than significant under any alternative.

In addition to the analysis contained in this Environmental Assessment/Environmental Impact Report (EA/EIR), as summarized above, public comments on the Draft EA/EIR related to navigational safety concerns (see Appendix C) were considered in the evaluation and comparison among alternatives.

As noted above, under CEQA, the Proposed Action/Project would have significant cumulative impacts to delta smelt and longfin smelt from entrainment. Under NEPA, the Proposed Action/Project would have less-than-significant cumulative impacts to delta smelt and longfin smelt from entrainment. Under both NEPA and CEQA, the reduced hopper dredge use alternatives would have less than significant cumulative impacts to delta smelt and longfin smelt from entrainment. For all other resource areas under all action alternatives, the project, in combination with other past, present, and reasonably foreseeable future projects, would not contribute to adverse cumulative impacts, or the project's contribution to cumulative impacts would not be cumulatively considerable or significant.

## **5.2 ENVIRONMENTALLY PREFERABLE/SUPERIOR ALTERNATIVE**

### **5.2.1 NEPA Environmentally Preferable Alternative**

Section 1505.2(b) of the NEPA regulations (40 C.F.R. § 1505.2) requires that a Record of Decision for an Environmental Impact Statement identify the environmentally preferred alternative; however, NEPA does not require that an Environmental Assessment and Finding of No Significant Impact identify the environmentally preferred alternative. Regardless, the environmentally preferred alternative under NEPA is presented here. Under NEPA, the environmentally preferred alternative is the alternative that "...promotes the national environmental policy as expressed in NEPA's Section 101" (42 U.S.C. § 4331). Section 101 of NEPA outlines Congress' policy of restoring and maintaining environmental quality for the overall welfare and development of man, and to create and maintain conditions under which man and

nature can exist in productive harmony. NEPA also allows lead agencies to consider "...relevant factors including economic and technical considerations and agency statutory missions" (33 C.F.R. pt. 1505.2). One of the USACE's statutory missions is to maintain navigation.

As described in Section 5.1, the type and degree of environmental impacts among all the alternatives is similar; differences in impacts are directly correlated to the degree of hopper dredge use versus mechanical dredging use under each alternative. Adverse impacts of the No Action/No Project Alternative would be similar to those of the Proposed Action/Project, because both alternatives would use the same dredge equipment. However, adverse impacts to longfin smelt and delta smelt would be greater under the No Action/No Project Alternative, because there would be fewer measures implemented to minimize entrainment impacts to these species. Increased use of mechanical dredges under the reduced hopper dredge use alternatives would have greater impacts on water quality, air quality, navigation, and underwater noise as a result of the increased duration of dredging operations (up to ten times longer), when compared to the Proposed Action/Project Alternative. Comparing the overall impacts of each alternative, rather than a single impact area, the Proposed Action/Project and reduced hopper dredge use alternatives could result in similar overall impacts to the environment. Therefore, the NEPA environmentally preferred alternative could be any one of the action alternatives (i.e., Proposed Action/Project, Reduced Hopper Dredge Alternative 1, or the Reduced Hopper Dredge Alternative 2). Because of the increased cost and time required to dredge the federal navigation channels with a mechanical dredge, the preferred alternative under NEPA is the Proposed Action/Project. The Proposed Action/Project provides a necessary balance between the quality of the environment, economic considerations, and USACE's statutory missions.

### 5.2.2 CEQA Environmentally Superior Alternative

CEQA does not provide specific direction regarding the methodology of comparing alternatives and the proposed project. Each project must be evaluated for the issues and impacts that are most important; this will vary depending on the project type and the environmental setting.

The CEQA Guidelines (Section 15126.6[e][2]) state that "If the environmentally superior alternative is the "No Project" alternative, the EIR shall also identify an environmentally superior alternative among the other alternatives."

As described in Section 5.1, the type and degree of environmental impacts among all the alternatives is similar; differences in impacts are directly correlated to the degree of hopper dredge use versus mechanical dredge use under each alternative. Adverse impacts of the No Action/No Project Alternative would be similar to those of the Proposed Action/Project, because both alternatives involve the same dredge equipment type use. However, adverse impacts to longfin smelt and delta smelt would be greater under the No Action/No Project Alternative, because there would be fewer measures implemented to minimize entrainment impacts to these species. Although both reduced hopper dredge use alternatives would have slightly greater impacts on water quality, air quality, navigation, and underwater noise than the No Action/No Project Alternative and Proposed Action/Project, none of those increased impacts would exceed their respective significance thresholds or criteria. The reduction in the potential for entrainment of delta smelt and longfin smelt afforded under the reduced hopper dredge use alternatives substantially reduces or eliminates the impacts to these species. Therefore, Reduced Hopper Dredge Use Alternative 2, which would minimize hopper dredge use and the potential for entrainment and adverse effects on special-status fish species, is considered to be the environmentally superior alternative under CEQA.

## 5.3 SIGNIFICANT IMPACTS

Section 15126(b) of the CEQA Guidelines requires that an EIR "describe any significant impact, including those which can be mitigated, but not reduced to a level of insignificance. Where there are

impacts that cannot be alleviated without imposing an alternative design, their implications and the reasons why the project is being proposed, notwithstanding their effect, should be described.”

Under CEQA, the Proposed Action/Project would have significant project-level and cumulative impacts to delta smelt and longfin smelt from entrainment. Although the Proposed Action/Project includes additional measures to minimize impacts to delta smelt and longfin smelt, as well as compensatory mitigation for potential impacts to listed fish species, the proposed extent of hopper dredge use under the Proposed Action/Project would substantially reduce the number of delta and longfin smelt. In consideration of the present status of these species’ populations, there would be significant project and cumulative impacts under the Proposed Action/Project under CEQA.

#### **5.4 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES**

Under 40 C.F.R. § 1502.16, NEPA requires description of the irreversible and irretrievable resource commitments related to the use of nonrenewable resources that could result from the implementation of the proposed project. Irreversible effects would primarily result from the use or destruction of a specific resource, such as energy and minerals that could not be replaced within a reasonable time frame. Irretrievable resource commitments would involve the loss in value of an affected resource that could not be restored as a result of the action; an example of this is the extinction of a threatened or endangered species, or the disturbance of a cultural resource.

Dredging and placement activities would require the use of fossil fuels for the operation of vessels and equipment. The commitment of these resources would apply irrespective of the alternative. Under all alternatives, the fossil fuel consumption would be similar to that under USACE’s historic and current maintenance dredging operations in San Francisco Bay.

An irreversible loss of special-status species could occur, should the project result in incidental take of federally listed fish species. However, measures have been identified that would minimize impacts to these species; therefore, USACE determined that an irretrievable loss of these species’ populations is not expected.

#### **5.5 RELATIONSHIP BETWEEN LOCAL SHORT-TERM USES OF THE ENVIRONMENT AND LONG-TERM PRODUCTIVITY**

Under 40 C.F.R. § 1502.16, NEPA requires consideration of the relationship between local short-term uses of the environment, and the maintenance and enhancement of long-term productivity.

Maintenance dredging and the placement of dredged material would result in short-term impacts on sediments, water quality, biological resources, air quality, and navigation. Short-term adverse impacts include increases in turbidity, disturbance of benthic communities, effects on fish and wildlife behavior, emissions of criteria pollutants, and delayed navigation of vessels; these impacts would be minor, localized, and temporary during dredging and placement activities. Entrainment of special-status fish species would result in permanent effects.

However, USACE determined that these potential adverse effects would be minimized by implementing the standard practices identified in Chapter 2 and the mitigation measures discussed in Chapter 3. Moreover, these short-term impacts are expected to be outweighed by long-term beneficial effects of maintaining the federal navigation channels to accommodate commercial, recreational, and emergency vessels. In addition, the beneficial reuse of dredged materials would contribute to the long-term productivity of the environment.

Therefore, the project would not be expected to adversely impact the long-term productivity of the environment.

FINAL INTEGRATED GENERAL REEVALUATION REPORT  
AND ENVIRONMENTAL IMPACT STATEMENT

SAN FRANCISCO BAY TO STOCKTON, CALIFORNIA  
NAVIGATION STUDY

JANUARY 2020

**This page is intentionally left blank.**

**FINAL INTEGRATED GENERAL REEVALUATION REPORT  
AND ENVIRONMENTAL IMPACT STATEMENT**

**SAN FRANCISCO BAY TO STOCKTON, CALIFORNIA, NAVIGATION IMPROVEMENT PROJECT**

**LEAD NEPA AGENCY:** Department of Army, U.S. Army Corps of Engineers, Jacksonville District

**NON-FEDERAL SPONSOR:** Port of Stockton

**ABSTRACT:** The San Francisco Bay to Stockton Navigation Improvement Project was originally authorized by Congress in the Rivers and Harbors (R&H) Act of 1965. The originally authorized study was scoped for a 78-mile long navigation project to include the John F. Baldwin and Stockton channels, however, it was re-scoped in 2016 to include navigation improvements up to Avon. The study area for this draft integrated General Reevaluation Report and Environmental Impact Statement (GRR/EIS) is a 13.2 mile length of navigation channel which spans from Central San Francisco Bay to Avon (just east of the Benicia-Martinez Bridge) and includes the Pinole Shoal Channel and the Bulls Head Reach portion of the Suisun Bay Channel. The channels in the study area primarily serve crude oil imports and refined product exports to and from several oil refineries and two non-petroleum industries. Although the navigation channels in the study area are authorized to a depth of up to -45 feet mean lower low water (MLLW), the channels are currently maintained to only -35 feet MLLW. The Recommended Plan/Proposed Project includes deepening the existing navigation channel to -38 feet MLLW (plus 2 feet of allowable overdepth), dredging a 2,600 foot sediment trap in Bulls Head Reach to -42 feet MLLW (plus 2 feet of allowable overdepth), leveling a rocky obstruction within the Pinole Shoal channel for navigability, and using the dredged material at beneficial reuse sites to contribute to restoration of tidal wetlands within the Delta.

## TABLE OF CONTENTS

### Using this Document

 **Report Reference Materials:** To ease navigation through the report, prompts are provided, alerting the reader to reference additional sections or graphics, or to explain the purpose of an ensuing discussion. In this report, these prompts can be identified by this blue box format.

Additionally, informational foldouts **Graphics Executive Summary 1 and 2** are provided in the Executive Summary to be used while reading the document as reference maps with key points and landmarks. In addition, an overall table of contents is provided, along with detailed tables of contents and an index at the end of the report.

Organization of this report follows Exhibit G-7 (Feasibility Report Content) provided in Appendix G of US Army Corps of Engineers Engineering Regulation (ER) 1105-2-100 (30 June 2004), documenting the iterative U.S. Army Corps of Engineers (USACE) Plan Formulation Process. The planning process consists of six major steps:

- (1) Specification of problems and opportunities
- (2) Inventory, forecast, and analysis of existing conditions within the study area
- (3) Formulation of alternative plans
- (4) Evaluation of the effects of the alternative plans
- (5) Comparison of the alternative plans
- (6) Selection of the Recommended Plan based upon the comparison of the alternative plans.

Steps may be repeated as problems become better understood and new information becomes available.

Steps 1 and 2 are discussed in Chapters 1-2, and provide the foundation for developing alternative plans and selection of a Recommended Plan outlined in Chapter 3.

Each chapter and summary graphic, as well as the Executive Summary, describe plan development as it progresses through the four integrated environments that shape a navigation project: **the built environment** (Federal project, port facilities, placement areas, transportation network, advance maintenance areas, etc.); **the natural environment** (physical and biological resources including species of concern); **the navigation environment** (navigation restrictions, etc.), and **the economic environment** (commodity movement, vessel fleet characteristics, and transportation costs). Concerns relative to plan formulation and National Environmental Policy Act (NEPA) review are summarized and encapsulated in the discussions of these four main environments. California Environmental Quality Act (CEQA) compliance is not addressed in this document.

The recommended format of an Environmental Impact Statement (EIS) is provided in 40 CFR 1502.10 and has been integrated into the General Reevaluation Report. The basic table of contents for the report outlines how the EIS format has been integrated into the planning process to develop a Recommended Plan that meets the requirements of both USACE Plan Formulation Policy and NEPA.

Note that sections pertinent to the NEPA analysis are denoted with an asterisk.

## EXECUTIVE SUMMARY

# FINAL INTEGRATED GENERAL REEVALUATION REPORT AND ENVIRONMENTAL IMPACT STATEMENT SAN FRANCISCO BAY TO STOCKTON, CALIFORNIA, NAVIGATION IMPROVEMENT PROJECT

Please refer to Graphic Executive Summary pages 1 and 2

## EXECUTIVE SUMMARY

### INTRODUCTION

The San Francisco Bay to Stockton Navigation Improvement Project was originally authorized by Congress in the Rivers and Harbors (R&H) Act of 1965. The authorization allowed for -45 foot channel depths, but the channels were only constructed to -35 feet mean lower low water (MLLW). This report is an interim response to the study authority.

The study was originally scoped for a 78-mile long navigation project to include the John F. Baldwin and Stockton channels, but was re-scoped in 2016 to only include improvements to Avon. The study area is a 13.2 mile length of navigation channel which spans from Central San Francisco Bay to Avon (just east of the Benicia-Martinez Bridge) and includes the Pinole Shoal Channel and the Bulls Head Reach portion of the Suisun Bay Channel. The channels in the study area primarily serve crude oil imports and refined product exports to and from several oil refineries and two non-petroleum industries. Although the navigation channels in the study area are authorized to a depth of up to -45 feet (MLLW), the channels are currently maintained to only -35 feet MLLW.

The U.S. Army Corps of Engineers (USACE) is responsible for preparing this integrated General Reevaluation Report (GRR)/Environmental Impact Statement (EIS) and is the lead Federal agency for National Environmental Policy Act (NEPA) compliance (42 U.S.C. §§ 4321 *et seq.*; 40 C.F.R. §1500.1). The Port of Stockton is the official non-Federal partner for the GRR/EIS.

Although this GRR was originally intended to be integrated with both NEPA and California Environmental Quality Act (CEQA) compliance requirements, this document may or may not be used as CEQA documentation; CEQA compliance will be determined by the non-Federal sponsor.

Although the non-federal sponsor (partner) for this project is the Port of Stockton, the navigation channel users benefitting from the proposed improvements are located within Contra Costa County. The County has been working to come to internal agreement to issue an updated Notice of Preparation (NOP) as CEQA lead for the project. However, at this time, Contra Costa County has determined they are unable to

## EXECUTIVE SUMMARY

complete this process. On March 11, 2019, the Port of Stockton informed the Corps they were considering acting as CEQA lead for the proposed project improvements included in this report through the issuance of a future NOP addressing project-level compliance for the Recommended Plan, and programmatic compliance for future deepening of the Stockton Deepwater Ship Channel (SDWSC). This intent has since been confirmed through a series of follow-on communications between the Port and Corps of Engineers' leadership in April 2019.

As stated in the current NOI issued on December 4, 2017 for this EIS and subsequent informal stakeholder discussions, the Corps of Engineers de-scoped the eastern portion of the original study area, which included the SDWSC, from consideration in this study. This GRR/EIS only addresses the study area from the Golden Gate Bridge to Avon and the Army Corps is not preparing a feasibility study or NEPA document from Avon to the Port of Stockton. The sponsor has not yet provided a formal letter of their intention for a future study from Avon to the Port of Stockton, but in the spirit of full transparency and long history regarding this project, recent communications by the Port of Stockton regarding their future interests are documented in this report. As such, with the knowledge of Port's intention to potentially deepen the navigation channel from Avon to Stockton, that potential action is addressed in the Cumulative Effects section in Chapter 4, **Table 4-22**.

### STUDY AREA, PURPOSE AND NEED

The navigation channels within the study area are regionally significant, providing navigation access to ports, harbors, refineries, and military terminals from San Francisco Bay through San Pablo and Suisun Bays and up the Sacramento-San Joaquin Delta and the San Joaquin River to the Port of Stockton.

The bays and delta through which the navigation channels cross are naturally shallow. Over time, channel deepening of the natural waterways and regular maintenance dredging has facilitated modern vessels to traverse the channels. The modern vessels crossing the channels can require up to 55 feet of draft when fully loaded. Given that these channels are maintained at -35 feet MLLW, most vessels must be “light-loaded”, or less than fully loaded with cargo, to navigate the channels with sufficient under-keel clearance. Light-loading increases the cost of transportation and, in turn, the cost of the shipped products because more trips must be made to carry the same volume of cargo. Within the study area, tankers carrying crude oil to California oil refineries and exporting petroleum are most impacted by light-loading practices.

According to the California Energy Commission, Californians consume nearly 44 million gallons of gasoline and 10 million gallons of diesel every day. California refineries produce these fuels and other products from crude oil and blending components. Transportation fuel production in California depends on the availability and quality of the crude oils used by refineries in the state. The supply of crude oil to California refineries has changed substantially in the last 10 years. Most notably, receipts of foreign crude oil have increased as production sources from California and Alaska have continued to decline. Each day approximately two million barrels (a barrel is equal to 42 U.S. gallons) of petroleum are processed into a variety of products, with gasoline representing about half of the total product volume. To comply with Federal and state regulations, California refiners invested approximately \$5.8 billion to upgrade their facilities to produce cleaner fuels, including reformulated gasoline and low-sulfur diesel fuel.

According to data from the Waterborne Commerce Statistics Center, 20 million to 27 million tons of commodities moved through the Carquinez Straight annually between 2005 and 2013. In terms of both

## EXECUTIVE SUMMARY

tonnage and value, the most important commodity that moves through the study is crude oil. Most of the crude oil moving through the channel is imported from foreign countries, although a small percentage of crude comes from domestic sources. This analysis focuses on the main oil refineries that import crude oil and export petroleum products. According to the Annual Energy Outlook (2015), the growth rate for crude oil imports is an annual rate of 0.3%, and petroleum and other liquid exports has an annual rate of 2.4%.

In order to maintain safety, the San Francisco Bar Pilots employ under-keel clearance of 3 feet for tankers and use of high tide when appropriate for vessels for fully loaded. It is a 5 hour transit from the entrance channel to refineries.

Given the constraints posed by existing channel depths, inefficient strategies that are currently employed to manage these constraints include:

- Vessels must light-load cargo
- Vessels must wait for favorable (high) tides which increases transportation costs
- High shoaling rates in Bulls Head Reach require dredging annually, incurring large mobilization and demobilization costs, and causing delays to vessels when dredging is postponed.

The Federal objective defining Federal interest in channel improvements is to reasonably maximize net benefits to the nation. Project specific objectives include:

1. Objective 1: Reduce transportation costs and increase deep draft navigation efficiency for the shipment of commodities to and from all facilities within the study area beginning in 2020
2. Objective 2: Maximize beneficial reuse of dredged material while minimizing placement costs
3. Objective 3: Reduce frequency of operation and maintenance dredging in high shoaling areas
4. Objective 4: Increase navigability to maintain safety

## ALTERNATIVE PLANS AND THE RECOMMENDED PLAN

### MEASURES

In order to address the problems and meet objectives, a total of 16 measures were initially considered: 8 non-structural and 8 structural. Non-structural measures considered were: congestion fees, intermodal transportation systems, lightering, light-loading, use of favorable tides and daylight transit only, traffic management, pipeline, and relocation of port facilities. Structural measures considered were: channel deepening to depths of -37 and -38 feet MLLW, sediment traps, rocky obstruction removal, and the beneficial reuse of material for dredged material placement.

The management measures were screened based on an assessment of how well they met the project objectives, the four planning and guidance accounts, and their ability to be complete, acceptable, efficient, and effective. The screening was performed to identify those measures appropriate for inclusion in developing alternative plans.

Non-structural and structural measures were compared and evaluated against a set of 13 different screening criteria to assess positive benefits and attributes which could be attained, worth a total of 2

## EXECUTIVE SUMMARY

points each, for a total maximum score of 26 points. Points were assigned as follows: Does Not Meet = 0; Partially Meets = 1; Fully Meets = 2. Negative scores up to -2 points were assigned for areas where negative effects could occur. The total score of each measure was then determined and only measures which scored greater than 13 (over half of the total available points) were carried forward to be combined into alternatives.

Measures which were screened out include all non-structural alternatives. Measures carried forward include the no-action plan, deepening alternatives at the -37 foot and -38 foot MLLW depth, a sediment trap at the -42 foot depth plus 2 feet of overdepth (based on the shoaling analysis conducted in 2015 titled "Bulls Head Deposition HydroSurvey Tech Memo"), removal of the rocky obstruction, and beneficial reuse of material.

### ALTERNATIVE DEVELOPMENT

Remaining measures were then combined into alternatives. These alternatives include the no-action alternative and two deepening alternatives; to depths of -37 feet and -38 feet MLLW, with the dredged material being beneficially used at one or more of the existing permitted beneficial reuse sites, namely, Cullinan Ranch Restoration Project (Cullinan Ranch), Montezuma Wetlands Project (Montezuma Wetlands), as well as other sites including San Francisco Deep Ocean Disposal Site (SF-DODS). A sediment trap measure is also included at Bulls Head Reach in both of the action alternatives as a separable element, as well as a measure removing a rocky obstruction for increased navigability.

### ALTERNATIVE COMPARISON

Per USACE guidance ER 1105-2-100, the final array of alternatives must be compared and evaluated against P&G criteria<sup>1</sup>, and additionally, an economic evaluation must be completed to identify which plan in the final array maximizes NED benefits. An environmental analysis must also be conducted under the National Environmental Policy Act (NEPA) to compare and evaluate the final array for a set of environmental factors, prior to determination of the Recommended Plan.

#### ***Plan Formulation Comparison and Evaluation of the Final Array.***

The initial array of alternatives were compared and evaluated against screening criteria, using an additional level of refinement in known information.

Comparison and evaluation of the initial array of alternatives ( **Table 3-3**) resulted in identification of those alternatives to be carried forward into the final array. The final array consists of the no action alternative, a -37 foot deepening alternative, and a -38 foot deepening alternative, both including a sediment trap, rock removal, and beneficial reuse placement. An analysis of placement sites for each alternative determined that split placement at Montezuma Wetlands and Cullinan Ranch was the least cost option. In-bay sites were screened out from consideration because they do not contain adequate site specific capacity/and initial deepening material does not have appropriate sediment composition for in-bay use; additionally, although material placement within the bay at these sites would keep material in the local system, it would not constitute beneficial reuse. Placement of material at SF-DODS is not ideal since it takes material out of the natural system, while both Cullinan Ranch and Montezuma Wetlands

---

<sup>1</sup> The Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies, established by the U.S. Water Resources Council on March 10, 1983, have been developed to guide the formulation and evaluation studies of the major Federal water resources development agencies. These principles and guidelines are commonly referred to as the "P&G," and will be cited throughout the plan formulation sections of this report.

## EXECUTIVE SUMMARY

both can beneficially use the material and are the least cost plan. While SF-DODS is not carried forward as a placement site, it is worth mentioning that it is an available placement site if needed, if there are no other beneficial reuse sites with available capacity prior to construction. More information on placement site screening and assumptions during plan formulation is found in Chapter 3.

### ***Economic Comparison and Evaluation of the Final Array.***

Preliminary screening level cost estimates were developed for the two proposed deepening alternatives and applied in the economic analysis. Costs shown in **Table 3-5** include Operation, Maintenance, Repair, Replacement, and Rehabilitation (OMRR&R) activities and Interest during Construction (IDC). Transportation costs and benefits were estimated using the USACE certified economic model *HarborSym* and estimated for a 50-year period of analysis for the years 2020 through 2069. The costs and benefits for each alternative were annualized at the FY16 price level and FY16 discount rate of 3.125% over 50 years.

The -38 foot deepening alternative provides higher net benefits than the -37 foot deepening alternative, and additionally meets planning criteria goals of being efficient, effective, acceptable, and implementable. The -38 foot deepening alternative also has a benefit to cost ratio greater than 1.

### ***Environmental Comparison and Evaluation of the Effects of the Final Array.***

The No Action Alternative is the NEPA benchmark or baseline for assessing environmental effects, including the cumulative impacts, of an action (e.g., project) alternative. The action alternatives are the -37 foot and -38 foot deepening alternatives. An alternative is considered to have a significant impact if it would cause a substantial adverse change in a resource compared to the NEPA baseline.

The effects of the alternatives on each resource category are described in Chapter 4. Effects of each of the action alternatives were found to be less than significant based upon the analyses. Impacts associated with hydrodynamic changes including salinity intrusion and water quality were addressed through extensive hydraulic modeling simulations (**Appendix B, Water Resources - Attachment 1, Salinity Model Report**). Modeling runs compared the hydrodynamic effects from the -37 foot, -38 foot, and the -38 foot with sediment trap and rocky obstruction alternatives. The effects of the proposed project deepening on X2, the distance up the axis of the estuary to the daily-averaged 2 practical salinity units (psu) near-bed salinity, and on water quality at municipal and industrial water intake and export locations in the Sacramento-San Joaquin Delta were evaluated (further description of X2 discussed in **Section 2.2.3.3 Salinity and water supply**). The sediment trap and rocky obstruction inclusion in modeling analyses were completed after the selection of the Recommended Plan, and were therefore only modeled in addition to the -38 foot depth. The change in X2 predicted in the model is insignificant with the -37 foot, -38 foot, and -38 foot plus sediment trap and rocky obstruction alternatives, further explained in Chapter 4.

Effects on the endangered delta smelt are described fully in the Biological Assessment (**Appendix G, Environmental - Attachment 4**). The project is not expected to result in the loss of the shallow water habitat needed for smelt reproduction and the slight shift in X2 would not be expected to significantly alter habitat for smelt or other fish species. The dredged material will be placed on beneficial reuse sites that will benefit upland, wetland, and tidal wetland species, offsetting the less than significant project effects to threatened and endangered species in the study area.

## EXECUTIVE SUMMARY

### THE RECOMMENDED PLAN

The discussion above shows that the **-38 foot deepening alternative** met P&G criteria, as well as all other screening criteria, and was identified as the NED plan which maximizes net benefits, and was fully evaluated under NEPA for effects. No locally preferred plan (LPP) has been identified. Therefore, the Recommended Plan is the -38 foot deepening alternative. The Recommended Plan is to deepen the existing maintained channel depth of the Pinole Shoal Channel and the Bulls Head Reach portion of the Suisun Bay Channel from -35 feet MLLW to -38 feet MLLW, with approximately 13.2 miles of new regulatory depths. Approximately 10.3 miles of the Pinole Shoal Channel (stations 0+00 to 548+00) and 2.9 miles of Bulls Head Reach to Avon (stations 0+00 62+00 and 88+00 to 160+00) would be dredged. A 2,600 foot-long sediment trap (width = 300 feet) is justified on its own as a separable element to reduce the frequency of operation and maintenance dredge events. It would be constructed at Bulls Head Reach (located between stations 62+00 and 88+00 of the Bulls Head Reach), with a depth of -42 feet MLLW, plus 2 feet of overdepth.

In summary, the Recommended Plan is the following:

- Deepen the existing maintained channel depth of the Pinole Shoal Channel and Bulls Head Reach (Suisun Bay) from -35 feet to -38 feet MLLW, with approximately 13.2 miles of new regulatory depths
- Dredge a 2,600 foot sediment trap at Bulls Head Reach with a depth of -42-feet MLLW, plus 2 feet of overdepth
- Level the rocky obstruction located to the west of Pinole Shoal from -39.7-feet MLLW to -43-feet MLLW
- Use dredged material at permitted beneficial reuse sites

The Recommended Plan would result in approximately 1.6 million cubic yards of dredged material from an approximate 390-acre footprint. The breakout of volumes for each feature is shown as follows:

- Pinole Shoal deepening = 1,443,900 cy
- Bulls Head Reach deepening = 38,700 cy
- Bulls Sediment Trap = 120,600 cy
- Rocky Obstruction (Suisun Bay Channel) = 40 cy of rock (950 sq. ft.)

All construction is expected to occur during the existing environmental work windows developed by the San Francisco Bay Long Term Management Strategy for the Placement of Dredged Material unless other windows are developed during consultation with the resource agencies. The environmental work window for the Pinole Shoal Channel is from June 1 through November 20 and the work window for the Bulls Head Reach portion of the Suisun Bay Channel is from August 1 through November 30.

It is assumed that the timing of the channel deepening will occur concurrently or immediately after completion of the O&M dredge cycle within each reach. Although feasible, dredging contract acquisition approach and timing is tight for accomplishment of both O&M dredging and channel deepening in one environmental work window therefore, this avoidance measure does carry some risk. Should dredging extend past the environmental work window, additional coordination would immediately be initiated with the appropriate agencies.

## EXECUTIVE SUMMARY

### ***Beneficial Reuse***

The Recommended Plan includes placing new construction material from the Pinole Shoal channel at a suitable and permitted site, currently assumed to be Cullinan Ranch Tidal Restoration, and the new construction material from Bulls Head Reach at a suitable and permitted site, currently assumed to be Montezuma Wetlands. Preliminary coordination with project stakeholders concluded their support and preference for the beneficial reuse placement at Cullinan Ranch and Montezuma Wetlands, or other available beneficial reuse sites. Placement of material in Cullinan Ranch Tidal Restoration and Montezuma Wetlands is the least cost placement alternative; additionally placement in these areas is considered to be beneficial reuse, and contributes to habitat needed for several species throughout the Delta, including the endangered delta smelt. Cullinan Ranch Tidal Restoration and Montezuma Wetlands contain their own monitoring programs (USACE and SCDM 1998; USFWS and CDFW 2008 – these documents are available upon request).

### **BENEFITS OF THE RECOMMENDED PLAN**

The Recommended Plan has estimated average annual net benefits of \$10.5 Million (FY2020 price levels, FY2020 2.75% discount rate), with a benefit to cost ratio of 4.4 to 1.0.<sup>2</sup>

In addition to maximizing net benefits and identifying the plan with the best benefit to cost ratio, the four P&G accounts below: National Economic Development (NED), Regional Economic Development (RED), Environmental Quality (EQ), and Other Social Effects (OSE) are always used as criteria in formulation and plan selection. These accounts are briefly summarized below.

#### ***National Economic Development (NED).***

This project reasonably maximizes net benefits in the amount of \$10.5 million average annual net benefits (FY2020, 2.75%), with a benefit to cost ratio of 4.4 to 1. The project allows tankers to utilize more of their existing capacity to transport all projected commodity volumes under existing and future conditions, reducing the amount of vessel transits in the future with-project compared to the future without-project scenario. By doing so, it provides transportation cost savings to the oil refineries, which are then passed on to the regional and national consumers who use the end product of the crude oil for gasoline, etc.

The sediment trap feature of the Recommended Plan provides direct benefit to channel users and vessel operations and is included as a separable element and incrementally justified feature of the Recommended Plan. It is sited in a portion of the channel that has traditionally required annual dredging at an estimated cost of \$1 million each year; based on the historical use of clamshell dredges which are mobilized and demobilized each year, in addition to numerous interim emergency dredging events. The sediment trap would reduce maintenance dredging requirements from an annual cycle to 2 dredge events every 3 years, thus creating a savings based on a reduction in the frequency of mobilization and demobilization 1 out of every 3 years. This creates a total present value savings of \$18 million for the O&M program, or an average annual equivalent savings of \$680,000 per year over a 50 period of analysis at a discount rate of 2.75%.

---

<sup>2</sup> This study occurred over the span of several years. Therefore, price levels and discount rates were used as appropriate depending on what year the economic analysis occurred for varying levels of plan formulation. As such, this report cites FY price levels and discount rates used for each economic analysis throughout the study.

## EXECUTIVE SUMMARY

### ***Environmental Quality (EQ).***

This project reduces the amount of vessel transits in the future with-project scenario. Reducing the number of vessels would also reduce potential disruptions to the environment as vessels transit, as well as the risk of oil spills. Beneficial reuse of material would create additional habitat for many species, including the federally endangered delta smelt.

### ***Regional Economic Development (RED).***

This project would likely temporarily stimulate the regional economy during construction.

### ***Other Social Effects (OSE).***

Through beneficially placing material at permitted wetland sites, this project would also help provide resiliency and storm surge protection to infrastructure located around the perimeter of the channel and bay margins. One viable beneficial reuse placement option for the dredged material from this project is use as fill material to restore the wetlands due to subsidence and combat the further loss of wetlands by raising surrounding wetland and tidal marsh elevations to accelerate their development. Additionally, removing the rocky obstruction in Pinole Shoal channel will greatly enhance the navigability of the channels for harbor pilots.

## **ENVIRONMENTAL CONSIDERATIONS**

Over the past few decades, significant coordination has taken place between USACE, the Port of Stockton, and Federal, state, and local agencies, water managers, businesses, organizations, and the general public. The coordination has identified the following key areas of concern and are addressed in Chapter 4:

- Salinity intrusion in the delta, particularly related to impacts on drinking water and the designated critical habitat of the Federal and state listed endangered delta smelt.
- Impacts to threatened and endangered species including longfin smelt, green sturgeon, and salmonids.
- The potential to beneficially use dredged material in existing habitat restoration projects within the study area.

The full environmental analysis determines that there are less than significant effects as a result of the Recommended Plan. As such, mitigation is not expected.

## **COST ESTIMATE AND IMPLEMENTATION**

The cost estimate below reflects all project features as described earlier, including removal of the rocky obstruction and sediment trap. There are no local facility costs associated with the project cost. Environmental windows factored heavily into construction windows and sequencing. The total project cost, including a risk-based contingency.

EXECUTIVE SUMMARY

Table ES-1. Project Cost and Cost Sharing, -38 foot deepening project (RECOMMENDED PLAN).

(October 1, 2019 Price Levels, Program Year 2020) <sup>1</sup>						
WBS Number	General Navigation Features	Project Cost	Contingency	Total Project Cost	Federal Share	Non-federal Share
					75%	25%
12	Mob, Demob, Dredging	\$45,548,000	\$9,115,000	\$54,663,000	\$40,997,000	\$13,666,000
30	Pre-Construction, Engineering, and Design	\$1,591,000	\$318,000	\$1,909,000	\$1,432,000	\$477,000
31	Construction Management (S&I)	\$501,000	\$100,000	\$601,000	\$451,000	\$150,000
	<b>Subtotal Construction of GNF<sup>2</sup></b>	<b>\$47,640,000</b>	<b>\$9,533,000</b>	<b>\$57,173,000</b>	<b>\$42,880,000</b>	<b>\$14,293,000</b>
1	Lands, Easements, Right-of-Ways, Relocations (LERR) <sup>3</sup> - Federal	\$23,000	\$2,000	\$25,000	\$18,750	\$6,250
1	Lands, Easements, Right-of-Ways, Relocations (LERR) <sup>3</sup> - Non-Federal	\$23,000	\$2,000	\$25,000	\$0	\$25,000
	<b>Total Project First Costs</b>	<b>\$47,663,000</b>	<b>\$9,535,000</b>	<b>\$57,200,000</b>	<b>\$42,880,000</b>	<b>\$14,320,000</b>
12	Aids to Navigation <sup>4</sup>	\$16,000	\$3,000	\$19,000	\$19,000	\$0
	Credit for Non-Federal LERR <sup>5</sup>	\$0			\$0	-\$31,250
	10% GNF Non-Federal <sup>6</sup>	\$0			(\$5,717,300)	\$5,717,300
	<b>Total Cost Apportionment</b>	<b>\$47,680,000</b>	<b>\$9,540,000</b>	<b>\$57,220,000</b>	<b>\$37,180,000</b>	<b>\$20,010,000</b>

1. Cost is based on Project First Cost (constant dollar basis) on Total Project Cost Summary Spreadsheet, at an effective price level 1 Oct 2019 (Cost Appendix). Aids to Navigation broken out and shown as a separate cost.

2. 75% Federal/25% non-federal including the cost of the sediment trap.

3. RE admin costs. There are no actual lands and damages but per USACE regulations, RE admin costs will be placed in the 01 account. Additional RE costs will be cost shared according to the GNF. Escalation from the TPCS accounts for some numerical differences.

4. Navigation Aids - 100% Federal (U.S. Coast Guard cost, not USACE cost). Includes 8 relocations at \$2,000 each.

5. Credit is given for the incidental costs borne by the non-Federal sponsor for lands, easements, rights of way and relocations (LERR) per Section 101 of WRDA 86, not to exceed 10% of the GNF.

6. The Non-Federal Sponsor shall pay an additional 10% of the costs of GNF of the NED plan, pursuant to Section 101 of WRDA 86. The value of LERR shall be credited toward the additional 10% payment except in the case of LERR for GNF.

**COORDINATION WITH AGENCIES AND THE PUBLIC**

A Notice of Intent (NOI) to Prepare an Environmental Impact Statement/Environmental Impact Report was published in the Federal Register on 4 December 2017. The current NOI announced the reduction in scope of this project (to include only the Pinole Shoal and the Bulls Head Reach portion of the Suisun Bay) from the NOI that was published on 4 March 2016. Scoping comments received in 2016 and 2018 are

## EXECUTIVE SUMMARY

located in **Appendix I, Pertinent Correspondence Part 1**, along with a Comment Response Matrix to address the comments.

USACE participated in and gained valuable feedback at many meetings involving state and Federal agencies through various stages of this project. Most recently, informal working group meetings were held in December 2018, with attendees from the Environmental Protection Agency, National Marine Fisheries Service, United States Fish and Wildlife Service, Regional Water Quality Board, USACE, Contra Costa County, the Port of Stockton, Anchor QEA, California Department of Fish and Wildlife, Bay Area Air Quality Management District, Bay Area Conservation and Development District, Department of Water Resources, Delta Stewardship Council, Bureau of Reclamation, and State Water Contractors, among others. Discussions and feedback from these working group meetings provided valuable feedback that was considered in this report.

A Notice of Availability was published for the draft GRR/EIS in the Federal Register on May 10, 2019, a press release to announce the location and comment period of the document, and it was also published on the California State Clearinghouse website. A letter was sent to the general public to notice release of the draft GRR/EIS (mailing list available upon request) and to also notice the public meeting time and location that occurred on June 11, 2019 from 6pm-8pm at the Contra Costa County Conservation and Development office in Martinez, at 30 Muir Road, Martinez, CA 94553. Hard copies of the draft GRR/EIS were made available at the following libraries:

Cesar Chavez Central Library, 605 N El Dorado St, Stockton, CA 95202  
Contra Costa County Library, Martinez Branch 740 Court St, Martinez, CA 94553

Comments on the draft GRR/EIS were received from May 10, 2019 through June 24, 2019 for a 45 day public review period. Comments received after June 24 through August 31, 2019 are included in the comment response matrix, located in **Appendix I, Pertinent Correspondence Part 2**. These comments and responses also include comments from the Dredge Material Management Plan (DMMP) meeting that occurred in San Francisco in July 2019.

The proposed project minimizes risk to environmental resources, and threatened and endangered species by:

- Working with the approved USFWS environmental work window for delta smelt, listed salmonids and green sturgeon
- Using a clamshell dredge to avoid entrainment of species
- Placing all dredged material from deepening onto beneficial reuse sites to create/enhance wetland habitats and conditions for species within the delta, including delta and longfin smelt
- Commitments in the Programmatic Agreement for Cultural Resources

Other environmental commitments related to threatened and endangered species are discussed in the Biological Opinion (BO) from the USFWS, received October 3, 2019 which is included in **Appendix G**. The BO contains one non-discretionary term and condition which is to implement the conservation measures listed on pages 2 and 3 of the BO. These conservation measures are already incorporated into the project description and will be followed.

A Letter of Concurrence with determination that the project is not likely to adversely affect ESA-listed salmonids or green sturgeon was received from NMFS on December 6, 2019 (**Appendix G**). NMFS also

## EXECUTIVE SUMMARY

provided EFH conservation recommendations, which USACE responded to as required on January 6, 2020 (**Appendix G**).

### ENVIRONMENTAL COMPLIANCE STATUS ON REMAINING ITEMS

Communication and coordination between agencies has been ongoing throughout the study process, and certain items of compliance are being deferred to the preconstruction, engineering and design phase of work. All regulatory agencies have been actively engaged, and feedback from agency coordination has been incorporated into the project planning process. As a result of those discussions to date, obtaining compliance is considered to be low risk to the project, and are discussed below in more detail.

**Coastal Zone Management Act (CZMA) Consistency Concurrence** – USACE has had several coordination meetings with the San Francisco Bay Conservation and Development Commission (BCDC). The typical process for BCDC would be to issue a final Consistency Concurrence during the USACE Pre-construction, Engineering and Design (PED) phase when detailed project design information is available. In the interim, BCDC has verbally indicated that a letter from the Chair of the Commission will be sent to USACE for inclusion in this report, which will summarize USACE coordination with BCDC to date and confirm their intent to consider CZMA Consistency when CEQA compliance has been completed and more detailed design information is available. BCDC feedback on the Recommended Plan is consistent with comments received during public review, for which substantive responses have been provided in this report. Responses to these comments have been considered in the decision put forth for action by the Director.

**Programmatic Agreement (PA) under Section 106** - The California State Historic Preservation Officer (SHPO) received a copy of the draft PA and provided their comments to USACE for revisions on January 8, 2020. Those comments were addressed and incorporated into the draft PA before being sent out for a second round of review on January 28, 2020. The SHPO's cultural resources staff found the draft PA to be in good standing and requested USACE debrief the SPN District Engineer and route a signed PA to their office for implementation. A signature from the SPN District Engineer occurred on February 7, 2020. The SHPO signed the PA on February 14, 2020 for execution. This executed PA ensures that USACE is in compliance with Section 106 for the study and will continue our obligations for deferred identification of historic properties, consultation with the SHPO and concurring parties, and determining the study's effects during Preconstruction Engineering and Design (PED).

**Water Quality Certification** - Staff from the Regional Water Quality Control Board participated in an early meeting with local agencies to help determine the scope of the water quality impact assessment. More recently in Spring and Fall of 2019, USACE received correspondence from the Regional Board indicating they typically would not issue a water quality certification without completion of CEQA documentation and design-level detail for the project being available. CEQA compliance is a non-Federal responsibility and the Port of Stockton is pursuing this compliance on a separate timeline. In January 2020, USACE met via teleconference call with representatives of the Regional Board regarding the path forward for obtaining 401 water quality certification of the recommended plan, and the timing of completion for the final report. During this meeting, the Regional Board representatives indicated that submittal of the WQC application would need to be deferred until the design phase of work and committed to transmittal of a letter to USACE in February 2020 confirming inter-agency coordination and the path forward for 401 water quality certification upon completion of CEQA compliance and design detail. Feedback received from Regional Board staff and other agencies at the USACE December 2016 agency workshop was wrapped into technical analyses and modeling as contained within this report, and considered in the development

## EXECUTIVE SUMMARY

of report recommendations. Upon receipt this letter will be included in the final report package prior to the Director's signing.

### **RESIDUAL RISK**

#### SEA LEVEL RISE

Sea level rise is expected to be the same in both the future with-project and future without-project conditions. Numerical modeling has found that sea level rise is not anticipated to cause any significant changes to flow rates within San Francisco Bay and the Sacramento-San Joaquin Delta for both future without-project conditions and the Recommended Plan. The modeling has found that sea level rise may cause an increase in salinity intrusion into the delta in both future without-project conditions and without-project if current reservoir operations are maintained. Therefore, there is no anticipated sea level rise change or impact as a result of the Recommended Plan.

#### STORM SURGE

Numerical modeling found that water elevations would be similar for future without-project conditions and the Recommended Plan. Therefore, there is no anticipated significant change in storm surge for future without-project conditions and the Recommended Plan.

#### SEDIMENT QUALITY

Sediment testing in 1998 to a depth of 49 feet showed chromium levels that would be higher than anticipated for wetland placement at the beneficial reuse sites. Recent sediment testing occurred in 2009 in Pinole Shoal from depths of -37 feet to -39 feet, similar to proposed Recommended Plan depth. The Pinole Shoal material to 39 feet was tested with no significant concerns. The sediment in Bulls Head Reach was not tested for chromium recently, but is assumed for the Recommended Plan depth to -38 feet plus 2 feet of overdepth that the sediment quality will likely be similar to that of Pinole Shoal's depth to 39 feet. However, the acreage of sediment from the sediment trap of -42 feet plus 2 feet of overdepth may only be compatible for foundation placement. Discussion on sediment is further described and evaluated in Sections 2.2.2 and 4.1.2. Overall, the sediment quality is assumed to be compatible with requirements for placement at the beneficial reuse sites, either as cover material or foundation placement. To confirm the suitability for marsh placement, sediment sampling of both Pinole Shoal and Suisun Bay will be redone during Preconstruction, Engineering, and Design (PED), based upon the project dredge template.

SAN FRANCISCO BAY TO STOCKTON NAVIGATION IMPROVEMENT

INTEGRATED GENERAL REEVALUATION REPORT AND ENVIRONMENTAL IMPACT STATEMENT

INTRODUCTION

BACKGROUND

The San Francisco Bay to Stockton, California, Navigation Improvement Project was originally authorized by Congress in the Rivers and Harbors Act of 1965. The authorization allowed for -45 foot depths, but the channels were only constructed to -35 feet. The study was originally scoped for a 78-mile long navigation project to include the John F. Baldwin and Stockton channels, but has since been re-scoped to a total of 13.2 miles in the Pinole Shoal Channel and Suisun Bay Channel, to Avon. According to data from the Waterborne Commerce Statistics Center, 20 million to 27 million tons of commodities moved through the Carquinez Straight annually between 2005 and 2016. In terms of both tonnage and value, the most important commodity that moves through the study is crude oil. Most of the crude oil moving through the channel is imported from foreign countries, although a small percentage of crude comes from domestic sources. This analysis focuses on the main oil refineries that import crude oil and export petroleum products. In order to maintain safety, the San Francisco Bar Pilots employ under-keel clearance of 3 feet for tankers and use of high tide when appropriate for vessels for fully loaded. It is a 5 hour transit from the entrance channel to refineries. The recommended plan (shown on the back) is to deepen from -35 feet to -38 feet in the Pinole Shoal Channel and Bulls Head reach portion of the Suisun Bay Channel. Additionally, the plan recommends a sediment trap at Bull's Head reach at cost savings of \$680,000 per year, dredging of a navigational hazard (rock outcropping), and beneficial use of material, which provides average annual savings of \$13.6M, and annual net savings of approximately \$10.5M.

PROBLEMS - ECONOMIC INEFFICIENCIES

Existing channel depths (-35 feet MLLW) require vessels to transit the harbor light loaded (less than fully loaded), which decreases economic efficiency and increases transportation costs which are passed on to the American consumer. Inefficient strategies that are currently employed include:

- Vessels must light-load cargo
- Vessels must wait for favorable (high) tides which increases transportation costs
- High shoaling rates in Bulls Head Reach often require emergency dredging outside of the regular scheduled dredging efforts, causing delays to vessels

PURPOSE OF THE STUDY

This is a single purpose navigation study to increase efficiency of existing tanker vessels. Due to the prior authorization, this study is a general reevaluation report to verify that the authorized project is still economically justified and in the Federal interest to cost share for construction. In concert with Federal law, this report also integrates an environmental impact statement (under the National Environmental Policy Act, or NEPA).

PLAN FORMULATION

PROJECT OBJECTIVES

- 1) Reduce transportation costs and increase deep draft navigation efficiency for the shipment of commodities to and from all facilities within the study area
- 2) Maximize beneficial reuse of dredged material while minimizing placement costs
- 3) Reduce frequent of O&M dredging in high shoaling areas
- 4) Increase navigability to maintain safety

PROJECT CONSTRAINTS

- 1) Avoid adverse impacts on species of special concern
- 2) Avoid impacts to water quality and water quantity

NON-STRUCTURAL MEASURES

- Congestion Fees
- Intermodal transportation systems
- Light loading
- Use of tides
- Traffic Management
- Pipeline

Relocate Port Facilities

Both non-structural and structural measures, as well as the no-action plan, were considered during plan formulation; however, the non-structural measures were all screened from further analysis since they are either already being done, do not meet project objectives, or are not supported by the non-federal sponsor. Analysis of alternatives were considered at depths of 37 and 38 feet MLLW as the increments of depth that would be most likely to efficiently address problems and objectives.. Depths deeper than -38 feet MLLW were not analyzed in detail due to potential concerns regarding salinity impacts, study timeframe, and funding limitations. The final array included the 37 foot and 38-foot deepening alternatives, with sediment traps and beneficial use placement. The 38-foot deepening alternative, with associated features, had the highest net benefits and tentatively selected as the National Economic Development (NED) Plan – the plan with reasonably maximizes the environment.

STRUCTURAL MEASURES

- Incremental depths of 37 and 38 feet MLLW
- Beneficial use of dredge material
- Sediment trap at Bulls Head Reach

ECONOMICS

TRANSPORTATION COST SAVINGS

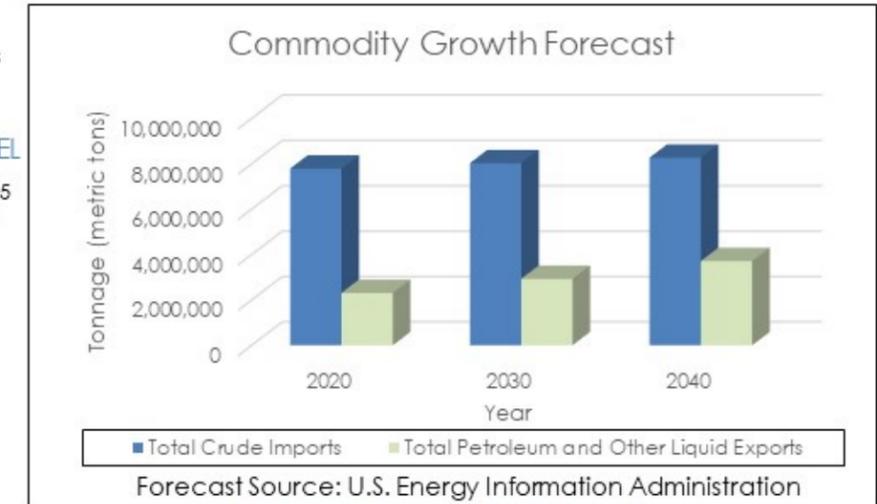

- Increased cargo vessel efficiency
  - Existing fleet of Panamax vessels will be able load more fully

BENEFITING VESSELS/DESIGN VESSEL

- DESIGN VESSEL - Panamax Tankers – 45 ft draft – represents more than 50% of vessels – benefits from project
- Aframax and Suezmax – 57 ft draft – visit other ports before visiting lightloaded – would not benefit

Benefiting vessels – 45 foot draft Panamax Tankers

Main Commodity – Crude Oil

California residents ultimately use crude oil for motor oil, fuel for thermal power, and liquefied petroleum gas. Crude oil is projected to grow at the same current rate of .30% and petroleum exports are projected to grow at the same current rate of 2.40% with or without the proposed project.

LIGHT-LOADING: Vessels can not use all available design cargo space, leading to more frequent trips, which translates to higher transportation costs.

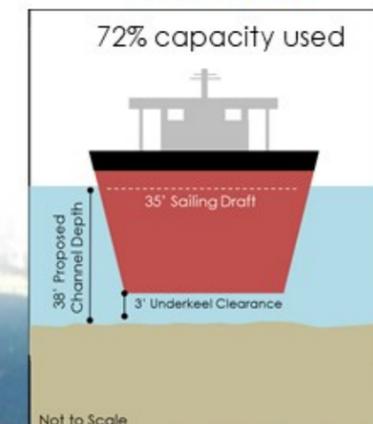

RECOMMENDED PLAN BENEFITS

- More efficient use of vessels = net savings of \$10.5M annually
- Sediment trap to avoid frequent dredging of high shoaling area = stand alone savings of \$680K annually
- This project will reduce the number of vessel transits by allowing current vessels to more fully load to capacity per trip.
- Vessel fleet won't be changing as a result of this project - Same size vessels bringing in goods at less cost.
- Benefit to Cost ratio = 4.4 to 1

EXISTING/FUTURE WITHOUT-PROJECT CONDITIONS

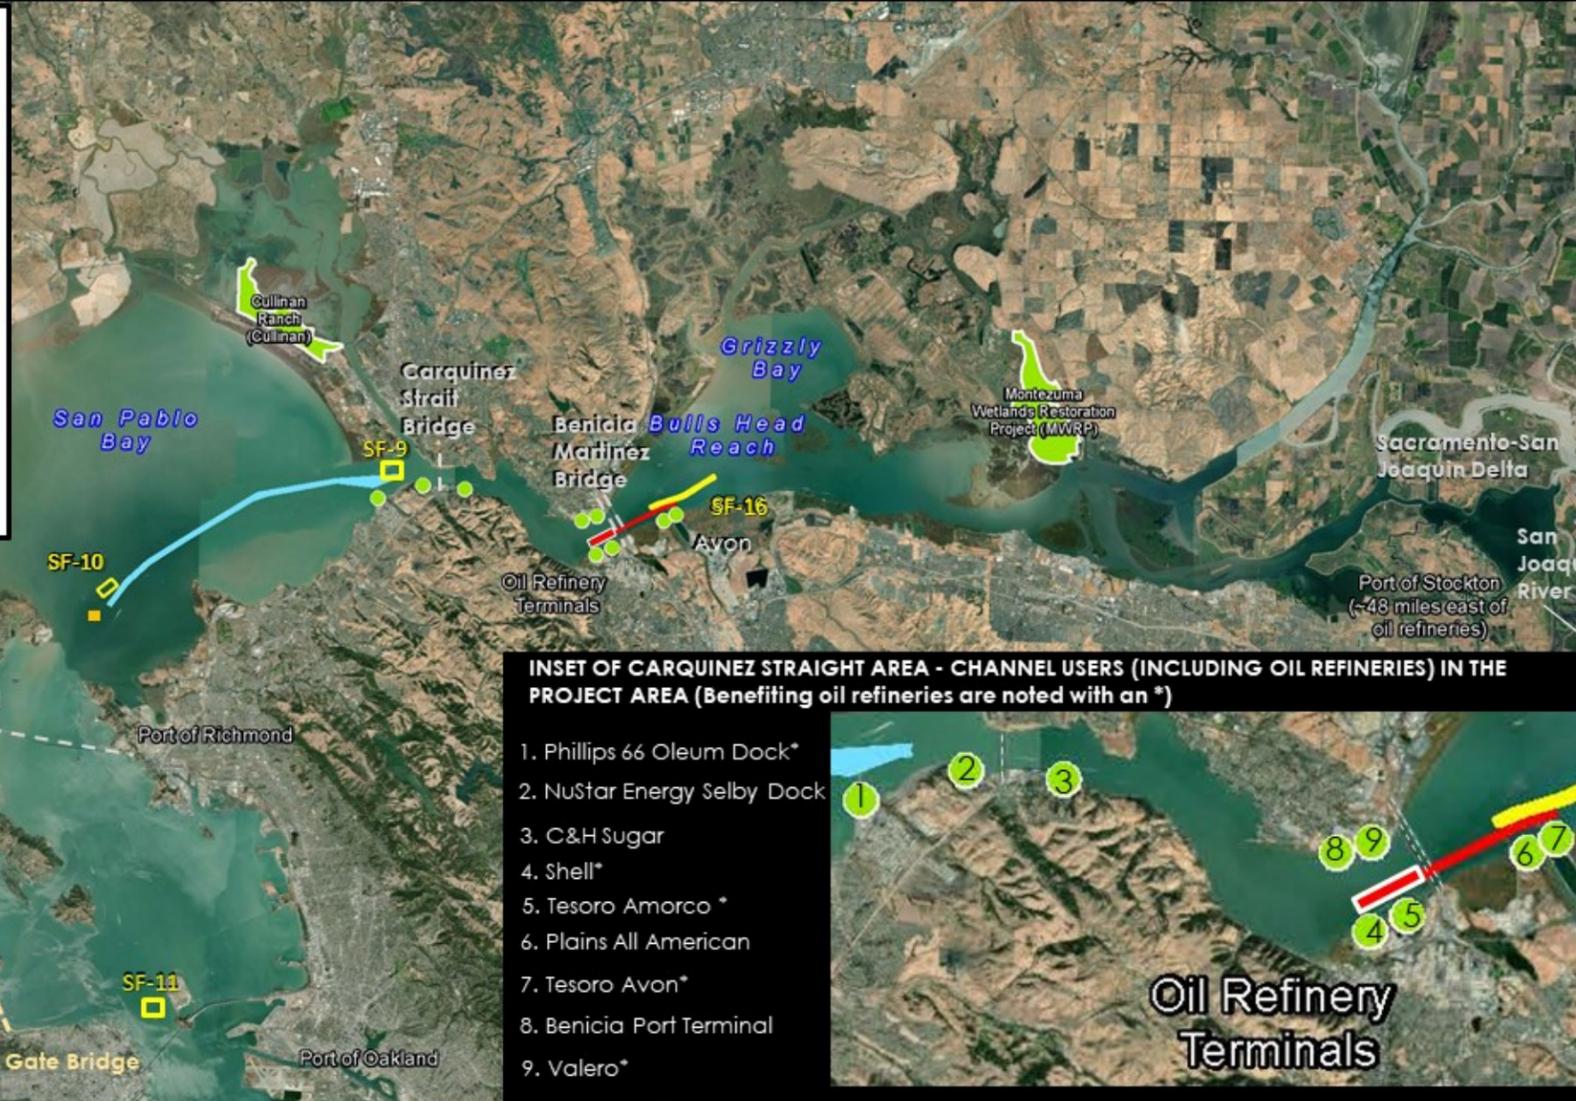

FUTURE WITH-PROJECT CONDITIONS

# RECOMMENDED PLAN- SAN FRANCISCO BAY TO STOCKTON NAVIGATION IMPROVEMENT

## LEGEND

- Deepen PSC from -35 ft to -38 ft MLLW + 2 ft overdepth
- Deepen BHR from -35 ft to -38 ft MLLW + 2 ft overdepth
- Oil Refineries (Channel Users)
- Beneficial Use Placement Sites
- BHR Sediment Trap to -42 ft MLLW + 2 ft overdepth
- Existing O&M Sites – SF-10, SF-16, SF-11, SF-9
- Existing rocky obstruction in existing Federal channel

### INSET OF CARQUINEZ STRAIT AREA - CHANNEL USERS (INCLUDING OIL REFINERIES) IN THE PROJECT AREA (Benefiting oil refineries are noted with an \*)

1. Phillips 66 Oleum Dock\*
2. NuStar Energy Selby Dock
3. C&H Sugar
4. Shell\*
5. Tesoro Amorco \*
6. Plains All American
7. Tesoro Avon\*
8. Benicia Port Terminal
9. Valero\*

## RECOMMENDED PLAN SUMMARY- 38-foot depth with sediment trap & rocky obstruction removal

### CHANNEL DEEPENING

- Deepen from -35 feet to -38 feet MLLW + 2 ft overdepth in two channels with clamshell:
  - TOTAL PROJECT LENGTH = 13.2 miles
  - (PSC): 10.3 miles; STA 0+00 to 547+00, Width=600 feet
  - (BHR): 2.9 miles, STA 0+00 to 62+00 and 88+00 to 160+00

### BULLS HEAD SEDIMENT TRAP

- Dredge trap to -42 feet MLLW + 2 ft overdepth
- Length = 2,600 feet; STA 62+00 to 88+00
- Width = 300 feet

### ROCKY OBSTRUCTION REMOVAL

- Dredge to -43 ft MLLW (via pneumatic jackhammer) to maintain navigation safety

### VOLUMES AND CONSTRUCTION DURATION

- TOTAL APPROX. PROJECT VOLUME = 1,603,200 cy
- Pinole Shoal = 1,443,900 cy
- Bulls Head Reach Channel = 38,700 cy
- Bulls Head Sediment Trap & Overdepth 2 ft = 120,600 cy
- Rocky Obstruction = 40 cy rock(950 sq. ft)
- Approximately 5 month construction duration

### PLACEMENT SITES & ASSUMPTIONS

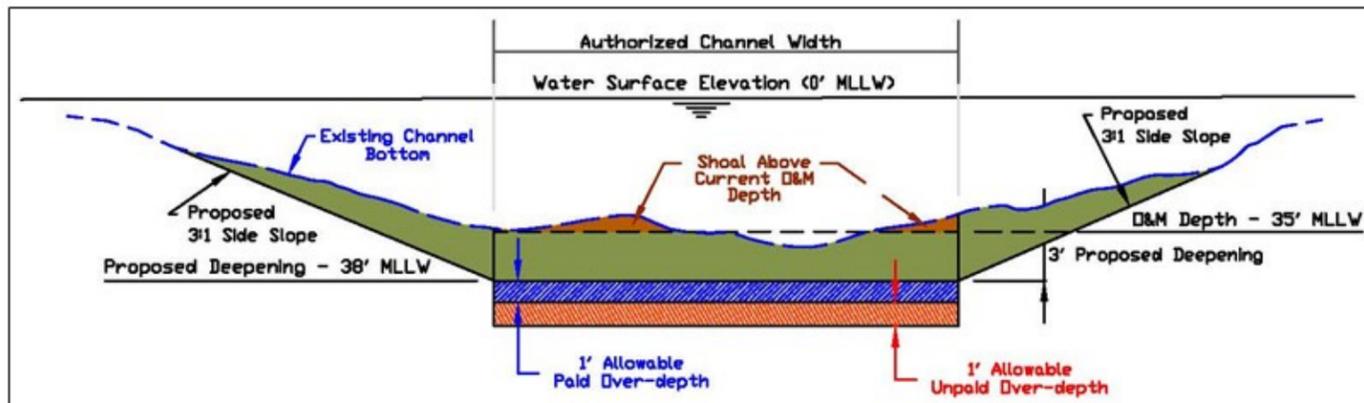

- Pinole Shoal Channel – Cullinan Ranch
- Bulls Head Reach– Montezuma Wetland
- O&M – SF-10 and SF-16 (Federal standard)
- SF-DODS – not assumed for placement but a backup site if needed

### COST & BENEFITS

- Project First Cost = \$57.2 M (includes contingency)
- Cost sharing 75% (Fed)/25% (Non-Fed)
- Average Annual Net Benefits = \$10.5M
- Benefit to Cost Ratio = 4.4 to 1

Pinole Shoal Channel (PSC); Bulls Head Reach (BHR); Bulls Head Sediment Trap (BHST)

### Typical Section

### OPERATIONS & MAINTENANCE

#### EXISTING (historical)

- Pinole Shoal Channel = 255,000 cy/2 years (hopper)
- Bulls Head Reach Channel = 25,000 cy/year (clamshell)
- Bulls Head Reach Advance Maintenance Area= Annual dredging to 37 feet MLLW + 2 feet overdepth

#### FUTURE WITH PROJECT

- Pinole Shoal = 351,800 cy/2 years (hopper)
- Bulls Head Reach Channel= 47,500 cy/year (clamshell)
- Bulls Head Reach Sediment Trap = 8,900 cy/year (average) and would be dredged twice every three years

The sediment trap would save \$1M for mob/demob costs once every 3 years, providing an average equivalent savings of \$680,000 to the Federal O&M program per year over 50 years. The net present value of savings is \$18 million. The initial investment will pay for itself 2 years after construction is complete.

### T&E Species - Delta Smelt Critical Habitat

### BENEFICIAL USE OF MATERIAL

- Beneficial Use of material in permitted sites Montezuma Wetlands and Cullinan Ranch Tidal Wetlands will create approximately 160 acres for wetland habitat

### ENVIRONMENTAL WORK WINDOWS:

- PSC- June 1 to November 30.
- BHR - August 1 to November 30.

1

# Introduction

# 1 INTRODUCTION\*

Please refer to Graphic Executive Summary Pages 1 and 2.

## 1.1 FEDERAL PROJECT PURPOSE\*

The Federal interest in navigation is established by the Commerce Clause of the U.S. Constitution. The project purpose is to provide safe, reliable, efficient, and environmentally sustainable waterborne transportation systems to contribute to national economic development (NED), for movement of commerce, national security, and recreation.

## 1.2 STUDY BACKGROUND AND LOCATION\*

The San Francisco Bay to Stockton Navigation Improvement Project was originally authorized by Congress in the Rivers and Harbors (R&H) Act of 1965. The authorization allowed for 45 foot channel depths, but the channels were only constructed and maintained to -35 feet MLLW. This report is an interim response to the study authority.

The study was originally scoped for a 78-mile long navigation project to include the John F. Baldwin and Stockton channels, but was re-scoped in 2016 to only include improvements to Avon. The re-scoped study area is a 13.2 mile length which spans from Central San Francisco Bay to Avon; just east of the Benicia-Martinez Bridge, and includes the Pinole Shoal Channel and the Bulls Head Reach portion of the Suisun Bay Channel. The channels in the study area primarily serve crude oil imports and refined product exports to and from several oil refineries and two non-petroleum industries.

## 1.3 STUDY SPONSOR

USACE is responsible for preparing the General Reevaluation Report (GRR) and is the lead Federal agency for NEPA compliance. The Port of Stockton is the official non-Federal partner for the GRR.

## 1.4 STUDY PURPOSE, NEED AND SIGNIFICANCE

The navigation channels within the study area are regionally significant, providing navigation access to ports, harbors, refineries, and military terminals from San Francisco Bay through San Pablo and Suisun bays and up the Sacramento-San Joaquin Delta and the San Joaquin River to the Port of Stockton.

The bays and delta through which the navigation channels cross are naturally shallow. Over time, channel deepening of the natural waterways and regular maintenance dredging has facilitated modern vessels to traverse the channels. The modern vessels crossing the channels can require up to 55 feet of draft when fully loaded. Given that these channels are maintained at -35 feet MLLW, most vessels must be “light-loaded”, or less than fully loaded with cargo, to navigate the channels with sufficient under-keel clearance. Light-loading increases the cost of transportation and, in turn, the cost of the shipped products because more trips must be made to carry the same volume of cargo. Within the study area, tankers carrying

crude oil to California oil refineries and those exporting petroleum are most impacted by light-loading practices.

According to the California Energy Commission, Californians consume nearly 44 million gallons of gasoline and 10 million gallons of diesel every day. California refineries produce these fuels and other products from crude oil and blending components. Transportation fuel production in California depends on the availability and quality of the crude oils used by refineries in the state. The supply of crude oil to California refineries has changed substantially in the last 10 years. Most notably, receipts of foreign crude oil have increased as production sources from California and Alaska have continued to decline. Each day approximately two million barrels (a barrel is equal to 42 U.S. gallons) of petroleum are processed into a variety of products, with gasoline representing about half of the total product volume. To comply with Federal and state regulations, California refiners invested approximately \$5.8 billion to upgrade their facilities to produce cleaner fuels, including reformulated gasoline and low-sulfur diesel fuel.

According to data from the Waterborne Commerce Statistics Center, 20 million to 27 million tons of commodities moved through the Carquinez Strait annually between 2005 and 2013. In terms of both tonnage and value, the most important commodity moved through the strait is crude oil. Most of the crude oil moving through the channel is imported from foreign countries, although a small percentage of crude comes from domestic sources. This analysis focuses on the main oil refineries that import crude oil and export petroleum products. According to the Annual Energy Outlook (2015), the growth rate for crude oil imports is an annual rate of 0.3% and petroleum and other liquid exports have an annual rate of 2.4%.

In order to maintain safety, the San Francisco Bar Pilots employ under-keel clearance of 3 feet for tankers and use of high tide, when appropriate, for vessels fully loaded. It is a 5 hour transit from the entrance channel to refineries.

Given the constraints posed by existing channel depths, inefficient strategies that are currently employed to manage these constraints include:

- Vessels must light-load cargo
- Vessels must wait for favorable (high) tides which increases transportation costs
- High shoaling rates in Bulls Head Reach require dredging annually, incurring large mobilization and demobilization costs and causing delays to vessels when dredging is postponed.

The Federal objective defining Federal interest in channel improvements is to reasonably maximize net benefits to the nation. Project specific objectives include:

- Objective 1: Reduce transportation costs and increase deep draft navigation efficiency for the shipment of commodities to and from all facilities within the study area beginning in 2020
- Objective 2: Maximize the beneficial reuse of dredged material while minimizing placement costs
- Objective 3: Reduce the frequency of operation and maintenance dredging in high shoaling areas
- Objective 4: Increase navigability to maintain safety

## 1.5 STUDY AUTHORITIES

- **1960 Rivers and Harbors Act, Pub.L. No. 86-845, Section 107, 84 Stat. 1818.** Authorizes the development and construction of small river and harbor improvement projects which will result in substantial benefits to navigation. This authorization facilitated the development and construction of a twenty-five (25) feet deep channel from Martinez to Avon.
- **1965 Rivers and Harbors Act, House Document 208, House Report 89-973 cited in Rivers and Harbors Act of 1965, Pub.L. No. 89-298, Section 301, 79 Stat. 1073.** Authorizes works of improvement of rivers and harbors and other waterways for navigation. This authority permits repair and restoration of works for wavewash protection within the limits of the modified San Joaquin River navigation project. This led to the modification of five existing projects:
  - San Francisco Harbor, Bar Channel – deepen to 55' [*completed 1974*]
  - Richmond Harbor, Richmond Channel, and maneuvering area – construct new 45' deep, 600' wide channel; deepen maneuvering area (Richmond Long Wharf) to 45' [*completed 1986*]
  - San Pablo Bay, Mare Island Strait – deepen to 45' Pinole Shoal Channel and maneuvering area at Oleum
  - Suisun Bay – deepen to 45' up to Chipps Island, and to 35' beyond, widen to 600' upstream to Middle Point and to 400' beyond
  - San Joaquin River – deepen to 35' and realign the channel; place rock revetment on levees bordering Stockton Deep Water Channel; provide public recreation along improved channel [*deepening completed 1988*]
  - Vicinity of Antioch – provide a 35' channel access and turning basin to accommodate a potential harbor
- **Energy and Water Development Appropriations Act, 1998.** The Act appropriated funds to the Department of the Army, under the supervision of the Chief of Engineers, for authorized civil functions of the U.S. Army Corps of Engineers. Included in this authorization was the expenditure of funds necessary for the study and restudy of authorized projects and the “preservation, operation, maintenance and care of existing river and harbor, flood control, and related works,” As such, USACE expended \$100,000 to initiate a reconnaissance study on deepening the Stockton DWSC to -40-feet MLLW. USACE also expended \$250,000 to complete the environmental review and continue preconstruction engineering and design for deepening the John F. Baldwin Ship Channel.
- **July 30, 2014, Resolution of the U.S. Senate Committee on Environment and Public Works.** The 2014 resolution provided authorization to study the San Francisco Bay to the Port of Stockton channels “in the interest of navigation, ecosystem restoration, flood risk reduction, recreation, and other water related resources purposes.”

## 1.6 RELATED DOCUMENTS\*

Numerous reports have been prepared in response to the Rivers and Harbors Act (RHA) of 1965 authorization:

- ***Final Environmental Impact Statement (EIS), Bank Protection, Filed with the Council on Environmental Quality on 11 October 1971.*** This document addressed impacts of the Venice Island to Stockton bank protection.
- ***San Francisco Bay to Stockton, California (Levee Setback), Interim GDM (No. 3), U.S. Army Corps of Engineers, Sacramento District, June 1969 (approved 6 January 1970).*** This document discussed the design and cost for construction of levees on a setback alignment at four locations between Venice Island and Stockton where channel excavation was within 50 feet of the toe of the existing levees.
- ***San Francisco Bay to Stockton, California (San Francisco Bar), Interim GDM (No. 4) and Final EIS, U.S. Army Corps of Engineers, San Francisco District, March 1971 (approved 17 August 1971).*** This document discussed the design, costs, construction methods, and environmental impacts of deepening the channel across the bar to -55 feet MLLW. Construction was completed in February 1974.
- ***San Francisco Bay to Stockton, California, (John F. Baldwin Ship Channel and Stockton DWSC) Avon to Stockton. Interim GDM and EIS (No. 1), U.S. Army Corps of Engineers, Sacramento District, September 1980.*** This project deepened the deep draft channels from Avon to the Port of Stockton to -35 feet MLLW. The project was completed in 1988.
- ***San Francisco Bay to Stockton, California, Project, FINAL Interim GDM (No. 5) and EIS (John F. Baldwin Ship Channel Phase II, Richmond Harbor Approach), U.S. Army Corps of Engineers, San Francisco District, May 1984.*** Construction of the West Richmond Channel and the maneuvering area near Richmond Long Wharf was addressed in the 1984 Interim Design Report and EIS. Deepening of the Richmond Long Wharf was completed in 1986. The West Richmond Channel has not been constructed to its authorized depth of -45 feet MLLW.
- ***SF Bay to Stockton Phase III (John F. Baldwin Ship Channel) Navigation Improvement Project Final EIR/EIS, U.S. Army Corps of Engineers, San Francisco District, September 1998.*** This document only analyzed improvement of the Western Reach channels and was prepared in tandem with the 1998 General Reevaluation Report (discussed below).
- ***SF Bay to Stockton, John F. Baldwin Ship Channel Phase III Contra Costa County, California Navigation Improvement Project General Reevaluation Report, U.S. Army Corps of Engineers, San Francisco District, 1998.*** The West Richmond Channel, Pinole Shoal Channel, Carquinez Strait, and the Bulls Head Reach portion of the Suisun Bay Channel were reevaluated in the 1990s. The resulting 1998 GRR recommended implementation of a crude oil pipeline alternative as a local plan in lieu of deepening because, at the time, the

deepening plan was "...essentially non-implementable... because of the severe and unresolved issues associated with salinity intrusion into the Sacramento-San Joaquin River Delta area." This proposed oil pipeline project was never implemented since it was not supported by local non-Federal interests.

## 1.7 FEDERAL PROJECTS & STUDIES NEAR THE STUDY AREA

- ***Final Composite Environmental Statement for Maintenance Dredging of Existing Navigation Projects, San Francisco Bay Region, California (December 1975)*** – The Statement of Findings recommended that maintenance dredging for federal navigation projects in San Francisco Bay be continued as authorized. Dredged material from 15 sites was recommended for open water disposal, although material from 5 additional sites was allowed to be considered for land placement pending further environmental review. Environmental impacts such as increased turbidity and disturbance of benthic organisms were determined to be adverse but limited, based on available data. Economic impacts were determined to be beneficial.
- ***Final Environmental Impact Statement for Designation of a Deep Water Ocean Dredged Material Disposal Site off San Francisco, California (August, 1993)*** - The EPA Final Rule initially designating the SF-DODS for dredged material disposal was published on August 11, 1994 (59 FR 41243). This initial rule established an "interim" allowable disposal volume of 6 million cubic yards per year. The maximum allowable disposal volume was reduced to 4.8 million cubic yards per year starting in January, 1997 (EPA Final Rule of December 30, 1996, 61 FR 68964). The reduction in allowable disposal volume was based on a revised prediction of long-term dredging needs conducted by the interagency Long Term Management Strategy (LTMS) for San Francisco Bay (LTMS 1996, 1998). The limit of 4.8 million cubic yards per year was subsequently made permanent in the EPA Final Rule published on July 23, 1999 (64 FR 39927). Through the 2007 disposal year, almost 16 million cubic yards of dredged material have been diverted to the SF-DODS from traditional in-Bay sites, reducing risks of disposal-related impacts within those sensitive waters, and, as described in this report, that reduction of risk has been accomplished without causing any significant impacts to the ocean.
- ***Final Environmental Impact Statement/Environmental Impact Report for Montezuma Wetlands Restoration Project (July 1998)*** – The purpose of the project is to combine the commercial placement of dredged materials within the restoration of a tidal wetland ecosystem. Approved cover and non-cover dredged materials taken from the San Francisco Bay Area would be used to raise the subsided land to elevations suitable for the restoration of tidal marsh and other habitats, including some seasonal wetland features.
- ***Long-Term Management Strategy for the Placement of Dredged Material in the San Francisco Bay Region (2001)*** – The project area is the San Francisco Bay in California. Policy objectives of the Long Term Management Strategy (LTMS) are to identify an acceptable array of dredge material placement sites, develop management, economic, and environmental plans for these sites, implement a decision making framework for site usage, streamline permit procedures, and establish long term site monitoring.

- ***Final Environmental Impact Statement/Environmental Impact Report for Cullinan Ranch Restoration Project, Solano and Napa Counties, CA. (April 2005)*** - The U.S. Fish and Wildlife Service (Service) and the California Department of Fish and Game are proposing a restoration plan for 1,500 acres of former hayfield farm land in the San Pablo Bay. This restoration project would combine tidal salt marsh habitat for endangered species, waterfowl, water birds, and fish, as well as public access features to increase accessibility to wildlife resource values in the San Pablo Bay, while minimizing project-induced flood impacts to Highway 37. The Cullinan Ranch is managed by the Service as part of the San Pablo Bay National Wildlife Refuge.
- ***Final Environmental Impact Statement/Environmental Impact Report for South San Francisco Bay Shoreline Project (Chief's Report December 2015)*** - This project will safeguard homes and businesses along the South Bay by restoring four miles of levees, as well as some 2,800 acres of tidal marsh, along with creating access for recreation. The region's flood risk has been compounded by threats of sea level rise which has become an increasingly urgent environmental issue for the Bay Area, including in San Francisco to the north.
- ***Final Environmental Assessment/Environmental Impact Report for Maintenance Dredging of the Federal Navigation Channels in San Francisco Bay, 2015-2024 (2015)*** – Sediment accumulation in these channels can impede navigability. Maintenance dredging removes this sediment and returns the channels to regulatory depths to provide safe, reliable, and efficient waterborne transportation systems (channels, harbors, and waterways) for the movement of commerce, national security needs, and recreation. Therefore, USACE's purpose in this project is to continue maintenance dredging of the Federal navigation channels in San Francisco Bay consistent with the goals and adopted plans of the LTMS, while adequately protecting the environment, including listed species.
- ***Delta Islands and Levees Feasibility Study Chief's Report (December 18, 2018)*** - recommends restoration of 340 acres of intertidal marsh at Big Break, located in Contra Costa County. The Recommended Plan would use approximately one million cubic yards of clean dredged material for annual maintenance of the Stockton Deep Water Ship Channel over an approximately 10 year period. The California Department of Water Resources is the non-Federal sponsor. The proposed restoration area is owned by the East Bay Regional Park District.

## 1.8 OTHER CURRENT NON-FEDERAL STUDIES AND PROJECTS ADJACENT TO OR NEAR THE STUDY AREA

Other non-Federal studies considered throughout this report, and cumulative effects, are located in **Table 4-27. Past, Present, and Reasonably Foreseeable Future Projects.**

- ***San Francisco Bay Living Shorelines Project*** – This project is managed by the State Coastal Conservancy and *is a multiple objective habitat restoration pilot project. Per the project website, "This experimental restoration project allows us to learn more about the best locations and techniques for native oyster and eelgrass restoration, to gather information about fish, invertebrate, and bird use of the reefs, and to assess whether the reefs can provide physical benefits such as reducing wave action and protecting adjacent shorelines. Oyster and eelgrass*

*reefs were constructed at two sites in San Francisco Bay in July and August 2012 (larger and small experiment at the San Rafael Shoreline, and small experiment at Hayward near the Eden Landing Ecological Reserve)."*

- **SF Bay Water Quality Improvement Fund (SFBWQIF) projects** – Over 30 projects are part of an EPA grant program to improve San Francisco Bay water quality. These are focused on restoring impaired waters and enhancing aquatic resources.

2

Existing and Future Without  
Project Conditions

## 2 EXISTING AND FUTURE WITHOUT-PROJECT CONDITIONS

Keeping in mind the initial problem statement in Chapter 1, this chapter describes the existing economic and environmental conditions, and the project alternative conditions are evaluated for the natural environment., where the project alternative conditions are evaluated for the natural environment.

### 2.1 GENERAL SETTING\*

Under the existing/no action/future condition, deepening the channel would not occur and all construction-related activities would be avoided. Ships would continue to employ inefficient strategies in managing channel depth constraints when transporting commodities to existing refineries. As no sediments would be dredged from channel deepening, there would be no placement of the proposed project sediments in the wetland creation sites in the San Francisco Bay area. However, maintenance dredging would continue and emergency or advanced maintenance dredging costs would be incurred on an as needed basis, with the Federal standard placement sites continuing to be used.

### 2.2 NATURAL ENVIRONMENT EXISTING CONDITIONS\*

The affected environment for all natural environment resources includes the Bay Area and Sacramento-San Joaquin Delta encompassing the New York Slough, Pinole Shoal, and the Bulls Head Reach portion of Suisan Bay. These areas are located within the counties of Marin, Contra Costa, and Solano. The natural environment resources described in the following sections (Section 2.2.1 through 2.2.16) are not expected to change under the future without-project condition, therefore the resource descriptions below apply to both existing and future without-project conditions (the No Action Alternative discussed in Chapter 4), with the exception of sea level rise. The timing and ability to know what changes would occur from existing conditions to the 50 year project condition with sea level rise are difficult to predict, and therefore are described together in this section.

#### 2.2.1 GEOLOGY AND SEISMICITY

**Seismicity.** Several Quaternary-active faults traverse the path of the navigation channels in the San Francisco Bay/Sacramento-San Joaquin Delta, including the Hayward fault zone, and the Franklin, Southampton, Green Valley, and Vaca faults. Quaternary-active faults are those that have slipped in Quaternary time (the last 1.8 million years). These are the most likely sources of future great earthquakes. The Hayward fault zone intersects the San Pablo Bay and the Pinole Shoal Channel; the Franklin and Southampton faults intersect the Carquinez Strait; the Green Valley fault zone and Concord fault intersect Suisun Bay at the Bulls Head Reach. The Vaca fault zone extends northwest to southeast immediately northwest of Sherman Island. There are no other Quaternary faults in the study area east of Sherman Island (USGS 2015).

The U.S. Geological Survey's (USGS 2010) 2009 Probable Seismic Hazard Analysis Program indicates that there is a 90 to 100 percent probability of a greater than 5.0 magnitude earthquake occurring within 50 years and 50 kilometers of the study area from the San Francisco Bay to McDonald Island. That probability

drops to 80 to 90 percent east of McDonald Island. There is a 40 to 50 percent probability of a 7.0 or greater earthquake occurring within 50 years and 50 kilometers of San Francisco Bay. The probability steadily decreases eastward from the Carquinez Strait, dropping to 0 to 10 percent for the Stockton area (USGS 2010).

The Federal Emergency Management Agency's (FEMA) Seismic Design Category ratings define the potential effects of shaking in the study area as follows:

- **D<sub>1</sub>, D<sub>2</sub>:** Very strong shaking—Damage slight in specially designed structures; considerable damage in ordinary substantial buildings with partial collapse. Damage great in poorly built structures, and
- **E:** Strongest shaking—Damage considerable in specially designed structures; frame structures thrown out of plumb. Damage great in substantial buildings, with partial collapse. Buildings shifted off foundations. Shaking intense enough to completely destroy buildings.

For the study area, shaking intensity generally declines moving eastward from San Francisco Bay, with the highest shaking potential centered on the Hayward and Green Valley fault zones and the Concorde fault (FEMA 2015).

Alquist-Priolo fault zones are present within the study area counties including Contra Costa, Marin and Solano Counties and within the cities of Richmond and Benicia. Alquist-Priolo fault zones generally occur within approximately 200 to 500 feet of major fault lines or zones. In the study area, this includes areas adjacent to the Hayward and Green Hill fault zones and the Concord fault (California Department of Conservation 1982a, 1982b, 1993)[CDC]. Alquist-Priolo fault zones are limited to land areas; delta and bay waters are not considered within these zones.

**Seismically Induced Liquefaction.** Liquefaction is a process in which saturated, loosely packed, coarse-grained soils transform from a solid to a near-liquid state as a result of seismic ground shaking. Effects of liquefaction may include slope instability, lateral spreading, loss of foundation bearing capacity, and ground settlement. It is important to distinguish between susceptibility and hazard for liquefaction. Susceptibility involves the presence of saturated sandy-to-silty Quaternary material. Hazard involves both the presence of such soils and the likelihood that they would be displaced during a particular seismic event, which may trigger liquefaction.

The Association of Bay Area Governments (ABAG) maintains comprehensive liquefaction hazard maps for the San Francisco Bay Area, including the study area from the San Francisco Bay east to Webb Tract. Liquefaction susceptibility varies within the study area, with several shoreline and nearshore areas identified as being moderately to highly susceptible to liquefaction. Areas of very high susceptibility occur scattered along the shorelines of coastal cities within the study area including Richmond, San Pablo, Pinole, Hercules, and Vallejo. Hazard maps identify delta islands as having high liquefaction potential (ABAG 2015a). East of Webb Tract, delta islands and shorelines are also identified as susceptible to liquefaction (Sacramento County 2011; San Joaquin County 2005).

**Slope Failure and Landslides.** Shoreline areas containing wetlands, marsh fill areas, and steep or unstable slopes—including certain levees—may be susceptible to landslides, slumping, soil slips, or rockslides. Inland dredged material placement sites containing steep slopes may also be susceptible to landslides. Although ABAG maintains landslide hazard maps for the San Francisco Bay Area, the shoreline and most inland areas adjacent to the study area have not been evaluated (ABAG 2015b). Slope or landslide hazard

areas occur along the coast of the study area, as identified in General Plans for Tiburon (2005), Richmond (2012), Pinole (2010), Solano (2008), and Contra Costa counties (2005). Underwater slope failures are also possible within the study area, although susceptible areas have not been documented.

**Other Upland Geologic Hazards.** In addition to liquefaction and landslides, upland areas potentially used for placement of dredge material may be susceptible to lateral spreading, subsidence, settlement, and erosion which may be caused or exacerbated by seismic activity. Unlike for liquefaction and landslides, comprehensive maps for these hazards have not been developed for the study area. Site susceptibility to these hazards is dependent upon their specific location, which has not been determined at this time.

**Shoreline Erosion.** Waves breaking on shore can suspend sediment and erode the shoreline. Larger waves contain more energy and have greater capacity to mobilize sediment. Deep draft vessels also produce waves as a result of the bow wave and displace water as they move. Larger, more fully loaded vessels have the potential to create larger waves when compared to smaller, lighter vessels. Shoreline erosion from vessel-induced waves is not expected to be a problem from vessels traveling in the open waters of the bays.

**Delta Levees.** Approximately 1,100 miles of levees and berms protect 700,000 acres of reclaimed marshland and uplands within the delta (LTMS 1998). In addition, many dredged material placement sites along the San Joaquin River contain berms or use the existing flood control levees to contain the dredged material. Levees and berms are critical infrastructure that protect agricultural lands, water supplies, upland development, and roads and railways from flooding. Delta levees also play a critical role in preventing intrusion of salty water from San Francisco Bay into the delta channels. These channels serve an integral role in the state's water transfer system, which provides water to approximately two-thirds of California's population. Adjacent landowners built and maintain the vast majority of the 1,100 miles of levees (LTMS 1998). Due to great variations in levee construction and soil types, geology, and other factors, levee conditions and maintenance requirements differ throughout the delta region.

**Bay Levees.** Levee failure is identified as a seismic hazard for Martinez (2015), Contra Costa (2005), and Solano Counties (2008). While failure-prone levees are not explicitly identified, landslide hazard areas identified in the general plans for the study area appear to include potentially unstable levee areas.

**Tsunamis and Seiches.** Seismic activity can potentially result in tsunamis or seiches, which would present a hydrological hazard. Tsunamis (seismic sea waves) are long-period waves typically caused by underwater seismic disturbances, volcanic eruptions, or submerged landslides. Tsunamis can travel across oceanic basins and cause damage several thousand miles from their sources. Low-lying coastal areas, such as tidal flats, marshlands, and former bay margins that have been artificially filled, but are still at or near sea level, are generally the most susceptible to tsunami inundation.

A seiche is caused by oscillation of the surface of an enclosed water body, such as San Francisco Bay, resulting from an earthquake or large wind event. Seiches can result in long-period waves that cause run-up; i.e. uprush on the shoreline or structures above the still water level or overtopping of adjacent landmasses, similar to tsunami run-up. The primary tsunami threat along the central California coast is from distant earthquakes along subduction zones elsewhere in the Pacific basin, including Alaska (City and County of San Francisco 2011).

The shoreline and some nearshore areas adjacent to the study area in Marin and Contra Costa Counties are within tsunami inundation areas as delineated on the State’s tsunami inundation maps (California Emergency Management Agency 2009a, 2009b). Based on a tsunami wave run-up of 20 feet entering the Golden Gate, the 2009 Contra Costa Countywide Comprehensive Transportation Plan indicates that tsunami attenuation in the San Francisco Bay would diminish the height of the wave to approximately 10 feet along the Richmond shoreline. East of Point Pinole, the wave height would diminish to approximately 2 feet (Contra Costa Transportation Agency 2009). Areas east of the Benicia Bridge are not included on State tsunami inundation maps. Tsunami effects are attenuated from their source, and tsunami effects extending east of the Benicia Bridge would be further attenuated by Suisun Bay and other upstream water bodies. The most recent local and significant tsunami event occurred in March 2011, when a tsunami originating in Japan caused a swell of two feet in the Bay (NOAA 2011). The NOAA operates the tsunami warning system serving the Pacific Northwest.

## 2.2.2 SEDIMENT AND SEDIMENTATION

### 2.2.2.1 SEDIMENTATION

The temporal fluctuation of maintenance dredging volumes depends primarily on the hydrologic conditions and the sediment supply from the Sacramento-San Joaquin Delta. Recent analyses of historical dredged material volumes and modeling results have indicated that sediment supply from tributaries to the Delta can vary by a factor of four or more between wet and dry years, and this can influence shoaling rates by a factor of two at some Federal navigation channels in Central Bay (Delta Modeling Associates 2015). However, the sediment supply to the Bay has decreased significantly in recent years (Schoellhamer 2011). Many factors contribute to the decreasing sediment yield; these factors may include depletion of erodible sediment from hydraulic mining, sediment impoundment by reservoirs, and riverbank protection.

### 2.2.2.2 SEDIMENT CHARACTERISTICS

The sediments within San Francisco Bay originate from erosion of surrounding hills or from later marine and riverine deposits. Generally, the upper several feet of the sediment profile in San Francisco Bay consists of more recently deposited marine and riverine sediments. The thickness of various underlying historic sediment formations varies throughout the San Francisco Bay/Delta Estuary and it can be several hundred feet thick. Large areas of San Francisco Bay, particularly in shallow areas, contain the marine clay-silt deposit termed “Bay Mud” several feet beneath softer, more recently deposited muds (USACE 2015b). In some areas of San Pablo Bay, Suisun Bay, and the Delta, natural peat deposits underlay more recent San Francisco Bay sediments. Estuary channels typically contain sandy bottoms, although regions where currents are strong, including the deep channels of San Francisco Bay and the central channels of the major rivers in the Delta, generally have coarser sediments (i.e., fine sand, sand or gravel) (LTMS 1998). San Francisco Bay surficial sediments have been deposited since industrialization began in California and, therefore, may have been exposed to anthropogenic sources of pollutants. Recent sand deposits, including riverine sand or sand bars in the San Francisco Bay, may also be exposed to anthropogenic sources of pollutants but typically do not accumulate significant pollutant concentrations. Data from monitoring sediment contaminants in the Bay indicate that overall, the peripheral industrialized areas have higher mean contaminant concentrations than Bay waters away from the shoreline (LTMS 1998). Over the years, sediment proposed for maintenance or new work dredging in the study area has undergone a significant amount of sediment sampling and analysis, including physical, chemical, and biological testing. In addition, sediment proposed for maintenance dredging from each channel has

undergone sediment testing according to the Master Sediment Sampling and Analysis Plan (Master SAP), for Pinole Shoal are located: [http://www.dmмосfbay.org/site/alias\\_8959/171100/default.aspx](http://www.dmмосfbay.org/site/alias_8959/171100/default.aspx) and for Bulls Head Reach: [http://www.dmмосfbay.org/site/alias\\_\\_8958/171080/default.aspx](http://www.dmмосfbay.org/site/alias__8958/171080/default.aspx). Sediment in the study area generally has low levels of contamination and does not contribute to significant environmental risks when dredged or disposed (LTMS 1998).

Sediment testing has been conducted to determine the suitability of dredged material for placement (e.g., either in ocean or in-Bay) or for beneficial reuse for the operations and maintenance dredging, and to evaluate potential contaminant releases during dredging. The data summaries presented in this section compare historic sediment quality results from the study area to regulatory criteria established by: the San Francisco Deep Ocean Disposal Site (SF-DODS) Ambient Concentrations of Toxic Chemicals Screening Levels (SFRWQCB 1998); Dredged Material Testing Thresholds for San Francisco Bay Area Sediments (SFEI 2014); Beneficial Reuse of Dredge Materials: Sediment Screening and Testing Guidelines (SFRWQCB 2000); and ambient or reference areas. This includes regulatory criteria for in-Bay placement, ocean, wetland cover material reuse, and wetland foundation material reuse.

Sediment from the Pinole Shoal Channel and Bulls Head Reach have been characterized and dredged. Overall, sediments in the Pinole Shoal Channel and Bulls Head Reach show little contamination and pose a low level of environmental risk (Lee 2000; Word and Kohn 1991). The following subsections discuss the sediment characterization studies and results in greater detail.

### 2.2.2.3 DEEPENING PROJECT CHARACTERIZATION OF THE JOHN F. BALDWIN SHIP CHANNEL

From 1989 to 1994, USACE conducted extensive testing under the guidelines in Evaluation of Dredged Material Proposed for Ocean Disposal - Testing Manual (USEPA/USACE 1991) of the John F. Baldwin Ship Channel sediments for a potential deepening project to -45 feet MLLW plus 2 feet of overdepth (Kohn et al. 1991; Kohn et al. 1993; Kohn et al. 1994; Word and Kohn 1990). USACE conducted Tier III testing requirements for ocean placement, which are considered to be the most stringent and protective of the environment. Tier III testing requires conducting chemical, toxicity, and bioaccumulation testing to evaluate the risks associated with dredging and ocean placement of sediment. The results of these investigations are summarized in the following paragraphs.

Sediment core samples were collected to a depth of -47 feet MLLW (-45 feet MLLW plus 2 feet overdepth) from three reaches of the John F. Baldwin Ship Channel (West Richmond Reach, Pinole Shoal, and Carquinez Strait) in 1990. In the absence of a designated placement site at the time of the study, reference sediments representing two potential placement sites (one ocean site and one in-Bay site) were tested concurrently. While the study was in progress, the USEPA was in the process of designating SF-DODS, which was referred to as the Deep Off-Shelf reference site at that time. Therefore, the John F. Baldwin Ship Channel sediment data was compared to that reference data. Comparisons included biological responses of aquatic organisms to sediment exposure such as survival and contaminant bioaccumulation, as well as the sediment's physical, geological, and chemical characteristics.

All sediment samples were analyzed for conventional sediment measurements (grain size, total organic carbon, total volatile solids, percent solids, oil and grease, and total petroleum hydrocarbons), polycyclic aromatic hydrocarbons (PAHs), metals, and butyltins. Sediment composites and reference sediments for biological testing were also analyzed for chlorinated pesticides and polychlorinated biphenyls (PCBs). The bioaccumulation tissue samples were analyzed for PAHs, metals, and butyltins.

Water column tests showed there was no acute toxicity. The solid-phase tests of John F. Baldwin Ship Channel sediments showed no acute toxicity to *M. nasuta*, *N. caecoides*, or *R. abronius* relative to the Deep Off-Shelf reference site. However, sediment from Pinole Shoal Channel resulted in significant decrease in normal development of echinoderm larvae. The bioaccumulation testing results revealed that nine measured compounds for which action limits are established in tissues did not exceed Food and Drug Administration (FDA) action limits. However, significant bioaccumulation of the pesticide 4,4'-DDD was measured in organisms exposed to Pinole Shoal Channel sediment relative to the reference site. Four PAH compounds and tributyltin also significantly bioaccumulated in organisms exposed to Pinole Shoal Channel sediment relative to the reference site.

Based on the results of this study, proposed dredged material from John F. Baldwin Ship Channel met the deposited sediment toxicity (benthic bioassay) criteria for ocean placement, but some water column and bioaccumulation effects were observed.

Additional testing was conducted in 2000 on sediment to a depth of -47 feet MLLW from the West Richmond Channel and Pinole Shoal Channel to evaluate the suitability of dredged material for wetland beneficial reuse (Lee 2000). The test resulted in high levels of Chromium, however, the test results indicated that wetland creation using the tested sediment would create wetlands comparable to existing wetlands in the San Francisco Bay Area. Wetland plants and animals would contain contaminant levels similar to those of existing wetlands. Restrictions on the use of the tested sediment for wetland creation was not required at the time.

More recent material was tested from dredging the Pinole Shoal and Bulls Head Reach channels in 2009. The 2009 sampling at Suisun (Suisun Bay Channel New Your Slough SAR 2009 Jul.pdf) included some overdepth sampling at Bulls Head Shoal (-37 to -39 feet). The samples were not analyzed for total solids content of metals, instead they were tested for elutriate concentrations which are reported in ug/L instead of mg/Kg (dissolved metals in solution) for comparison with drinking water standards, leaching standards and RWQCB standards to determine suitability for in water placement and upland placement instead of wetland placement.

Based on the 2009 sampling results, it appears the material would be acceptable for in water placement and upland placement. There were no other non-maintenance event sampling reports available in USACE records. The 1990 samples in Suisun Bay showed chromium concentrations that exceed 250 mg/Kg, however, based other nearby sediment samples, dredge material from -38 to -40 feet may be suitable for wetland cover, while depths below that may exceed criteria for wetland cover but could possibly meet the criteria for use as foundation material in the wetland placement sites. The Bulls Head Reach sediment trap will be dredged deeper and this material may have higher concentrations of chromium. The sediment trap portion of new work material amounts to approximately 100,000 cubic yards. Testing of new work material will be done during the PED phase to determine its suitability for marsh placement (foundation or cover material) or alternative non-marsh placement.

The 2009 sediment testing data for Pinole Shoal from initial dredging for sample testing of -37 to -39 feet resulted in Chromium concentrations range from 51 to 61 mg/kg. The threshold criteria for wetland placement at surface is 112 mg/kg. Therefore, the material would be suitable for cover or wetland placement at the beneficial reuse sites. Confirmatory testing will be completed prior to placement at the reuse sites.

### 2.2.3 WATER QUALITY AND HYDROLOGY

The study area encompasses the waters of Central San Francisco Bay, San Pablo Bay, and Suisun Bay, and the lower Sacramento/San Joaquin Delta. **Figure 2-1** shows a map of the lower Sacramento and San Joaquin River basins which contribute freshwater flows that pass through Suisun Bay into San Francisco Bay.

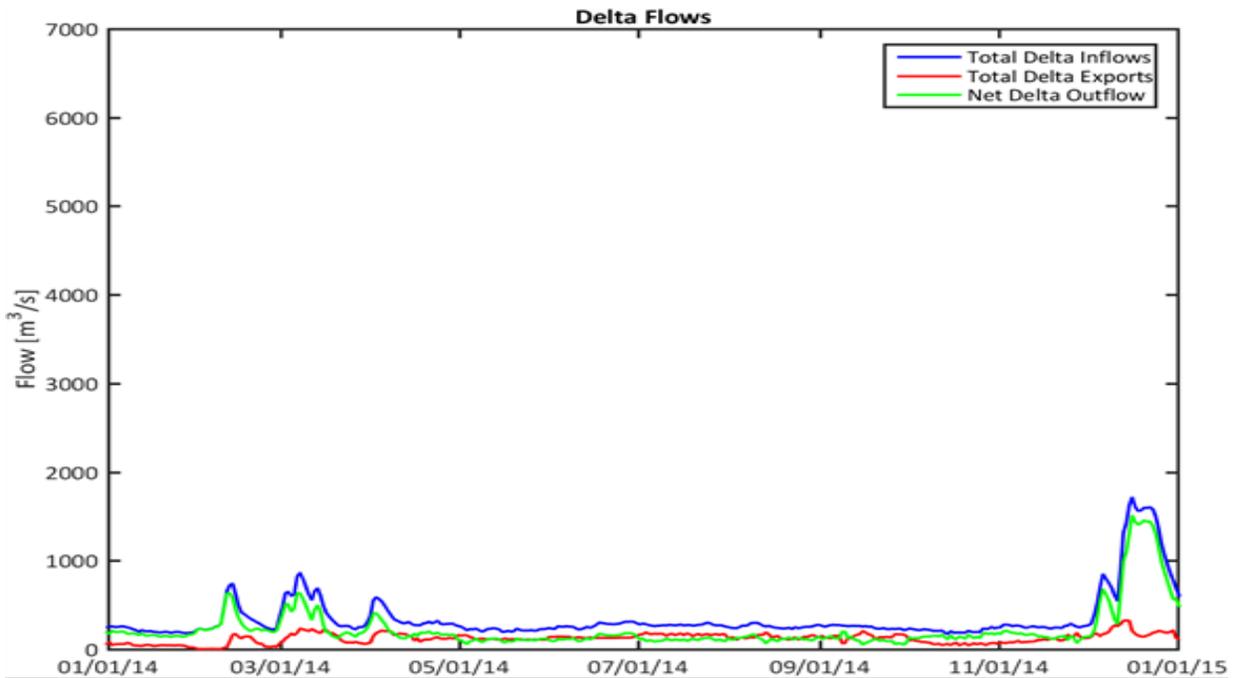

**Figure 2-1. Map of Sacramento and San Joaquin River Basins upstream of Suisun Bay (USGS, 2015). <https://ca.water.usgs.gov/projects/2015-17.html>**

Most of the precipitation in the study area falls as rain during winter and spring, which enters the Sacramento/San Joaquin Delta through surface water runoff and riverine flow. Precipitation varies significantly from year to year. Water years (WYs) are used to designate the differences in precipitation between years. Water years in California span the 12-month period between October 1 and September 30 (e.g., WY2014 spans from October 1, 2013 to September 30, 2014). This designation allows for all precipitation over the “wet season” (typically December through March) to be included in a single year. Water years are classified into five categories (e.g., critical (driest), dry, below normal, above normal, and wet (wettest)) based on inflows to the Delta. These are used to calculate Sacramento and San Joaquin

Valley Water Year Hydrologic Classification Indices. The frequency of each WY type based on the Sacramento Valley Water Year Hydrologic Classification for the 109-year period of record between WY1906 and WY2014 is as follows:

- Critical (Driest) WY 13.8 percent occurrence over 109-year record
- Dry WY 21.1 percent occurrence over 109-year record
- Below Normal WY 18.3 percent occurrence over 109-year record
- Above Normal WY 13.8 percent occurrence over 109-year record
- Wet (Wettest) WY 33.0 percent occurrence over 109-year record

Delta inflows, exports and outflows can vary significantly between critical and wet water years. WY2014 was designated as a critical water year (California Department of Water Resources 2016) [CDWR], the driest classification category. Baseline conditions during and following a critical year were established for the 1-year period spanning January 1, 2014, through December 31, 2014. This period spans winter and spring period during a critical WY, followed by the fall period between October 1 and December 31 of the subsequent WY. **Figure 2-3** shows the total delta exports (blue) and inflows (red), and the net delta outflow (green) during 2014. During this entire period, both Delta inflow and Delta outflow was extremely low.

**Figure 2-2. Total Delta Inflow, Exports, and Outflow for Year 0 Simulation Period Based on 2014 (Critical Year) Historic Conditions.**

WY2012 was designated as a below normal year (CDWR 2016). The conditions during and following the below normal WY for the 1-year period spanning from January 1, 2012, through December 31, 2012, show that during this period monthly flows were below average for most of the water year. **Figure 2-3** shows the total delta exports (blue) and inflows (red), and the net delta outflow (green) during 2012.

In contrast, WY2011 was designated as a wet WY (CDWR 2016), the wettest classification category. The conditions during and following a wet WY for the 1-year period spanning from January 1, 2011, through December 31, 2011, show that during this entire period, both Delta inflow and Delta outflow were significantly higher throughout the wet WY (Figure 2-4) than during the below normal WY (Figure 2-3) and critical WY (Figure 2-2).

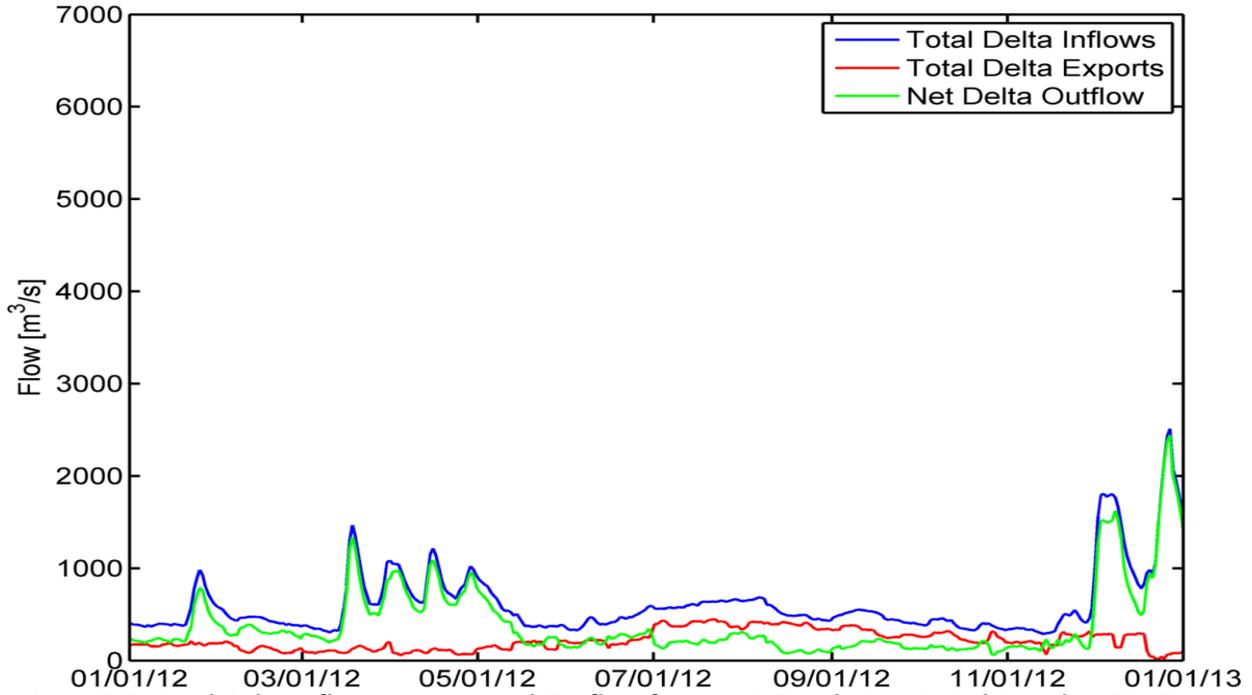

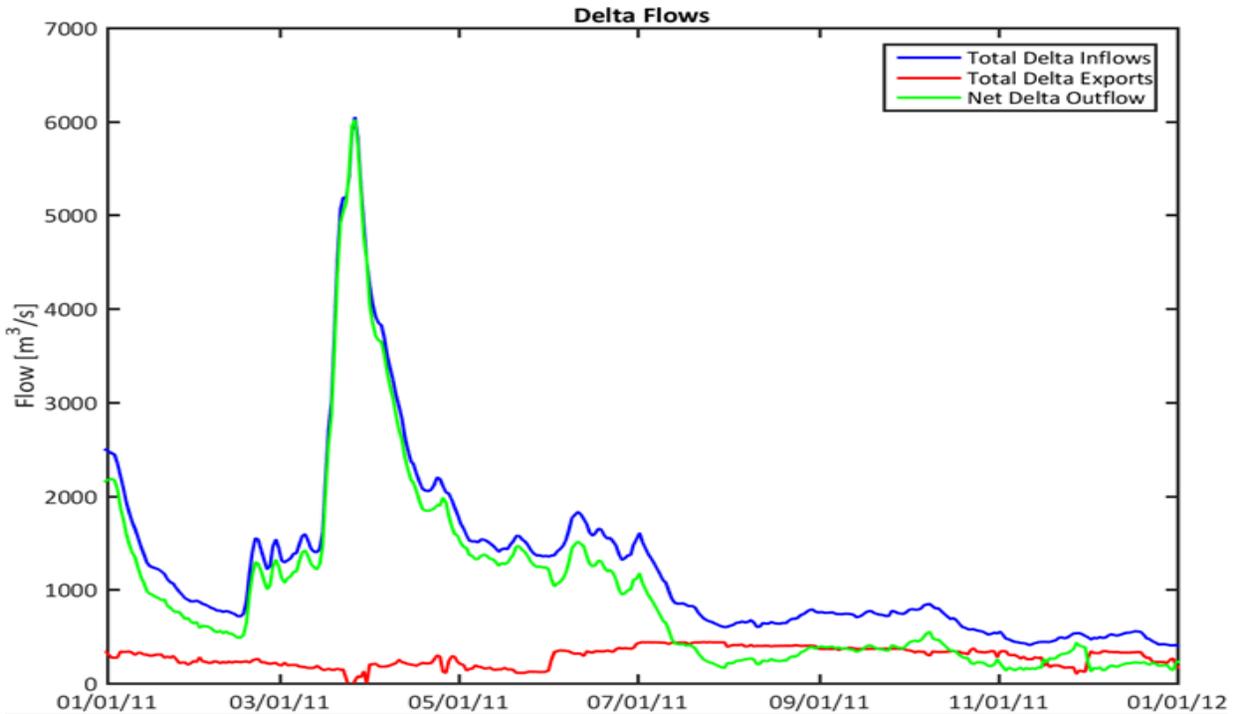

Figure 2-3. Total Delta Inflow, Exports, and Outflow for Year 0 Simulation Period Based on 2012 (Below Normal Year) Historic Conditions.

**Figure 2-4. Total Delta Inflow, Exports, and Outflow for Year 0 Simulation Period Based on 2011 Historic Conditions Classified as a Wet (Wettest) Water Year.**

Table 2-1, Table 2-2, and Table 2-3 provide the total monthly Delta inflow, exports and outflow for 2014, 2012, and 2011 periods evaluated in this analysis (CDWR 2019). For the critical year (2014) simulation period the total inflow, exports and outflow was 9,086 kac-ft/yr, 2,062 kac-ft/yr, 6,045 kac-ft, respectively. For the below normal year (2012) simulation period, the total inflow, exports and outflow was 15,673 kac-ft/yr, 4,652 kac-ft/yr, 10,131 kac-ft/yr, respectively. For the wet year (2011) simulation period, the total inflow, exports and outflow was 32,379 kac-ft/yr, 6,546 kac-ft/yr, 24,774 kac-ft/yr, respectively.

**Table 2-1. Monthly Total Delta Inflows, Exports, and Outflow during 2014.**

Month	Monthly Total Inflow [Acre-Feet]	Monthly Total Exports [Acre-Feet]	Monthly Total Outflow [Acre-Feet]
January 2014	463,639	99,192	293,939
February 2014	679,002	147,251	614,295
March 2014	999,902	269,545	782,311
April 2014	724,473	236,038	470,840

### 2.2.3.1 REGIONAL HYDRODYNAMICS

The San Francisco Estuary is bathymetrically and hydrodynamically complex. Freshwater, sediment, nutrients, and pollutants are carried to the estuary by river flow. The largest sources of freshwater to the estuary are the Sacramento and the San Joaquin Rivers. Historically, the Delta was characterized by tidal wetlands and interweaving water channels. However, this original wetland landscape was diked, drained, and converted into islands surrounded by levees.

The mixing of this freshwater with the salt water from the Pacific Ocean results in an estuary-wide horizontal salinity gradient, with salinity varying from full marine conditions (more than 30 practical salinity units [psu]) near the Golden Gate Bridge to freshwater conditions (less than 0.1 psu) in the Sacramento River (The Bay Institute 1998; CALFED 2000a). However, there is a net westward water flow from the Delta through the San Francisco Bay resulting from the net freshwater outflow from the Delta. Inflows into the Delta are controlled by upstream dams and reservoirs, which restrain peak flows in the winter and spring for flood control and storage, and release water in the summer and fall to meet agricultural and municipal demands—both for exports to interaction of the semidiurnal tides with a complicated bathymetry (Cheng and Gartner 1984). During flood tides, the water flows into the San Francisco Bay and the Delta, and the water level increases and higher salinity travels upstream. During ebb tides, the river water flows out of the Delta and freshwater pushes saline water into the Bay.

As the precipitation-induced channel inflows increase in the winter months, flows in some Delta channels can become one-directional (i.e., downstream). During this period, the tidal influence is minimal and overshadowed by precipitation-induced channel inflows. During the summer months, the flow patterns more closely correspond with the flood/ebb tidal cycles because net inflows to the Delta and San Francisco Bay tend to be lower during the summer months.

Delta water users including the U.S. Bureau of Reclamation’s Central Valley Project, the CDWRs’ State Water Project, as well as other agricultural and municipal water users have adapted their water supply systems to the daily, seasonal, and inter-annual variations that occur in delta water availability. Designated beneficial reuses of water for this area are presented in **Table 2-4**.

**Table 2-4. Study Area Beneficial Reuses Designation.**

Water body	Designated Beneficial Reuse														
	AGR	MUN	IND	PROC	COMM	SHELL	FRESH	EST	MIGR	RARE	SPWN	WILD	REC-1	REC-2	NAV
Bulls Head Reach			E		E	E		E	E	E	E	E	E	E	E
West Richmond Channel			E	E	E	E		E	E	E	E	E	E	E	E
Pinole Shoal Channel			E	E	E			E	E	E	E	E	E	E	E

- Notes: AGR - Agricultural Supply
- COMM - Commercial and Sport Fishing
- E - Existing Beneficial Reuse
- EST - Estuarine Habitat
- FRESH - Freshwater Habitat
- IND - Industrial Service Supply
- MIGR - Fish Migration
- MUN - Municipal and Domestic Supply
- NAV - Navigation

- RARE - Preservation of Rare and Endangered Species
- REC1 - Water Contact Recreation
- REC2 - Noncontact Water Recreation
- SHELL - Shellfish Harvesting
- SPWN - Fish Spawning
- WILD - Wildlife Habitat

**2.2.3.2 TIDAL HYDRAULICS**

Astronomical tides in the study area are characterized as having a mixed semidiurnal tidal cycle, which means that the area experiences two high tides and two low tides of unequal height each lunar day. **Table 2-5** presents the mean and diurnal ranges at NOAA tidal gauge locations within the study area. The San Francisco, Richmond, and Martinez-Amorco Pier NOAA stations are located within the study area, while the Port Chicago station is outside of the study area (east). Tidal range increases from the San Francisco NOAA station into Central and South San Francisco Bays, and decreases moving west through San Pablo and Suisun Bays.

**Table 2-5. Tidal Ranges at NOAA Stations within the Study Area.**

NOAA Station Location	NOAA Station Identification No.	Mean Tidal Range (feet)	Diurnal Range (feet)
San Francisco	9414290	4.09	5.84
Richmond	9414863	4.32	6.06
Martinez-Amorco Pier	9415012	3.93	5.31

### 2.2.3.3 SALINITY AND WATER SUPPLY

Salinity is a long-standing management concern in the Delta, since increased salt concentrations can adversely affect municipal, agricultural, and industrial water supplies, as well as aquatic habitat conditions. Salinity levels are influenced by tidal cycles, freshwater inflow, water intakes and exports, and agricultural diversions and return flows in the Delta. “Exports” divert water for use outside the legal boundary of the Delta. The two primary Delta exporters are the State Water Project and the Central Valley Project, which are located in the south Delta (see **Figure 2-5**). Delta water “intakes” divert water for use within the legal boundary of the Delta. Intakes in the study area include in-Delta diversions for agricultural use and Contra Costa Water District (CCWD) intakes at Rock Slough, Old River, and Middle River at Victoria Canal (see **Figure 2-5**). Consideration of salinity levels is critical for supporting municipal, agricultural, and industrial uses, as well as maintaining habitable conditions for fish and wildlife.

The abundance or survival of several estuarine biological populations in the San Francisco Estuary have historically been positively correlated with freshwater flow, as indexed by the position of the **daily-averaged 2 psu isohaline near the bed**, (i.e., bottom) or **X2** (Jassby et al. 1995; Kimmerer et al. 2009; Kimmerer et al. 2013) as measured in kilometers from the Golden Gate Bridge as shown in **Figure 2-6**. In 1995, the State Water Resources Control Board (SWRCB) adopted X2 as a water quality standard to help restore the relationship between springtime precipitation and the geographic location and extent of estuarine habitat.

Water Rights Decision 1641 D-1641 (SWRCB 2000) requires that freshwater inflows to the Bay be sufficient to maintain X2 at specific locations for specific numbers of days each month during the spring (February through June). The objective of this “Spring X2” requirement is to help restore the relationship between springtime precipitation and the geographic location and extent of estuarine habitat. The Spring X2 requirement at Port Chicago (SWRCB 2000) applies only in months when the average electrical conductivity (EC) at Port Chicago (X2 = 64 km) during the 14 days just before the first day of the month is less than or equal to an EC measurement of 2.64 millimhos per centimeter (mmhos/cm). However, when X2 is less than 64, there are no current regulatory requirements that regulate the position of X2.

The Biological Opinion for delta smelt (*Hypomesus transpacificus*) calls for efforts to increase outflow to enlarge the area of habitat with suitable salinity (i.e., the low salinity zone) for this fish and has established X2 requirements during fall months following wet or above normal water years (USFWS 2008).

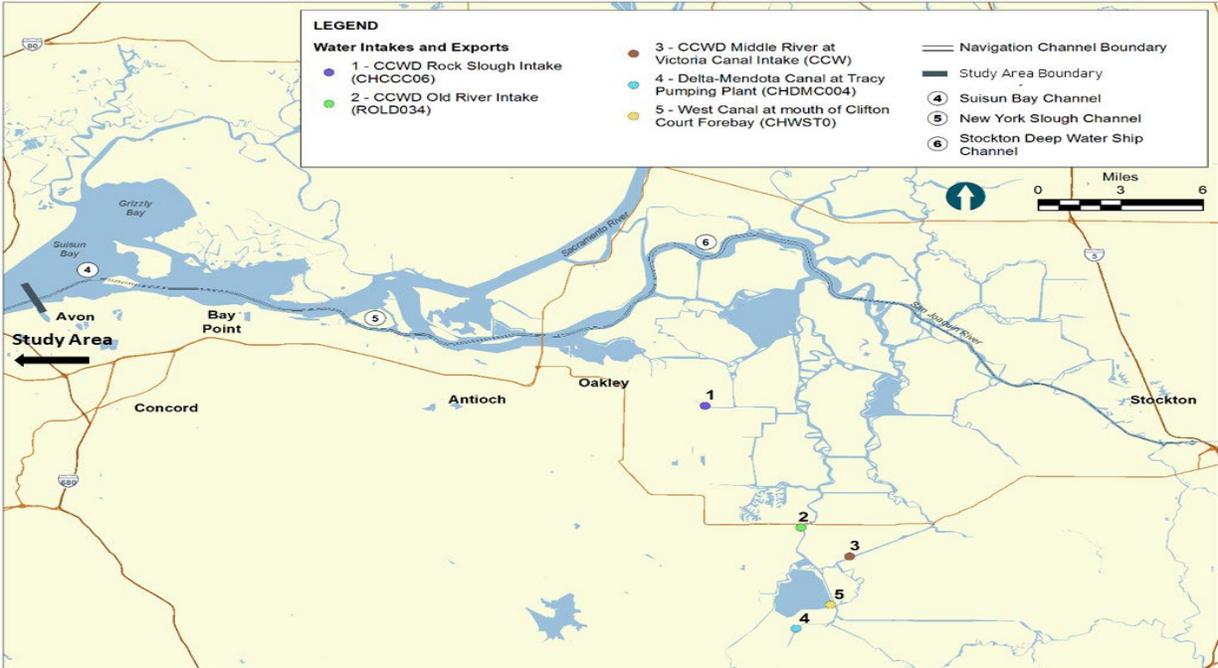

Figure 2-5. Locations of Water Intakes and Water Exports in the Delta.

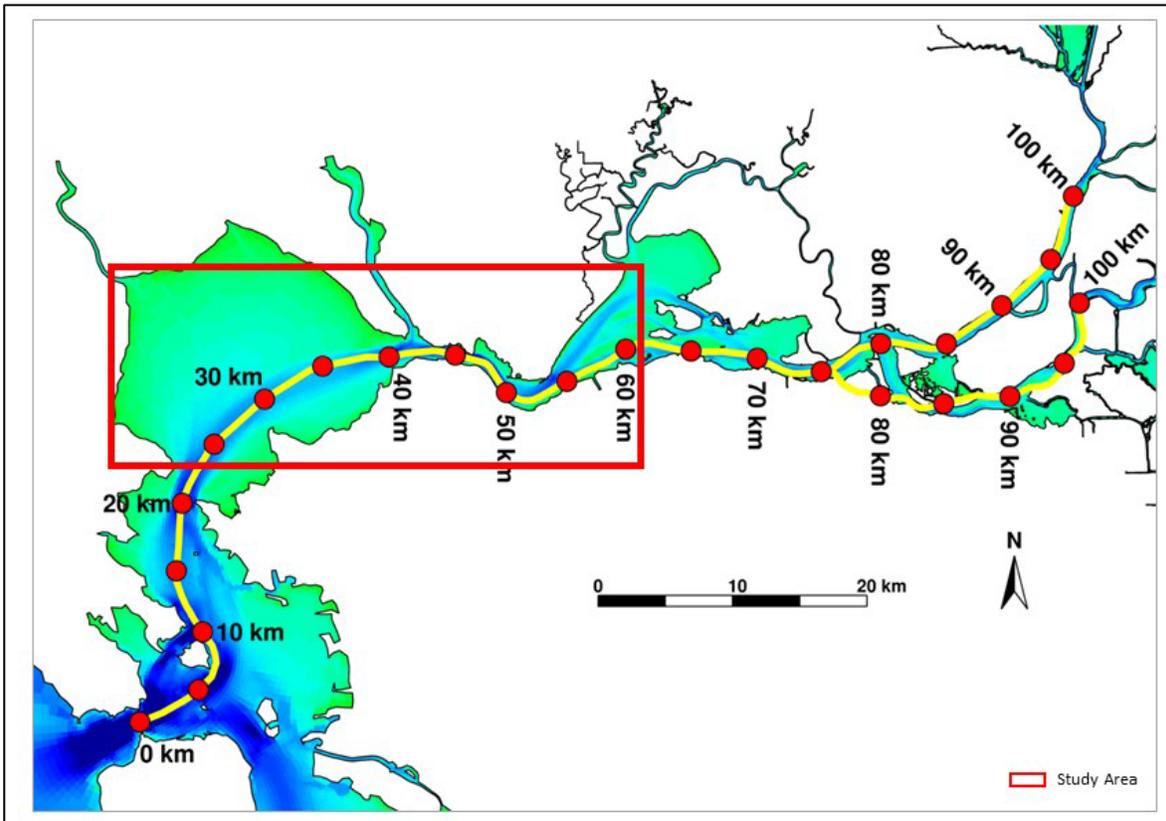

Figure 2-6. Transects Along Axis of Northern San Francisco Bay Used to Measure X2.

To meet the spring and fall X2 requirements, real-time operational changes are made to either increase the upper basin reservoir discharges or decrease Delta exports at the CVP and SWP pump stations or change both to increase the net delta outflow and push the 2 PSU isohaline downstream. While changing pumping rates and reservoir releases can be made with relative precision, the same cannot be said for the measurement of X2 or net Delta outflow. Delta outflow and X2 are utilized when assessing export pumping operations. The estimate for Delta outflow is prepared using a mass balance approach to sum all of the estimated inflows and outflows to compute a Net Delta Outflow Index (NDOI). Several of these flows such as net precipitation and agricultural consumptive use are inherently difficult to measure. The measurement errors from each of the components of the NDOI are additive and under low Delta outflow conditions can be substantial. Measurement of net Delta outflow using Doppler instrumentation is also imprecise, since filtering out tidal exchange volumes (which can be an order of magnitude greater than net outflow) requires accuracy that is beyond the ability of the current technology (particularly when net Delta outflow is below 10,000 cfs).

The measurement of X2 is similarly imprecise. For instance, while X2 is defined as the 2 PSU bottom salinity isohaline location, it is estimated using near surface salinity/electro conductivity measurements collected at four stations spaced approximately 10 kilometers apart. Since bottom salinity differs from surface salinity, an adjustment is applied to transform the interpolated average surface salinity 2 PSU location to the bottom 2 PSU isohaline location. Though the standard X2 estimate uses a single value for the surface to bottom salinity gradient adjustment, there have been several adjustment factors developed since X2 was originally conceived (Hericks et al, 2017). Mathematical estimation of the daily X2 location can also be done using autoregressive equations that consider the prior X2 location and current Delta outflow. The error in X2 location as estimated using autoregressive equations varies between 3.1 and 9.2 kilometer (Hericks et al 2017, MacWilliams et al, 2015).

The inability to accurately estimate X2 and net Delta outflow (NDOI) likely results in operational changes that at times results in either the targeted environmental conditions not being achieved because X2 is under estimated or the targeted environmental conditions are exceeded at the expense of thousands of acre-feet of project water released perhaps unnecessarily due to X2 being over-predicted (Hericks et al, 2017). Given the imprecision in measuring X2 and net Delta inflow, small changes to X2 positioning are generally not considered to be significant.

Impacts to X2 directly affect fish and wildlife through changes to the salinity distribution, and therefore, available low salinity zone habitat. Impacts also potentially affect water supply reliability during periods of the year when the position of X2 is managed by regulating (i.e., increasing) Delta outflow to push the X2 farther west. Within the study area/channel deepening, salinity varies significantly both geographically and seasonally. At the western end of the project area near the West Richmond Channel, salinity is typically around 30 psu, except during periods of very high Delta outflow. At the eastern end of the project area near Avon, salinity levels can be less than 1 psu during very high Delta outflows, but are generally more than 10 psu during periods of lower Delta outflow. Salinity gradients are also pushed seasonally westward into San Pablo Bay during typical periods of high Delta outflow in the winter and spring. In turn, salinity levels in Suisun Bay and the western Delta gradually increase in the summer and fall during periods of generally low Delta outflow. During critical WYs (**Figure 2-3**), Delta outflows can remain low throughout the year, leading to higher salinity in Suisun Bay and the western Delta than during wet WYs (**Figure 2-4**), when higher outflows through the winter and spring months push salinity gradients westward.

The D-1641 water quality objectives for municipal and industrial beneficial reuse stipulates a maximum allowable concentration of 250 milligrams per liter (mg/L) chloride at the municipal water intakes. It also stipulates a 150 mg/L chloride standard at either the intake to the Contra Costa Canal at Pumping Plant No. 1 or the City of Antioch's intake on the San Joaquin River. The 150 mg/L standard must be met for 155 to 240 days per year, depending on the type of WY. High bromide concentrations in raw water diverted from the Delta can also cause high concentrations of disinfection byproducts when water is treated for drinking water purposes. The disinfection byproducts are suspected carcinogens and are regulated by the USEPA. CCWD water plants include several treatment processes to minimize bromide/bromate and disinfection byproducts including coagulation, filtration, granulated activated carbon, chloramination, and ozone. The CCWD has a source water quality goal of 0.050 mg/L bromide concentrations. For the 1992 to 2004 period, the monthly average bromide concentration at the CCWD Rock Slough intake ranges between 0.10 mg/L in April to 0.44 mg/L in December (2010 USBR). In practice, the bromide goal is not typically met since 0.050 mg/L bromide equates to a concentration of 20 mg/L chloride which is well below the average chloride inflow concentration at any of the CCWD intake pump stations.

#### 2.2.3.4 MERCURY AND METHYLMERCURY

Mercury and methylmercury contamination is another long-standing management concern in San Francisco Bay and the Delta. Methylmercury is an organometallic bioaccumulative environmental toxicant produced naturally by bacterial action on inorganic mercury (i.e., methylation). Once formed, methylmercury can also be converted back to inorganic mercury through demethylation.

The microbial mediated processes of methylation and demethylation are complex and often occur simultaneously (LTMS 2010). While the processes are not completely understood, methylmercury production appears to occur primarily in the absence or near-absence of oxygen. Therefore, methylation rates and the total abundance of methylmercury tend to be highest in shallow natural aquatic systems with fine, organic-rich sediments (such as wetlands). Methylmercury can be toxic to humans, fish, and wildlife and is of particular concern because it bioaccumulates and biomagnifies (i.e., becomes present in successively increasing quantities higher up in the food chain) and can cause sub-lethal effects.

The Central Valley RWQCB issued an amendment to the Central Valley Basin Plan that established a total maximum daily load (TMDL) for methylmercury, effective October 2011 (CVRWQCB 2011). The TMDL also requires that dredging activities and dredged material reuse projects in the Delta minimize increases in methylmercury and total mercury discharges to Delta waterways. The potential for methylmercury formation within wetland or upland dredged material placement sites has generated recent attention. Methylmercury can accumulate in wildlife directly from contact with water in the placement sites, or indirectly, after water from the dredged slurry is released back into the receiving water.

The San Francisco Bay RWQCB established a mercury TMDL in 2008 to protect both people who consume Bay fish and aquatic organisms and wildlife. The TMDL calls for Waste Discharge Requirements for dredging and placement operations and requires conducting studies to better understand how their operations affect mercury fate, transport, and biological uptake (USEPA 2015a).

Various studies conducted in the San Francisco Bay and Delta area have examined not only the relationship between mercury, methylmercury, and bioaccumulation, but also potential management practices for minimizing methylmercury generation in the placement sites. These studies suggest methylmercury production, transport, and bioaccumulation can vary widely across a range of spatial and

temporal scales but it appears to be related to the availability (speciation) of inorganic mercury, organic matter, microbial activity (particularly sulfate-reducing and iron-reducing bacteria), and oxidation-reduction (redox) conditions in water and sediment, light level, and hydroperiod. A 2010 symposium on dredging operations and methylmercury convened by the San Francisco Bay LTMS summarized previous and ongoing pertinent research (LTMS 2010). The interim conclusion from the symposium was that although understanding of the relationship between specific environmental factors and mercury methylation is increasing, the current state of the science was not sufficiently advanced to promulgate best management practices (BMPs) for minimizing methylation.

USACE has undertaken studies in the Delta aimed at: (1) understanding the potential for placement sites to act as sources of methylmercury; and (2) identifying BMPs for mitigating methylmercury discharges. The results of these studies indicate that water column concentrations of methylmercury at dredged material placement sites generally increased and appeared to correlate with increases in water column total organic carbon. However, baseline data on both potential receiving water and natural occurrences (e.g., rainfall events) were not collected during this initial effort (Applied Marine Sciences 2010).

As part of its commitment to minimize dredging effects, the Corps has undertaken studies of methylmercury mobilization associated with its dredge material disposal practices. In 2011 and 2014, the Corps conducted sampling of inflow and outflow water at its Roberts Dredge Management Placement Site (USACE 2015) on the Sacramento River Deep Water Ship Channel (DWSC). The results indicated that total mercury concentrations were below the General Order permit standard but that the methylmercury concentration in the effluent was above the 0.06 ng/L Delta TMDL criteria.

McCord and Heim (2015) investigated management practices that would minimize methylmercury production in agricultural fields and wetlands. Their study identified several hydrologic management practices for managed wetlands that would reduce methylmercury concentrations within these systems but did not identify any management practices for unmanaged tidal marshes. The USGS (Valoppi, L, 2018) completed Phase I mercury studies at the South Bay Salt Pond Restoration project in 2015. They investigated the impact of hydrologic manipulation on methylmercury release from a coastal marsh. They found that methylmercury concentrations spiked in marsh discharges that occurred subsequent to opening tidal gates that had been shut for several months. One potential solution that the USGS researchers discussed was potentially limiting periods of no tidal interaction to minimize the potential for increased methylmercury concentrations within tidal marshes. A phase II study was proposed for the South Bay Salt Ponds to further evaluate further methylmercury management measures in tidally influenced wetlands.

#### 2.2.3.5 CHEMICAL POLLUTANTS

The overarching chemical water pollutant issues in the study area result from depleted freshwater flows, municipal and industrial wastewater discharges, agricultural drainage, and runoff. The chemical water pollutant issues for the study area are a result of municipal and industrial wastewater discharges and stormwater runoff. In urban areas, stormwater drainage systems may contain heavy metals and chemicals generated from vehicles and yard chemicals from residential and commercial areas. Because of pollutant loading, the Central Valley and San Francisco Bay Regional Water Quality Control Boards (RWQCBs) have developed and continue to develop programs in an effort to control pollutants from their sources, which include municipal, domestic, industrial, and agricultural wastewater and stormwater.

In San Francisco Bay, the San Francisco Estuary Institute (SFEI) administers a Regional Monitoring Program (RMP) for the San Francisco Bay RWQCB and major dischargers. SFEI conducts monitoring to assess spatial patterns and long-term trends in contamination throughout San Francisco Bay. To assess water quality, metals and organic (e.g., pesticides and polychlorinated biphenyls [PCBs]) contaminants are measured in water samples collected during the dry season. In 2011, results of the RMP showed significant improvements in basic water quality conditions due to investments in wastewater treatment (SFEI 2011). In 2018, results of the RMP report noted among other items that recent monitoring results were used to reclassify Polybromated diphenyl esters (PBDEs) from “moderate concern” to “low concern”. The recent RMP report also indicated that dioxin continues to be a source of use impairment and that storm event sampling showed that the Guadalupe River was a significant source of mercury load to the bay especially from larger storm events (SFEI 2018).

#### 2.2.3.6 NUTRIENTS

When discussing water quality, the term “nutrients” typically refers to nitrogen and phosphorus. Farmers apply fertilizer nutrients in the form of nitrogen, phosphorus, and potassium to prevent these elements from becoming limiting in the soil, and these nutrients eventually enter Delta waters as runoff. In addition, these elements become concentrated in wastewater discharges and can promote aquatic plant and algal growth to an excessive extent. Nitrogen in water can be used by aquatic plants in its inorganic form, either as nitrates or nitrites (combination of nitrogen and oxygen) or as ammonia (a combination of nitrogen and hydrogen). High levels of ammonia are believed to stimulate the growth of phytoplankton and be a threat to aquatic species. The sources of high ammonia contributions are likely wastewater treatment plants and, to a lesser extent, agricultural runoff from the use of nitrogenous fertilizers (CALFED 2009).

Excessive aquatic plant nutrients in the form of nitrogen and phosphorus compounds are causing and/or contributing to water quality issues in the Delta. These issues include:

- Excessive growth of algae causes severe taste and odor problems for domestic water utilities that use Delta water as a raw water source. This requires additional expenditures for water treatment. Harmful algal blooms may be caused by a combination of high nutrient concentrations and warm temperatures. Harmful algae compete with and may exclude diatoms and dinoflagellates, thus reducing primary production. Harmful algal blooms can produce powerful toxins that kill fish, shellfish, mammals, and birds, and may directly or indirectly cause illness in people. *Microcystis aeruginosa* (a common species of cyanobacteria) is an invasive alga that is common in the Delta during warmer months and may contribute to a reduction in copepod productivity (Lehman and Waller 2003).
- Excessive growths of water hyacinth (*Eichhornia crassipes*) and Brazilian elodea (*Egeria densa*), two highly invasive aquatic species, cause ecological impacts, impair recreational use of the Delta, and require herbicides to control, thus adding to water quality concerns. Further, after dying by herbicides, the decomposition of the dead plant materials can cause local declines in dissolved oxygen (DO) levels.
- Nutrient-rich waters may lead to increases in algal growth, which can also reduce DO levels through respiration and subsequent decomposition of the algal mats.
- San Francisco Bay has long been recognized as a nutrient-enriched estuary. However, DO concentrations in San Francisco Bay are much higher and phytoplankton biomass and productivity are substantially lower than would be expected from high nutrient enrichment. Studies suggests that phytoplankton growth and accumulation are largely controlled by a combination of factors,

such as strong tidal mixing, light limitation due to high turbidity, and grazing pressure by clams (Cloern and Jassaby 2012).

#### 2.2.3.7 CLEAN WATER ACT (CWA) 303(D) LISTED IMPAIRED WATERS

Section 303(d) of the CWA requires the identification of water bodies that do not meet, or are not expected to meet, water quality standards (i.e., impaired water bodies). The affected water body, and associated pollutant or stressor, is then prioritized in the 303(d) List. The CWA further requires the development of a TMDL for each listing.

The study area channels are located within portions of San Francisco Bay that are listed as impaired for pesticides (e.g., chlordane, dichloro-diphenyl-trichloroethane (DDT), dieldrin, dioxin and furan compounds), mercury, invasive species, PCBs, selenium, and trash. In greater San Francisco Bay, Suisun Bay and San Pablo Bay are listed for these same parameters, except for trash (SFBRWQCB 2010). In the Delta, the California Department of Water Resources (CDWR) and the Interagency Ecological Program operate several water quality monitoring sites. Based on data collected at these monitoring sites, SWRCB and CVRWQCB have found Delta waters to contain sufficient concentrations of various pollutants that are in violation of water quality standards. As such, the standard of water quality for beneficial reuses identified within the Delta is not being met. The Delta is listed as impaired for insecticides (i.e., diazinon, chlorpyrifos), pesticides, mercury, invasive species, PCBs, and selenium.

Dredging and dredged material placement can release sediment-associated metals and other pollutants by dispersion within the resulting sediment plume (Eggleton and Thomas 2004; Levine Fricke 2004) [LFR]. A number of studies have examined the release of contaminants into the water column (Bloom and Lasora 1999; Pieters et al. 2002; Vale et al. 1998), but general conclusions are difficult to draw because of the complex and specific nature of the physiochemical processes in each case. While the processes and mechanisms are well known, the exact results are dependent on numerous conditions that regulate them. Research to date has investigated the effect of dredging-induced sediment resuspension on many potentially toxic metals. However, despite the many comprehensive studies, there is very little consensus on the release of metals and their effects. Organic contaminants such as pesticides, PCBs, and PAHs (polycyclic aromatic hydrocarbons) are generally not very soluble in water and direct toxicity by exposure to dissolved concentrations in the water column is not very likely. Thus, the resulting short-term water quality impacts due to metal and organic contaminant releases from dredging activities do not appear to be a major issue.

Upstream of the study area, low DO is a concern in the interior Delta particularly upstream of Jersey Island. The causes of low DO include discharge of treated effluent loading from the City of Stockton, agricultural runoff, and reduced flushing of dead-end channels.

#### 2.2.3.8 GROUNDWATER

Most groundwater wells used for potable water in the study area are hundreds of feet deep, due to the thickness of the overburden above the deep aquifer (Wu 2010).

#### 2.2.4 AIR QUALITY

Air quality is affected by the rate, amount, and location of pollutant emissions and the meteorological conditions that influence pollutant movement and dispersal. Atmospheric conditions, including wind speed, wind direction, and air temperature, in combination with local surface topography (i.e., geographic

features such as mountains, valleys, and large water bodies), determine the effect of air pollutant emissions on local air quality.

**2.2.4.1 CRITERIA AIR POLLUTANTS**

As required by the Federal Clean Air Act (CAA) passed in 1970, the U.S. Environmental Protection Agency (USEPA) has identified six criteria air pollutants that are pervasive in urban areas and for which state and national health-based ambient air quality standards have been established. The USEPA calls these pollutants “criteria air pollutants” because they are regulated by developing specific public health- and welfare-based criteria as the basis for setting permissible levels. Ozone, carbon monoxide (CO), nitrogen dioxide (NO<sub>2</sub>), sulfur dioxide (SO<sub>2</sub>), particulate matter (PM), and lead are the six criteria air pollutants regulated by the USEPA. PM is measured in two size ranges: PM10 for particles less than 10 microns in diameter, and PM2.5 for particles less than 2.5 microns in diameter.

**Table 2-6** lists the criteria pollutants and their major health effects.

**2.2.4.2 TOXIC AIR CONTAMINANTS**

Toxic air contaminants (TACs) are air pollutants that may lead to serious illness or increased mortality, even when present in relatively low concentrations. Potential human health effects of TACs include birth defects, neurological damage, cancer, and death. There are hundreds of different types of TACs with varying degrees of toxicity. Individual TACs vary greatly in the health risk they present. At a given level of exposure, one TAC may pose a hazard that is many times greater than another.

**Table 2-6. Criteria Pollutants and Health Effects.**

Pollutant	Description	Health Effect
Ozone	Ozone is a secondary air pollutant produced in the atmosphere through a complex series of photochemical reactions involving reactive organic gases (ROG, also sometimes referred to as volatile organic compounds or VOC by some regulating agencies) and nitrogen oxides (NO <sub>x</sub> ). The main sources of ROG and NO <sub>x</sub> , often referred to as ozone precursors, are combustion processes (including motor vehicle engines) and the evaporation of solvents, paints and fuels. Ozone is referred to as a regional air pollutant because its precursors are transported and diffused by wind concurrently with ozone production through the photochemical reaction process.	Ozone causes eye irritation, airway constriction, and shortness of breath, and can aggravate existing respiratory diseases such as asthma, bronchitis, and emphysema.
Carbon Monoxide	CO is an odorless, colorless gas usually formed as the result of the incomplete combustion of fuels. The single largest source of CO is motor vehicles; the highest emissions occur during low travel speeds, stop-and-go driving, cold starts, and hard acceleration. CO concentrations have declined dramatically in California due to existing controls and	Exposure to high concentrations of CO reduces the oxygen-carrying capacity of the blood and can cause headaches, nausea, dizziness, and fatigue, impair central nervous system function, and induce angina (chest pain) in persons with serious heart disease. Very high levels of CO can be fatal.

Pollutant	Description	Health Effect
	programs and most areas of the state, including the study area, have no problem meeting the state and Federal CO standards.	
Particulate Matter (PM10 and PM2.5)	PM10 and PM2.5 are also termed respirable particulate matter and fine particulate matter, respectively, and are a class of air pollutants that consists of heterogeneous solid and liquid airborne particles from manmade and natural sources.	These particulates are small enough to be inhaled into the deepest parts of the human lung and can cause adverse health effects. Among the criteria pollutants that are regulated, particulates represent a serious ongoing health hazard.
Nitrogen Dioxide (NO <sub>2</sub> )	NO <sub>2</sub> is a reddish brown gas that is a byproduct of combustion processes. Automobiles and industrial operations are the main sources of NO <sub>2</sub> . NO <sub>2</sub> may be visible as a coloring component on high pollution days, especially in conjunction with high ozone levels.	Aside from its contribution to ozone formation, NO <sub>2</sub> can increase the risk of acute and chronic respiratory disease and reduce visibility.
Sulfur Dioxide (SO <sub>2</sub> )	SO <sub>2</sub> is a colorless acidic gas with a strong odor. It is produced by the combustion of sulfur-containing fuels such as oil, coal and diesel.	SO <sub>2</sub> has the potential to damage materials and can cause health effects at high concentrations. It can irritate lung tissue and increase the risk of acute and chronic respiratory disease (BAAQMD 2012).
Lead	Leaded gasoline (phased out in the U.S. beginning in 1973), lead based paint (on older houses and cars), smelters (metal refineries), and manufacturing of lead storage batteries have been the primary sources of lead released into the atmosphere.	Lead has a range of adverse neurotoxic health effects, of which children are at special risk. Some lead-containing chemicals cause cancer in animals. Lead levels in the air have decreased substantially since leaded gasoline was eliminated. Ambient lead concentrations are only monitored on an as-warranted, site-specific basis in California.

**2.2.4.3 ODORS**

Odors are generally regarded as an annoyance rather than a health hazard. Manifestations of a person’s reaction to odors can range from psychological (e.g., irritation, anger, or anxiety) to physiological (e.g., circulatory and respiratory effects, nausea, vomiting, and headache). The ability to detect odors varies considerably among the population and overall is quite subjective. People may have different reactions to the same odor. An odor that is offensive to one person may be perfectly acceptable to another. An unfamiliar odor is more easily detected and is more likely to cause complaints than a familiar one. Known as odor fatigue, a person can become desensitized to almost any odor and recognition only occurs with an alteration in the intensity. The occurrence and severity of odor impacts depends on the nature, frequency, and intensity of the source; wind speed and direction; and the sensitivity of receptors. Odor impacts should be considered for any proposed new odor sources located near existing receptors, as well

as any new sensitive receptors located near existing odor sources. Generally, increasing the distance between the receptor and the odor source will mitigate odor impacts.

#### 2.2.4.4 SENSITIVE RECEPTORS

Air quality does not affect every individual in the population in the same way, and some groups are more sensitive to adverse health effects than others. Population subgroups sensitive to the health effects of air pollutants include the elderly and the young, those with higher rates of respiratory disease such as asthma and chronic obstructive pulmonary disease, and those with other environmental or occupational health exposures (e.g., indoor air quality) that affect cardiovascular or respiratory diseases.

Land uses such as schools, children's day care centers, hospitals, and nursing and convalescent homes are considered to be more sensitive than the general public to poor air quality because the population groups associated with these uses have increased susceptibility to respiratory distress. Parks and playgrounds are considered moderately sensitive to poor air quality because persons engaged in strenuous work or exercise also have increased sensitivity to poor air quality. However, exposure times are generally far shorter in parks and playgrounds than in residential locations and schools. Residential areas are considered more sensitive to air quality conditions compared to commercial and industrial areas because people generally spend longer periods of time at their residences, with associated greater exposure to ambient air quality conditions.<sup>11</sup>

Sensitive receptors include children, adults, and seniors occupying or residing in residential dwellings, schools, colleges and universities, daycares, hospitals, and senior-care facilities. Workers are not considered sensitive receptors because all employers must follow regulations set forth by the Occupation Safety and Health Administration to ensure the health and well-being of their employees.

#### 2.2.4.5 REGIONAL SETTING

The geographic scope of the study area includes the waters within the North San Francisco Bay, San Pablo and Suisun Bays, covering the counties of Marin, Sonoma, Napa, Solano, Contra Costa, Alameda, and San Francisco. The majority of the project area is located within the boundaries of the San Francisco Bay Area Air Basin (SFBAAB), though portions extend into the Sacramento Valley Air Basin (SVAB).

#### 2.2.4.6 SAN FRANCISCO BAY AREA AIR BASIN

The SFBAAB encompasses a nine-county region, which includes all of Alameda, Contra Costa, Santa Clara, San Francisco, San Mateo, Marin and Napa counties, and the southern portions of Solano and Sonoma counties. The Bay Area Air Quality Management District (BAAQMD) has jurisdiction over air quality within the SFBAAB. The climate of the SFBAAB is determined largely by a high-pressure system that is almost always present over the eastern Pacific Ocean off the west coast of North America. During winter, the Pacific high-pressure system shifts southward, allowing more storms to pass through the region. During summer and early fall, when few storms pass through the region, emissions generated within the Bay Area can combine with abundant sunshine under the restraining influences of topography and subsidence inversions to create conditions that are conducive to the formation of photochemical pollutants such as ozone and secondary particulates such as nitrates and sulfates.

#### 2.2.4.7 SACRAMENTO VALLEY AIR BASIN

The SVAB encompasses an eleven-county region, which includes all of Butte, Colusa, Glenn, Sacramento, Shasta, Sutter, Tehama, Yolo, and Yuba counties, and portions of Placer and Solano counties. The Yolo-

Solano Air Quality Management District (YSAQMD) is responsible for Yolo County and the eastern portion of Solano County. Other counties within the SVAB are outside of the study area. The climate in the SVAB is Mediterranean. Prevailing winds originate offshore of San Francisco Bay and flow through the Carquinez Strait, then north through the Sacramento Valley. Elevations of the broad valley floor range from 60 to 500 feet above mean sea level. The valley is bordered to the north by the Sierra Cascade Mountains, to the east by the Sierra Nevada, and to the west by the Coast Ranges. The topography and climate of the air basin create a high potential for air inversions. Inversions occur frequently during all seasons. The most stable of these inversions occurs in the late summer and early fall, when cool coastal air is trapped beneath a warm air mass. Photochemical smog (i.e., ozone) trapped in these inversions is often exacerbated when preceded by sunny days with relatively high temperatures. During late fall and winter, air inversions occurring at ground level often result in low-lying fog when valley air becomes trapped and does not mix with coastal air. It is during these periods that the air basin experiences the highest concentrations of CO, NO<sub>x</sub>, and PM.

**2.2.4.8 EXISTING AIR QUALITY**

The BAAQMD, YSAQMD, and the ARB all monitor regional air quality through a network of monitoring stations, which record ambient concentrations of non-attainment criteria air pollutants. Probable future levels of air quality in the study area can generally be inferred from ambient air quality measurements conducted at the nearest monitoring stations by examining trends over time. The data gathered at these monitoring stations present the nearest available benchmark reference point as to what the pollutants of greatest concern are in the region and the degree to which the area is out of attainment with specific air quality standards.

The two closest monitoring stations to the study area in the SFBAAB are in Vallejo and San Pablo. **Table 2-7** shows a 3-year (2015 through 2017) summary of monitoring data for ozone, PM10, and PM2.5 recorded at these stations. These stations recorded no violations of ozone or PM10 standards but identified violations of state and Federal 24-hour PM2.5 standards.

Table 2-8 shows a 3-year (2015 through 2017) summary of monitoring data for ozone, PM10, and PM2.5 recorded at the Vacaville and Davis air monitoring stations, which are the stations closest to the study area within the SVAB. These stations recorded violations of the ozone Federal standards, but no violations of the state or Federal PM2.5 standards. Neither station monitors PM10 concentrations.

The YSAQMD currently meets the USEPA's health standards for five pollutants. The YSAQMD is part of the SVAB regional non-attainment area for ground-level ozone and fine particulate pollution.

### 2.2.5 CLIMATE CHANGE

Global warming is the increase in average global temperatures of the earth’s surface and atmosphere. The natural balance of GHGs in the atmosphere regulates the earth’s temperature. Without this natural

greenhouse effect, the earth's surface would be approximately 60° F cooler (U.S. Global Change Research Program 2014) [USGCRP]. Various gases in the earth's atmosphere, classified as atmospheric GHGs, play a critical role in determining the earth's surface temperature through the greenhouse effect. Among the prominent GHGs contributing to the greenhouse effect are carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>), ozone (O<sub>3</sub>), water vapor, nitrous oxide (N<sub>2</sub>O), and chlorofluorocarbons (CFCs). Human-caused emissions of these GHGs in excess of natural ambient concentrations are responsible for enhancing the greenhouse effect, or climate change, which contributes to global warming.

Existing sources of GHGs in the study area are extensive and include vehicles, marine vessels, industry, and farms. However, the effect of GHGs differ from other pollutants in that they do not directly impact local or even regional settings and are not often the effect of individual large sources. Rather, excess GHG emissions from many different sources combine to increase mean global temperatures, which in turn have numerous direct and indirect effects on the environment and humans on regional and local scales.

In California, an assessment of climate change impacts predicts that temperatures will increase from 4.1° F to 8.6° F by 2100, based on low and high global GHG emission scenarios (CCCC 2012). In 2013, the California Office of Environmental Health Hazard Assessment report identified changes to California's climate because of GHG emissions (OEHHA 2013). Changes identified in the report include the following:

- Exacerbation of air quality problems,
- Reduction in municipal water supply from the Sierra snowpack,
- SLR that could displace coastal businesses and residences,
- Increase in wildfires,
- Damage to marine and terrestrial ecosystems, and
- Increase in the incidence of infectious diseases, asthma, and other human health problems (CCCC 2012).

Observed environmental changes in California due to global warming include rising temperatures, rising sea levels, a lengthened growing season, and shifts in plant and animal ranges. At a local level, the navigation channel and surrounding area may be at greater risk of changing weather patterns, such as the current drought affecting water resources, the increasing intensity of rainfalls that can cause localized flooding, and the local effects from SLR. As discussed above, because the effects of climate change are regional in nature, the environmental setting in regards to climate change is the same throughout the study area.

## 2.2.6 BIOLOGICAL RESOURCES

The affected environment for biological resources was identified from existing information available for the San Francisco Bay Area and Sacramento San Joaquin Delta.

### 2.2.6.1 HABITAT TYPES

The study area provides habitat for a wide variety of aquatic species, including species associated with the benthos, such as annelids, mollusks, and crustaceans; phytoplankton and zooplankton; common fish species; special status fish species; invasive aquatic plants, fish, and invertebrates; and marine mammals. Aquatic habitats include tidal marsh and tidal mudflats; intertidal, shallow sub-tidal, and deep sub-tidal habitats; managed wetlands; rocky intertidal and subtidal; and open bay waters. Land adjacent to the San Joaquin River as it passes through the Delta is primarily used for agricultural purposes with pockets of

residential, commercial, and industrial development. Much of the land adjacent to the Carquinez Strait, San Pablo Bay, and the San Francisco Bay is developed. Suisun Bay is adjacent to Suisun Marsh and other wetland areas, as well as some developed shorelines. Land adjacent to Suisun Bay, the Carquinez Strait, San Pablo Bay, and the San Francisco Bay is largely developed. The habitat types around the Bay and Delta often blend with one another and with nearby upland habitats in transition zones called ecotones. Species found in these areas often occur in more than one habitat type (USACE 2014a).

**Tidal Marsh.** Tidal marsh habitat is comprised of tidally inundated vegetated wetland that may be salt or brackish, depending on the extent of freshwater influence. The plant communities found in this marsh-type habitat are influenced by salinity, substrate, wave energy, marsh age, erosion, and accretion. Marshes provide important rearing and refuge habitat for juvenile salmon, steelhead, and longfin smelt, and a wide variety of birds use tidal marshes for nesting, foraging, and refuge.

Tidal marshes occur at scattered locations along the waterways of the Delta and Bay, at the margins of San Pablo Bay, and in Suisun Marsh. The Suisun Marsh is located north of San Pablo Bay and Grizzly Bay. Suisun Marsh includes 52,000 acres of managed wetlands; 27,700 acres of upland grasses; 6,300 acres of tidal wetlands; and 30,000 acres of bays and sloughs. The Marsh serves as the resting and feeding ground for thousands of waterfowl migrating on the Pacific Flyway. Suisun Marsh is designated EFH for Pacific salmonids and Pacific groundfish, as well as critical habitat for Chinook salmon, steelhead, delta smelt, and green sturgeon. Suisun Marsh supports the state's commercial salmon fishery by providing important tidal rearing areas for juvenile fish, which allows them to grow twice as fast as those reared in the upper watershed, which greatly enhances their survival (Interagency Ecological Program n.d.) [IEP].

**Tidal Mudflats.** Tidal mudflats occur from below mean lower low water (MLLW) to mean tide level. These flats are characterized by a fine-grained silt and clay substrate and usually include minimal vascular vegetation. They are generally associated with tidal freshwater or brackish emergent wetlands at their upper edge and the tidal perennial aquatic community at their lower edge. Tidal mudflats support ecologically important benthic communities that include aquatic worms (*Oligochaeta*), crustaceans, and mollusks and provide fertile feeding grounds for various shorebird species. When the tidal mudflat community is flooded at high tide, it serves as shallow open water habitat for pelagic fish species (including Sacramento splittail and salmonids) and benthic fish species (including sturgeon) (CDWR 2013).

**Rocky Intertidal and Subtidal Habitat.** Rocky intertidal and subtidal habitat occurs around the margins of the Central Bay and San Pablo Bay. A diversity of wildlife occurs in these areas, which provide encrusting habitat for invertebrates that in turn attract foraging fishes. Pacific herring spawn on rocky habitat and the algae attached to rocky substrates (State Coastal Commission 2010) [SCC]. Shorebirds also utilize these habitats, and harbor seals often come ashore (haul out) on rocky shores (USACE 2014a).

**Open Bay.** The open bay includes both deep waters (deeper than -18 feet MLLW) and shallow bay waters (shallower than -18 feet MLLW) which comprise a majority of the open bays. Deep bay areas are inhabited by free swimming invertebrates and fish and provide roosting habitat for waterbirds. A variety of fish species inhabit the shallow bay which provides Pacific herring spawning habitat and functions as nursery habitat for juvenile halibut and sanddabs (*Citharichthys stigmaeus*), shiner perch (*Cymatogaster aggregata*), herring, and other fishes. Eelgrass, the Bay's only rooted seagrass, is present in some shallow bay areas. Several species of fish frequent both the deep and shallow bay, as do marine mammals. Anadromous fish use both the deep and shallow bays as migratory pathways (USACE 2014a).

**Managed Wetlands.** Managed wetlands are intentionally flooded and managed to enhance habitat values for specific wildlife species. Managed wetlands are present in Suisun Marsh (CDWR 2013).

**Terrestrial Habitats.** The proposed dredged material placement sites are the only areas that include terrestrial habitat and are described within relevant environmental documents prepared for each site (USACE and SCDEM 1998; USFWS and CDFW 2008).

#### 2.2.6.2 AQUATIC SPECIAL STATUS SPECIES

The discussion presented in this section is limited to protected aquatic resources, including Federal and/or state endangered or threatened species and their habitats; candidate Endangered Species Act (ESA) and California Endangered Species Act (CESA) species and their habitats; species of special concern and their habitats; and designated critical habitat for federally listed species. **Appendix G - Attachment 4** includes a list of aquatic special status species with recorded occurrences in the study area and identifies habitat types suitable for these species.

**Special Status Fish Species and Critical Habitat.** **Table 2-9** provides a summary of the habitat requirements; occurrence, life stage, and timing information; and designated critical habitat for special status fish species expected to occur in the study area.

Several species listed in **Table 2-9** have been identified as occurring in the study area by the California Department of Fish and Wildlife's (CDFW's) Fall Midwater Trawl (FMWT) program (CDFW 2015a). Additionally, USACE has conducted entrainment monitoring aboard the hopper dredge *Essayons* periodically since 2010 in Suisun Bay and San Pablo Bay (DR Reed et al. 2018). A discussion of these studies and results are provided below. In general, the dredging work windows that will be used (i.e., August 1 to November 30 at Bulls Head Reach and June 1 to November 30 at Pinole Shoal) will avoid most impacts to salmonids and limit impacts to other species due to the reduced time of exposure especially during spawning. The use of clamshell dredging for this project is thought to greatly reduce the likelihood of dredge entrainment.

The CDFW's FMWT began in 1967 and has sampled every year except 1974 and 1979 (CDFW 2014; Feyrer et al. 2007; Stevens and Miller 1983). The FMWT samples at more than 100 stations from San Pablo Bay landward into the Sacramento-San Joaquin Delta. Each station is typically sampled once each month from September through December. The FMWT was designed to index the year-to-year relative abundance of juvenile (age-0) striped bass (*Morone saxatilis*) (Stevens and Miller 1983). However, all captured species are identified and measured and the FMWT has become a long-term indicator of population trajectories for several small, pelagic fish, including delta smelt (Moyle et al. 1992; Sommer et al. 2007). The FMWT sampling methods are less likely to encounter mature individuals of larger species such as green sturgeon, salmonids, and striped bass.

**Table 2-9. Special Status Fish Species with Potential to Occur in the Study Area.**

DPS/ESU	Legal Status	Habitat Association	Occurrence	Critical Habitat in Study Area
Southern DPS green sturgeon ( <i>Acipenser medirostris</i> )	Federal threatened/ state species of special concern	Spawns in fast-moving, cool freshwater habitat in Sacramento, Klamath, and Trinity Rivers; juveniles rear in estuarine waters	Throughout Sacramento San Joaquin Delta and San Francisco Bay; spawn primarily in upper main stem of Sacramento River	Critical habitat present within the Sacramento-San Joaquin Delta and Suisun, San Pablo, and San Francisco bays
Delta smelt ( <i>Hypomesus transpacificus</i> )	Federal threatened/ state endangered	Inhabits open surface water; spawns primarily in sloughs and shallow edge-waters of channels in the upper Delta and Sacramento River	Known to occur in Sacramento-San Joaquin Delta and seasonally in Suisun Bay, Carquinez Strait, and San Pablo Bay	Critical habitat includes the Delta west to Carquinez Bridge
Sacramento River winter-run ESU Chinook salmon ( <i>Oncorhynchus tshawytscha</i> )	Federal endangered /state endangered	Migrates through the northern and central portions of San Francisco Bay; spawns in the spring and summer, primarily in the Sacramento River	Commonly found migrating through the northern portion of San Francisco Bay; spawn primarily in the Sacramento River	Critical habitat present in all waters from Sacramento River at Chipp’s Island to San Francisco Bay (north of the San Francisco/Oakland Bay Bridge)
Central Valley spring-run ESU Chinook salmon ( <i>Oncorhynchus tshawytscha</i> )	Federal threatened/ state threatened	Spawns in freshwater; juveniles rear in fresh and estuarine water before migrating to ocean	Commonly found migrating through the northern portion of San Francisco Bay; spawn in the Sacramento River Basin	Critical habitat present within the San Francisco-San Pablo-Suisun Bay complex
Central Valley DPS steelhead ( <i>Oncorhynchus mykiss irideus</i> )	Federal threatened	Spawns in freshwater; juveniles rear in fresh and estuarine water before migrating to ocean	Populations in the San Joaquin River and its tributaries	Critical habitat includes portions of the San Francisco-San Pablo-Suisun Bay estuarine complex
Central Coast DPS steelhead	Federal threatened/ state species of special concern	Spawns in freshwater; juveniles rear in fresh and estuarine water before migrating to ocean	Spawn in tributaries of San Francisco Bay, including in the San Joaquin watershed	Critical habitat includes portions of the San Francisco-San Pablo-Suisun Bay estuarine complex

DPS/ESU	Legal Status	Habitat Association	Occurrence	Critical Habitat in Study Area
Longfin smelt ( <i>Spirinchus thaleichthys</i> )	state threatened, state species of special concern/ Federal candidate	Euryhaline, nektonic, and anadromous; found in open waters of estuaries, mostly in middle or bottom of water column	Spawn from Suisun Bay into upper area of estuary near Rio Vista; larval longfin smelt concentrated in Suisun and San Pablo bays	No critical habitat
Central Valley fall-run/late-fall-run ESU Chinook salmon ( <i>Oncorhynchus tshawytscha</i> )	state species of special concern	Spawns in freshwater; juveniles rear in fresh and estuarine water before migrating to ocean	Commonly found migrating through the northern portion of San Francisco Bay; spawn in the Sacramento and San Joaquin River basins	No critical habitat
River lamprey and Pacific lamprey ( <i>Entosphenus tridentatus</i> ; <i>Lampetra ayresii</i> )	state species of special concern	Spawns in freshwater habitats in riffles; ammocoetes rear in freshwater benthos for 3 to 5 years before emerging and migrating to Ocean	Found in the San Francisco Bay, San Joaquin Delta, San Pablo Bay, and Suisun Bay watersheds	No critical habitat
Sacramento splittail ( <i>Pogonichthys macrolepidotus</i> )	state species of special concern/ Federal candidate	Slow moving river sections, dead end sloughs; requires flooded vegetation for spawning and foraging for young	Range includes the lower part of the Delta and sloughs adjoining Suisun and San Pablo bays	No critical habitat
Sacramento perch ( <i>Archoplites interruptus</i> )	state species of special concern	Historically found in the sloughs, slow-moving rivers, and lakes of the Central Valley	May be extirpated from native Delta (Crain et al. 2007)	No critical habitat

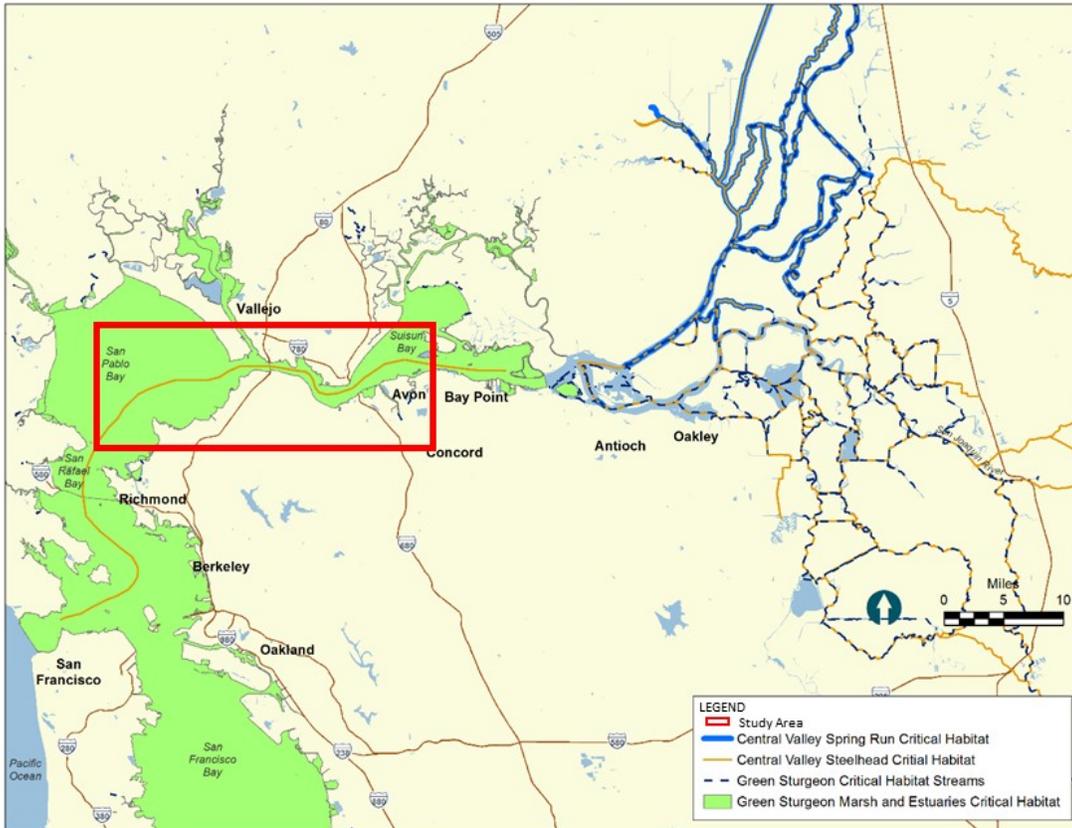

DPS = Distinct Population Segment      ESU = Evolutionarily Significant Unit      NA = Not applicable

Southern Distinct Population Segment Green Sturgeon (*Acipenser medirostris*) (Federal Threatened; State Species of Special Concern). The Southern Distinct Population Segment (DPS) of green sturgeon includes fish that inhabit the San Francisco Bay and Delta and spawn in the Sacramento River basin. Sub-adults and adults of this species inhabit nearshore oceanic waters, bays, and estuaries while also migrating to and from freshwater habitats. Freshwater occurrence of this species transpires during the early life-history stage (less than 4 years old), and later when adults return to freshwater to spawn (spawn age range of 10 to 15 years old). Spawning occurs in the spring and summer, as recorded in the upper Sacramento River and tributaries such as the Feather, Yuba, and American rivers. During the juvenile stage, green sturgeon can be found throughout the freshwater portions of their habitat the entire year. Juveniles of two apparent size groups (fork length range of 20 to 58 cm) have been collected in the Sacramento and San Joaquin rivers and Suisun Bay. However, there are substantial gaps regarding knowledge of this species’ biology, ecology, and habitat within the study area (USACE 2015e).

Green sturgeon individuals were not collected during the 2014 USACE maintenance dredging surveys, although individuals have been collected in the Stockton DWSC during previous years (USACE 2015f). This includes a total of four green sturgeon individuals from 2005 through 2014, all of which were collected during community monitoring, with none having been entrained by dredging equipment.

A primary factor for the decline of the green sturgeon is the restriction of spawning habitat to a limited area below Keswick Dam. Also contributing to the decline are flows of sufficient velocity to initiate the upstream spawning migration (Kohlhorst et al. 1991 as cited in CDFG 2002; NOAA 2008). Reduced flows have been identified as a factor in weakened year class recruitment in the white sturgeon population and are believed to have the same effect on green sturgeon recruitment. In addition to the adverse effects of impassable barriers, numerous agricultural water diversions exist in the Delta along the migratory route of larval and juvenile sturgeon. Entrainment and impingement in water pumps and screens are serious threats to sturgeon during their downstream migration. Sturgeon are also susceptible to uptake of contaminants from contaminated sediments through both dermal contact and incidental ingestion of sediments while feeding. Bioaccumulation is also a concern due to their long life. All of the above threats were identified by the NMFS Biological Review Team as potentially affecting the continued existence of the southern DPS of green sturgeon (70 FR 17386).

Critical habitat for the green sturgeon was designated on October 9, 2009 (50 FR 226). In California, critical habitat for green sturgeon in the Delta includes all waterways up to the elevation of mean higher high water (MHHW) within the area defined in California Water Code 12220, although some waterways are specifically excluded. As shown in **Figure 2-7**, the entire San Francisco Bay below MHHW is also designated as critical habitat, which includes the portion of San Francisco Bay that overlaps with the study area (NOAA 2009).

**Figure 2-7. Designated Critical Habitat for Green Sturgeon and Central Valley Steelhead in the Northern San Francisco Bay System and Watershed.**

Central Valley Distinct Population Segment Steelhead (*Oncorhynchus mykiss*) (Federal Threatened, State Threatened). The Central Valley DPS of steelhead includes all populations in the Sacramento and San Joaquin rivers and their tributaries. The current distribution ranges from Keswick Dam in the Upper Sacramento River to the Merced River in the San Joaquin River Basin, with distribution primarily limited by impassable dams.

Anadromous adults of the Central Valley steelhead Evolutionarily Significant Unit (ESU) make their upstream spawning migrations beginning in July (peaking in September and October) after residing in the ocean for 2 to 3 years. Spawning occurs from December through April. The study area is primarily used as a migration corridor. Spawning, incubation, and the majority of rearing occurs farther upstream than the study area. Juveniles reside in freshwater from 1 to 3 years, primarily occurring near the surface and in the water column above the benthos when over deeper waters. Juveniles feed on a diverse array of aquatic and terrestrial insects and other small invertebrates. Most juvenile Central Valley steelhead are found migrating through the study area during the spring, although outmigration occurs from December through August (USACE 2015e). No steelhead specimens have been encountered during USACE entrainment and community monitoring conducted during annual dredging from 2005 through 2014 (USACE 2015f). USACE maintenance dredging of the Stockton DWSC was accomplished in 2006 and 2007

during the June 1 through December 31 dredging windows, and from 2008 to the present during August 1 through November 30 dredging window.

Factors that limit productivity of steelhead populations include periodic reversed flows due to high water exports (drawing juveniles into large diversion pumps); loss of fish into unscreened agricultural diversions; predation by introduced species; and reduction in the quality and quantity of rearing habitat due to channelization, pollution, riprapping, and other factors (CACST 1988; Dettman et al. 1987; Kondolf et al. 1996a, 1996b as cited in NOAA 2006).

*Central Valley Spring-Run Evolutionarily Significant Unit Chinook Salmon (*Oncorhynchus tshawytscha*) (Federal Threatened, State Threatened)*. The Central Valley spring-run ESU of Chinook salmon is one of four distinct runs of salmon that spawn in the Sacramento-San Joaquin River system. The Chinook was historically the most abundant salmon species in the Central Valley. Populations remain in some tributaries of the Sacramento River, including Butte, Mill, Deer, Antelope, and Beegum creeks and the Yolo Bypass.

In general, spring-run Chinook salmon are found in the Suisun Marsh/North San Francisco Bay, Delta, Sacramento River, Feather River/Sutter Basin, Butte Basin, and North Sacramento Valley Ecological Zones (CDFG 1998). Spring-run Chinook adults typically migrate upstream to spawn from April to October, and spawn from August through October. Chinook alevins have been collected from Suisun Bay in January and February. Larger parr juveniles have been found from April to June. Juvenile life stages are commonly found inshore, in shallow water and throughout estuarine habitat. Some Chinook salmon delay their downstream migration until the early smolt stage. Juvenile outmigration peaks from May to June (USACE 2015e).

Similar to Central Valley steelhead, factors that limit productivity of salmonid populations include periodic reversed flows due to high water exports (drawing juveniles into large diversion pumps); loss of fish into unscreened agricultural diversions; predation by introduced species; and reduction in the quality and quantity of rearing habitat due to channelization, pollution, riprapping, and other factors (CACST 1988; Dettman et al. 1987; Kondolf et al. 1996a, 1996b as cited in NOAA 2006).

*Central Valley Fall-run/Late-fall-run Evolutionarily Significant Unit Chinook Salmon (*Oncorhynchus tshawytscha*) (State Species of Special Concern)*. The Central Valley fall-run and late-fall-run ESU of Chinook salmon are two of the four distinct runs of salmon that spawn in the Sacramento-San Joaquin River system. Late-fall-run Chinook are often larger than fish from other runs. They are most similar genetically to fall-run Chinook and are often combined into a single ESU, despite having distinctive life histories. The NMFS designated the Central Valley fall-run/late-fall-run Chinook salmon ESU as a candidate for listing on September 16, 1999, although the listing was later deemed unwarranted (50 CFR 223; NMFS 2009). The Central Valley fall-run/late-fall-run Chinook salmon ESU is a state species of special concern. The ESU includes all naturally spawned populations of fall-run Chinook salmon in the Sacramento and San Joaquin River Basins and their tributaries, east of Carquinez Strait. Fall-run Chinook are the most abundant run in the Central Valley (Moyle 2002).

Fall-run Chinook spawn in upstream reaches of the Sacramento River from October through December, peaking in late October and November. Fall-run Chinook emerge between approximately December and March and out-migrate to the ocean between December and June. Late-fall-run adults enter the Sacramento River from October through April and spawn from January to April, peaking in February and

March. Late-fall-run Chinook fry typically emerge from April to June and rear year-round. Fall-run Chinook tend to mature in the ocean before returning to spawn, while late-fall-run Chinook may return to freshwater as immature adults (BCAG 2011).

*Sacramento River Winter-run Evolutionarily Significant Unit Chinook Salmon (*Oncorhynchus tshawytscha*) (Federal Endangered, State Endangered)*. The Sacramento River winter-run ESU of Chinook salmon differs from other Chinook ESUs in that they have characteristics of both stream- and ocean-type races (Healey 1991). Study area waters are primarily used by winter-run Chinook for adult spawning migrations and juvenile out-migrations, with some usage overlap for juvenile rearing. Winter-run Chinook spawning occurs in accessible upper reaches of the Sacramento River basin from April through July, with adults migrating upstream from December to July. Chinook alevins have been collected from Suisun Bay in January and February. Larger parr juveniles have been found from April to June. Juvenile life stages are commonly found inshore, in shallow water and throughout estuarine habitat. Some Chinook salmon delay their downstream migration until the early smolt stage. Juvenile outmigration peaks from May to June (USACE 2015f).

Activities identified by the NMFS (NOAA 1994) that affect winter-run Chinook habitat include water management operations by the Central Valley Project (CVP) and the State Water Project (SWP), small and large water diversions by other private entities, bank restoration, dredging, and other construction-related activities in the Sacramento River and Delta.

*Longfin Smelt (State Threatened, Federal Candidate)*. Longfin smelt is state-listed as threatened and is a Federal candidate species. Longfin smelt, a small sized euryhaline and anadromous fish, was historically among the most abundant fish in the San Francisco estuary and the Delta. Significant declines in longfin smelt abundance have occurred throughout its range during the past quarter century. Longfin smelt are distinguished by their long pectoral fins, which reach or nearly reach the base of their pelvic fins. They reach a maximum size of about 150 mm (total length), and reach maturity near the end of their second year. As they mature in the fall, adults found throughout San Francisco Bay migrate to brackish or freshwater in Suisun Bay, Montezuma Slough, and the lower reaches of the Sacramento and San Joaquin rivers. Spawning adults congregate at the upper end of Suisun Bay and in the lower and middle Delta, especially in the Sacramento River channel and adjacent sloughs (USACE 2015f). Spawning occurs primarily from January through March, after which most adults die (CDFG 2009a). In April and May, juveniles are believed to migrate downstream to San Pablo Bay. Juvenile longfin smelt are collected throughout the Bay during the late spring, summer, and fall and occasionally venture offshore as far as the Gulf of the Farallones. Juveniles typically inhabit the middle and lower portions of the water column (USACE 2015f).

Since 1967, CDFW has conducted monthly trawl surveys for longfin smelt during September through December at sampling sites throughout the Sacramento and Stockton DWSCs. The FMWT samples 122 stations each month from September to December and a subset of these data is used to calculate an annual abundance index. These 122 stations range from San Pablo Bay upstream to Stockton on the San Joaquin River, Hood on the Sacramento River, and the Sacramento Deep Water Ship Channel. Survey results from 8-year period 2010 through 2018 are presented in **Table 2-10**. Longfin smelt populations have seen a significant decline since CDFW surveys began in 1967, when a total of 81,737 individuals were collected (CDFW 2015b).

**Table 2-10. CDFW Fall Midwater Trawl Indices for Longfin Smelt.**

Year	September	October	November	December	Total
2010	2	7	4	178	191
2011	68	16	92	301	477

Source: CDFW 2015b, updated in 2019.

The annual abundance of longfin smelt is significantly and positively correlated with the amount of freshwater flow during spawning and larval periods (Baxter 1999; Hieb and Baxter 1993; Jassby et al. 1995; Stevens and Miller 1983). Three factors were identified as potentially responsible for this significant correlation: (1) a reduction in predation during high flows; (2) increased habitat availability that may improve survival by reducing intraspecies competition; and (3) an increase in nutrients stimulating the base of the food chain (Stevens and Miller 1983). However, the relationship changed to substantially lower longfin smelt abundance after the introduction of the invasive Amur River clam in the late 1980s. This corresponded with a decline in phytoplankton and zooplankton abundance due to grazing by the Amur River clam (Bennett et al. 2002). Other introduced species such as striped bass and inland silversides have had an impact on longfin smelt populations due to predation (CDFG 2009b).

In 2004, numbers of longfin smelt (along with other pelagic species including Delta smelt, striped bass, and threadfin shad) exhibited a sharp decline in abundance that has continued to the present time. The Pelagic Organism Decline (POD) phenomenon is currently under investigation to better understand how stock-recruitment effects, declines in habitat quality, increased mortality rates, and reduced food availability due to invasive species may be working separately or together to contribute to declining abundance of longfin smelt and other pelagic species.

*Delta Smelt (Hypomesus transpacificus) (Federal Threatened, State Endangered).* The delta smelt is a euryhaline fish with a habitat range extending from the lower reaches of the Sacramento and San Joaquin rivers, through the Delta, and into Suisun Bay. This Delta endemic species is currently found in very low abundance within the Sacramento and Stockton DWSCs.

Delta smelt was listed as a threatened species under the ESA on March 5, 1993 (58 FR 12854). The state status of delta smelt under CESA was elevated from threatened to endangered (March 4, 2009). On March 24, 2009, the USFWS initiated a 5 year status review of delta smelt. As of April 7, 2010, and again reconfirmed on December 5, 2014 (79 FR 72450), reclassification status of delta smelt to endangered was found warranted but precluded by other higher priority ESA listing actions (75 FR 17667).

Presence and abundance of delta smelt is closely associated with salinities between 0 and 7 practical salinity units (psu). The upper salinity tolerance for this species is 19 psu, with a strong preference for habitat near or upstream of the 2 psu isohaline. Delta smelt are not present in waters over 25°C and are

rarely found in water temperatures above 22°C. Spawning habitat is present in dead-end sloughs, near inshore areas of the Delta, and shallow fresh water channels of the Delta and Suisun Bay. During the fall prior to spawning, delta smelt congregate in upper Suisun Bay and the lower reaches of the Delta. The spawning period is estimated to be from February to June. Delta smelt may prefer spawning over vegetation, if present, but often deposit their eggs over submerged tree branches and stems or in open water over sandy and rocky substrate, and they may even use the shallower areas of Delta levees. Eggs are demersal and adhesive. Newly hatched larvae float near the surface of the water, with movements following tides and discharge. Sommer and Meija (2013) state that delta smelt are more commonly associated with lower salinities and higher turbidities, moderate temperatures, and some tidal influence (USACE 2015f).

Larger juveniles and adults are most abundant during the spring and summer in Suisun Bay and the Delta, as evidenced from trawl and trap net catch data. Seasonal migrations occur within a short section of the upper estuary. Juvenile smelt move downstream to San Pablo Bay and Carquinez Strait before turning back to Suisun Bay or upstream sloughs for spawning. During average and high outflow years, delta smelt congregate from upper Suisun Bay to the Sacramento River near Decker Island. During low outflow and drought years, their pre-spawning congregations are centered in the channel of the Sacramento River and are rarely found further downstream in Suisun Bay (USACE 2015f).

Since 1967, CDFW has conducted monthly trawl surveys for delta smelt during September through December at sampling sites throughout the Sacramento and Stockton DWSCs. Survey results from the 8-year period 2010 through 2018 are presented in **Table 2-11** (CDFW 2015b). Entrainment monitoring conducted aboard the hopper dredge *Essayons* demonstrates that both delta smelt and longfin smelt may be present in the project area during the specified work windows (**Table 2-12**; DR Reed et al. 2018), although the entrainment numbers shown are not comparable among years due to variable sampling effort that cannot be measured accurately. Again, the proposed action would minimize the likelihood of entrainment by utilizing clamshell dredging rather than hopper dredging.

Delta smelt are threatened by loss of estuarine habitat; entrainment during water diversion operations for the CVP, SWP, and the myriad of agricultural diversions; pulses of pesticides; food shortages; and predation by and competition from invasive species (Bennett 2005; CDFG 2009c; SWCA 2009). In 2004, scientific monitoring of aquatic organisms and water quality in the San Francisco estuary revealed a synchronous decline of several pelagic fish species (delta smelt, longfin smelt, striped bass, and threadfin shad) (Baxter et al. 2008). This POD is being investigated to better understand how stock-recruitment effects, declines in habitat quality, increased mortality rates, and reduced food availability due to invasive species, may be working separately or cumulatively to cause POD. Further information on the delta smelt is provided in the Biological Assessment (**Appendix G, Environmental - Attachment 4**).

*Sacramento Splittail (Pogonichthys macrolepidotus) (State Species of Special Concern).* The Sacramento splittail was federally-listed as threatened from 1999 to 2003 (68 FR 183) and is found exclusively in the Sacramento-San Joaquin Delta, Central Valley streams, and the Napa and Petaluma rivers. In 2003, the

USFWS removed the splittail from the threatened species list, after litigation by water agencies challenged the listing. The listing was reconsidered following a 2009 suit by the Center for Biological Diversity, but it was determined the listing was not warranted. The species remains a state species of special concern.

The splittail is relatively long-lived (up to 9 years) and can grow up to 400 mm long. Historic populations occurred as far north as Redding in the Sacramento River, and as far south as Friant Dam near Fresno in the San Joaquin River. The splittail has adapted to living in estuarine systems and is tolerant of salinities from 10 to 18 parts per thousand. Young-of-year and yearling splittail abundance is highest in shallow water. Adults move slowly upstream during winter and spring to forage and spawn in flooded areas. The splittail’s small, subterminal mouth with barbels and pharyngeal teeth, along with the large upper tail lobe, reflect their preference for feeding on bottom invertebrates in low to moderate current strength. Splittail reach adulthood in their second year at approximately 170 mm (USACE 2015f).

Since 1967, the CDFW has conducted monthly trawl surveys for Sacramento splittail during September through December at sampling sites throughout the Sacramento and Stockton DWSCs. Survey results from the 5-year period 2010 through 2014 are presented in **Table 2-13** (CDFW 2015b).

Populations of splittail have declined due to dams and other impassable barriers and modifications to flood basins that have reduced spawning habitat (Moyle 2002; UCCE 2010).

*River Lamprey (Lampetra ayresii) (State Species of Special Concern) and Pacific Lamprey (L. [Entosphenus] tridentate) (State Species of Special Concern).* Anadromous Pacific and river lamprey both occur in the project area. River lamprey in California have primarily been recorded within the Feather River and the lower Sacramento-San Joaquin River system, including both DWSCs. Less is known about the southern distribution of the river lamprey. Both species of lamprey have adult upstream migrations during the early spring and spawn from late spring to early summer in gravel substrates upstream of the Delta and lower Sacramento-San Joaquin river system (USACE 2015f).

During their upstream spawning migration, adult Pacific lamprey generally hibernate in freshwater for up to 1 year. They hibernate in substrates near their spawning area and do not feed prior to spawning the following year. River lamprey begin their transformation from ammocoete to adult form at about 120 mm total length, and Pacific lamprey at approximately 140 to 160 mm. River lamprey metamorphosis

lasts from 9 to 10 months. During this time, both lamprey species congregate close to the saltwater-freshwater interface in estuaries. The lamprey's transformational stage between filter-feeding ammocoete and parasitic adult is known as macrophthalmia. Adult teeth develop and grow during this period (USACE 2015f).

Migration of fully developed macrophthalmia to the ocean likely occurs between late fall and spring, when outflows are high. However, some river lamprey may spend their entire life history in freshwater. River lamprey appear to be more parasitic in freshwater than Pacific lamprey. Adult river lampreys spend less time in the ocean or estuary migrating back to freshwater in the fall and winter. In general, adult Pacific lamprey migrate from stream to spawning areas in winter and spring (USACE 2015f).

During the 2014 USACE entrainment monitoring for Stockton and Sacramento DWSCs maintenance dredging, a total of 131 river lamprey were collected. During entrainment monitoring for maintenance dredging from 2005 through 2014, a total of 461 lampreys (211 river lamprey and 250 undetermined lamprey specimens) were collected (USACE 2015f).

*Sacramento Perch (Archoplites interruptus) (State Species of Special Concern)*. The Sacramento perch is a benthopelagic freshwater fish found in the Sacramento, San Joaquin, Pajaro, and Salinas River drainages (UCCE 2010). They prefer vegetated sloughs, pools in sluggish rivers, and lakes. Sacramento perch are most common in ponds and impoundments where they have been introduced throughout the state such as in Clear Lake and Alameda Creek (Crain et al. 2007). However, they may be mostly extirpated from their native Delta (FISHBIO 2010; Moyle 2002). These fish may be impacted by potential saltwater intrusion into freshwater habitat, though they are capable of surviving high temperatures, salinities of up to 17 parts per thousand, high turbidity, and low water clarity (UCCE 2010).

Sacramento perch are found along the bottom of inshore regions, feeding opportunistically throughout the day on small crustaceans within the sediment. Adult fish may feed on other fish, including juvenile perch. Sacramento perch reach sexual maturity in year 2 or 3 and generally spawn from March through early August when water temperatures range from -17.4 to -17.2°C. Prior to spawning, perch gather in shallow areas abundant with filamentous algae and macrophytes. Male perch create shallow nests, which are visited by a female. Upon release of eggs and milt, the female abandons the nest and the male remains to guard the nest and embryos for several days. Emergent larvae are planktonic for approximately 2 weeks.

Sacramento perch have not been collected during USACE community monitoring for Stockton and Sacramento DWSCs maintenance dredging (USACE 2015f).

*Striped Bass (Morone saxatilis) (Federally Protected Game Fish)*. Striped bass is a federally protected game fish (72 FR 205) introduced into the Delta in 1879 with the goal of introducing a commercial fishery. Within ten years of their introduction, the fishery had been established. Striped bass currently support one of California's largest commercial fisheries (CDWR 2013).

Striped bass move readily between saltwater and freshwater, spending most of their life cycle in estuaries. They are sensitive to temperatures above 25°C, but adults can also withstand the rapid changes in temperature that can be associated with changes in salinity. Striped bass need three very specific habitat features: (1) a large cool river for spawning, with enough flows sufficient to keep larvae suspended as they drift downstream to the estuary; (2) a large waterbody with plenty of fish to eat; and (3) a protective

estuary for juveniles to grow by feeding on invertebrates. In California, the only area that satisfies these criteria is the San Francisco Bay estuary and its surrounding water bodies (UCCE 2010). Striped bass populations spend the majority of their time in bays but will move out into the ocean during El Niño years and winter in the Delta until the end of the spawning season.

Since 1967, the CDFW has conducted monthly trawl surveys for striped bass (age-0) during September through December at sampling sites throughout the Sacramento and Stockton DWSCs. Survey results from the last 5 years (2010 through 2014) are presented in **Table 2-14** (CDFW 2015b).

**Table 2-14. CDFW Fall Midwater Trawl Indices for Striped Bass (age-0).**

Year	September	October	November	December	Total

Source: CDFW 2015b, updated 2019.

**Marine Mammals.** The most common marine mammals to inhabit the San Francisco Bay estuary are Pacific harbor seals (*Phoca vitulina*) and California sea lions (*Zalophus californianus*). Other marine mammal species that occasionally inhabit the Bay and that could be considered transient visitors in the study area include the gray whale (*Eschrichtius robustus*), harbor porpoise (*Phocoena phocoena*), northern elephant seal (*Mirounga angustirostris*), Steller sea lion (*Eumetopias jubatus*), northern fur seal (*Callorhinus ursinus*), and, less frequently, the southern sea otter (*Enhydra lutris*) (URS 2003). On rare occasions, individual humpback whales (*Megaptera novaeangliae*) have entered the Bay. Marine mammals generally do not occur in Delta rivers, although in 2014 a wayward sea lion was found in the San Joaquin River (USFWS 2014).

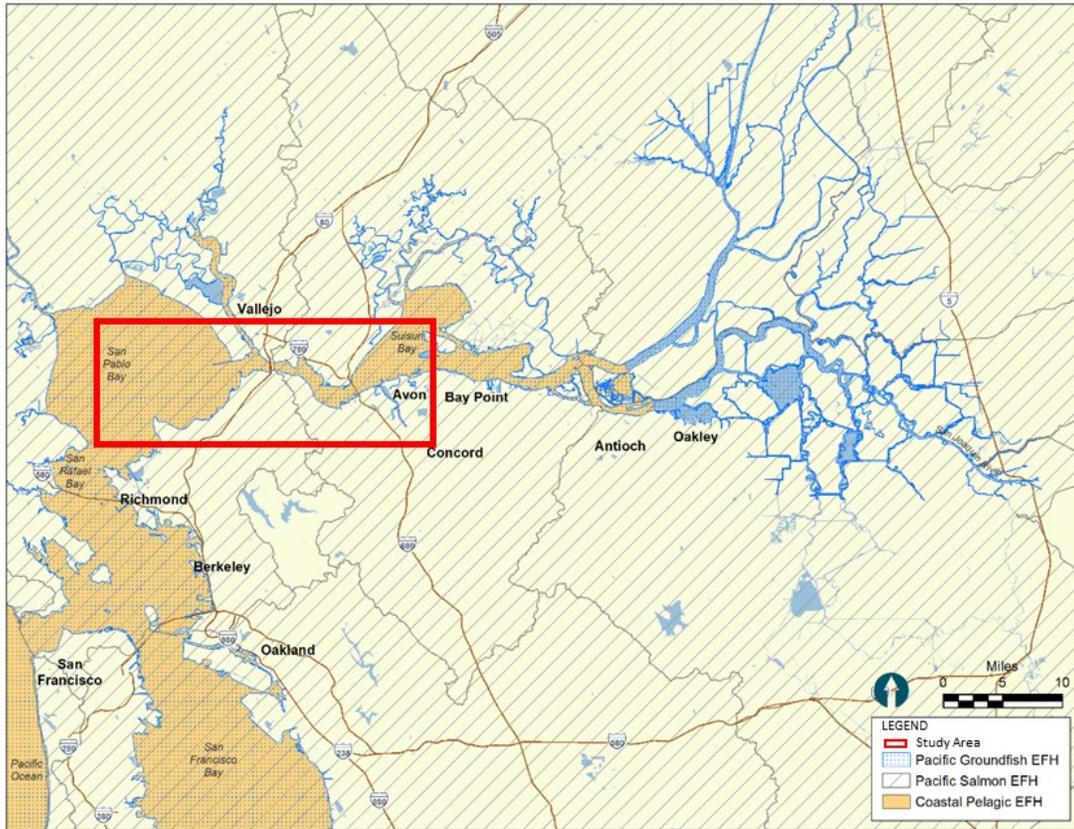

Pacific harbor seals are non-migratory, have limited seasonal movements associated with foraging and breeding activities, and use the Bay year-round (Kopec and Harvey 1995). Harbor seals forage in shallow waters on a variety of fish and crustaceans and, therefore, can occasionally be found foraging in the study area. Harbor seals haul out in groups ranging in size from a few individuals to several hundred. Habitats used as haul out sites include tidal rocks, bayflats, sandbars, and sandy beaches (Zeiner et al. 1990). California sea lions breed in Southern California and along the Channel Islands. After the breeding season, males migrate up the Pacific Coast and enter into the Bay. During anchovy and herring runs, approximately 400 to 500 sea lions (mostly immature males) feed almost exclusively in the North and Central Bay (USFWS 1992) and could occasionally forage in the study area. There are no haul-out sites for either the harbor seal or the California sea lion within the Federal navigation channels.

**Essential Fish Habitat.** The Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) was enacted to maintain healthy populations of commercially important fish species. Under

the Magnuson-Stevens Act, eight regional Fishery Management Councils are responsible for developing Fishery Management Plans (FMP) to manage the specified commercial species. The Sustainable Fisheries Act of 1996 amended the Magnuson-Stevens Act, requiring the protection of the habitats of species for which there is a fishery management plan. These habitats are designated as Essential Fish Habitat (EFH), being defined as “...those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity.” EFH can consist of both the water column and the underlying surface (e.g., seafloor) of a particular area, and it includes those habitats that support the different life stages of each managed species. A single species may use many different habitats throughout its life to support breeding, spawning, nursery, feeding, and protection functions. As shown in **Figure 2-8**, the study area is within the EFH for Pacific salmon, Pacific groundfish (fish that live on, in, or near the bottom of the water body they inhabit), and coastal pelagic species (fish that inhabit the water column, neither near the bottom nor shore of the water body they inhabit).

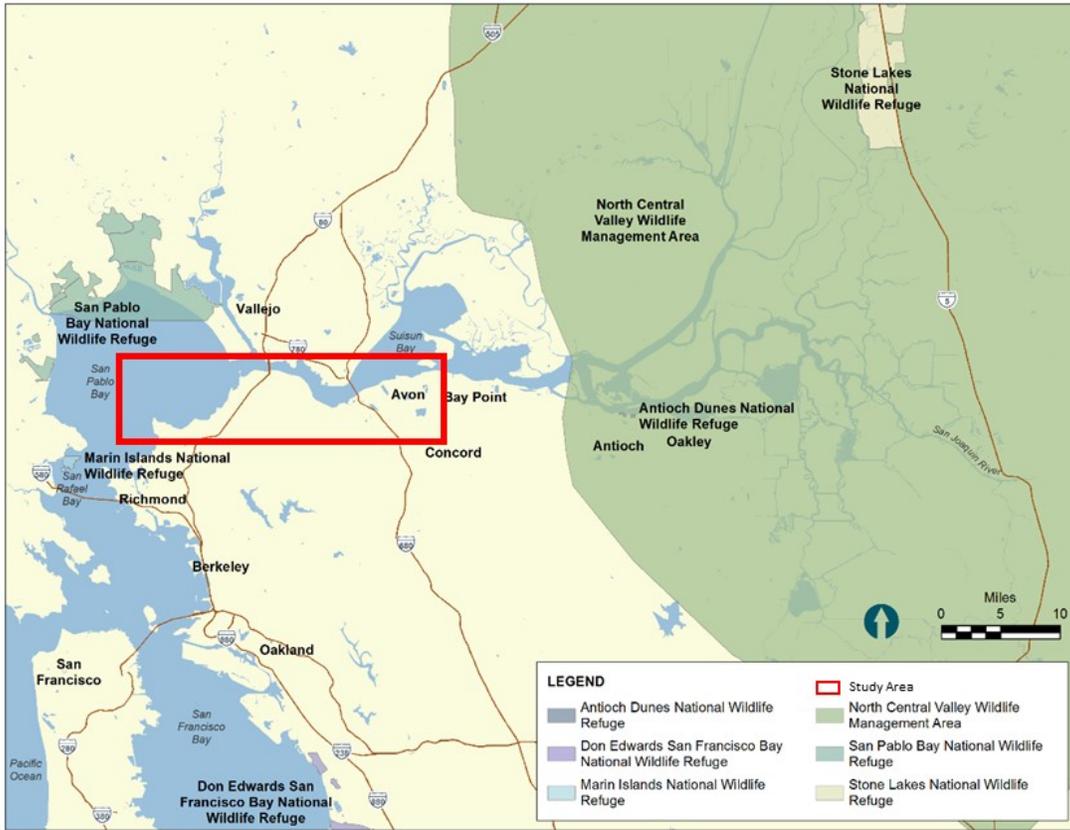

The Pacific salmon FMP includes Chinook and coho salmon (*Oncorhynchus kisutch*), and on occasion includes pink salmon (*Oncorhynchus gorbuscha*), sockeye (*Oncorhynchus nerka*), and chum (*Oncorhynchus keta*). The Pacific Groundfish FMP is designed to protect habitat for more than 90 species of fish, including rockfish, flatfish, some sharks and skates, and other species that associate with the underwater substrate, including both rocky and soft substrates. The coastal pelagic species EFH is defined as all marine and coastal waters from the shoreline offshore to the limits of the exclusive economic zone. The coastal pelagic FMP includes market squid (*Loligo opalescens*), Pacific sardine (*Sardinops sagax*), Pacific mackerel (*Scomber japonicus*), jack mackerel (*Trachurus symmetricus*), and northern anchovy (*Engraulis mordax*).

**Eelgrass Beds.** Eelgrass requires specific environmental conditions to flourish, primarily salinity, light transmittance, and water depth. The proposed dredging areas within the study area include waters which are generally too deep, turbid, and fresh for eelgrass to survive. Thus, eelgrass is not expected to be present in the channel areas where dredging operations would take place.

**Figure 2-8. Essential Fish Habitat for Pacific Groundfish, Pacific Salmon, and Coastal Pelagic Fish in the Northern San Francisco Bay System.**

**Wildlife Management Areas.** Figure 2-9 shows the wildlife management areas and national wildlife refuges in the study area that are managed by the CDFW, the USFWS, or similar entities. In these areas, lands are either enhanced for wildlife or permanently protected from development (USFWS 2010). The Federal Antioch Dunes National Wildlife Refuge (NWR) is located along the southern shore of the San Joaquin River south of West Island (USFWS 2010). It was the first NWR in the United States established to protect endangered plants and insects (USFWS 2010b). Established in 1980, the refuge provides protection for three endangered species: Lange’s metalmark butterfly (*Apodemia mormo langei*), Antioch Dunes evening primrose (*Oenothera deltoides ssp. howellii*), and Contra Costa wallflower (*Erysimum capitatum*) (USFWS 2010b). The state-run Lower Sherman Island Wildlife Area is located at the confluence of the Sacramento and San Joaquin rivers (CDFG 2010). It includes approximately 3,100 acres of primarily marsh and open water habitat in the western Delta (CDFG 2010). The project area of San Pablo Bay and the Bulls Head Reach portion of Suisun Bay do not include any wildlife management areas.

**Figure 2-9. National Wildlife Refuges and Wildlife Management Areas in the Study Area.**

### 2.2.7 LAND USE AND PLANNING

**Marin County.** The jurisdictions included within Marin County include the cities of Tiburon, San Rafael and Novato. There is moderate to low development in the Richardson Bay planning area, which contains watersheds that drain to Richardson Bay. The San Rafael Basin planning area is primarily within a city-centered corridor and is more highly developed. The Novato planning area is part of the city-centered/Baylands corridor, which generally contains watersheds that also drain to San Pablo Bay, and includes the unincorporated community of Bel Marin Keys and the Hamilton Wetlands Preserve (Marin County 2007).

**Contra Costa County.** As a whole, Contra Costa County is relatively undeveloped. Growth in the County is broken into the subareas of West County, Central County and East County. In the West and Central County areas, the suburban cities and towns are primarily residential, commercial, and industrial. In the East Central County and East County areas, land use is designated primarily for agriculture and general open space. The West County area consists of five cities, four of which (Richmond, Pinole, Rodeo and Hercules) are located in the study area. The city areas are developed with a wide variety of uses, but mostly contain a proportional mix of principal urban land uses. The Central County area includes the City of Martinez; the East County area includes Pittsburg, Oakley and Antioch. The affected uses within the Central and East County areas are predominantly residential, agricultural, recreational and open space.

In these areas, development is concentrated in collections of small urban communities and mid-sized cities (Contra Costa County 2005).

The Contra Costa County Northern Waterfront is also located within the study area. The Northern Waterfront is approximately one-mile-wide and 55 miles long and contains 63.86 square miles. It includes six cities, several unincorporated communities, and a variety of unincorporated pockets of land (developed and undeveloped) located in the county. Within the Northern Waterfront there is a wide range of land uses from industrial, commercial, residential, marinas, public, and recreational uses, to natural habitat, open space, and wildlife refuges (Craft Consulting Group and Cambridge Systematics 2013) [CCG&CS]. The Northern Waterfront is located between the Port of Richmond on the west and the Ports of West Sacramento and Stockton on the east. Along this stretch of the John F. Baldwin Channel from the Carquinez Strait to Suisun Bay and the Delta there are a number of marine terminals and wharfs. These facilities are privately owned and primarily serve the adjacent manufacturing operations which include: C&H sugar refinery in Crockett; Tesoro and Shell at Martinez and Phillips 66 in Rodeo; the Mirant power plant, Dow chemical plant, and the USS-POSCO's steel-coil processing plant in Pittsburg (CCG&CS 2013).

**Solano County.** Solano County is divided into two topographic sections. The study area extends into the foothills of the coastal range and is characterized by steep slopes, which become more gently rolling in the east. The remainder of the County is part of the Sacramento Valley, which is characterized by level topography, with some isolated areas of low rolling hills. Approximately 14 percent of the total land area of the County is in cities. The remainder of the County (over 329,000 acres) is in agricultural use, 70 percent of which is unincorporated. The southern extent of the County (including the cities of Vallejo and Benicia), consists of waterfront area adjacent to San Pablo Bay and the John F. Baldwin Channel. Development in Vallejo and Benicia is a mixture of open space, residential, commercial, and waterfront. Agricultural land is concentrated in the eastern portion of the County and includes the watershed lands contiguous with the water bodies. A significant feature of the County is the Suisun Marsh, which has an area of more than 30 square miles (Solano County 2008).

### 2.2.8 MINERAL RESOURCES

Mineral resource deposits are described based on broad geologic classifications or resource zones. For purposes of addressing mineral resources, the affected environment discussion focuses on mineral resources within the counties adjacent to the navigation channels in the study area. Information was obtained directly from maps, interpretation of aerial photographs, and from plans and other documents associated with the various jurisdictions within which the study area coincides.

The mineral resources within the study area are shown in **Figure 2-10** and described in detail below.

#### **Marin County**

Of the eight mineral resource sites designated in Marin County, four are located in proximity to the study area and include:

- Ring Mountain (Tiburon Peninsula): A 190-acre site that is considered to be a Scientific Resource Zone rather than a production site due to the rare geologic formations found there. The site contains rare, colorful and enigmatic metamorphic rock as well as many species of rare plants. This preserve is the type location for the mineral Lawsonite.

- Section D-1 Novato Conglomerate (Black Point): Located adjacent to Bel Marin Key, this site is located within the city of Novato and is an alluvial resource, which contains a thick accumulation of well-rounded pebbles, cobbles and boulders in a well-cemented sandy matrix. This material has been found to be suitable for use in Portland Concrete Cement.
- Sector D-2 Novato Conglomerate (Black Point): Located adjacent to Bel Marin Key, this site is located at the Renaissance Faire/Living History Centre and was once quarried for the conglomerate it contains. The material in this sector is a similar alluvial deposit as in Sector D-1 above.
- Sector I Franciscan Complex Sandstone (San Pedro Hill): This site is located at the tip of the San Pedro Peninsula just outside San Rafael City limits and has been mined since the beginning of the 20th century. The site has yielded crushed stone suitable for Portland Cement Concrete aggregate and rip rap. Shale deposits are also present and these materials have been developed by several quarries throughout the years to supply bricks, tile and lightweight aggregate (Marin County 2005b).

Figure 2-10. Mineral Resources.

**Contra Costa County**

The only mineral resource located near the study area in Contra Costa County is the shale deposit located on land near Port Costa. The Carquinez Strait Regional Shoreline Park surrounds the site. The mineral deposit is designated for protection in the County Conservation Plan (Contra Costa County 2005).

**Solano County**

The only regionally significant mineral resource near the study area in Solano County is the Sulphur Springs Mountain Deposit, which is a deposit of igneous rock from which aggregate is produced. The aggregate is used in the manufacture of asphaltic concrete, Portland Cement Concrete, rip-rap, drain rock and road base. An active quarry within the deposit exists along Lake Herman Road west of Lake Herman in the boundary hills between Benicia and Vallejo. Quarrying there has resulted in a cut face, which is visible from the Lake Herman area. Several abandoned mercury mines exist in the Sulphur Springs Mountain

area. These mines have not been in production since the mid-1940s. This deposit is located on land and not in the navigation channel (Solano County 2008).

### 2.2.9 AGRICULTURE

There are no agricultural resources within the zone of impact (one-mile buffer) of the channel or the proposed beneficial reuse locations. Agricultural resources within the surrounding counties are too distant to potentially experience direct impacts by the alternatives considered, and no possible indirect effects can be identified.

### 2.2.10 AESTHETICS

The navigation channels within the portion of San Francisco Bay, San Pablo Bay and the small part of the Carquinez Strait included within the study area can be seen from parks, industrial areas, bridges, some roads, recreational boating, and residential areas. The area includes scenic views of water, hills, bridges, ships in the shipping channel, and recreational boats.

Sensitive visual receptors are locations or populations particularly exposed to visual impacts, or zones where visual impacts would be more apparent than elsewhere. They include residential areas and park users, such as those within the Point Pinole Regional Shoreline and Knox/Miller Regional Shoreline Parks in Richmond; China Camp State Park in Marin County; and the Martinez Regional Shoreline Park. Topography varies from beach areas adjacent to the waterways to higher elevations on natural hillsides. Lighting from urban uses exists in developed areas and on transportation infrastructure such as roads and bridges.

Most of the deep draft navigation channels in the study area are visible from open space; parks; agricultural, industrial, commercial, and residential land uses; bridges and some roads and recreational boating areas. The topography ranges from flat areas to hillsides. Existing users of the waterways are comprised of large ships, such as car carriers; other cargo ships; oil tankers; tug boats; barges; maintenance dredging equipment; and recreational users, such as small motor boats, sailboats and non-motorized craft, such as kayaks and paddle boards.

### 2.2.11 CULTURAL RESOURCES

This section summarizes existing cultural and historic resources that are located within the study area. For the purposes of this discussion the Area of Potential Effects (APE) is approximately ¼ mile around the project features where cultural resources could be impacted. The boundary of the APE will be further refined during PED. Cultural resources include prehistoric and historic archaeological sites; architectural properties such as buildings, bridges, and infrastructure; and resources of importance to Native Americans (traditional cultural properties and sacred sites). “Artifacts” include any objects manufactured or altered by humans. The following are common terms used to discuss the regulatory requirements and treatment of cultural resources:

- **Cultural resources** describe several different types of properties: prehistoric and historical archaeological sites; architectural properties such as buildings, bridges, and infrastructure; and resources of importance to Native Americans or other groups of people.
- **Historic properties** are defined by the National Historic Preservation Act (NHPA) as any prehistoric or historic district, site, building, structure, shipwreck, or object included on, or

eligible for inclusion on, the National Register of Historic Places (NRHP), including artifacts, records, and material remains related to such a property.

- **Historical resources** include buildings, sites, structures, objects, or districts, each of which may have historical, prehistoric, architectural, archaeological, cultural, or scientific importance, and is eligible for listing or is listed in the California Register of Historical Resources (CRHR) or a local register of historical resources. The CRHR also includes resources listed in or formally determined to be eligible for listing in the NRHP, as well as some California State Landmarks and Points of Historical Interest.

This section summarizes the cultural and historic settings of the general region within which the affected environment is located, and discusses in more detail the prehistoric and historic resources relevant to the study area.

**Prehistoric Period.** During the last major ice age, what is now San Francisco Bay was well above sea level, with today's underwater areas being an exposed valley of dry land. Within that valley, converging rivers drained through the Golden Gate and across the continental shelf toward the then Pacific coastline. Glacial melt began approximately 15,000 years ago, and meltwaters began filling San Francisco Bay around 10,000 to 11,000 years before present (B.P.). Around 8,000 B.P., marine waters rose to levels sufficient to enter San Francisco Bay. Sea levels rose rapidly until approximately 6,000 B.P., and have continued to rise more slowly since then (Moratto 1984).

San Francisco Bay, San Pablo Bay, the Carquinez Strait, Suisun Bay, the San Joaquin River and surrounding waterways, marshlands and uplands were used extensively by humans during prehistoric and historic times. Before circa A.D. 1770, around the time of the first major European contact, the San Francisco Bay and Delta regions were occupied by Miwok, Patwin, and Costanoan/Ohlone Native American people. The Costanoan/Ohlone population in 1770 has been estimated at 7,000. Archaeological remains related to the prehistoric occupation of the area are evidenced by hundreds of shellmounds and occupation sites that lined the shores of San Francisco, San Pablo, and Suisun Bays. Native people were also known to produce and use the naturally-occurring salt deposits that exist along San Francisco Bay. The locations of these shellmounds approximately follow the current shoreline, but also occur along major tributaries draining into the Bay (Moratto 1984).

Shellmounds are mounds or deposits containing shells, animal bones, and potentially human remains and other evidence of prehistoric settlement of an area. Many of the shellmounds known to be located around San Francisco Bay have been found in close relationship with marshy areas. A number of known shellmounds stand partially below current sea level, indicating that their accumulations began during lower water level occurrences in the past. Given the long duration for the bay water rise and human occupation of the shore zone, it is likely that earlier use and occupation sites, such as shellmounds, are present below current sea levels (Moratto 1984).

The configuration of the San Francisco Bay shoreline has also changed in the roughly last one hundred and fifty years due to deposition of gold mining sediments flowing downstream from hydraulic mining locations, agriculture, the narrowing of river channels through levee construction, construction of salt ponds, development of "man-made land," and more modern construction and fill near the shore. For example, it is estimated that 875 million cubic meters of sediment were deposited in the Bay between 1850 and 1914 as a result of mining in the Sierra Nevada foothills (Moratto 1984).

**Spanish Time Period.** Spanish explorers are said to have first visited the entrance to San Francisco Bay in 1769. Spanish explorers came into increasing contact with Native Americans in the first half of the 1770s as expeditions were led through the region. Travel from the sea into the Bay first occurred in 1775. Spanish exploration in the late 1700s and 1800s led to the establishment of permanent settlements along the coast of California, mostly in the form of missions (USACE and RWQCB 2015; USFW and CDFG 2008).

**Mexican Time Period.** In 1821 Mexico gained independence from Spain and California changed from Spanish to Mexican control. With this change in control came the relaxation of trade restrictions. Merchant ships, occasional whalers, and warships from the U.S. and Europe began freely entering the Bay. The change to Mexican independence brought new laws, administrators and a shift of power from missionaries to secular governors and ranching families. The decline of the missions allowed for the rise of extensive ranching along the California coast as well as in the Sacramento Valley area. What was then Native American land was divided into more than 500 land grants (i.e., Ranchos) distributed to prominent California families. Then followed a period of skirmishes and battles between the Mexican army and Native Americans. This and parceling of the land into Ranchos, along with epidemics of smallpox and malaria that spread through Native populations resulted in the further decimation of the Native population and culture (Paddison 2015; Sturtevant 1978; USACE and RWQCB 2015).

**American Time Period.** California became a part of the U.S. as a result of the Mexican-American War that ended in 1848. The Gold Rush (lasting from 1849 to approximately 1855) generated a large population increase of immigrants and gold seekers to California. The Gold Rush also resulted in a large increase in ships traveling into the Bay, with San Francisco becoming a major city and port. Various other cities also grew along the waterways within the Bay Area. Commercial whaling and salmon fishing began in the 1850s. Fishing and shrimping grew into major industries. Ferries became popular ways to travel throughout the Bay Area until the construction of train and car bridges, which caused people to switch modes of local travel (USACE and RWQCB 2015).

### KEY RESOURCES OF THE STUDY AREA

**Shipwrecks in San Francisco Bay.** Since its exploration by Spanish navigators began in 1769, San Francisco Bay and its associated waterways have been the site of numerous shipwrecks. The California State Lands Commission (CSLC) has created a database of more than 1,500 shipwrecks off the coast of California and within its bays and waterways (CSLC 2015). The database includes the approximate latitude and longitude and other available information for each shipwreck. The data describes potential resource locations, since exact locations for many of the shipwrecks may not be known. In addition, NOAA's Automated Wreck and Obstruction Information Center includes over 13,000 listed shipwrecks and obstructions (NOAA 2013). Lastly, the U.S. National Parks Service (2015) maintains a list of shipwrecks that are on the National Register of Historic Places.

All three databases were searched for any known shipwrecks located in the areas that could be affected by the alternatives. No shipwreck locations listed on the NRHP were reportedly located in the area of potential effects (APE) of the alternatives considered. The CSLC database identifies 172 shipwrecks within the counties bounded by the study area which sank between 1595 and about 1979, and 24 within the project vicinity. Two of these shipwreck locations are reported within 0.25-miles of the proposed APE. Even though some shipwrecks have been salvaged through time, the CSLC database does not indicate if such salvaging has taken place for any of the shipwrecks contained on its list of wrecks.

In addition, to the reported shipwrecks, USACE contracted a submerged cultural resource survey of portions of the proposed APE which is documented in a report titled *Report on a Nautical Archaeological Survey of Four Areas in the John F. Baldwin Ship Channel* (Sullivan and Allan 1996). The survey identified eight acoustic targets in the vicinity of the Pinole Shoal Channel that are believed associated with the schooner *Sagamore*, which sank in 1864. The potential wreck was designated as the Baldwin Channel Wreck but was not assigned a trinomial archaeological site number. Instead, the site was designated by the state with two primary numbers (07-002760 and 07-0598) due to its location along the boundary of two counties.

It is possible that many of the shipwrecks identified within the CSLC and NOAA databases were salvaged or intentionally demolished to reduce risks to ship traffic. Dredging has taken place in the Federal shipping channels for a number of years. Dredging may have removed or disturbed evidence of shipwrecks that potentially present within the study area; however, portions of the channel are not in active shoaling areas and may still contain intact cultural resources. A submerged cultural resource target cluster consisting of eight acoustic targets were identified as part of the Baldwin Channel Wreck site within the Pinole Shoal Channel. The wreck was located in the vicinity of the rocky obstruction just west of Pinole Shoal that is proposed for removal (07-002760 and 07-0598). These targets and the two other reported shipwreck locations may potentially be located on and/or within the bottoms affected by the alternatives are shown in **Table 2-15**.

**Table 2-15. A list of 24 historic shipwrecks reported within approximately 5-miles of the APE.**

### 2.2.12 ENVIRONMENTAL JUSTICE

The specific affected areas for Environmental Justice (EJ) impact analysis were determined in accordance with the Council of Environmental Quality’s (CEQ) guidance for identifying the “affected community.” This requires consideration of the nature of the likely project impacts and identification of an associated Area of Potential Effects (APE) within a corresponding unit of geographic analysis.

For the purpose of EJ analysis, the APE corresponds to the areas of effect associated with the specific environmental issues analyzed in this document. The APE includes communities (U.S. Census-designated places such as towns, cities, and neighborhoods) adjacent to the navigation channels: Tiburon, Corte Madera, Larkspur, San Rafael, Santa Venetia, Novato, Black Point – Green Point, Richmond, Bayview – Montalvin, Pinole, Hercules, Rodeo, Crockett, Vallejo, Benicia, Martinez, Bay Point, Pittsburg, Antioch, Oakley, Bethel Island, Country Club, and Stockton. The unincorporated community of Avon is heavily industrialized and does not have residents, so it is not a Census-designated community.

Census data describing residents of the communities in the APE are shown in **Table 2-16**.

In the study area, the communities of Richmond, Hercules, Vallejo, and Rodeo have a greater percentage of minority residents than the APE as a whole. Richmond also has a higher percentage Hispanic or Latino residents than the APE as a whole. Therefore, impacts that disproportionately affect residents of these communities more than other communities in the APE could constitute an EJ impact.

**Table 2-16. Characteristics of the Residents of the APE.<sup>1</sup>**

<sup>1</sup> APE = Area of Potential Effect (Consists of the communities of Tiburon, Corte Madera, Larkspur, San Rafael, Santa Venetia, Novato, Black Point – Green Point, Richmond, Bayview – Montalvin, Pinole, Hercules, Rodeo, Crockett,

Towns and Cities Comprising the APE	Percent Minority (Non-White) <sup>2</sup>	Percent Hispanic or Latino	Percent in Poverty <sup>3</sup>	Percent Under Age 18
Tiburon	12	5	5	25
Corte Madera	16	8	4	27
Larkspur	14	8	4	19
San Rafael	29	30	12	22

<sup>2</sup> Any person identifying as other than “one race, White”

<sup>3</sup> Source: U.S. Census Bureau 2013.

**Table 2-17** compares data describing residents of the APE to data describing residents of the surrounding 7-county region within which the APE is located and to the State of California as a whole. Based on the data, the APE does not have a greater proportion of residents who are children (e.g., under the age of 18) or living in poverty (e.g., family of 4 with a household income of \$23,550.00) compared to the surrounding 7-county region as a whole. The APE also does not contain a greater proportion of residents who are Hispanic or Latino, children, or living in poverty compared to California as a whole.

However, **Table 2-17** does show the APE has a greater proportion of residents who are Hispanic or Latino than the totality of the surrounding 7 counties. In addition, the APE has a greater percentage of residents who are minority compared to both the entire 7-county region and California as a whole. In summary, the APE is located in a part of the surrounding region that has a higher degree of minority and Hispanic or Latino residents.

**Table 2-17. Comparison of Residents of the APE to Residents of the Region and State.<sup>1</sup>**

Location	Percent Minority (Non-White) <sup>2</sup>	Percent Hispanic or Latino	Percent In Poverty	Percent Under Age 18
APE <sup>3</sup>	53	32	18	27
Surrounding Region <sup>4</sup>	44	26	16	26
California	42	38	17	25

<sup>1</sup> Source: U.S. Census Bureau 2013.

<sup>3</sup> APE = Area of Potential Effects

<sup>4</sup> Surrounding Region = Marin, Sonoma, Napa, Contra Costa, Solano, Sacramento, and San Joaquin Counties

### 2.2.13 NOISE

The study area deep draft channels are flanked by shorelines characterized by parks and open space, residential areas, industrial zones, bridges and some roads. The distance from the channel to the shoreline ranges from as little as 0.2 mile (at station 72+00 of the Bulls Head Reach alignment) to as many as 7.76 miles (at station 113+00 of the Pinole Shoal Channel alignment).

Existing noise producers in the channels and waterways include large ships, such as car carriers, other cargo ships, oil tankers, tug boats, barges, maintenance dredging equipment and recreational users, such as motor boats. Along the Contra Costa shoreline, railroad noise contributes to the ambient noise, until the train tracks reach the railroad bridge across the Carquinez Strait between the Cities of Martinez and Benicia. Noise-sensitive receptors along the study area route include residential areas and park users, such as those within the Point Pinole Regional Shoreline and Knox/Miller Regional Shoreline parks in Richmond, China Camp State Park in Marin County, and the Martinez Regional Shoreline Park. Recreational boaters may also be noise receptors in the study area.

Ambient noise levels along shoreline areas of Contra Costa County adjacent to the study area range from 60 to 65 dB (L<sub>dn</sub>) near roadways and trains, and 70 and 75 dB (L<sub>dn</sub>) adjacent to the two bridges (Contra Costa County 2005).

### 2.2.14 PUBLIC HEALTH AND ENVIRONMENTAL HAZARDS

**Hazardous Materials Sites.** Sites potentially containing hazardous materials were identified through database record searches for sites with known or potential hazardous waste and/or materials within the study area. This included a search of the California Department of Toxic Substances Control (CDTSC) EnviroStor database (CDTSC 2015), the State Water Resources Control Board (SWRCB 2015) GeoTracker database and the National Oceanic and Atmospheric Administration (NOAA) Office of Response and Restoration’s “Where we Work” database (NOAA 2015). These databases list 83 sites with an active, open or unidentified status within 1,000 feet of the proposed deepening channel shoreline.

**Hazardous Materials Transportation.** Various products, including hazardous materials, are transported on shipping routes that cross the San Francisco Bay and the Sacramento-San Joaquin Delta. Transportation of hazardous materials involves some risk of spillage and subsequent contamination of soil, water or sediments. Hazardous materials shippers and transporters must comply with specific requirements of 49 CFR 171, including proper classification, labeling, packaging and handling.

Detailed information on commodities shipped and routes taken is not readily available due to security and proprietary reasons. However, entities that transport certain types and quantities of hazardous materials are required by the Hazardous Materials (HM)-232 final rule (49 CFR 172) to develop and implement security plans, as administered by the U.S. Department of Transportation's (DOT's) Research and Special Programs Administration. Security plans are considered "security sensitive information," available only on a "need to know" basis to those with relevant responsibilities or appropriate security clearance (Batelle and Total Security. US n.d.; 49 CFR 172, Section 172.802[c]). While non-disclosure of information concerning materials and routes is not a specific requirement of HM- 232, it is a common feature of security plans (Coleman personal communication as cited in ICF International 2013).

Information on specific types and quantities of hazardous materials transported through shipping channels in the study area is limited to publicly available information. Typical cargos at the Port of West Sacramento include cement, bulk and bagged fertilizer, pelletized Kaolin clay and anhydrous ammonia (ICF International 2013). Commodities brought through the Port of Stockton include bulk materials, such as aggregate, coal, petroleum coke, ores, clay, sulfur and anhydrous ammonia (Port of Stockton 2010).

**Oil Production, Transport and Spills.** Oil has been imported along the John F. Baldwin Ship Channel since at least the late nineteenth century. There are currently five refineries in Northern California, four of which are located in the study area. Shell, Tesoro, ConocoPhillips and Valero own four refineries. The fifth, Chevron, is located nearby at the Port of Richmond. There are also nine terminals that receive oil within the study area. Crude oil is the commodity imported to the terminals, while petroleum products are exported from the terminals.

A single oil spill has been recorded in study area waters. On February 10, 2015, the Shell refinery in Martinez reported a spill of crude oil from a line undergoing hydrostatic testing. The release occurred near the seaward end of the Shell pier, where a fixed containment boom is maintained. Response contractors were on the scene before sunset and applied additional containment boom and deployed skimmers (NOAA 2015). In addition to that occurrence, there is a single recorded instance of an oil spill attributable to a 2007 vessel collision in the San Francisco Bay (well out of the study area), when the *Cosco Busan* container ship struck a San Francisco-Oakland Bay Bridge tower, spilling 53,000 gallons of fuel oil (NOAA 2015).

### 2.2.15 RECREATION RESOURCES

The San Francisco Bay area and Delta combine to form a unique geographic region that provides exceptional recreational opportunities including boating, fishing, hunting, hiking, biking, camping and wildlife viewing. Across the Bay and Delta, opportunities for water and shoreline recreation are provided by wetlands, wildlife refuges, state parks, shoreline parks and waterfront areas, and landing/launching facilities (BCDC 2008). There are no national parks located in the study area.

Population is the most important driver of the demand for recreational opportunities in the San Francisco Bay region, including the demand for waterfront-oriented recreation. It is estimated that there is a pool of nearly 9.0 million persons considered to be potential recreationalists within a reasonable travel distance of the Delta and San Francisco Bay area (Delta Protection Commission 2005). Recreational users originate from both within and outside of these areas. The majority of the recreational activities within the Delta are focused on the navigable waterways which are publicly accessible. Boating use totals more

than 6.4 million visitor days annually, and is composed of 2.13 million annual boat trips in the larger Delta-Suisun area (California Department of Water Resources 2007) [CDWR].

The existing supply of waterfront parks, beaches, 75 public fishing piers, regional trails, launching lanes and marinas in the San Francisco Bay area comprises a substantial part of the large, complex web of the region's recreational opportunities. The current waterfront park acreage in the region totals approximately 25,000 acres. The entire bay is relatively shallow, with narrow, deep channels near the Golden Gate Bridge and Carquinez Strait which tend to be maintained by tidal currents. Therefore, boating (including canoeing and sail boating), fishing, and windsurfing are common activities. There are 174 launching lanes (some ramps have multiple lanes) within the San Francisco Bay area, providing 18 percent of the State's boating facilities (BCDC 2006).

Most of the recreational facilities within the Delta are provided through private marinas and several thousand boat berths. Private facilities also provide launching facilities, recreational vehicle and tent camping, picnicking, restaurants, and bait and tackle shops.

Five fishing access/launching facilities owned by the California Department of Fish and Game and managed by Sacramento and Yolo Counties are located within the Delta. San Joaquin County provides land and water access at Westgate Park. Brannan Island State Recreation Area provides boat launching, camping, swimming, nature interpretation, and wind surfing. Hunting occurs mainly on private lands, although some hunting is allowed on state and federally owned lands and waterways (Delta Protection Commission 2015).

**Marin County.** Water-based recreational areas within Marin County include the San Pablo Bay National Wildlife Refuge, Marin Island National Wildlife Refuge, Hamilton Wetlands Preserve, and Corte Madera Marsh State Marine Park. Other recreational opportunities include camping, picnic areas, fishing access, trail access, and various preserves and state parks (e.g., Hamilton Wetlands Preserve, Tiburon Uplands Nature Preserve, China Camp State Park and Angel Island State Park). There are 17 public and private marinas within the study area channels that provide access to the Bay (CA Division of Boating and Waterways 2015).

**Contra Costa County.** Recreation areas within Contra Costa County include Browns Island (within the City of Pittsburg), Winter Island, Jersey Island, Bradford Island, Webb Tract, Holland Tract, Palm Tract, Orwood Tract, Knightsen area, and Coney Island, Bethel Island, Hotchkiss Tract and Veale Tract. Water areas include Big Break, partially owned by East Bay Regional Park District, Franks Tract and Clifton Court Forebay (Delta Protection Commission 2005). Access to these areas is provided by approximately 40 public and private marinas and launch facilities.

Other recreational opportunities include camping, picnic areas, fishing access (at a few marinas and at several sites created specifically for fishing), trail access, and three public parks (Antioch/Oakley Regional Shoreline, Barbara Price Marina Park and Riverview Park). In addition, Franks Tract State Recreation Area and Big Break allow public hunting access during waterfowl hunting season. The California Department of Fish and Game's Rhode Island Wildlife Area also allows fishing and hunting from boats only. In addition to these public opportunities, there are private hunting clubs operating on Winter Island and Veale Tract (Delta Protection Commission 2005).

**Solano County.** Solano County's recreational areas include Hastings Tract, Prospect Island, and Ryer Island. Waterways in the County include Barker Slough, Cache Slough, Hastings Cut, Hoss Slough, Lindsey Slough, the Sacramento River, and the Sacramento Deep Water Ship Channel. Solano County has four marinas (Arrowhead Harbor, Snug Harbor Resort, Hidden Harbor Marina and Delta Marina Yacht Harbor) and five launching facilities providing access to the Delta and nearby areas. All marinas and launching facilities are located along or near a confluence of the Sacramento River. Other recreational opportunities in Solano County include camping, fishing access, picnic areas, trail access, and one public park (Delta Protection Commission 2005).

## 2.2.16 SOCIO-ECONOMICS

The socio-economics of the surrounding community area are summarized in this section. The factors used to describe the demographic and socioeconomic environment include recent trends in population, as well as employment and income. More detailed information can be found in **Appendix D - Economic Analysis**.

### 2.2.16.1 POPULATION

California is ranked as the largest state in terms of resident population as of 2016, with 37.3 million residents. Between the years 1990 and 2010, California's population increased by 25.2%, from 29.8 million to 37.3 million people, which is higher than the national growth over the same historical period. All counties within the immediate economic regions of San Francisco Bay have seen a growth in population according to 2010 census data.

Census data from 2010 show increases in population across the bay area. Specifically, Contra Costa County (10.6 percent), Solano County (4.8 percent), and Marin County (2.1 percent). San Francisco is the largest city in the bay area, with a population of more than 800,000, followed by Stockton (291,707), Concord (122,067), and Vallejo (115,942).

Population projections (California Department of Transportation) forecast an increase of 8.12% from 2020 to 2030 and 6.52% from 2030 to 2040.

### 2.2.16.2 EMPLOYMENT AND INCOME

California private sector annual employment in 2014 totaled 13.5 million, with average annual wage of \$69,880. Of the major industry sectors within the State, the Health Care and Social Assistance sector employs the most persons, with 2,000,372 employees. Retail Trade and Accommodation and Food Services follow closely behind in total employed persons, with 1,623,371 and 504,176 employees, respectively. County industry sectors yield employment distributions similar to the State level, with few exceptions.

Of the private sector industries, Mining, Quarrying, and Oil and Gas Extraction sector employees are paid the highest in average annual earnings, slightly over \$138,000, followed by Information sector employees, earning on average \$136,214. The average annual earnings of Mining, Quarrying, and Oil and Gas Extraction sector employees nearly doubles the average annual wage earnings across all industry sectors. In December of 2014, the unemployment rate in California was 7 percent, higher than all but two other locations in the U.S. (Mississippi and Washington, D.C.). In October of 2015, California experienced the

largest job growth in the country, adding nearly 41,200 new jobs and bumping its unemployment rate down to 5.8 percent.

### 2.2.16.3 SPECIFIC SOCIO-ECONOMICS IN THE STUDY AREA

According to the 2010 U.S. Census, the Bay Area and the State of California have higher percentages of minority populations relative to the total United States population. Within the Bay Area, approximately 55 percent of the population identified as White, 8.3% of the population identified as Black or African American, 18.5 percent of the population identified as Asian, and 11.1 percent of the population identified as Other. San Francisco County contained the highest percentage of minority populations relative to other area counties.

As a whole, the Bay Area in 2010 had a higher median age than the State of California and equaled the median age for the United States. Marin County and Contra Costa County all had median ages higher than or equal to the State and National median age. Solano County's median age was higher than the State level, but lower than the National level.

All counties had higher median household (2010 Census) incomes than the State of California.

Marin County had the highest median household income and per capita income. Marin County, Contra Costa County, and Solano County all had lower percentages of people living below poverty level compared to the State of California.

Marin County and Contra Costa County had higher percentages of people over the age of 25 that earned a Bachelor's Degree or higher when compared to the State of California and the United States. Solano County had lower percentages of people over the age of 25 that earned a Bachelor's Degree or higher, at 24.3 percent and 18.1 percent, respectively.

### 2.2.16.4 ECONOMIC SPENDING

Maritime infrastructure and recreation are the economic spending components included in this analysis due to their potential to be impacted.

**Maritime Infrastructure.** The major ports in San Francisco Bay include the ports of San Francisco, Oakland, Redwood City and Richmond. Contra Costa's Northern Waterfront includes ports and marine terminals on San Pablo Bay, Carquinez Strait, Suisun Bay and the Sacramento-San Joaquin River. The river ports include the Port of West Sacramento (79 nautical miles from the Golden Gate Bridge through the San Francisco Bay and the 30 foot deep Sacramento Ship Channel). The river ports are broadening their base away from their heavy dependence on construction materials by developing new export and import operations (Craft Consulting Group and Cambridge Systematics 2013) [CCG&CS].

The Bay Area ranks as the fourth largest exporting region in the U.S. in terms of tonnage. While the Port of Oakland handles 82 percent of the region's maritime trade, the Bay Area's ports at Richmond, Benicia, San Francisco and Redwood City, plus the inland port at Stockton, also handle significant maritime trade. The Port of Stockton is the primary Northern California port for bulk cargo, with the remainder handled at San Francisco and Redwood City. Richmond and Benicia handle mostly automobiles and trucks. Although it is a substantial maritime center, Northern California handles only 10.7 percent of West Coast

tonnage, which primarily passes through the Port of Los Angeles (31.9 percent) and the Port of Long Beach (25.6 percent) (CCG&CS 2013).

**Recreation.** Recreational opportunities provide a large economic benefit to the region and to the State as a whole. Annual gross receipts in the Delta are over \$247 million by boaters and over \$186 million by anglers, as reported in the 1998 Delta Recreational User Survey report prepared by the U.S. Department of Agricultural and Resource Economics for the Delta Protection Commission and the Department of Boating and Waterways. These two recreation groups also impact spending on other industries (e.g., groceries, restaurants, gas stations and drugstores) in connection with their boating and fishing activities. When a multiplier was incorporated into the model to account for actual expenditures plus value-added dollars in the Delta, the annual estimated figures rose to over \$444 million for boaters and over \$336 million for anglers.

### 2.2.17 NATIVE AMERICANS

USACE has initiated consultations with Native American tribes with interests in the project area including Amah Mutsun Tribal Band of Mission San Juan Baptista, Cloverdale Rancheria of Pomo Indians, Coastanoan Rumsel Carmel Tribe, Cortina Rancheria Kletsel Dehe Band of Wintun Indians, Dry Creek Rancheria Band of Pomo Indians, Federated Indians of Graton Rancheria, Indian Canyon Mutsun Band of Costanoan, Kashia Band of Pomo Indians of the Stewarts Point Rancheria, Lytton Rancheria, Middletown Rancheria, Mishewal Wappo Tribe of Alexander Valley, Muwekma Ohlone Indian Tribe of the SF Bay Area, North Valley Yokuts Tribe, Ohlone Indian Tribe, United Auburn Indian Community of the Auburn Rancheria, Wilton Rancheria, and Yocha Dehe Wintun Nation. These tribes have a long history of living in the vicinity of the project area and maintain a strong connection to the region through continued use. In addition to the federally-recognized tribes, additional tribes who are not federally recognized have expressed a general interest in projects in the general vicinity of the study. The following tribes have provided responses to letters sent asking for input on the project on January 31, 2019 (see **Appendix H, Cultural Resources Correspondence**): the United Auburn Indian Community of the Auburn Rancheria, Wilton Rancheria, the Indian Canyon Band of the Costanoan, Lytton Rancheria, Northern Valley Yokut, Wilton Rancheria, and the Yocha Dehe Wintun Nation.

## 2.3 NAVIGATION ENVIRONMENT

### 2.3.1 VESSEL USE AND OPERATION

#### EXISTING CONDITIONS

Vessel traffic movement in the study area is managed by the San Francisco Bar Pilots, in coordination with the U.S. Coast Guard's Vessel Traffic Services (VTS). A bar pilot will board all deep draft vessels calling on ports and harbors, beginning at the offshore sea buoy, before vessels enter the San Francisco Bay through the -55 foot MLLW Main Ship Channel.

Once aboard, the pilot updates VTS with location and destination information, as well as any safety concerns, as necessary. In turn, VTS keeps pilots alert of other vessels, including other deep draft vessels, ferries, recreational vessels, tugs, and dredges navigating in the Bay. This close coordination between the bar pilots and VTS helps maintain safe navigation in the Bay Area. Early coordination between shipping companies and the bar pilots ensures that deep draft vessels arrive at the pilot station with an appropriate

draft meeting under-keel regulations and at specific times such that vessels having deeper drafts can take advantage of prevailing tidal conditions to "ride the tide" if necessary.

Astronomical tides in the San Francisco Bay area are mixed, semi-diurnal, with two highs and two lows of unequal height occurring each lunar day. The largest changes in water level typically occur as the tide falls from higher high to lower low water, an event generally requiring 7 to 8 hours. Tidal influence causes water in the San Joaquin River to flow out to sea during ebb tide, while reversing flow upstream towards Stockton during flood tide.

In the bay area, a 2 foot under-keel<sup>3</sup> clearance is required for non-hazardous material, and a 3 foot under-keel clearance is required for hazardous material (i.e., petroleum). This safety measure helps reduce the risk for a vessel to run aground while transiting the channel. Considering prevailing tidal conditions, the shallowest portion of the channel which the vessel must navigate determines the operating draft of each vessel.

Daylight restrictions, fog conditions, excessive shoaling, and other factors further restrict the maximum allowable draft of vessels over the course of the year. Maximum vessel drafts using the channels over the past 5 years have averaged about -33.5 feet for bulk and general carriers, and -29.5 feet for liquid tankers. These maximums take into account the required under-keel clearances for the different vessel types.

Often deep draft vessels will take advantage of tides higher than MLLW to allow for deeper drafts of ships transiting the channels. For example, an oil tanker with a required 3 foot under-keel travelling to an oil terminal in the vicinity of Carquinez Strait may arrive at the offshore pilot station with a draft of -37 feet MLLW, to navigate safely through the Pinole Shoal Channel, the tanker may traverse the channel on a high tide of at least 5 feet above the -35 foot MLLW channel depth (or limiting shoal) – this is referred to as "riding the tide". If a vessel has to wait for a high tide to safely navigate a channel with the appropriate under-keel clearance, this is referred to as a "tidal delay."

In general, the longest tidal delay for most vessels calling at the refineries near Carquinez Strait is approximately 12 hours, although there are reports of some vessels having to wait nearly 24 hours for the higher of the two daily high tides before moving through the channels. Typically, shippers try to reduce tidal delays by coordinating early and often with the bar pilots to ensure that they know what the anticipated operating depth is when they plan to arrive. The bar pilots will not only provide the anticipated operating depth of the day the vessel will arrive, but also the timeframe the respective vessel must be at the offshore pilot station to successfully use the tide to accommodate the vessel's draft. Typically, the timeframe is only an hour. Outgoing vessels also take advantage of tides to move fully loaded vessels.

Lightering<sup>4</sup> of petroleum products is no longer allowed in San Francisco Bay. Light-loading refers to vessels carrying less cargo than their design allows in order to reduce their draft so that they can safely access a channel.

The operational strategies described above (riding the tide and light loading) are used by the deep draft vessels that call at the oil refineries located throughout the study area. They are all economically

---

<sup>3</sup> Under-keel clearance is the vertical difference between the lowest protruding section of the hull and the minimum actual channel depth.

<sup>4</sup> Lightering is the process of transferring cargo between vessels of different sizes to reduce a vessel's draft in order to enter port facilities.

inefficient, causing loss of time and money. More detailed information about navigation economics can be found in Section 2.5.

### FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

These procedures for vessel operations, and inefficiencies, will continue to occur in the future without-project condition.

#### 2.3.2 SEA LEVEL CHANGE

To incorporate the direct and indirect physical effects of projected future sea level change on design, construction, operation, and maintenance of projects, the U.S. Army Corps of Engineers (USACE) has provided guidance in the form of Engineering Regulation, ER 1100-2-8162 and Engineering Technical Letter (ETL) 1100-2-1. Three scenarios are required by Engineering Regulation (ER) 1100-2-8162: a Baseline (or “Low”) scenario, which is based on historic sea level rise and represents the minimum expected sea level change; an Intermediate scenario; and a High scenario representing the maximum expected sea level change.

### EXISTING CONDITIONS

According to the Oceanic and Atmospheric Administration tide gauge (9414290) at San Francisco, California, the historic sea level rise rate was determined to be 0.00659 feet per year.

### FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

Following procedures outlined in ER 1110-2-8162 and ET 1100-2-1, low, intermediate, and high sea level rise values were estimated over the life of the project using the official USACE sea level change calculator tool. Projections for sea level rise are based on a start date of 1992, which corresponds to the midpoint of the current National Tidal Datum Epoch of 1983-2001. In the future without-project conditions, sea level rise could be expected to increase by 0.5 feet (low), 1 foot (intermediate), and 2.7 feet (high) by year 2070 with respect to the above mentioned present local mean sea level tide datum. The potential impacts of rising sea level include increased salinity intrusion into the Sacramento-San Joaquin Delta, overtopping of waterside structures, increased shoreline erosion, and flooding of low lying areas.

#### 2.3.3 STORM SURGE

### EXISTING CONDITIONS

An excerpt from the USACE Deep Water Shipping Scenario Report (2011) predicted water stage at San Francisco Fort Point NOAA station (9414290) for the baseline scenario under 2007-2008 historic conditions. A tidally-averaged stageplot noted potential for existing storm surge within the study area of almost 1.64 feet (0.5 m), which was used under the baseline scenario.

### FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

Storm surge would be expected to remain approximately the same in the future without-project, but could increase with increased sea level rise.

## 2.4 BUILT ENVIRONMENT

### 2.4.1 EXISTING FEDERAL PROJECT

#### EXISTING CONDITIONS

The existing Federal navigation project within the study area is described in this section, and portions of the project proposed for deepening are detailed in **Table 2-18**. Other areas of the existing channel not presented below have naturally deep water at 39 feet MLLW or more. Pinole Shoal Channel is a length 10.3 miles, and the Bulls Head Reach portion of Suisun Bay is 2.9 miles long. The high shoaling area (referred to in this report as the advance maintenance area, and the area where the proposed sediment trap would be) in Bulls Head Reach is currently deepened to -37 feet MLLW + 2 feet of overdepth annually. Maintenance dredging events for these areas are described in the next section.

**Table 2-18. Existing Federal Project Dimensions Within the Study Area.**

Channel	Length (feet)	Existing	
		Depth (feet MLLW)	Width (feet)
Pinole Shoal Channel	54,800	-35	600
Bulls Head Reach (in Suisun Bay)	15,900	-35	300
Bulls Head Reach Advance Maintenance Area	2,600	-37	300

#### FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

In the future, these channels will continue to have the projects depths as stated above.

### 2.4.2 OPERATIONS AND MAINTENANCE (INCLUDING HIGH SHOALING AREAS)

#### EXISTING CONDITIONS

USACE maintains the navigability of Federal navigation channels to either the authorized depth or a lesser regulatory depth. The regulatory depth is the depth to which environmental compliance has been completed. Accumulated sediments settling in the channels can impede navigability in the study area channels. Maintenance dredging removes this sediment and returns the channels to regulatory depths to provide safe, reliable, and efficient waterborne transportation systems. For the foreseeable future, hopper dredging will continue to be used to maintain Pinole Shoal, whereas clamshell dredging will be used to maintain Bulls Head Reach as has been required by USFWS since 2017.

**Table 2-19 Maintenance Dredging within the Study Area.**

Channel	Dredge Type	Typical Dredging Frequency (years) <sup>5</sup>	Median Volume Dredged Annually (CY) <sup>6</sup>	Federal Placement Site
Pinole Shoal Channel	Hopper	2	255,000	SF-10 (San Pablo Bay)
Bulls Head Reach	Clamshell	1	25,000	SF-16 (Suisun Bay)
Bulls Head Reach Advance Maintenance Area	Clamshell	1		SF-16 (Suisun Bay)

*HIGH SHOALING AREA IN BULLS HEAD REACH*

The Bulls Head Reach advance maintenance area portion of the Suisun Bay Channel begins approximately 1 mile south of the Interstate 680 Benicia-Martinez Bridge and extends east approximately 3 miles to the Avon Wharf.

USACE typically elects to perform advance maintenance every year in this area because it shoals faster than the annual dredging cycle, and it is essential for USACE to maintain the utility of the channel as long as possible before needing to address any shoaling issues outside of the work windows established by the Long Term Management Strategy (LTMS) Plan within which USACE may conduct maintenance dredging activities so as to minimize impacts to listed species and species of concern. Within the study area, maintenance dredging is constrained for environmental reasons to the period between June and November in the West Richmond and Pinole Shoal channels, and to the period between August and November in the Bulls Head Reach.

Since 2000, emergency dredging actions have been performed in Bulls Head Reach outside of the regular maintenance window with an average frequency of approximately 3 years. Beginning in 2012, the high shoaling area within Bulls Head reach was deepened for advance maintenance to -37 ft MLLW plus 2 ft of overdepth and since then, emergency dredging outside of the scheduled O&M dredging has not been required – however, annual dredging of this advance maintenance area still occurs, and is performed as described below.

For the immediate future, hopper dredges will no longer be permitted to dredge in the Suisun Bay Channel, including Bulls Head Reach, because of the presence of delta smelt, which is a listed endangered species. Therefore, annual advance maintenance dredging actions will be performed using clamshell dredge plants. Currently, each annual advance maintenance effort must be consulted and coordinated with the environmental resource agencies and the Major Subordinate Command (South Pacific Division) for authorization and approval. This effort can take two to three months to complete at an annual cost of approximately \$75,000 in labor for all involved, and at a cost of \$1,000,000 for mobilization and demobilization (not including the cost of the removal of the material itself).

<sup>5</sup> Note that this dredging frequency is meant to capture existing conditions. Pinole channel is currently dredged every two years; however, prior to 2017, it was dredged annually.

<sup>6</sup> Median Annual Maintenance Volumes from Fiscal Year 2005 to 2014.

### FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

Maintenance dredging of the channels would continue to occur at the same frequency and would generate the same volumes of dredged material as under the existing conditions, with additional time and cost spent for each event as described above. Maintenance dredging will continue to occur annually at Bulls Head Reach and every two years at Pinole Shoal to maintain the current depth of -35 feet MLLW + 2 feet of overdepth. Maintenance dredging should continue to produce annual volumes of dredged sediments similar to those shown in **Table 2-19**, with the dredged sediments continuing to be disposed in a similar fashion as is presently done.

For the high shoaling area in Bulls Head Reach, advance maintenance dredging actions will be performed annually using clamshell dredge plants (to -37 feet MLLW + 2 feet of overdepth), with emergency maintenance events outside of planned maintenance dredging if needed.

### 2.4.3 DREDGED MATERIAL PLACEMENT/BENEFICIAL REUSE

#### EXISTING CONDITIONS

USACE is a partner in the Dredged Material Management Office (DMMO) along with the San Francisco Bay Regional Water Quality Control Board (Water Board), San Francisco Bay Conservation and Development Commission (BCDC), State Lands Commission, and the U.S. Environmental Protection Agency (USEPA). The DMMO was created as a recommendation of the 2001 LTMS to coordinate dredging and dredged sediment placement and placement within San Francisco Bay. The LTMS was approved in 2001 and set goals for beneficial reuse and in-Bay open water placement of dredged material.

In April 2015, USACE and the Water Board completed an Environmental Assessment and Environmental Impact Report for Maintenance Dredging of the Federal Navigation Channels in San Francisco Bay, Fiscal Years 2015-2024 (Maintenance Dredging EA/EIR). That document is intended to fulfill NEPA and CEQA requirements for maintenance dredging of the Federal navigation channels in San Francisco Bay for the Federal fiscal years 2015 through 2024.

#### **POTENTIAL BENEFICIAL REUSE SITES**

In addition to using dredged sediment to restore ecosystems in the Delta, a combination of existing and newly permitted beneficial reuse sites as well as existing and new upland dredged material placement sites used by USACE and the Port of Stockton for annual maintenance dredging events can be considered.

**CULLINAN RANCH TIDAL RESTORATION SITE.** Cullinan Ranch is a beneficial reuse site owned by the USFWS. Once restored, the site will become part of the larger San Pablo Bay Wildlife Refuge. The site is fully permitted and has been accepting dredged material from Federal and non-Federal maintenance dredging projects since 2013. The site consists of diked baylands and was used for agriculture until the late 1980s. Following diking and draining the site, much of the land lost up to 6 feet of elevation as a result of sediment deposition, soil compaction, and loss of organic matter. Dredged material is being used to raise site elevations for wetland restoration. Cullinan Ranch currently has capacity of approximately 2.8 million cubic yards of dredged material, but, it is in the process of amending the permit to increase the capacity to 9 million cubic yards. The Cullinan Ranch Tidal Restoration Site is located immediately adjacent to State

Highway 37. The southern off-loader location is within 200 feet of the Highway 37 Mare Island Bridge over the Napa River, with the northern off-loader location being approximately 750 feet north of the Mare Island Bridge.

Details on the purpose and need, design, construction requirements, and environmental impacts are provided in the Cullinan Ranch Wetland Restoration Site's EIS/EIR (USFWS and CDFW 2008; CSLC 2012). This GRR/EIS incorporates the beneficial reuse site NEPA documents by reference and therefore does not provide further details regarding the construction activities associated with restoration construction or off-loading dredged material.

**MONTEZUMA WETLANDS RESTORATION PROJECT.** Montezuma Wetlands restoration site is an approximate 2,400-acre privately-owned upland beneficial reuse site that has been receiving dredged material from Federal and non-Federal dredging Projects since 2001. It is located on the eastern edge of Suisun Marsh, west of Collinsville, in Solano County. The purpose of the site is to restore approximately 1,800 acres of tidal wetlands, seasonal wetlands, intertidal ponds, vernal pools, and upland buffer zones. Montezuma is a fully permitted ecosystem restoration and beneficial reuse site. Ground elevations have subsided by up to 10 feet and dredged material is used to raise site elevation such that restoration can occur. The site has a current capacity for approximately 12 million cubic yards of dredged material and can accept both cover and non-cover material.

Dredged material scows having a capacity of 4,000 to 5,000 cubic yards would be transported anywhere from 16 to 32 miles from the area of deepening to the off-loader anchored at the mouth of Montezuma Slough adjacent to the site. Implementation of the project could deliver sediment to the Montezuma off-loader. The off-loader is located approximately 100 feet offshore of the southeastern levee of the Montezuma site, approximately 0.5 mile east of the mouth of Montezuma Slough and 0.2 mile north of Chain Island. The hamlet of Collinsville, which contains several residences, is located approximately 1,900 feet east of the off-loader location. Recreational boaters are likely to pass by this site, and the Department of Water Resources Collinsville Day-Use area is about 2 miles northwest of the off-loader location. In the area of the Montezuma Wetlands, ambient noise, consisting of nearby roadway noise, is estimated to be less than 60 dB. (Solano County 2015). The off-loader would pump the slurry from the scows into the designated cells within the Montezuma site. The water used to make up the slurry would be pumped from Montezuma Slough. The Montezuma site is permitted to draw water from Montezuma Slough and discharge any water used during the process of off-loading dredged material back into the bay water via Montezuma Slough, provided it meets the site's waste discharge requirements. Once dredged material is off-loaded to the site, it would be placed in cells where it would be available for onsite ecosystem restoration.

The Montezuma Wetlands Restoration Site is responsible for all environmental impacts associated with off-loading, placing, and managing the dredged sediment. Details on the purpose and need, design, construction requirements, and environmental impacts are provided in the Montezuma Wetland Restoration Site's EIS/EIR (USACE and SCDEM, 1998). This GRR/EIS incorporates the NEPA analysis of the beneficial reuse sites by reference and therefore does not provide further details regarding the construction activities associated with restoration construction or off-loading of dredged material; the reader is referred to the Montezuma EIS/EIR for that information.

**DELTA ISLANDS RESTORATION SITE.** USACE and the California Department of Water Resources (DWR) propose to restore approximately 340 acres of intertidal marsh habitat in the Sacramento-San Joaquin River Delta (Delta). The restoration work would involve placing dredged material into the shallow open water of a

flooded Delta island and planting aquatic vegetation over an estimated 10-year period to create 340 acres of intertidal marsh in an area now lost to land subsidence. The Delta Islands converted into farmland until a levee break in 1928 inundated the island. Since then, Big Break has remained unvegetated open water.

The Final EIS can be found here:

[https://www.spk.usace.army.mil/Portals/12/documents/civil\\_works/Delta/DeltaStudy/FinalEIS/Delta\\_Islands\\_Final\\_Feasibility\\_Report-EIS\\_Sep2018.pdf?ver=2018-09-14-162532-197](https://www.spk.usace.army.mil/Portals/12/documents/civil_works/Delta/DeltaStudy/FinalEIS/Delta_Islands_Final_Feasibility_Report-EIS_Sep2018.pdf?ver=2018-09-14-162532-197). The Recommended Plan in the Delta Islands study include three sources of material for subsidence reversal: direct placement from O&M dredging operations, previously dredged stockpiled material, and a gross assumption of trucking/barging similar material from a 30 mile radius. All material sourced from direct placement from O&M dredging operations is included in the Recommended Plan.

### FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

The future without-project would not contribute sediment to the beneficial reuse sites. The sites would continue to accept material from other dredging projects throughout the area.

#### 2.4.4 CHANNEL USERS

### EXISTING CONDITIONS

The channels in the study area serve crude oil imports and refined product exports to and from facilities located on the shoreline of Carquinez Strait. Channel users include seven petroleum related facilities (oil refineries and tank farms), one marine terminal, and a sugar factory. The nine channel users are described below:

- **Phillips 66, Oleum Dock, Rodeo:** Phillips 66 Oleum operates three docks located in the waters off Rodeo, California, at the eastern end of the Pinole Shoal Channel. Crude oil is received by pipelines from California oil fields and also from tankers. The facility has a total capacity of 1 million barrels of crude oil and 2.9 million barrels of petroleum products. The dock has three berthing areas totaling about 2,500 feet. The berths can accommodate vessels up to 1,000 feet long with depths up to -38 feet MLLW. Crude oil pipelines extend from the dock areas to 45 steel storage tanks.
- **NuStar Energy, Selby Dock, Rodeo:** NuStar Energy is a privately owned trans-shipper of petroleum products located in Crockett, California. NuStar Energy does not own products shipped through the facility. Rather, it warehouses products for its customers. The facility has 24 storage tanks with a capacity of 3.04 million barrels per day. Crude oil is delivered to refineries through the Kinder Morgan pipeline system and by sea. It operates one dock for off-loading petroleum products to storage tanks. The dock has one berth with a draft of -45 feet MLLW and can accommodate vessels up to 831 feet long and 100,000 dead weight tons. NuStar Energy is also serviced by trucks and rail.
- **C&H Sugar, Port of Crockett:** C&H Sugar is located east of the Carquinez Bridge on the southern shore of Carquinez Strait, in Crockett, California. The port contains five berths that can accommodate vessels up to 750 feet long with depths up to -36 feet MLLW. It receives unrefined sugar and ships packaged refined sugar. The current capacity is approximately 112 thousand tons of sugar. The facility is also serviced by the Union Pacific Railroad.

- Shell Oil Refinery, Martinez:** Shell Oil Refinery is located on approximately 1,100 acres along the southern shore of Carquinez Strait in Martinez, California. The refinery has a tanker and barge petroleum loading and unloading facility that imports and refines crude and exports refined petroleum products. It converts approximately 165,000 barrels of crude oil per day into gasoline, jet fuel, diesel, petroleum coke, industrial fuel oil, liquefied petroleum gas, asphalt, and sulfur. The docking facilities provide four berthing areas. Berths 1 and 2 are on the channel side and are currently in operation. The berths can accommodate vessels up to 1,000 feet long that draw up to -39 feet MLLW. Berths 3 and 4 are on the south side of the dock (inland side) and not currently maintained.
- Tesoro Amorcó Marine Oil Terminal, Martinez:** Amorcó Marine Oil Terminal is owned and operated by Tesoro Refining and Marketing Company. The terminal is a tanker and barge petroleum unloading facility (i.e., import only) used by Golden Eagle Refinery, located in Martinez, Contra Costa County, California. The terminal imports crude oil to Tesoro's Amorcó Tank Farm immediately upland where it later is transferred to Tesoro's Golden Eagle Refinery for refining. The single berth dock is approximately 1,130 feet long by 150 feet wide with a depth of up to -40 feet MLLW. The terminal can accommodate up to 190,000 dead-weight ton (DWT) vessels with displacements up to 200,000 DWT. Annual ship and barge traffic averages about 69 vessels per year. The current throughput of the terminal is 16.9 million barrels.
- Plains All American Terminal, Martinez:** The Plains All American Oil Terminal is a 225-acre site located on the south shore of Carquinez Strait, in Martinez, California. The oil terminal owns and operates the Shore Terminal docks in Martinez. The dock is a single-vessel berth with associated pumps and pipelines to transport crude to upland storage tanks and refinery. The dock is approximately 100 feet long, 40 feet wide, with a -38 foot MLLW berthing area that operates as a barge and tanker loading and unloading facility. The dock can currently handle vessels up to 950 feet long and 150,000 deadweight tonnage (DWT) displacements.
- Tesoro Avon Marine Terminal:** Tesoro Avon Marine Terminal is owned and operated by Tesoro Refining and Marketing Company (Tesoro). The terminal is a tanker and barge petroleum export facility associated with the Golden Eagle Refinery, located in Contra Costa County, California. The facility exports refined petroleum products, including premium fuel oil, gas oil, diesel, and cutter stock, from the refinery to tanker vessels for export. Although the Avon terminal is a multi-berth terminal facility consisting of two berths (Berth 1 and Berth 2), the terminal currently supports only Berth 1. The docking facility is approximately 1,520 feet long and ranges from 20 to 80 feet wide, with a depth of -40 feet MLLW. The terminal can accommodate vessels up to 113,635 DWT with displacements of up to 102,600 long tons. Annual ship and barge traffic averages 124 vessels per year (between 2004 and 2013) and the throughput ranges from about 5.1 to 12.8 million barrels per year.
- Benicia Port Terminal Company AmPorts:** The Port of Benicia is located in the Benicia Industrial Park, immediately west of the Martinez Bridge. It is a small port (640 acres) owned and operated by AMPORTS, one of North America's largest auto processors, processing more than 1 million vehicles each year. The port also provides break bulk service. The port is located near rail service. It can handle up to three -38 foot deep MLLW draft vessels along its 2,400 foot long wharf.

- **Valero Benicia Refinery:** Valero Refinery is located on the northeastern shore of Carquinez Strait, in Benicia, Solano County, California. The facility currently processes crude oil received by pipeline and marine tanker and barge vessels. It also has significant asphalt production capabilities, producing 25 percent of the asphalt supply in northern California. Currently, Valero refines domestic crude from the San Joaquin Valley (delivered by pipeline) and Alaska North Slope (delivered by tanker or barge), as well as foreign sour crude. The refinery has a throughput capacity of 170,000 barrels per day. The dock has a berthing length of 1,100 feet and a depth of -32 feet MLLW

#### FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

These channel users will continue to use the channels in the future without-project conditions.

### 2.4.5 MARITIME INFRASTRUCTURE WITHIN THE STUDY AREA

#### EXISTING CONDITIONS

Major ports located within the study area include the Ports of Richmond and Benicia and the Contra Costa County Northern Waterfront. The Port of Stockton is also a major port whose customers utilize these navigation channels, although port facilities are located at the terminus of the Stockton Deep Water Ship Channel, outside the area of proposed improvements.

**Port of Richmond.** The Port of Richmond is located approximately nine miles northeast of the Golden Gate Bridge on the eastern shore of San Francisco Bay. The Port encompasses five city-owned terminals and ten privately owned terminals for handling bulk liquids, dry bulk materials, metals, vehicles and break bulk cargoes. In 2008, the Port handled 19 million short tons of cargo, primarily in the form of liquid petroleum. In recent years, the Port has expanded its dry bulk, break bulk and containerized cargo handling capabilities and has increased its automobile processing facilities. It ranks number one for ports in San Francisco Bay in vehicles and liquid bulk. In addition to these general commodities, the Port can also handle dry-bulk, break bulk and containers. The Port is connected to a sophisticated rail network served by four major rail companies (CCG&CS 2013).

**Port of Benicia.** The Port of Benicia is a privately owned and operated port located in Solano County. The Port specializes in handling bulk goods such as agricultural products and motor vehicles. There is direct port access to I-680 and I-780 interstate freeways; UP Rail service; a dockside water depth of -38 feet and a 2,400 foot long deep water pier. The Port also has an oil terminal for the Valero oil refinery at Benicia (CCG&CS 2013).

**Contra Costa County Northern Waterfront.** The Northern Waterfront is located between the Port of Richmond on the west and the ports of West Sacramento and Stockton on the east. Along this stretch of the channel from the Carquinez Strait to Suisun Bay and the Delta there are a number of marine terminals and wharfs. These facilities are privately owned and primarily serve the adjacent manufacturing operations including: C&H sugar refinery in Crockett; Tesoro and Shell at Martinez and Phillips 66 in Rodeo; and Mirant power plant, Dow chemical plant, and the USS-POSCO's steel-coil processing plant in Pittsburg (CCG&CS 2013).

FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

These ports will continue to use the channels in the future without-project conditions.

2.4.6 BRIDGES

EXISTING CONDITIONS

Vehicle traffic in the study area is limited to five bridges that cross the Central San Francisco Bay, the Carquinez Strait and the San Joaquin River (**Table 2-20**). The vehicle bridges are all of fixed height, ranging between 135 to 148 feet vertical clearance as measured from the water surface at high tide. Therefore, the movement of vehicle traffic on Interstate 80, Interstate 580, Interstate 680, and State Route 160 is not affected by vessel traffic.

**Table 2-20. Bridges in the Study Area.**

Official Name	Common Name	Number of Spans	Vertical Clearance <sup>1</sup>	Vertical Clearance with Projected High RSLC <sup>1</sup>	Waterbody	Purpose
Golden Gate Bridge	Golden Gate Bridge	2	220 feet	217.3 feet	Central San Francisco	Vehicle Traffic on the National Highway System
N/A	Richmond-San Rafael Bridge	2	185 feet	182.3 feet	Central San Francisco/San Pablo Bays	Vehicle traffic on Interstate 580
Alfred Zampa Memorial Bridge	Carquinez Bridge	Two	148 feet	145.3 feet	Carquinez Strait	Vehicle traffic on Interstate 80
George Miller, Jr. Bridge	Benicia-Martinez Bridge	Two	138 feet	135.3 feet	Carquinez Strait	Vehicle traffic on Interstate 680
Union Pacific Rail Bridge	Part of the Benicia-Martinez Bridge	One lift-span	Closed 70 feet Open 135 feet	Closed 76.3 feet/Open 67.3 feet	Carquinez Strait	Union Pacific, Burlington Northern Santa Fe, and Amtrak trains

<sup>1</sup> Vertical clearance at high tide

## FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

The bridges will continue to be built and function as described above. Projected regional sea level change (RSLC) under the USACE high curve scenario was factored in to calculate how vertical clearance could be affected. All numbers are referenced to high tide. In this event, current vessels would not be impacted, or vessels could choose to sail at a lower tide.

### 2.4.7 UTILITIES AND PUBLIC SERVICE

The Utility Investigation Report for the San Francisco to Stockton Deep Water Ship Channel (USACE 2011) was the primary source of information considered for known utility channel crossings. The most recent NOAA Nautical Charts covering the study area were also consulted to identify locations where the deep draft shipping channels intersect with overhead transmission lines or buried cables and pipelines.

Known utilities in the study area include the buried Trans Bay Cable<sup>7</sup> and other transmission lines, buried pipelines, and overhead transmission lines as discussed in the following sections. The region is served by an extensive network of natural gas pipelines and a number of these pipelines cross the study area navigation channels. In addition, there are a number of petroleum refineries in the region and some petroleum product pipelines originating at the refineries cross the study area navigation channels. Other underwater cables crossing the shipping channels within the study area include both telephone and fiber optic lines.

#### 2.4.7.1 BURIED/UNDERWATER CABLES (UWC)

The 53-mile long Trans Bay Cable runs between the converter stations in Pittsburg, Contra Costa County, and the City of San Francisco (**see Figure 2-11**). This power transmission cable, carrying 400 megawatts (high voltage) of direct current, generally runs east-west along the same route as the shipping channels, close to the West Richmond Channel, the Pinole Shoal Channel, through the Carquinez Strait and close to the Bulls Head Reach. Plan and profile drawings of the cable were included in the Utility Investigation Report (USACE 2011). Design documents indicate that the cable was to be buried at a depth of 3 to 6 feet below the bottom sediments. Based on available information, the Trans Bay Cable crosses the dredged channels at two locations (UWC-3 and UWC-4). Although the crossing designated UWC-1 is included for completeness, it is located in the West Richmond Channel which, currently, is not dredged.

---

<sup>7</sup> Utilities in the overall study area are assessed in this section. However, subsequent sections of the report in Section 4.1.18 and Section 5.1 evaluate utilities within the project footprint and determine that there will be no impacts to any utilities or any relocations needed.

**Figure 2-11. Buried/Underwater Cables.**

Other buried cables found in the study area cross the ship channel at the Richmond-San Rafael Bridge, in the Carquinez Strait, and at the Benicia-Martinez Bridge. The Level 3 Communications fiber optic cable at the Benicia-Martinez Bridge, designated as UWC-9, is the only other cable that crosses a dredged portion of the navigation channel.

**Table 2-21. Known Buried/Underwater Cable Crossings.**

Designator on Figure 4-20	Near or in Channel	Location Description	Depth Below Channel Bottom	Description of Crossing
UWC-1	West Richmond Channel	Southern extremity of the West Richmond Channel	6 feet	Trans Bay Cable
UWC-2	West Richmond Channel	Richmond - San Rafael Bridge	Unknown	Two Pacific Telephone and Telegraph lines

Designator on Figure 4-20	Near or in Channel	Location Description	Depth Below Channel Bottom	Description of Crossing
UWC-3	Pinole Shoal Channel	Western extremity of Pinole Shoal Channel	6 feet	Trans Bay Cable
UWC-4	Pinole Shoal Channel	Eastern extremity of the Pinole Shoal Channel	6 feet	Trans Bay Cable runs in parallel and within with the shipping channel
UWC-5	Carquinez Strait	Western extremity of Carquinez Strait, west of Carquinez Bridge, Vallejo	Unknown	A 12-inch fiber optics conduit owned by Level 3 Communications
UWC-6	Carquinez Strait	Within Carquinez Strait, east of Carquinez Bridge	Unknown	Two Pacific Telephone and Telegraph lines
UWC-7	Carquinez Strait	Within Carquinez Strait, east of Carquinez Bridge	Unknown	Unknown
UWC-8	Carquinez Strait	Within Carquinez Strait, west of Benicia-Martinez Bridge	20 feet	A 3-inch steel pipe with fiber optic cable owned by AT&T
UWC-9	Bulls Head Reach	At the Benicia-Martinez Bridge	Unknown	A fiber optics line owned by Level 3 Communications

Sources: eCoastal 2015; NOAA 2015; USACE 2011.

#### 2.4.7.2 BURIED/UNDERWATER PIPELINES (PLC)

Available information indicates that there are at least seven buried pipelines crossing the navigation channel. There is a natural gas pipeline crossing at the Carquinez Bridge (PLC-1) and there are six pipelines that cross at the Benicia-Martinez Bridge (PLC-2) (see **Figure 2-12**)

The existing 35 foot channel is not currently dredged at the Carquinez Bridge and as a result of prevailing natural depths it is not proposed for deepening. The existing 35 foot depth of the Bulls Head Reach at the Benicia-Martinez Bridge is maintained by annual dredging, or on an as needed basis. The locations of the pipeline crossings are shown in **Figure 2-12** with details provided in **Table 2-22**.<sup>8</sup>

<sup>8</sup> Sources: California Natural Gas Pipelines (California Energy Commission 2015) [CEC]; Final Environmental Impact Report for the Proposed Trans Bay Cable Project (URS 2006); Utility Investigation Report San Francisco to Stockton Deep Water Ship Channel (USACE 2011); and NOAA Nautical Charts (NOAA 2015).

**Table 2-22. Buried/Underwater Pipeline Crossings**

Designator on Figure 4-21	Near or in Channel	Location	Depth Below Channel Bottom	Description
PLC-1	Carquinez Strait	At the Carquinez Bridge, Vallejo	Unknown	A Pacific Gas and Electric (PG&E) natural gas pipeline
PLC-2	Bulls Head Reach	At the Benicia-Martinez Bridge	Unknown	Six pipelines cross below the surveyed channel bottom. Three are owned and operated by Valero Benicia Refinery and three are owned and operated by Kinder Morgan.

Sources: CEC 2015; NOAA 2015; URS 2016; USACE 2011.

**Figure 2-12. Buried/Underwater Pipelines.**

### 2.4.7.3 OVERHEAD POWER TRANSMISSION LINES (OHC)

There are two overhead transmission line crossings in the Carquinez Strait (OHC-1 and OHC-2), as shown in **Figure 2-13**. The height of power lines crossing over the channels does not limit the safe clearance and passage of vessels traveling in the channels because some bridges in the study area are lower.

**Figure 2-13. Overhead Cables.**

## 2.5 ECONOMIC ENVIRONMENT

The section differs from the previous socio-economics section in that it discusses the economics of the navigation environment. The base year for this economic analysis is 2020.<sup>9</sup>

<sup>9</sup> Environmental analyses in the following sections use 2023 as the base year. The 3 year difference is negligible for the overall assumptions in the analyses.

2.5.1 COMMODITIES

EXISTING CONDITIONS

Commodity forecasts for deep-draft navigation studies typically use three to five years of empirical data to determine a baseline average on which to project commerce. Baseline averages over a longer period of time can lead to an underestimation of port growth. To minimize the impact of potential anomalies in trade volume on a long-term forecast, three years of empirical data (2011-2013) were used to establish the baseline for the commodity forecast.

Crude oil represented the majority of the total tonnage of import commodities that moved through the study area to port facilities in the study area. Most of the crude oil moving through the channel is imported from foreign countries, although a small percentage of crude comes from domestic sources such as Alaska.

All of the crude oil shipments arrive at the various oil industry ports in the vicinity of Avon. Crude oil is imported, while petroleum products are exported. Historical imports and export moving through the oil terminals from 2011 to 2013 are provided in **Table 2-23**.

**Table 2-23. Historical Imports and Exports.**

Petroleum Product Movements	2011	2012	2013	3-year Average
Total Crude Imports	7,864,034	7,729,726	7,292,532	<b>7,628,764</b>
Total Petroleum Exports	1,813,297	1,949,962	2,109,409	<b>1,957,556</b>

FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

Estimates of growth for the oil refineries that import crude oil and export petroleum products are described in the **Appendix D, Economic Analysis**. Crude oil imports are projected to grow at an annual rate of 0.3%. Petroleum and other liquid exports are projected to grow at an annual rate of 2.4%. **Table 2-24** shows the commodity forecast for years 2020, 2030, and 2040. Even though port and terminal capacity would not be reached, for the purposes of this report’s analysis, it is assumed that tonnage would be held constant after year 2040<sup>10</sup>.

**Table 2-24. Commodity Forecast 2020-2040 (metric tons).**

Commodity	2020	2030	2040
Total Crude Imports	7,790,000	8,027,000	8,271,000
Total Petroleum and Other Liquid Exports	2,311,000	2,930,000	3,714,000

<sup>10</sup> Per ER 1105-2-100, "specific commodity studies are of limited value for projections beyond approximately 20 years". This is a general guideline for deep draft navigation studies due to uncertainty in forecasts.

2.5.2 FLEET

EXISTING CONDITIONS

Vessels in the study area are primarily tankers with maximum design drafts ranging from -40 to -55 feet MLLW as shown in **Table 2-25**. Crude oil vessels can generally be classified into two groups:

- **Group 1:** Aframax and Suezmax tankers with DWTs typically between 80,000 and 150,000 dead weight tons (DWT). These vessels have design drafts of as much as -55 feet, and arrive in Northern California only after having lightered elsewhere, typically Southern California. These vessels arrive less than half full and will often, but not always need to use the tides to deliver their remaining load.
- **Group 2:** Panamax tankers. Because of the draft restrictions in the channels, the tankers will arrive between 70 percent and 80 percent loaded and will use the available tide to arrive drafting between -35 feet and -37 feet.

Tankers from both groups typically deliver approximately 50,000 metric tons of commodities. **Table 2-25** shows vessel fleet data for foreign deep draft vessels calling the refineries. **Table 2-26** shows the 2000 distribution of oil tankers calling at ports in the study area by weight. More than 50 percent of the vessels are 50,000 or 70,000 DWT. **Table 2-27** shows the annual transits in 2015 in both directions (i.e., inbound and outbound) and sailing drafts in the study reach channels.

**Table 2-25. Vessel Types and Attributes.**

Vessel Type	Capacity (DWT)	Maximum Design Draft	Maximum Beam	Maximum Length Overall	Tons Per Inch (TPI)
Panamax Medium	16,000-40,000	40	101	700	100
Panamax	35,000-77,000	45	106	760	154
Aframax	77,001-120,000	50	160	920	238
Suezmax	120,001-195,000	55	165	960	299

**Table 2-26. Tankers by Class - Year 2000.**

DWT	20k	25k	35k	50k	60k	70k	80k	90k	110k	150k	165k
Vessel Calls	28	79	102	44	34	15	7	15	14	14	35
Percentage of Calls	7%	20%	26%	11%	9%	4%	2%	4%	4%	4%	9%

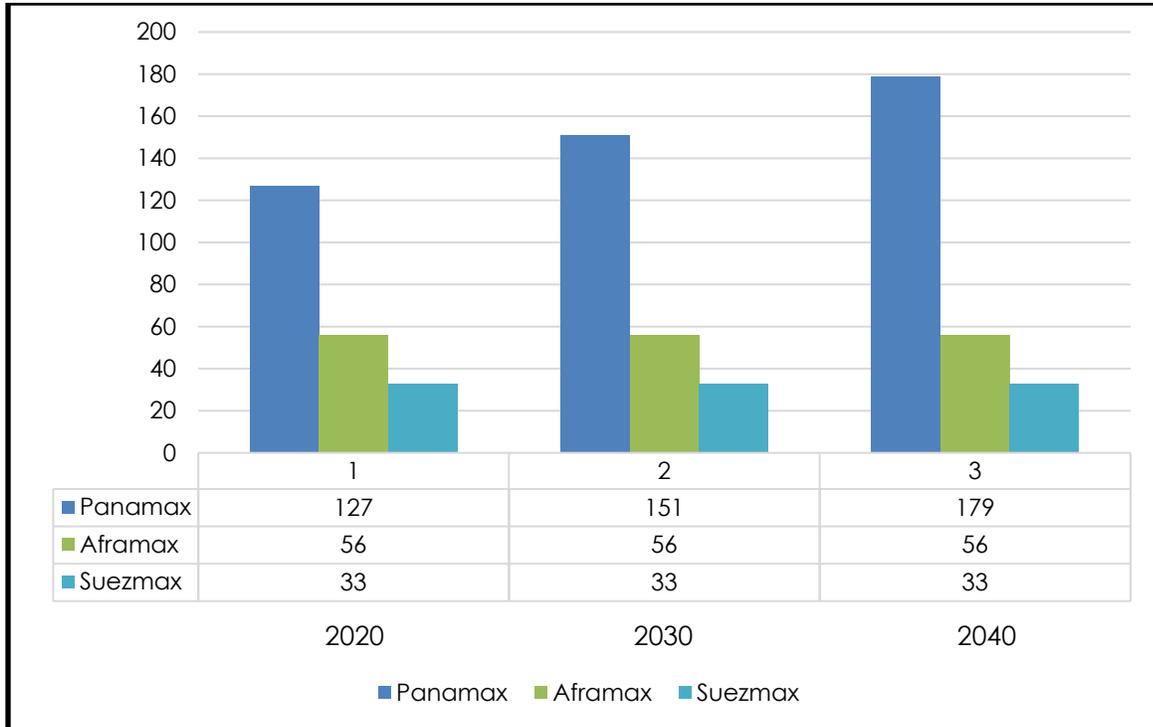

**Table 2-27. Tankers by Class - Year 2015.**

DWT	20k	25k	35k	50k	60k	70k	80k	90k	110k	150k	165k
Vessel Calls	1	1	59	27	34	72	0	34	75	34	0
Percentage of Calls	0%	0%	18%	8%	10%	21%	0%	10%	22%	10%	0%

Vessels in the existing condition may wait on high tide (which can be up to 6 feet) in order to maximize their loading capacity. For the current channel depth of 35 feet, a vessel using low tide can transit the channel at 32 feet (allowing 3 feet of underkeel clearance).

FUTURE WITHOUT-PROJECT CONDITIONS (NO-ACTION ALTERNATIVE)

Figure 2-14 shows the forecast of vessels calling on the terminals within the study area if there is no action taken, where vessel transits could increase from 127 in 2020 to 179 in 2040. Panamax vessels will continue to transit the most frequently and experience the most inefficiencies.

**Figure 2-14. Forecast of Vessels calling at terminals within the study area.**

In the future with-out project condition, vessels with sailing drafts greater than 32 feet will encounter tidal delays.

3

## Plan Formulation

## 3 PLAN FORMULATION

### 3.1 PLAN FORMULATION RATIONALE

The Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies, established by the U.S. Water Resources Council on March 10, 1983, have been developed to guide the formulation and evaluation studies of the major Federal water resources development agencies. These principles and guidelines are commonly referred to as the “P&G,” and will be cited throughout the plan formulation sections of this report.

Plan formulation is the process of developing alternative plans to address a given problem and established objectives. The first step in plan formulation involves identifying all potential management measures for the given problems. A management measure is a structural or nonstructural action that can be implemented at a specific geographic site to address one or more planning objectives.

An alternative plan includes one or more management measures to address the problem. Alternative plans can differ by types of measures, or how measures are combined or defined, including dimensions, quantities, materials, locations or implementation time frames.

Four accounts (P&G 1983) facilitate the evaluation of management measures and display the effects of alternative plans.

- **National Economic Development (NED) account:** Includes consideration of a measure’s potential to meet the planning objective to reduce storm damages, as well as decrease costs of emergency services, lower flood insurance premiums, and consider project costs. Costs and benefits used to fully evaluate the NED objective are not calculated at this stage; however, estimates can be made to gage the overall cost-effectiveness of a measure for this initial screening. Effects of sea-level change and a measure’s adaptability to such change were considered under the National Economic Development (NED) account.
- **Environmental Quality (EQ) account:** Considers ecosystem restoration, water circulation, noise level changes, public facilities and services, aesthetic values, natural resources, air and water quality, cultural and historic preservation, and other factors covered by the National Environmental Policy Act (NEPA).
- **Other Social Effects (OSE) account:** Includes considerations for the preservation of life, health, and public safety; community cohesion and growth; tax and property values; and, the displacement of businesses and public facilities. For evaluation purposes, the OSE account is inclusive of the planning objectives to maintain recreation and maintain a safe evacuation route, and the planning constraint to avoid conflict with legal requirements.
- **Regional Economic Development (RED) account:** Considers the potential impacts on the local economy. .

The P&G require the NED plan to be selected as the Recommended Plan, unless an exception is granted. The NED plan must also be evaluated in consideration of the P&G criteria of completeness, effectiveness, efficiency, and acceptability. Each alternative plan is formulated in consideration of these four criteria.

Preliminary plans were formulated by combining management measures. Each plan was formulated in consideration of the following four criteria described in the Principles and Guidelines (P&G):

1. **Completeness:** Extent to which the plan provides and accounts for all necessary investments or actions to ensure realization of the planning objectives
2. **Effectiveness:** Extent to which the plan contributes to achieving the planning objectives
3. **Efficiency:** Extent to which the plan is the most cost-effective means of addressing the specified problems and realizing the specified opportunities, consistent with protecting the nation's environment
4. **Acceptability:** Workability and viability of the alternative plan with respect to acceptance by Federal and non-federal entities and the public, and compatibility with existing laws, regulations, and public policies

## 3.2 SCOPING\*

### DETERMINATION OF STUDY AREA AND SCOPE

A Ship Simulation Study (*Vessel Simulation Navigation Study of the Proposed John F. Baldwin Ship Channel – Phase III Proposed Channel Improvements*, DTMA 91-88-C-80024, Final Report) was completed in August 1992 for USACE by Marine Safety International. The study used a USACE-approved numerical model that met the acceptance criteria identified in EM 1110-2-1613, and was conducted with input from the San Francisco Bay Harbor Pilots. The design vessel for the study was the Exxon Benicia<sup>11</sup>. In addition to proposed deepening alternatives (which were being explored at that time), the preliminary design included some minor channel realignments but did not include any widening. The Pilots made recommendations for relocation of navigation aids and channel realignment details that would increase navigation safety and satisfy their concerns. The final study report confirmed that if the recommendations were incorporated into the proposed channel design, there would be no need for any widening. Since the ship simulation was performed, all of the pilot's recommendations have been incorporated into the existing channel configurations, with the exception of the actual deepening. The pilots also requested that USACE consider another measure, such as a sediment trap to control excessive shoaling that occurs in the Suisun Bay Channel in the Bulls Head reach north of the Martinez Bridge.

The study area was originally scoped in 2008 to include the entire 78-mile long navigation project to include the John F. Baldwin and Stockton channels, however, it was re-scoped in 2016 to include

<sup>11</sup> Dimensions of the Exxon Benicia were as follows: LOA = 906 feet; Beam = 173 feet; Draft = 43 feet. Current dimensions of the Panamax tanker design vessel is: LOA = 750 feet; Beam = 105 feet; Draft = 45 feet.

navigation improvements up to Avon. The re-scoped study area described in this report is more appropriate for the immediate problems facing existing vessels and the study fits into the three year timeframe required for USACE feasibility studies. The study area now encompasses the area which spans from Central San Francisco Bay to Avon (just east of the Benicia-Martinez Bridge). All other existing channels within this area are already naturally deep, and therefore Pinole Shoal Channel, and the Bulls Head Reach portion of the Suisun Bay Channel are the focused areas carried forward for the study area.

### PUBLIC AND AGENCY INPUT

On March 12, 2008, USACE and the Port of Stockton published the original Notice of Intent/Notice of Preparation (NOI/NOP) for an EIS/EIR. Two public scoping meetings were held on March 26 and April 2, 2008. Comments and questions were solicited for consideration in evaluating potential impacts, environmental issues, and alternatives for the proposed channel deepening between San Francisco Bay and the Port of Stockton.

Because of the amount of time that has passed since the original NOI/NOP were published, USACE and the Port of Stockton published a supplemental NOI and supplemental NOP on March 4, 2016, to notify the public of the preparation of this EIS/EIR, provide an update on the study description, and re-open the public scoping process. Because the 2016 NOI/NOP was a supplement to the original, no additional public meetings were held during the scoping period. The public scoping period ended on April 4, 2016.

An additional NOI was published in the Federal Register on December 4, 2017. The current NOI announced the reduction in scope of this project (to include only Pinole Shoal and the Bulls Head Reach portion of the Suisun Bay) from the NOI that was published on March 4, 2016. Scoping comments received in 2016 and 2017/2018 are located in **Appendix I, Pertinent Correspondence Part 1**, along with a comment response matrix to address the comments.

Agency meetings were held in December 2018 to discuss the scope of the project, as well as the updated salinity information that is contained within the draft and final GRR/EIS.

A Notice of Availability was published for the draft GRR/EIS in the Federal Register on May 10, 2019, a press release to announce the location and comment period of the document, and it was also published on the California State Clearinghouse website. A letter was sent to the general public to notice release of the draft GRR/EIS (mailing list available upon request) and to also notice the public meeting time and location that occurred on June 11, 2019 from 6pm-8pm at the Contra Costa County Conservation and Development office in Martinez, at 30 Muir Road, Martinez, CA 94553. Hard copies of the draft GRR/EIS were made available at the following libraries:

Cesar Chavez Central Library, 605 N El Dorado St, Stockton, CA 95202

Contra Costa County Library, Martinez Branch 740 Court St, Martinez, CA 94553

Comments on the draft GRR/EIS were received from May 10, 2019 through June 24, 2019 for a 45 day public review period. Comments received after June 24 through August 31, 2019 are included in the comment response matrix, located in **Appendix I, Pertinent Correspondence Part 2**. These comments and

responses also include comments from the Dredge Material Management Plan (DMMP) meeting that occurred in San Francisco in July 2019.

## 3.3 PROBLEMS AND OPPORTUNITIES\*

### 3.3.1 PROBLEMS

The study area as described earlier is the existing navigation channel from the Golden Gate Bridge to Avon (approximately 44 miles), with a specific focus on the Pinole Shoal and Bulls Head Reach portion of the Suisun Bay Channel.

Pinole Shoal Channel and Bulls Head reach are maintained at -35 feet MLLW. However, even the smallest class of vessels, the panamax class, has the capacity to draft at -45 feet MLLW. Therefore, vessels must be “light-loaded”, or less than fully loaded with cargo, to navigate the channels with sufficient under-keel clearance (for liquid tankers, under-keel clearance is 3 feet). Light-loading increases the cost of transportation and, in turn, the cost of the shipped products because more trips must be made to carry the same volume of cargo.

Channel depths in ship channel are inadequate for fully loaded modern deep-draft vessels, which increases transportation costs and decrease economic efficiency. Inefficient strategies that are currently employed include:

- Insufficient Depth, leading to inefficient use of capacity and inefficient transit schedules:
  - All vessels must light-load cargo to safely transit the -35 foot channel depth.
  - Panamax tankers are the smallest class and most easily affected, lightloading to -32 feet and unable to use their full draft capacity of -45 feet
  - Vessels will often wait for favorable (high) tides of up to 6 feet in a two hour window (up to 12 hours of delay) to in order to gain additional draft efficiencies.
- Additional time and cost to project:
  - High shoaling rates in Bulls Head Reach often require additional dredging outside of the regular scheduled dredging efforts. The U.S. Coast Guard considers any shoaling above the currently maintained depth of -35 feet MLLW in Bulls Head Reach to be a hazard to navigation.

### 3.3.2 OPPORTUNITIES

- **Increase efficiency of vessels (both in capacity used and in transit schedules)**
- **Reduce transportation costs**
- **Reduce frequency of operation and maintenance dredging intervals in high shoaling areas**
- **Opportunity to beneficially use dredged material.** Several opportunities to beneficially use dredged material for habitat restoration exist at a number of wetland restoration sites within the San Francisco Bay Area. These opportunities would be enhanced by deepening the ship channel

since new work material is superior to maintenance material to accomplish the habitat restoration objectives at these sites. For implementation and permitting, an important consideration in any navigation improvement project is ensuring maximum beneficial reuse of dredged material, also echoed in the San Francisco Bay Long Term Management Strategy (LTMS) for dredged material.

## 3.4 CONSTRAINTS

### 3.4.1 PLANNING CONSTRAINTS

A constraint is a restriction that limits the extent of the planning process; it is a statement of effects that alternative plans should avoid. Constraints are designed to avoid undesirable changes between without and with-project future conditions. The planning constraint for this study area is to avoid conflict with Federal regulations, as stated in Federal law, USACE regulations, and executive orders, and specifically to:

1. Avoid adverse impacts on species of special concern:

Avoid Salt Water Intrusion: Deepening beyond certain depths in the channel could potentially allow saltwater to flow upstream into freshwater habitat, which has the potential to adversely impact several state and federally-listed threatened and endangered species, such as salmonids, green sturgeon, and delta and longfin smelt, as well as aquatic habitats in the Delta.

Dredge Within Environmental Windows: To minimize effects to special status species from in-water work, several environmental work windows have been established in San Francisco Bay and the Delta. Environmental work windows limit the timeframe when in-water work can occur, which would affect any construction schedule developed to implement a project. In addition, some of the listed species are present all year long, thereby further complicating construction activities. The work windows to protect special status species vary from 4 months to 6 months during the year, with actual months in which dredging is prohibited depending on the specific channel location. Permission to dredge outside of the established work windows would require extensive coordination with the resource agencies.

Type of Dredge: To minimize effects to listed species due to entrainment, a mechanical clamshell dredge will be used for all work associated with this channel deepening project, including at Pinole Shoal.

The existing Biological Opinions for the maintenance dredging require construction to occur within special status work windows. Since 2017, mechanical clamshell dredges have been required by USFWS in the Bulls Head Reach area.

2. Avoid significant impacts to water quality and water supply: A measure considered to improve navigation efficiency in the project study area must not significantly impact California water supply and quality without acceptable mitigation. Water quality and water supply in the Sacramento-San Joaquin Delta is a very contentious issue in California, particularly considering drought years. Water that flows through the Delta provides drinking water to more than 25 million Californians, irrigation waters to approximately 1 million acres of farmland, and water to

more than 3 million acres of wildlife refuges. Affected water supply stakeholders include, but are not limited to:

- Contra Costa Water District
- Metropolitan Water District of Southern California (a consortium of 26 cities and water districts that provides drinking water to nearly 19 million people in parts of Los Angeles Orange, San Diego, Riverside, San Bernardino and Ventura counties)
- California Department of Water Resources
- U.S. Bureau of Reclamation
- Westlands Water District

### 3.4.2 LOCAL CONSTRAINTS

Local and state laws, such as California State statutes, do not constrain NED formulation. However, they may be considered in the selection of a Locally Preferred Plan (LPP).

## 3.5 OBJECTIVES

### 3.5.1 FEDERAL AND PROJECT SPECIFIC OBJECTIVES

The Federal objective, as stated in the P&G, is to contribute to national economic development (NED) consistent with protecting the nation's environment, pursuant to national environmental statutes, applicable executive orders, and other Federal planning requirements. Contributions to NED are increases in the net value of the national output of goods and services, expressed in monetary units. Contributions to NED are the direct net economic benefits that accrue in the study area and the rest of the nation. development (NED) consistent with protecting the nation's environment, pursuant to national environmental statutes, applicable executive orders, and other Federal planning requirements. Contributions to NED are increases in the net value of the national output of goods and services, expressed in monetary units. Contributions to NED are the direct net economic benefits that accrue in the study area and the rest of the nation. development (NED) consistent with protecting the nation's environment, pursuant to national environmental statutes, applicable executive orders, and other Federal planning requirements. Contributions to NED are increases in the net value of the national output of goods and services, expressed in monetary units. Contributions to NED are the direct net economic benefits that accrue in the study area and the rest of the nation.

The Federal objective is to reasonably maximize net benefits to the nation, and as such, it does not seek to identify specific targets within objectives.

1. Objective 1: Reduce transportation costs and increase deep draft navigation efficiency for the shipment of commodities to and from all facilities within the study area beginning in 2020
2. Objective 2: Maximize beneficial reuse of dredged material while minimizing placement costs
3. Objective 3: Reduce frequency of operation and maintenance dredging in high shoaling areas
4. Objective 4: Increase navigability to maintain safety

### 3.5.1.1 FEDERAL ENVIRONMENTAL OBJECTIVES

USACE strives to balance the environmental and development needs of the nation in full compliance with the National Environmental Policy Act environmental concerns relative to the study. Therefore, significant environmental resources to the fullest extent. Significant adverse impacts that cannot be avoided are mitigated to on significant resources. Significant adverse impacts that cannot be avoided are mitigated to on significant resources. Significant adverse impacts that cannot be avoided are mitigated as required by Section 906(d) of WRDA 1986.

This report is an integrated General Reevaluation study and Environmental Impact Statement, which discusses and documents the environmental effects of the Recommended Plan and summarizes compliance with Federal statutes and regulations.

### 3.5.1.2 ENVIRONMENTAL OPERATING PRINCIPLES

Consistent with the NEPA, USACE has formalized its commitment to the environment by creating a set of “Environmental Operating Principles” applicable to all its decision making and programs. These principles foster unity of purpose regarding environmental issues and ensure that environmental conservation and preservation, and restoration are considered in all USACE activities. Section 6.6.27 includes a discussion of USACE Environmental Operating Principles and how the study addresses them.

### 3.5.1.3 CAMPAIGN PLAN OF THE U.S. ARMY CORPS OF ENGINEERS (USACE)

USACE Campaign Plan goals and objectives are derived, in part, from the Commander’s intent, the Army Campaign Plan, and the Office of Management and Budget. The four campaign plan goals and their associated objectives also build on prior strategic planning efforts. Each campaign plan goal and objective is led by a USACE senior leader who manages and oversees actions to reach the goal and objectives.

The successful achievement of the campaign plan goals and objectives are dependent on actions implemented by the entire USACE team. The implementing actions supporting each goal and objective are contained in the headquarters staff and Major Subordinate Command (MSC) implementation guidance for the Campaign Plan. The four goals of the Campaign Plan are:

**Goal 1:** Deliver innovative, resilient, and sustainable solutions to the Department of Defense (DoD) and the nation.

**Goal 2:** Deliver enduring and essential water resource solutions, utilizing effective transformation strategies.

**Goal 3:** Deliver support that responds to, recovers from, and mitigates disaster impacts to the nation.

**Goal 4:** Build resilient People, Teams, Systems and Processes to sustain a diverse culture of collaboration, innovation and participation to shape and deliver strategic solutions.

These Campaign Plan goals and associated objectives will be addressed through the course of this feasibility study.

### 3.5.2 STATE AND LOCAL OBJECTIVES

State and local objectives in this case are consistent with the Federal and project objectives.

## 3.6 SUMMARY OF MANAGEMENT MEASURES

Assessment and avoidance of measures that would result in significant changes in salinity was a large factor in the consideration, comparison and evaluation of measures during this study. As noted in the existing conditions chapter of this report, salinity variations within the channel are a high priority concern for the communities and ecological resources (delta smelt being the most sensitive species to salinity changes in the area) in the immediate study area. As such, this was a heavily weighted factor under the environmental quality P&G account, which resulted in the screening of several deeper channel depths of -40 feet, -43 feet and -45 feet from further consideration.

### 3.6.1 IDENTIFICATION OF MANAGEMENT MEASURES

The following non-structural and structural management measures were considered and screened for possible inclusion in alternative plans. A short description of each measure is listed below.

#### NON-STRUCTURAL (AN ACTIVITY) MEASURES

1. **Congestion fees.** Congestion fees are charged when high traffic results in delays unloading cargo. This measure was screened out because congestion in the channels is not a problem and not projected to be a problem in the future. Therefore, fees would be ineffective at meeting the planning objectives.
2. **Intermodal Transportation Systems.** Since commercial enterprises and industries utilizing shipping channels are profit-maximizing entities, a reasonable assumption is that movement of goods and commodities already employ the most effective and efficient intermodal means of transportation, given current channel depth constraints in conjunction with other operational considerations. If modification or improvements utilizing one of the other modes to reduce transportation costs were more effective and efficient, the commercial enterprises and industries would likely pursue that that approach in lieu of channel deepening. Diverting shipped cargo to overland transportation networks may also incur adverse impacts associated with increased traffic congestion and air pollution in the region. Because navigation is the most efficient way of transporting goods to the port facilities in the study area with the least emissions, this measure was considered ineffective at meeting planning objectives and was screened out.
3. **Lightering.** This measure was screened out because Petroleum lightering is prohibited in San Francisco Bay and it is assumed that this will still be prohibited in the future without-project condition.
4. **Light Loading.** This measure refers to vessels not loading to their full capacity, in order to safely transit existing channel depths. This measure is already being employed, and it is assumed to be a part of the future without-project condition; therefore it was screened from further analysis.

5. **Use of Favorable Tides and Daylight Transit Only.** Use of favorable tides refers to vessels entering a channel at high tide so that they can come in at a deeper draft than they would be able to at low tide. This measure (i.e., “riding the tide”) was screened out because it is already being implemented to the maximum extent possible and is also considered a component of the future without-project condition.
6. **Traffic Management.** Traffic management of commercial vessels is not a problem in the study area. Therefore, the traffic management measure were screened out because it would be ineffective in meeting the planning objectives.
7. **Pipeline.** The pipeline measure was selected in the 1998 GRR as the locally preferred plan. The pipeline was conceptually designed to utilize an existing pipeline owned by PG&E and to construct portions of a new pipeline between Avon and Richmond. This alternative also proposed to construct a -45 foot MLLW deep-draft berth near Richmond where oil tankers could unload petroleum products. After the 1998 GRR was finalized, it was determined that USACE does not have the authority to construct an oil pipeline. Subsequently, the oil industry determined that it was not in their interest to proceed with the pipeline because it was not cost effective. Today, the non-Federal sponsor does not support this management measure as an alternative, and it is no longer within the re-scoped study area.
8. **Relocate Port Facilities.** Relocating port facilities to deeper water and/or docking boats in the bay was screened out due to the extensive landside development investment associated with the existing refinery sites and due to safety concerns.

### STRUCTURAL (CONSTRUCTION/ASSEMBLY ON-SITE) MEASURES

**Channel Deepening.** Various intermediate depths beyond the existing -35 foot MLLW maintained depth were considered/Depths of -37 foot MLLW and -38 foot MLLW were analyzed in detail, as described as follows for Pinole Shoal and Bulls Head reach portion of Suisun Bay to Avon. These depths were considered to be the increments that would be most likely to efficiently address the problems and objectives. Depths deeper than -38 foot MLLW were not analyzed in detail due to potential concerns regarding salinity impacts and study time and funding limitations.

1. **Deepen to -37 Feet MLLW.** Deepening to -37 feet MLLW would result in approximately 0.8 million cubic yards of material being dredged from the ship channel. This measure meets the overall goal of reducing the transportation costs and increasing the efficiencies of transporting commodities to and from facilities, and improves travel schedules for vessels arriving at and departing from San Francisco Bay. Based on draft salinity intrusion significance thresholds used for the EIS analyses (as defined in CCWD 2010), salinity modeling results indicate that potential impacts from deepening to -37 feet MLLW would likely not result in salinity intrusion that would require mitigation.
2. **Deepen to -38 Feet MLLW.** Deepening to -38 feet MLLW would result in approximately 1.4 million cubic yards of material being dredged from the ship channel. This measure meets the overall goal of reducing the costs and increasing the efficiencies of transporting commodities to and from facilities,

and improves travel schedules for vessels arriving at and departing from San Francisco Bay. Based on draft salinity intrusion significance thresholds developed for the EIS analyses (as defined in CCWD 2010), salinity modeling results indicate that potential impacts from deepening to -38 feet MLLW would also likely not result in salinity intrusion that would require mitigation.

3. **Sediment Trap.** A sediment trap was considered to address the consistent high rate of shoaling in the advanced maintenance area within this reach, as requested by the San Francisco Bar Pilots. Existing conditions require advance maintenance during regular maintenance dredging episodes or emergency dredging to retain the dredged depth throughout the year (see Section 2.4.2). To reduce the likelihood and frequency of dredging for the Bulls Head Reach, a shoal analysis was performed which showed a sediment trap of an additional 4 foot depth could be dredged to ensure that the Bulls Head Reach is maintained reliably and is consistent with the prevailing maintained depth of the connecting Federal channels. The estimated increase in dredging volume associated with deepening the sediment trap is considered negligible when compared to the total volume of material that would be dredged with any of the alternative channel depths considered in this study; therefore, volume estimates for a sediment trap have been included with the total estimated volume of material that would be dredged for each channel depth discussed above.
4. **Rocky obstruction removal.** This measure refers to a small area of natural buried rock of approximately 950 square feet just south of Pinole Shoal Channel, within the Federal navigation channel, which is a navigation hazard to vessels and could become more so if Pinole Shoal is deepened, as reported by the San Francisco Bar Pilots. Bar pilots need at least a 3 feet underkeel below design depth plus 2 feet allowable overdepth. This measure would propose to level the rock using a pneumatic jackhammer from -39.7 feet MLLW to approximately -43 feet MLLW (depending on design depth), which is estimated to be 40 cubic yards, to maintain safety for vessels entering or departing the Pinole Shoal Channel.

**Dredged Material Placement Sites.** This is a required measure associated with channel dredging measures, regarding the identification and use of a site(s) to place the material removed from the channel. Several placement site options were considered, including existing in-bay sites (SF-10, SF-16, SF-9, SF-11), the San Francisco Bay Deep Ocean Disposal Site (SF-DODS), using existing beneficial reuse sites, constructing new beneficial-use sites, and partnering with other projects and programs in the region that could benefit from the availability of project-generated material. It was determined that owing to unknowns related to the completion of design and receipt of construction funding for this project relative to other regional efforts, those opportunities would be reevaluated during the design phase of work. The existing sediment chemistry, physical characteristics, and bioassay data for the material proposed for dredging were evaluated and that data was compared to the requirements of each available placement site. In addition, the available capacity of each placement site was compared against the volume of material estimated to be dredged, as well as if the site would be available to accept dredged material when the channels in the study area would be deepened. The analysis also included other proposed deepening projects within San Francisco Bay (e.g., Redwood City Harbor) and maintenance dredging projects that could also use the placement sites.

In-bay sites SF-10 (San Pablo Bay) has a site specific capacity limit of 500,000 cy per year and SF-11 (Suisun Bay) has a site specific capacity limit of 200,00 cy per year. Placement in these sites would be exceeded

by placement of the large volume of deepening material. SF-11 (Alcatraz) is located farther from the other in-bay sites has a site specific capacity of 400,000 cy from October to April and 300,000 cubic yards per month from May to September. This site is not only a much farther distance from the project area but also would have capacity exceeded by the large volume of deepening material. While initially thought to be a feasible disposal site, SF-9 was eliminated upon more detailed consideration. A recent review of the site has shown that a significant mound has been building on the site since 1999. Currently, portions of the site sit as high as 8ft and total disposal capacity is estimated to be only 1.31M. As such, the Dredged Material Management Office (DMMO) agencies have agreed to more actively manage the site to prevent further mounding. The composition of the initial deepening material is unknown; however, previously un-dredged material is more consolidated and less dispersive than operation and maintenance dredge material and concerns have been raised that Pinole Shoal material may not be as dispersive as required for the SF-9 site. Considering those factors, use of SF-9 has been screened from consideration for this deepening project<sup>12</sup>. Additionally, USACE is a signatory on the San Francisco Bay Long Term Management Strategy (LTMS) agreement, along with Environmental Protection Agency (EPA) and state signatories, where the goal among signatories is to reduce in-bay disposal over time and to apply beneficial reuse when possible. Due to limited site specific capacity, incompatible sediment composition of initial deepening material with the in-bay sites, and in keeping with the LTMS, in-bay disposal was screened out early on in the plan formulation of placement sites. The analysis and rationale as described above resulted in three sites chosen to be carried forward for consideration as the most likely sites given current assumptions, and are briefly discussed below:

1. **Cullinan Ranch.** Cullinan Ranch, a 1,575-acre parcel in the San Pablo Bay National Wildlife Refuge, was originally purchased by the USFWS for the purpose of increasing habitat for salt marsh harvest mouse (*Reithrodontomys raviventris*) and California clapper rail (*Rallus longirostris obsoletus*). Located in Solano County, the southern property boundary of the parcel is a naturally formed levee that is the base for State Highway 37. The western property boundary of the parcel comprises Dutchman Slough and South Slough, both of which flow into the nearby Napa River. Cullinan Ranch is a tidal restoration project with the goal of restoring diked baylands to historic tidal marsh conditions by using dredged material to raise site elevations by approximately 6 feet. Cullinan Ranch is permitted to receive up to 9 million cubic yards of dredged material and currently has the capacity to accept up to 2.4 million cubic yards of dredged material. The Redwood City Harbor deepening project and other maintenance dredging projects are also considering using this site. Placing material at Cullinan meets the planning objective of maximizing beneficial reuse of dredged material.
2. **Montezuma Wetlands.** The approximately 1,800-acre Montezuma Wetlands Restoration Project is a privately owned and operated wetland restoration project located adjacent to Montezuma Slough in northern Honker Bay. In the early 1900s, the site was diked, drained, and used for agriculture. Since the site was diked, the land has subsided up to 10 feet and dredged material is being used to raise site elevations for wetland restoration. The site can take dredged material with elevated concentrations of constituents of concern, as long as this

---

<sup>12</sup> While the in-bay was not considered to be a viable option for initial construction placement due to site specific capacity limitations of all sites/and or incompatible sediment composition, in-bay could be used for operation and maintenance (O&M) material.

sediment is buried under 3 feet of clean cover material. The Montezuma site currently has the capacity to accept up to 12 million cubic yards of dredged material. However, the Redwood City Harbor deepening project is also considering using this site for dredged material. Placing material at Montezuma Wetlands meets the planning objective of maximizing beneficial reuse of dredged material.

3. ***San Francisco Bay – Deep Ocean Disposal Site (SF-DODS)***. The SF-DODS is located in the Pacific Ocean, approximately 55 nautical miles west of the Golden Gate Bridge. The site is the deepest and farthest-offshore ocean placement site in the nation. The regulatory site capacity of SF-DODS is 4.8 million cubic yards per year. Sediment placed at SF-DODS can have higher concentrations of constituents of concern compared to many beneficial-use sites.

### 3.6.2 PRELIMINARY SCREENING OF MEASURES

The management measures presented above were screened based on an assessment to meet project objectives, avoid constraints, ability to meet the four P&G accounts, and ability to meet the 4 P&G criteria. The screening was performed to identify those measures that are appropriate for inclusion for development of alternative plans. **Table 3-1 and Table 3-2** provides an overview of the screening results for the measures identified for the project study area.

Non-structural and structural measures were compared and evaluated against a set of 13 different screening criteria to assess positive benefits and attributes which could be attained, worth a total of 2 points each, for a total maximum score of 26 points. Points were assigned as follows: Does Not Meet = 0; Partially Meets = 1; Fully Meets = 2. Negative scores up to -2 points were assigned for areas where negative effects could occur. The total score of each measure was then determined, and only measures which scored greater than 13 (over half of the total available points) were carried forward to be combined into alternatives.

**Table 3-1.Preliminary Structural Measures Screening.**

1. Measures				
2. Impact Assessment (4 P&G Accounts)	Deepen to -37 feet MLLW	Deepen to -38 feet MLLW	Sediment Trap	Rocky Obstruction Removal
A. National Economic Development (NED)	F -Acheives NED benefits. 2	F -Acheives NED benefits. 2	P - Likely to achieve NED benefits. 1	P - Likely to contribute to NED benefits when combined. 1
B. Environmental Quality (EQ)	P - May have some environmental affects but not likely to have salinity intrusion which would require mitigation. 1	P - May have some environmental affects but not likely to have salinity intrusion which would require mitigation. 1	P - May have some environmental affects but not likely to have salinity intrusion which would require mitigation. 1	P - Unlikely to have environmental affects. 1
C. Regional Economic Development (RED)	P - Could have some RED during construction. 1	P - Could have some RED during construction. 1	P - Could have some RED during construction. 1	P - Contributes toward RED when combined 1
D. Other Social Effects (OSE)	P - Community may be affected in the short term during construction but overall would benefit. 1	P - Community may be affected in the short term during construction but overall would benefit. 1	P - Community may be affected in the short term during construction but overall would benefit. 1	F - Improves navigability for vessels. 2
<b>3. Plan Evaluation</b>				
<b>A. Contribution to Planning Objectives</b>				
Objective 1: Reduce transportation costs and increase deep draft navigation efficiency for the shipment of commodities to and from all facilities within the study area beginning in 2020	F - Would likely reduce transportation costs and increase efficiency. 2	F - Would likely reduce transportation costs and increase efficiency. 2	F - Would likely reduce transportation costs and increase efficiency. 2	P - Will contribute to this objective when combined. 1
Objective 2: Maximize beneficial reuse of dredged material while minimizing placement costs	F - Would likely be able to have an opportunity to place material at beneficial use site. 2	F - Would likely be able to have an opportunity to place material at beneficial use site. 2	F - Would likely be able to have an opportunity to place material at beneficial use site. 2	P - Possibility of beneficial reuse 1
Objective 3: Reduce frequency of operation and maintenance dredging in high shoaling areas	F - Would likely be able to reduce operation and maintenance in shoaled areas. 2	F - Would likely be able to reduce operation and maintenance in shoaled areas. 2	F - Would likely be able to reduce operation and maintenance in shoaled areas. 2	O - Does not contribute. 0
Objective 4: Increase navigability to maintain safety	O - Removal of hazard would not occur. 0	O - Removal of hazard would not occur. 0	O - Removal of hazard would not occur. 0	F - Rock outcropping hazard would be removed to increase navigability and maintain safety 2
<b>B. Response to Planning Constraints</b>				
(1) Avoid conflict with state and Federal regulations, as stated in Federal law, USACE regulations and Executive Orders.	F - Fully meets 2	F - Fully meets 2	F - Fully meets 2	F - Fully meets 2
<b>C. Response to Evaluation Criteria</b>				
(1) Completeness	F - Complete 2	F - Complete 2	F - Complete 2	P -Must be combined with deepening to be complete. 1
(2) Effectiveness	F - Meets all objectives. 2	F - Meets all objectives. 2	F - Meets all objectives. 2	P - Meets some obejctoves when combined. 1
(3) Efficiency	F - Is cost-effective 2	F - Is cost-effective 2	F - Is cost-effective 2	F - Is cost-effective when combined. 2

1. Measures								
2. Impact Assessment (4 P&G Accounts)	No-Action	Congestion Fees	Intermodal transportation systems	Lightering/Light Loading	Tides and Daylight Transit Only	Traffic Management	Relocate Port Facilities	Pipeline
A. National Economic Development (NED)	O - Does not improve NED. 0	O - Congestion is not an issue; Would not create benefits and would likely have no benefits to offset the costs. 0	O - Would not be more cost effective than vessel transportation. 0	P - Possibly could be cost efficient and have reasonable benefits. 1	O - This measure is already being done and is not providing needed benefits in the existing conditions. 0	O - Traffic Management is not an issue; Would not create benefits and would likely have no benefits to offset the costs. 0	O - This measure could have NED benefits but the large landside cost investment could outweigh the benefits. 0	P - This measure could have NED benefits but the large cost investment could outweigh the benefits. 1
B. Environmental Quality (EQ)	P - Environmental effects will continue with current trends. 1	O - Would not affect the environment in positive or negative ways. 0	O - Would not be more advantageous than vessel transportation. 0	O - There are potential negative environmental impacts associated with lightering 0	O - Would not affect the environment in positive or negative ways. 0	O - Would not affect the environment in positive or negative ways. 0	O - This measure could have impacts with moving the existing oil refinery to a new location. 0	P - There are potential negative environmental impacts associated construction of a pipeline. 1
C. Regional Economic Development (RED)	O - Does not improve RED. 0	P - Could provide slight increase in regional economy through fees. 1	P - Could provide some regional economic development through other transportation modes. 1	P - Could provide some regional economic benefit development associated with private companies performing lightering operations 1	O - This measure is already being done and would not provide additional regional economic development benefits. 0	O - Would not provide regional economic benefits. 0	P - Could provide some regional economic development during relocation and new construction. 1	P - Could provide some regional economic development during pipeline construction. 1
D. Other Social Effects (OSE)	P - Community would not be affected beyond future without project trends. 1	O - Would not affect public in positive or negative ways. 0	P - Could create positive or negative effects (ie negative: More trucks on the road = more congestion for community) 1	O - There are potential negative environmental impacts associated with lightering, which affect the community's environmental and well-being 0	P - This measure is likely not affecting the community in a negative way. 1	O - Would not affect public in positive or negative ways. 0	O - Relocation may not be acceptable to the community in terms of noise, construction activity, potential environmental impacts and safety concerns. 0	P - Pipeline may not be acceptable to the community in terms of noise, construction activity, and potential environmental impacts. 1
<b>3. Plan Evaluation</b>								
<b>A. Contribution to Planning Objectives</b>								
Objective 1: Reduce transportation costs and increase deep draft navigation efficiency for the shipment of commodities to and from all facilities within the study area beginning in 2020	O - Would not reduce transportation costs 0	O - Congestion in the channels is not a problem; therefore this measure would meet the objective. 0	O - Would not reduce transportation costs as shipping is generally the least cost of all modes. 0	P - Could potentially reduce transportation cost. 1	O - This measure is already being done and is not providing needed benefits in the existing conditions. 0	O - Congestion in the channels is not a problem; therefore this measure would meet the objective. 0	P - Relocation to deeper water could meet this objective. 1	P - Could potentially reduce transportation cost. 1
Objective 2: Maximize beneficial reuse of dredged material while minimizing placement costs	P - Beneficial use could occur independent of a project. 1	O - This objective would not be met. 0	O - Would not apply to this objective. 0	O - Would not apply to this objective. 0	O - Would not apply to this objective. 0	O - This objective would not be met. 0	P - This could potentially be met. 1	P - This could potentially be met. 1
Objective 3: Reduce frequency of operation and maintenance dredging in high shoaling areas	O - Reduction of operation and maintenance would not occur. 0	O - This objective would not be met. 0	O - This objective would not be met. 0	O - This objective would not be met. 0	O - This objective would not be met. 0	O - This objective would not be met. 0	P - Depending on the new location, shoaling could potentially decrease or increase. 1	O - This objective would not be met. 0
Objective 4: Increase navigability to maintain safety	O - Removal of hazard would not occur. 0	O - This objective would not be met. 0	O - This objective would not be met. 0	O - This objective would not be met. 0	O - This objective would not be met. 0	O - This objective would not be met. 0	O - This objective would not be met. 0	O - This objective would not be met. 0
<b>B. Response to Planning Constraints</b>								
(1) Avoid conflict with state and Federal regulations, as stated in Federal law, USACE regulations and Executive Orders.	F - Fully meets 2	F - Fully meets 2	F - Fully meets 2	O - Petroleum lightering in not allowed in San Francisco Bay. 0	F - Fully meets 2	F - Fully meets 2	P - Fully meets; uncertain if this could feasibly be done within regulations. 1	P - Decision by vertical team post 1998 GRR that Corps is not authorized to construct this measure. Non-Federal sponsor could construct but does not support, nor do the oil refineries. 1
<b>C. Response to Evaluation Criteria</b>								
(1) Completeness	F - Complete. 2	P - Could potentially be combined for completeness. 1	P - Could potentially be combined for completeness. 1	P - Could potentially be combined for completeness. 1	O - This measure is not complete. 0	O - This measure is not complete. 0	P - This measure would likely be complete. 1	O - This measure is not complete. 0
(2) Effectiveness	O - Not effective in meeting objectives. 0	O - Not effective in meeting objectives. 0	O - Not effective in meeting objectives. 0	O - Not effective in meeting objectives. 0	O - Not effective in meeting objectives. 0	O - Not effective in meeting objectives. 0	P - Would meet objectives. 1	O - Not effective in meeting objectives. 0
(3) Efficiency	O - Would not provide needed benefits - therefore not cost effective. 0	O - Would not provide needed benefits - therefore not cost effective. 0	O - Would not provide needed benefits - therefore not cost effective. 0	P - Could possibly achieve some benefits. 1	O - Would not provide needed benefits - therefore not cost effective. 0	O - Would not provide needed benefits - therefore not cost effective. 0	O - Benefits would likely not outweigh costs 0	O - Would not provide needed benefits - therefore not cost effective. 0
(4) Acceptability	P - Would be generally acceptable but not to Port. 1	P - Would be generally acceptable. 1	P - May or may not be acceptable to the public and agencies. 1	O - Would not be acceptable. 0	P - Would be generally acceptable. 1	P - Would be generally acceptable. 1	O - Would likely be unacceptable to Port due to high cost and coordination, and community. 0	O - This is not acceptable to Port or Oil Refineries. 0

O = Does not meet; P = Partially meets; F = Fully meets								

## 3.7 ALTERNATIVE FORMULATION STRATEGY

**Table 3-1 and Table 3-2** show evaluation and screening criteria, along with additional pertinent information.

As mentioned earlier, comparison and evaluation of effects of measures to potential salinity changes, and its subsequent effects towards communities and species (in particular, delta smelt) as a result of deepening was a major factor in the screening process.

Another key consideration during this process was to set an objective to integrate the dredged material beneficially into the environment for each alternative. The contribution of dredged material to the beneficial reuse sites would contribute to additional wetland and benthic habitat, and benefit several sensitive species, including delta smelt habitat beyond what is currently in the area.

Measures which were screened out include all non-structural alternatives, as they are already being implemented or did not compete well relative to other measures.

Measures carried forward as feasible ways to alleviate problems, meet objectives, show benefits under the P&G accounts, meet P&G screening criteria, and have low risk in terms of adverse environmental effects include the no-action plan, deepening alternatives at the -37 foot and -38 foot MLLW depth, sediment trap at the -42 foot depth plus 2 feet of overdepth (based on the shoaling analysis titled Bulls Head Deposition HydroSurvey Tech Memo- 2015), and removal of the rocky obstruction in Pinole Shoal channel.

These remaining measures were then combined into alternatives. These alternatives include the no-action alternative and two deepening alternatives (to depths of -37 feet and -38 feet MLLW), with the dredged material being beneficially used at one or more of the existing permitted beneficial reuse sites, namely, Cullinan Ranch, Montezuma Wetlands, or other sites such as SF-DODS, and in-bay placement. A sediment trap measure is also included at Bulls Head Reach in both of the action alternatives, as well as the measure addressing removal of the rocky obstruction for increased navigability.

## 3.8 ALTERNATIVE COMPARISON AND EVALUATION OF THE FINAL ARRAY

**Table 3-3** displays the initial array of alternatives, which were then compared and evaluated against screening criteria, using an additional level of refinement with known information. A description of each alternative is below.

**No-Action:** The no-action alternative is defined as the continuation of present-day policies and actions to maintain the existing Federal project channel dimensions within the study area, assuming no new Federal actions re: channel improvements over the next 50 years. The purpose of the no-action alternative and subsequent alternative analyses is to provide a comparison of the magnitude of environmental effects of the action alternatives against a benchmark of no-action. This comparison also demonstrates the degree to which the need for channel improvement is real and that it was thoroughly considered and appropriately and adequately answered.

The shipping channel in the study area would continue to remain in place and function at the existing constructed depths. Maintenance dredging of the channel would continue to occur at the same frequency and would generate the same volumes under current conditions, and would occur annually at both the Pinole Shoal Channel and at Bulls Head Reach to maintain the current depth of -35 feet MLLW. Maintenance dredging would continue to be managed and environmental review of maintenance dredging would continue to be performed by USACE.

**-37 foot MLLW Alternative:** The -37 foot MLLW alternative would deepen Pinole Shoal channel and the Bulls Head Reach portion of Suisun Bay channel within the shipping channels to a depth of -37 feet MLLW. The existing advance maintenance area within Bulls Head Reach Channel would be further deepened from -37 feet MLLW (plus 2 feet of overdepth) to -42 feet MLLW (plus 2 feet of overdepth) to function as a sediment trap. In the future with project condition, the design vessel (Panamax) with a sailing draft greater than 34 feet (37 foot channel minus 3 feet underkeel clearance) will encounter tidal delays, rather than at 32 feet (35 foot channel minus 3 feet underkeel clearance) in the future without project condition. Therefore, the increased loading capacity in the future-with project condition would reduce vessel calls and partially reduce tidal delays.

The total dredging volume for the -37 foot MLLW Alternative would be approximately 860,000 million cubic yards from over approximately 200 acres of channel bottom. An estimated 438,500 cubic yards of sediment would be dredged to reach -37 feet MLLW and an additional 422,800 cubic yards of sediment would be dredged if the allowable overdepth (2 feet) was fully dredged.

To reduce the risk of entrainment of special status fish, dredging would be conducted during approved seasonal environmental work windows and by using a mechanical clamshell dredge. Dredged material would be placed in scows and, once full, transported by tugs to one of the sites where it would be off-loaded to the respective beneficial reuse site. Deepening under this alternative would take approximately 3 months and would be completed in 1 year during the existing environmental work windows for Pinole Shoal and Bulls Head Reach. The environmental work windows for these channels are June 1 through November 30 and August 1 through November 30, respectively.

Environmental resources that have the potential to be affected include special status fish, native and commercially important fish, benthic resources, water quality, and air quality. Dredging within the existing work windows with a clamshell dredge would ensure that impacts to special status fish are avoided or minimized. Impacts to water quality could result from increases in suspended sediment concentrations and minor salinity intrusion. Impacts resulting from increased suspended sediment and turbidity would be temporary and localized around the vicinity of dredging. Impacts to air quality would result from emissions during dredging and dredged material transport to the beneficial-use sites. As this alternative would use existing sites with all environmental permits to accept dredged material, analysis of the impacts of off-loading the dredged material and any habitat construction activities once the material is off-loaded is not required in this report.

**-38 foot MLLW Alternative:** The -38 foot MLLW Alternative would deepen Pinole Shoal channel and the Bulls Head Reach portion of Suisun Bay channel to a depth of -38 feet MLLW of the advance maintenance area within Bulls Head Reach Channel would be further deepened from -38 feet MLLW (plus 2 feet of overdepth) to -42 feet MLLW (plus 2 feet of overdepth) to function as a sediment trap. In the future

with project condition, the design vessel (Panamax) with a sailing draft greater than 35 feet (38 foot channel minus 3 feet underkeel clearance) will encounter tidal delays, rather than at 32 feet (35 foot channel minus 3 feet underkeel clearance) in the future without project condition. Therefore, the increased loading capacity in the future-with project condition would reduce the number of vessel calls and partially reduce tidal delays.

The total dredging volume for the -38 foot MLLW Alternative would be approximately 1.5 million cubic yards from over approximately 390 acres of channel bottom. An estimated 861,300 cubic yards of sediment would be dredged to reach -38 feet MLLW and an additional 646,200 cubic yards of sediment would be dredged if the allowable overdepth (2 feet) was fully dredged.

To reduce the risk of entrainment of special status fish, dredging would be conducted during approved seasonal environmental work windows and by using a mechanical clamshell dredge at Pinole Shoal (i.e., which typically is maintained by using a hopper dredge) as well as at Bulls Head Reach. Similar to the -37 foot MLLW Alternative, dredged material would be transported by tugs to one of the sites where it would be off-loaded. Deepening under this alternative would take approximately 4.5 months and would be completed in 1 year during the existing environmental work windows for Pinole Shoal and Bulls Head Reach.

Environmental resources that have the potential to be affected are similar to those discussed in for the -37 foot MLLW Alternative.

#### **Removal of Rocky Obstruction**

This measure refers to a small natural buried rock of approximately 950 square feet just south of Pinole Shoal Channel, within the Federal navigation channel, which is a navigation hazard to vessels and could become more so if Pinole Shoal is deepened, as reported by the San Francisco Bar Pilots. Bar pilots need at least a 3 feet underkeel below design depth plus 2 feet allowable overdepth. This measure would propose to level the rock using a pneumatic jackhammer from -39.7 feet MLLW to approximately -43 feet MLLW (depending on design depth), which is estimated to be 40 cubic yards, to maintain safety for vessels entering or departing the Pinole Shoal Channel.

**Table 3-3. Initial Array of Alternatives Criteria and Screening.**

Alternatives	No Action (Future Without-Project)	Placement Site: SF-DODS		Placement Site: Cullinan Ranch		Placement Site: Montezuma Wetlands		Placement Site: Split between Cullinan Ranch & Montezuma Wetlands

**Table 3-4. Final Array of Alternatives.**

Alternative	Description of Alternative	Screening Outcome
No Action	No action would be taken to reduce the cost of transportation and increase economic efficiencies.	<b>Retained</b>
<u>Deepen</u> : -37 feet MLLW <u>Placement Site</u> : Existing permitted beneficial reuse sites	<ul style="list-style-type: none"> <li>• Deepen to -37 feet MLLW with 2 feet of overdepth.</li> <li>• Includes sediment trap at Bulls Head Reach.</li> <li>• Beneficially use approximately 860,000 cubic yards of dredged sediment at Montezuma Wetlands or Cullinan Ranch.</li> <li>• Rocky obstruction removal.</li> </ul>	<b>Retained</b>
<u>Deepen</u> : -38 feet MLLW <u>Placement Site</u> : Existing permitted beneficial reuse sites	<ul style="list-style-type: none"> <li>• Deepen to -38 feet MLLW with 2 feet of overdepth.</li> <li>• Includes sediment trap at Bulls Head Reach.</li> <li>• Beneficially use approximately 1.6 million cubic yards of dredged sediment at Montezuma Wetlands or Cullinan Ranch.</li> <li>• Rocky obstruction removal.</li> </ul>	<b>Retained</b>

Comparison and evaluation of the initial array of alternatives shown in **Table 3-3** resulted in a reduced array of alternatives moving forward to the final array of alternatives, shown in **Table 3-5**. A cost analysis for potential placement sites was conducted for the following options: 1) All material placed at Cullinan Ranch, 2) All material placed at Montezuma Wetlands, 3) Split material between Cullinan Ranch and Montezuma Wetlands, and 4) All material at SF-DODS. The analysis determined that split placement between Montezuma Wetlands and Cullinan Ranch was the least cost option. Additionally, this maximizes the planning objective to beneficially use material. Placement of material at SF-DODS would be economically justified and material is anticipated to be suitable for this site, but is not the least cost placement site, and additionally is not ideal since it takes material out of the natural system. Should material be unsuitable for upland placement or if upland placement is otherwise not available, material may be disposed of at SF-DODS. Appropriate coordination with EPA would be done prior to disposal. While SF-DODS is not carried forward as a placement site, it is worth mentioning that it is an available placement site if needed, if there are no other beneficial reuse sites with available capacity prior to construction.

### 3.9 ECONOMIC EVALUATION OF THE FINAL ARRAY

Preliminary screening level cost estimates were used for the two proposed deepening alternatives for use in the economic analysis. Costs shown in **Table 3-5** include Operation, Maintenance, Repair, Replacement, and Rehabilitation (OMRR&R) activities and Interest during Construction (IDC). Transportation costs and benefits were estimated using the USACE certified economic model, HarborSym, and estimated for a 50-year period of analysis for the years 2020 through 2069. For this comparison, the costs and benefits were annualized at the FY16 discount rate of 3.125% over 50 years.

The -38 foot alternative provides higher net benefits than the -37 foot alternative, and additionally meets planning criteria goals of being complete, efficient, effective, and acceptable. The -38 foot alternative also shows a positive benefit to cost ratio of 3.1 to 1.

**Table 3-5. Final Array – Economic Evaluation & Comparison.**

	ALTERNATIVES		
	No-Action (35')	37'	38'
<b>AAEQ Transportation Cost</b>	\$209,846,000	\$202,221,000	\$198,534,000

### 3.10 ADDITIONAL ANALYSIS FOR THE FINAL ARRAY

The final array of alternatives must be compared and evaluated against P&G criteria, as displayed throughout this chapter. Additionally, an economic evaluation must be made to identify which plan in the final array maximizes NED benefits, discussed above. An environmental analysis must also be conducted under NEPA to compare and evaluate the final array for a set of environmental factors (Chapter 4), prior to determination of the Recommended Plan. At the time of environmental analyses, the Recommended Plan was not yet identified; however, for the purposes of readability in this report, the 38 foot MLLW deepening alternative plus sediment trap and rocky obstruction removal is referred to as the Recommended Plan in the following chapter.

4

# Comparison of Environmental Effects of Alternative Plans

## 4 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

This section describes the potential environmental effects (direct, indirect, and cumulative) anticipated to result from the alternatives as compared to the NEPA baselines, and the methods used to conduct the evaluation. The environmental effects are evaluated against “significance impact thresholds” identified for each resource. Significance thresholds specify the level of impact beyond which an alternative is considered to have a significant impact.

This EIS classifies effects as follows:

- A **beneficial effect** would generally be regarded as an improvement or substantial positive change in the resource
- A **negligible effect /no impact** would cause a slight adverse, beneficial or negative change in the resource, but one that generally would not be either noticeable or unacceptable
- A **less-than-significant impact/adverse but not significant effect** would cause an adverse change in the resource that would likely be noticeable, but would not cross the specified significance threshold
- A **significant effect** would cause adverse effects greater than the specified significance threshold; the alternative would cause a substantial adverse change in the resource that would significantly affect its condition; the severity of the impact could be reduced by pursuing specific mitigation measures
- A **significant and unavoidable adverse effect** would result in adverse effects that exceed the specified significance impact threshold, and the use of mitigation measures would not reduce this impact to less than significant levels
- An **adverse effect** is found when an undertaking alters, directly or indirectly, any of the characteristics of a historic property that qualify the property for listing in the NRHP in a manner that would diminish the integrity of the property’s location, design, setting, materials, workmanship, feeling, or association.
- If there is insufficient information to evaluate the effect of an alternative, a result of **no determination** may be made.

The environmental consequences analyses also distinguish between the effects that would be associated with the construction and subsequent operational phases.

As previously described, construction of the alternatives will include the dredging and associated activities required to deepen the channels for each depth considered in the final array of alternatives. The analyses consider all activities and consequences resulting from construction up to and including transport of dredged material to the off-loaders at the beneficial reuse sites proposed for material placement. However, the analysis does not address the subsequent activities undertaken at the placement sites using the dredged material because those activities have already been covered in relevant environmental documents prepared for each site (USACE and Solano County Department of Environmental Management [SCDEM] 1998; USFWS and CDFW 2008).

The operations phase includes the long-term activities, including periodically performing maintenance dredging, disposing of the resulting dredged material, and maritime activities in the study area over the

50-year evaluation period. A 50-year period was selected to analyze environmental effects because USACE policy specifies that the economic life of deep draft navigation projects is 50 years (see **Appendix D, Economic Analysis**). For the -37 foot and -38 foot MLLW Alternatives, the 50-year period covers the years 2020 to 2069.

When a significant effect to a resource is anticipated for an alternative, mitigation measures are identified to avoid, minimize, reduce, rectify, or compensate for the anticipated impact. Where possible, the effect analyses also predict the residual impacts that would still exist after all available mitigation measures are implemented.

## 4.1 NATURAL ENVIRONMENT

A summary of the environmental effects impact rating is presented first in this chapter. Each section will describe the effects of the alternatives in further detail. As described in Chapter 3, the alternatives include No Action, deepening the navigation channel to -37 foot MLLW or -38 foot MLLW. Preliminary modeling of the final array of alternatives (-37 foot MLLW and -38 foot MLLW) did not include the sediment trap or rocky obstruction. The analysis in each resource section describes the effects of the -37 and -38 foot alternatives without a sediment trap and rocky obstruction. If effects on each resource are similar for -37 foot MLLW, -38 foot MLLW, and 38 foot MLLW plus the sediment trap and rocky obstruction, the effects are described within the same paragraph. The Recommended Plan (-38 foot MLLW plus sediment trap and rocky obstruction removal) was further modeled to show any incremental effects of adding the sediment trap to the 38 foot depth. The 38 foot MLLW plus sediment trap at Bulls Head Reach plus the rocky obstruction result in different effects from the -37 and -38 foot deepening only alternatives for the water quality, biological resources, and cultural resources. The results of the effects analysis for these resources are described with a subheading of -38 foot + Sediment Trap and Rocky Obstruction.

**Table 4-1** provides a summary of the environmental effects and benefits that would occur for each of the alternatives. The level of adverse impact for a given resource is defined as: (0) negligible/no impact; (-1) adverse but not significant impact/less than significant; (-2) significant but mitigatable adverse impact; (-3) significant and unavoidable adverse impact that cannot be mitigated. Beneficial impacts are indicated in the table by “B”.

**Table 4-1. Summary of Environmental Effects with Impact Ratings.**

Significance Impact Threshold ID	Significance Impact Threshold Description (An alternative is considered to have a significant impact if it would)	Impact Rating <sup>1</sup> (Primary/Cumulative)			Mitigation Measures <sup>1</sup>		
		No Action	-37 Foot	-38 Foot	Measure Number	Mitigation Measure Description	Residual Impact
<b><i>Geology and Seismicity</i></b>							
GSS-01	Increase potential risks related to rupture of a known earthquake fault; seismic shaking; tsunami or seiche; or seismic related ground failure, including liquefaction or landslides.	0/0	0/0	0/0	NM	NM	NA
GSS-02	Cause geologic units or soils to become unstable and potentially result in on-site or off-site landslide, lateral spreading, subsidence, liquefaction, collapse, or erosion.	0/0	-1/-1	-1/-1	NM	NM	NA
<b><i>Sediment and Sedimentation</i></b>							
SS-01	Substantially degrade sediment quality due to dredging and placement of dredged materials.	0/0	-1/0	-1/0	NM	NM	NA
SS-02	Cause substantial modification of sedimentation or sediment transport processes that results in significant effects on downstream areas.	0/0	-1/0	-1/0	NM	NM	NA
<b><i>Water Quality and Hydrology</i></b>							
WQ-01	Substantially degrade water quality through alteration of temperature, salinity, pH, and dissolved oxygen; increased turbidity, or nutrient loading.	0/0	-1/0	-1/0	NM	NM	NA
WQ-02	Violate quality standards because of mobilization of contaminated sediments or release of hazardous materials.	0/0	-1/0	-1/0	NM	NM	NA
WQ-03	Negatively impact groundwater or surface water quality from leaching of contaminants or surface water runoff from placement sites.	0/0	-1/0	-1/0	NM	NM	NA

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

Significance Impact Threshold ID	Significance Impact Threshold Description (An alternative is considered to have a significant impact if it would)	Impact Rating <sup>1</sup> (Primary/Cumulative)			Mitigation Measures <sup>1</sup>		
		No Action	-37 Foot	-38 Foot	Measure Number	Mitigation Measure Description	Residual Impact
WQ-04	Cause substantial modification of tidal hydraulics, tidal currents, and circulation that would result in significant effects on water levels or tidal flows within either San Francisco Bay or the Sacramento-San Joaquin Delta.	0/0	-1/0	-1/0	NM	NM	NA
WQ-05	Substantially impair water quality for municipal and industrial beneficial reuses.	0/0	-1/-1	-1/-1	NM	NM	NA
WQ-06	Substantially affect water exports and operations due to shifts in X2.	0/0	-1/-1	-1/-1	NM	NM	NA
<b>Air Quality</b>							
AQ-01	Violate any air quality standard, or contribute substantially to an existing or projected air quality violation.	0/0	-1/0	-1/0	NM	NM	0
AQ-02	Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is nonattainment under an applicable Federal or state ambient air quality standard, including releasing emissions that exceed quantitative thresholds for ozone precursors.	0/0	-1/0	-1/0	NM	NM	0
AQ-03	Expose sensitive receptors to substantial pollutant concentrations.	0/0	0/0	0/0	NM	NM	0
AQ-04	Create objectionable odors affecting a substantial number of people.	0/0	0/0	0/0	NM	NM	0
AQ-05	Conflict with, or obstruct implementation of the applicable air quality plan.	0/0	0/0	0/0	NM	NM	0
<b>Climate Change</b>							
CC-01	Directly or indirectly exceed applicable Federal or state GHG standards.	0/0	0/0	0/0	NM	NM	0

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

Significance Impact Threshold ID	Significance Impact Threshold Description (An alternative is considered to have a significant impact if it would)	Impact Rating <sup>1</sup> (Primary/Cumulative)			Mitigation Measures <sup>1</sup>		
		No Action	-37 Foot	-38 Foot	Measure Number	Mitigation Measure Description	Residual Impact
CC-02	Conflict with an applicable plan, policy, or regulation adopted to reduce GHG emissions and climate change impacts.	-1/0	-1/-1	-1/-1	NM	NM	--1
<b>Biological Resources</b>							
BR-01	Cause increased turbidity that adversely affects special-status species and critical habitat.	0/0	-1/-1	-1/-1	NM	NM	NA
BR-02	Cause benthic habitat disturbance that adversely affects special-status species, critical habitat, or habitat for commercially valuable marine species.	0/0	-1/-1	-1/-1	NM	NM	NA
BR-03	Cause underwater noise that adversely affects special-status fish and marine mammals.	0/0	-1/-1	-1/-1	NM	NM	NA
BR-04	Adversely affect special-status or commercially or recreationally important marine species through entrainment.	0/0	-1/-1	-1/-1	NM	NM	NA
BR-05	Result in the disturbance of EFH and "Special Aquatic Sites," including eelgrass beds and mudflats.	0/0	-1/-1	-1/-1	NM	NM	NA
BR-06	Interfere with the movement of resident or migratory fish or wildlife species.	0/0	-1/-1	-1/-1	NM	NM	NA
BR-07	Adversely affect special-status fish species, including their critical habitat, as a result of X2 shifts.	0/0	-1/-1	-1/-1	NM	NM	NA
<b>Land Use and Planning</b>							
LU-01	Introduce land uses or activities incompatible with existing or adjacent land uses.	0/0	-1/0	-1/0	NM	NM	NA
<b>Mineral Resources</b>							

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

Significance Impact Threshold ID	Significance Impact Threshold Description (An alternative is considered to have a significant impact if it would)	Impact Rating <sup>1</sup> (Primary/Cumulative)			Mitigation Measures <sup>1</sup>		
		No Action	-37 Foot	-38 Foot	Measure Number	Mitigation Measure Description	Residual Impact
MIN-01	Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the State or a locally important mineral resource recovery site delineated in a county General Plan, specific plan, or other land use plan.	0/0	0/0	0/0	NM	NM	NA
<b>Agricultural Resources</b>							
AG-01	Degrade the quality, or agricultural productivity, of Important Farmland or farm resources (including irrigation water systems, levees, drainage systems), or directly or indirectly cause lands presently in agricultural production (including Important Farmland) to convert to non-agricultural uses.	0/0	0/0	0/0	NM	NM	NA
<b>Aesthetics</b>							
AE-01	Have a substantial adverse effect on a scenic vista or substantially degrade the existing visual character or quality of the site and its surroundings.	0/0	0/0	0/0	NM	NM	NA
AE-02	Create a new source of substantial light or glare that would adversely affect day or nighttime views in the area.	0/0	0/0	0/0	NM	NM	NA
<b>Cultural Resources and Native American Trust Assets</b>							
CR-01	Cause an adverse effect to a historic property (including shipwrecks and shellmounds).	0/0	0/0	0/0	NM	NM	NA
					NM	Archaeologist oversight	
CR-02	Disturb any human remains, including those interred outside of formal cemeteries.	0/0	0/0	0/0	NM	NM	NA
<b>Environmental Justice and Community Effects</b>							
EJ-01	Disproportionately affect environment of communities within the APE when compared to surrounding areas.	0/0	0/0	0/0	NM	NM	NA

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

Significance Impact Threshold ID	Significance Impact Threshold Description (An alternative is considered to have a significant impact if it would)	Impact Rating <sup>1</sup> (Primary/Cumulative)			Mitigation Measures <sup>1</sup>		
		No Action	-37 Foot	-38 Foot	Measure Number	Mitigation Measure Description	Residual Impact
<b>Navigation, Transportation and Circulation</b>							
NT-01	Change vessel traffic patterns, resulting in unplanned or regularly occurring delays, adverse change in freedom of movement, increase safety risks, or introduction of safety hazards.	0/0	-1/0	-1/0	NM	NM	NA
<b>Noise</b>							
NOI-01	Result in a 90 dBA equivalent continuous sound level over a 1-hour period in a residential or public park area, or a 100 dBA equivalent continuous sound level over a 1-hour period in an industrial area.	-1/-1	-1/-1	-1/-1	NM	NM	NA
<b>Public Health and Environmental Hazards</b>							
PH-01	Operations occur on a site that is included on a list of hazardous material sites and, as a result, create a significant hazard to the public or the environment.	0/0	0/0	0/0	NM	NM	NA
PH-02	Create a significant hazard to the public or the environment by disrupting the routine transport, use, or placement or storage of hazardous materials or wastes.	0/0	0/0	0/0	NM	NM	NA
PH-03	Impair implementation of, or physically interfere with, an adopted emergency response plan or emergency evacuation plan.	0/0	0/0	0/0	NM	NM	NA

<p><sup>1</sup>Impact Rating - First number denotes primary impact. Second number (after the slash) denotes cumulative impact, following these rating definitions:</p> <ul style="list-style-type: none"> <li>-3 = significant and unavoidable adverse impact</li> <li>-2 = significant but mitigable adverse impact</li> <li>-1 = adverse but not significant impact/less than significant impact</li> <li>0 = negligible or no impact</li> <li>B = beneficial</li> </ul> <p>MM = Mitigation measure (see text for description of measure)            NM = No mitigation required            NA = No residual impacts            ND = No impact determination can be made at this time</p>							

#### 4.1.1 GEOLOGY AND SEISMICITY

Impacts on or associated with geology were qualitatively evaluated based on the potential to temporarily or permanently alter geologic or seismic conditions of the study area. In addition, because geological hazards such as earthquakes happen independently of the project, the potential for increased risk of injury due to geologic and seismic hazards were qualitatively evaluated.

Under NEPA, an alternative would be considered to have a significant impact on or associated with geology and seismicity if it would:

Impact GSS-01: Increase potential risks related to rupture of a known earthquake fault; seismic shaking; tsunami or seiche; or seismic-related ground failure, including liquefaction or landslides; or

Impact GSS-02: Cause geologic units or soils to become unstable and potentially result in onsite or offsite landslide, lateral spreading, subsidence, liquefaction, collapse, or erosion.

#### NO ACTION ALTERNATIVE

It is anticipated that the current hazard resulting from fault rupture or seismic-induced hazards will persist over the 50-year analysis addressed in this report. This would continue to present a risk of very strong to strongest ground shaking throughout the study area. The risk of seismically induced liquefaction or slope failure in areas prone to instability would remain, including coastal areas with wetlands, marsh fill, steep or unstable slopes, and within certain levees in Contra Costa and Solano counties. It is also anticipated that the current hazard resulting from tsunami and seismically induced seiche on the San Francisco Bay and Delta would continue. The hazard of a substantial tsunami affecting the Delta and the Suisun Marsh appears to be minor because of their distance from the Pacific Ocean and the attenuating effect of San Francisco and Suisun Bay waters. Therefore, the No Action Alternative, which involves continued maintenance dredging and use of the existing deep draft navigation channels, would have no impact related to the rupture of a known earthquake fault; seismic shaking; tsunami or seiche; or seismic-related ground failure, including liquefaction; or landslides. The No Action Alternative would also have no impact related to geologic units or soils becoming unstable.

#### FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVE

##### **Evaluation of Impact GSS-01: Increase potential risks related to rupture of a known earthquake fault; seismic shaking; tsunami or seiche; or seismic-related ground failure, including liquefaction or landslides:**

The -37 foot and -38 foot MLLW Alternative would be constructed and maintained within the same footprint as the existing -35 foot MLLW channel and context of the same potential geologic hazards described above for the No Action Alternative. Thus, it is anticipated that the current hazards resulting from fault rupture or seismic-induced hazards would persist. Channel deepening would not result in an increased risk of fault rupture or ground shaking and would not result in construction of any structures that would be susceptible to seismic hazards. While dredging would occur in waters adjacent to potentially unstable coastlines, the dredge prism would be designed to avoid underwater sloughing that could potentially undermine levee or shoreline stability. All construction would occur in compliance with Title 23, Division 1, Article 8, Sections 111137 of the CCR and other applicable regulations. Tsunami and seiche hazards in the study area would be unaffected by this alternative and would remain minimal. This alternative would not interfere with any tsunami warning systems or response plans. Neither Alternative

would, therefore, have no impact related to rupture of a known earthquake fault; seismic shaking; tsunami or seiche; or seismic-related ground failure, including liquefaction; or landslides.

**Evaluation of Impact GSS-02: Cause geologic units or soils to become unstable and potentially result in onsite or offsite landslide, lateral spreading, subsidence, liquefaction, collapse, or erosion:**

Geologic hazards potentially resulting from upland placement of dredge material were addressed during the evaluation and construction of existing placement sites, and would be analyzed separately for any new placement sites that are separately permitted and used for both alternatives. Dredging and deepening would not create unstable geologic units within the navigation channel, as existing side slopes ratios would be maintained. Although this alternative may result in minimal erosion of the channel sides from sloughing after dredging due to the disturbance of sediments, historic patterns of erosion and sediment accumulation would not be expected to change.

Certain shoreline areas adjacent to the Alternatives dredging footprint may be susceptible to geologic hazards, however, the dredge prism would be designed to avoid underwater sloughing that could potentially undermine levee or shoreline stability. All construction would occur in compliance with Title 23, Division 1, Article 8, and Sections 111137 of the CCR, the USACE Coastal Engineering Manual, and other applicable regulations.

The deeper channel would be able to accommodate more fully loaded vessels, potentially creating larger waves and increased shoreline erosion. However, the number of shipping vessels under both alternatives is projected to decrease slightly compared to the No Action Alternative. Any potential increase in shoreline erosion from more fully loaded vessels would, therefore, be nominal when considered in the context of potential reduction in shipping vessels and broader vessel activity in the Bay and Delta. Therefore, the both alternatives would have less than significant impacts related to geologic units or soils becoming unstable.

#### 4.1.2 SEDIMENT AND SEDIMENTATION

Impacts on or associated with sediment and sedimentation were qualitatively evaluated based on the potential for the alternatives to temporarily or permanently alter sediment quality or transport conditions in the project area. Under NEPA, an alternative could have an impact from sediment if it would cause the following:

Impact SS-01: Substantially degrade sediment quality due to dredging and placement of dredged materials; or

Impact SS-02: Cause substantial modification of sedimentation or sediment transport processes that results in significant effects on downstream areas.

For each of the thresholds established previously, the effect of the project was evaluated using available information and data.

#### NO ACTION ALTERNATIVE

Under the No Action Alternative, maintenance dredging would continue to occur where and when needed. Historic sediment testing data show low levels of contamination throughout the study area. Sediments from the area are typically suitable for placement in the ocean, in-bay, and for beneficial reuse. USACE would continue to conduct sediment testing for maintenance dredging activities in accordance with appropriate Federal and regional guidelines and continue to obtain all necessary permits and approvals as

described above. Therefore, the No Action Alternative would continue to not degrade sediment quality as a result of regular dredging and placement of dredged materials in the study area.

Under the No Action Alternative, existing sedimentation patterns would continue to occur and periodic maintenance dredging would also continue to be performed in the present manner such that the channels in the study area are maintained at the existing -35 foot regulated depths. Thus, there would be no change in sedimentation or sediment transport processes.

#### FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**Evaluation of Impact SS-01: Substantially degrade sediment quality due to dredging and placement of dredged materials:** Based on historic sediment testing data, sediment from the dredge prism for the -37 foot and -38 foot MLLW Alternatives show low levels of contamination and it was determined suitable for placement in-bay or for wetland or upland beneficial reuse. USACE will conduct all necessary testing and coordination required with the DMMO and obtain all necessary approvals for dredging and placement of dredged material prior to construction. Conformance with guidelines and agency review would ensure that dredging and dredged material placement activities would not substantially degrade sediment quality either in the channels, or at placement sites or placement sites. For these reasons, the -37 foot and -38 foot MLLW Alternative would result in less than significant impacts on sediment quality.

**Evaluation of Impact SS-02: Cause substantial modification of sedimentation or sediment transport processes that results in significant effects on downstream areas:** The effects of deepening the navigation channels were evaluated by estimating the increase in channel sedimentation resulting from the deepening. USACE estimated an increase in channel sedimentation (for combined Pinole Shoal Channel, Bulls Head Reach and the sediment trap) of 185,200 cubic yards as a result of deepening to -37 feet MLLW (**Appendix A - Civil Site**) and 230,500 cubic yards as a result of deepening to -38 feet MLLW. The increase in dredging volumes required to maintain the depth of -37 feet MLLW is estimated to be only 0.5 percent of the average annual sediment flux to San Francisco Bay, and 1.2 percent for -38 feet, based on sediment flux estimates by McKee et al. (2013). As breakouts of the total volumes described above, the estimated increase in channel sedimentation for deepening the sediment trap under the -37 foot alternative is 5,700 cy and under the -39 foot alternative is 8,900 cubic yards (**Appendix A - Civil Site**). The increase in dredging volumes required to maintain the navigation channel to a depth of -38 feet MLLW plus the sediment trap is estimated to be only 1.2 percent of the average annual sediment flux to San Francisco Bay, based on sediment flux estimates by McKee et al. (2013).

As a result, the effect of both alternatives is expected to result in a less than significant impact on sedimentation and sediment transport processes in areas downstream of the study area.

#### 4.1.3 WATER QUALITY AND HYDROLOGY

Water quality variables that are potentially affected by dredging operations include turbidity, dissolved oxygen, nutrients, salinity, temperature, pH, and concentrations of trace metals and organic contaminants if they are present in the sediments.

The analysis considered whether the alternatives would:

- Substantially degrade water quality through alteration of temperature, salinity, pH, and dissolved oxygen; increased turbidity; or nutrient loading

- Violate any water quality standards (**Table 4-2**), or substantially degrade water quality because of mobilization of contaminated sediments or release of hazardous materials during dredging and placement activities.

The analysis also describes Best Management Practices (BMPs) and other measures to avoid, minimize, or mitigate potential adverse impacts on water quality, including measures mandated under existing regulations and programs, as applicable.

Under NEPA, an alternative would be considered to have a significant impact on water quality, water supply, and/or hydrology and hydraulics if it would:

Impact WQ-01: Substantially degrade water quality through alteration of temperature, salinity, pH, and dissolved oxygen; increased turbidity, or nutrient loading; or

Impact WQ-02: Violate quality standards because of mobilization of contaminated sediments or release of hazardous materials; or

Impact WQ-03: Negatively impact groundwater or surface water quality from leaching of contaminants or surface water runoff from placement sites; or

Impact WQ-04: Cause substantial modification of tidal hydraulics, tidal currents, and circulation that would result in significant effects on water levels or tidal flows within either San Francisco Bay or the Sacramento-San Joaquin Delta; or

Impact WQ-05: Substantially impair water quality for municipal and industrial beneficial reuses; or

Impact WQ-06: Substantially affect water exports and operations due to shifts in X2.

In an effort to easily compare the effect analysis of each alternative, this water quality and hydrology section is arranged per impact rather than by alternatives in the previous sections.

**Table 4-2. Water Quality Objectives (Standards).**

**Notes:**

WQOs for metals are based on the dissolved fraction unless noted otherwise.

- As defined in the SF Bay Basin Plan
- As defined in the Water Quality Control Plan for the Sacramento River and San Joaquin River Basins
- Applicable to the portion of the delta located in the San Francisco Bay Region, Suisun Bay, Carquinez Strait, San Pablo Bay, Central San Francisco Bay, and the portion of Lower San Francisco Bay north of the line representing the Hayward Shoals
- Downstream of Carquinez Bridge = 5.0 mg/L minimum; Upstream of Carquinez Bridge = 7.0 mg/L minimum
- Based on the total fraction
- Based on hardness; value shown assume hardness of 100 mg/L

-- = No guidance value

µg/L = micrograms per liter

mg/L = milligrams per liter

PAH = polycyclic aromatic hydrocarbon

WQO = Water Quality Objectives

***EVALUATION OF IMPACT OF WQ-01: SUBSTANTIALLY DEGRADE WATER QUALITY THROUGH ALTERATION OF TEMPERATURE, SALINITY, PH, AND DISSOLVED OXYGEN; INCREASED TURBIDITY, OR NUTRIENT LOADING*****NO-ACTION ALTERNATIVE**

The No Action Alternative would continue ongoing maintenance dredging, placement of dredged material in approved open water placement sites, and use of the channel. There would be no long-term changes in water quality from baseline conditions. Sediment sampling and analysis would be required for ongoing maintenance dredging efforts to avoid potential sediment and water quality impacts. Therefore, temperature, salinity, pH, and dissolved oxygen, increased turbidity, or nutrient loading would remain unchanged from baseline conditions.

**FUTURE WITH -37 FOOT ALTERNATIVE**

Background concentrations of suspended particulates and resulting turbidity measurements, as well as other water quality parameters, already vary as a result of numerous natural and anthropogenic factors including ship traffic, erosion, storms, and seasonal high freshwater inflows into the Delta during the winter and spring. Dredging for the -37 foot MLLW Alternative would temporarily re-suspend sediments in the water column, thereby increasing turbidity, and affecting other water quality parameters.

Mechanical dredging is proposed for the -37 foot MLLW Alternative. Operating from a crane or derrick on a barge, the clamshell bucket is lowered, filled with sediment, raised through the water column, and positioned above the dump barge for temporary containment prior to placement. Clamshell dredging generates turbidity from the impact of the bucket with the channel bottom and from spillage and leakage of material from hoisting the bucket through the water column and swinging it over the barge. Key factors that influence turbidity in the water column are the cycle time of the dredging, the bucket type, the amount of bottom sweeping/smoothing, and the number of passes at a specific location (Collins 1995). Clamshell dredging activities typically result in localized water column concentrations of re-suspended sediment of several hundred mg/L near the dredging operation. The extent of sediment resuspension is a byproduct of several factors, including physical properties of the sediment, site conditions, nature and extent of debris and obstructions, and operational considerations of the dredge equipment and operator. Levels of suspended sediment are expected to be highest closest to the dredging operations. Concentrations typically become reduced to near background levels within several hundred feet of the dredge (Palermo et al. 1990; Bridges et al. 2008). Suspended sediment plumes generated in the immediate vicinity of the dredge are transported by currents to nearby areas until they settle out of the water column (Anchor 2003).

Increased suspended sediments can affect aquatic organisms both directly and indirectly. The level of impact to individual organisms depends on the amount of time an individual organism is exposed to suspended sediments, the concentration of suspended sediment in the water column, and the composition of the sediments (fine-grained versus coarse-grained and chemical associations). An extensive literature review on the subject of dredging-induced turbidity and potential effects on aquatic organisms concluded that it is very unlikely that total suspended solids (TSS) levels would reach harmful concentrations as a result of dredging (Anchor 2003). The length of time it takes the suspended material to settle, combined with the current direction and velocity, would determine the size and duration of the turbidity plume. It is expected that the mixing zone would rapidly return to background or preconstruction conditions upon

completion of the construction activities. Furthermore, settling rates are largely determined by the grain size of the suspended material.

Potential impacts from dredging also include short-term decreases in DO and increases in nutrients, or changes in temperature or pH, due to resuspension of sediment and sediment-bound organic material. These impacts would be temporary, generally being confined to the dredging area, and would return relatively quickly to background levels following construction (Jones and Lee 1978; LaSalle 1990; Lee et al. 1978; Simenstad 1988). USACE research has shown that there are techniques (e.g., slowing the dredge cycle, use of silt curtains, dredge bucket design) that can be employed to dredge sediment and cause a limited amount of sediment to be re-suspended (USACE 1986).

Under the -37 foot MLLW Alternative, impacts from changes in temperature, salinity, pH, and DO; increased turbidity; or nutrient loading would be short-term. Measurements of these water quality parameters would rapidly return to baseline conditions once construction in a given area concludes. Because the changes in salinity and tidal flows are minor in comparison to the baseline conditions, the project's impact on HABs/blooms is likely to be limited to a relatively small geographical displacement of algal blooms with minimal impact on duration or intensity. In all, project related effects on algal blooms is expected to be insignificant in comparison to other algal bloom driving factors such as relative sea level rise and general warming trends for ocean water and river flows. Additionally, the alternative does not propose to dredge farther than Port Chicago, which is at least 25 miles downstream of Jersey Island and the area where DO is currently low. Thus, impacts to water quality from construction are expected to be less than significant as a result of the -37 foot MLLW Alternative as compared to the baseline.

#### FUTURE WITH 38 FOOT ALTERNATIVE

Potential water quality impacts of the -38 foot MLLW Alternative due to construction would be the same as those of the -37 foot MLLW Alternative, although they would occur on proportionally larger scales due to the larger volume of dredged material. However, the impacts to water quality due to construction are expected to be less than significant as a result of the -38 foot MLLW Alternative as compared to the baseline.

#### FUTURE WITH 38 FOOT ALTERNATIVE + SEDIMENT TRAP AND ROCKY OBSTRUCTION (RECOMMENDED PLAN)

Potential water quality impacts of the Recommended Plan Alternative due to construction would be the similar to those of the -38 foot MLLW Alternative, although they would occur on proportionally larger scales due to the larger volume of dredged material from the sediment trap and rock removal. The impacts to water quality due to construction of this alternative are expected to be less than significant as a result of the Recommended Plan Alternative as compared to the baseline.

#### ***EVALUATION OF IMPACT OF WQ-02: VIOLATIONS OF WATER QUALITY STANDARDS BECAUSE OF MOBILIZATION OF CONTAMINATED SEDIMENTS OR RELEASE OF HAZARDOUS MATERIALS***

Dredging of sediments has the potential to release contaminants into the water column if they are present in the material at high concentrations. The suspension of sediment can mobilize sediment-bound contaminants into the water column, where they have the potential to dissolve into the water. However, most contaminants are tightly bound to finer sediment, such as silt, clay, and organic matter and are not readily water soluble or easily released during short-term resuspension of sediments, as would be the case

during dredging operations and from the passage of ships (LTMS 1998). Release of hazardous materials can also occur as a result of mishaps associated with shipping traffic.

#### NO ACTION ALTERNATIVE

The No Action Alternative would continue ongoing maintenance dredging, placement of dredged material in approved open water placement and upland placement sites, and use of the channel. As a result, there would be no changes from the present strategy for evaluating the potential of mobilizing contaminated sediments or release of hazardous materials above baseline conditions. As discussed in **Section 2-4**, there have been no contaminated sediment issues with ongoing maintenance dredging efforts. Therefore, there would be no new impact related to violations of water quality standards, and water quality would be unchanged from baseline conditions. One potential issue for future maintenance and deepening events is the potential for changes to water quality criteria which may affect acceptability of future sediment assessment results. For instance, the USEPA has proposed new selenium criteria for aquatic life for the San Francisco Bay and Delta (USEPA, 2016). This proposed criteria includes maximum tissue selenium concentrations and water column selenium concentrations. The proposed water column concentrations of 0.2 ug/L and 1.0 ug/L, dissolved and particulate fractions, respectively are significantly lower than the existing chronic criteria of 5.0 ug/L for total recoverable selenium. At present, it is unknown whether this new selenium rule if enacted will compel changes to the existing channel maintenance program. No change is expected in the likelihood of an accidental spill or release from shipping traffic.

#### FUTURE WITH -37 FOOT ALTERNATIVE

Prior to dredging the -37 foot MLLW Alternative, sediment chemistry testing would be done to ensure that the new work material does not contain contaminants at concentrations that might result in elevated levels in the water column during dredging. Prior testing has been done in some reaches of the channel to this depth and the results indicated that mobilization into the water column is not likely to result in water quality violations. Future sediment quality assessments would take into account revised water quality criteria such as the USEPA's proposed revision to aquatic selenium criteria for the Bay and Delta.

Sediment within the study area is expected to be suitable for beneficial reuse or unconfined placement as is noted in **Section 2-4** (Sediment and Sedimentation). Past characterizations have not determined the presence of any contaminated materials. Prior to dredging, sediment within the dredge footprint for the -37 foot MLLW Alternative would be sampled and analyzed as described in **Section 2.2.2 and 4.1.2**. This process would also identify contaminated sediments (e.g., sediments unsuitable for beneficial reuse or placement at approved sites) or any hazardous waste. If any such sediments were identified, appropriate dredging and placement methods would be implemented as a condition of the project approvals.

Additionally, USACE would implement BMPs and comply with water quality protection measures included as conditions to the WDRs and WQCs issued by RWQCB and the letter of concurrence issued by the BCDC for USACE's consistency determination. Adherence to these measures and BMPs would minimize the potential for water quality degradation.

Vessels would be operated in compliance with all applicable regulations related to the prevention of water pollution by fuel, harmful substances, and garbage, as well as from accidental discharges. During transport, the dredged material would be secured, with precautions in place to minimize any risk of spills. As such, the potential for the release of hazardous substances from vessel operations during dredging, transport, and placement activities would be minimal.

Therefore, dredging and placement activities are not expected to increase contaminant concentrations in the water column above background conditions, or result in violation of a water quality standard. Impacts of dredging to water quality standards under the -37 foot MLLW Alternative would be less than significant as compared to the baseline.

Deepening the channel will allow petroleum tankers to carry more cargo on each transit of the channel which will result in fewer transits relative to the base condition. Fewer transits of loaded tanker ships should reduce the probability of a spill or accidental release relative to baseline conditions.

#### FUTURE WITH 38 FOOT ALTERNATIVE

Potential water quality impacts of the -38 foot MLLW Alternative are likely to be the same as those of the -37 foot MLLW Alternative, although they would occur on proportionally larger scales due to the larger volume of dredged material. Dredging and placement activities are not expected to increase contaminant concentrations in the water column above background conditions, or result in violations of water quality standards. Thus, short-term, less than significant impacts to water quality are expected under the -38 foot MLLW Alternative as compared to the baseline. Relative to the 37 ft alternative, a 38 ft channel should have a slightly smaller probability of a spill or accidental release of hazardous material. Future sediment quality assessments would take into account revised water quality criteria such as the USEPA's proposed revision to aquatic selenium criteria for the Bay and Delta.

#### FUTURE WITH 38 FOOT ALTERNATIVE + SEDIMENT TRAP AND ROCKY OBSTRUCTION

Potential water quality impacts of the Recommended Plan are likely to be the same as those of the -38 foot MLLW Alternative, although they would occur on proportionally larger scales due to the larger volume of dredged material. Dredging and placement activities are not expected to increase contaminant concentrations in the water column above background conditions, or result in violations of water quality standards. Thus, short-term, less than significant impacts to water quality are expected under this Alternative as compared to the baseline. Relative to the 37 ft alternative, a 38 ft channel should have a slightly smaller probability of a spill or accidental release of hazardous material because of a slight reduction in ship calling frequency due to greater loading capacity associated with increased draft. Future sediment quality assessments would take into account revised water quality criteria such as the USEPA's proposed revision to aquatic selenium criteria for the Bay and Delta.

#### ***EVALUATION OF IMPACT OF WQ-03: NEGATIVE IMPACT TO GROUNDWATER OR SURFACE WATER QUALITY FROM LEACHING OF CONTAMINANTS OR SURFACE WATER RUNOFF FROM PLACEMENT SITES***

#### NO ACTION ALTERNATIVE

The No Action Alternative would continue ongoing maintenance dredging of the existing 35 foot channels and placement of dredged material in designated open water placement areas. This alternative would not result in new sources of contaminant leaching compared to baseline conditions. Therefore, there would be no negative impact to groundwater or surface water quality at the placement sites compared to baseline conditions.

#### FUTURE WITH -37 FOOT ALTERNATIVE

Based on historic sediment testing conducted for the study area (see **Section 2.2.2**), dredged material is expected to meet both upland and wetland beneficial reuse placement criteria. However, if dredged

material were placed at an upland or beneficial reuse site, additional tests to estimate leachate concentrations from sediments would need to be conducted. Wetland or upland placement of dredge material must comply with Subchapter 15 of the Porter-Cologne Water Quality Control Act, which regulates the upland placement of spoil material and subsequent diffuse discharge of water that may affect groundwater quality. The RWQCB is responsible for regulating discharges of waste that could affect the quality of waters of the State. These regulations consider the groundwater-surface water interface within the basin, and are designed to reduce potential groundwater quality impacts from dredged material placement to a less than significant level. The -37 foot MLLW Alternative does not involve excavation to depths that would affect aquifer systems or groundwater movement, and would not involve the construction of substantial new impervious surfaces that would impede groundwater recharge. Thus, less than significant impacts to groundwater or surface water quality are expected under the -37 foot MLLW Alternative as compared to the NEPA baseline.

#### FUTURE WITH 38 FOOT ALTERNATIVE

Potential water quality impacts of the -38 foot MLLW Alternative would be the same as those of the -37 foot MLLW Alternative, although they would occur on proportionally larger scales due to the larger volume of dredged material. Thus, less than significant impacts to groundwater or surface water quality are also expected under the -38 foot MLLW Alternative as compared to the NEPA baseline.

#### FUTURE WITH 38 FOOT ALTERNATIVE + SEDIMENT TRAP AND ROCKY OBSTRUCTION

Potential water quality impacts of this Alternative would be the same as those of the -38 foot MLLW Alternative, although they would occur on proportionally larger scales due to the larger volume of dredged material. Thus, less than significant impacts to groundwater or surface water quality are also expected under this Alternative as compared to the NEPA baseline.

#### ***EVALUATION OF IMPACT OF WQ-04: CAUSE SUBSTANTIAL MODIFICATION OF TIDAL HYDRAULICS, TIDAL CURRENTS, AND CIRCULATION THAT WOULD RESULT IN SIGNIFICANT EFFECTS ON WATER LEVELS OR TIDAL FLOWS WITHIN EITHER SAN FRANCISCO BAY OR THE SACRAMENTO-SAN JOAQUIN DELTA***

#### NO ACTION ALTERNATIVE

Under the No Action Alternative, sedimentation and periodic maintenance dredging would continue to occur as the study area channels have traditionally been maintained at their existing -35 foot MLLW depths. As a result, there would be no changes to the existing geometry of the study area and, therefore, there would be no impact on existing water levels or tidal flows.

#### FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION (RECOMMENDED PLAN) ALTERNATIVES

A detailed analysis of the effect of deepening the navigation channels to the maximum depths under evaluation on water levels, tidal velocities, and tidal flows throughout San Francisco Bay and the Delta is presented in **Appendix B, Water Resources**. Impacts were shown to be less than significant.

#### ***EVALUATION OF IMPACT OF WQ-05: SUBSTANTIALLY IMPAIR WATER QUALITY FOR MUNICIPAL AND INDUSTRIAL BENEFICIAL REUSES***

The D-1641 salinity requirements pertaining to the study area, as well as high bromide concentration concerns for drinking water, are discussed in **Section 2.2.3**. The significance threshold for the project is defined as a violation of D-1641 water quality criteria, or a detectable, measurable adverse impact to drinking water quality due to changes in chloride or bromide concentration. Evaluation of project impacts

against published water quality compliance criteria is normally straightforward. However, there is no single widely accepted criterion for what constitutes a detectable, measurable adverse impact to drinking water quality when criteria are met. Previous studies in the Delta have applied thresholds based on monthly-average salinity differences between conditions with and without a project corresponding to a chloride concentration increase of more than 5 percent or 5 mg/L whichever is greater (e.g., CCWD 2010). Other studies have evaluated water quality impacts based on how or whether the timing of exports would be shifted to maintain water quality conditions equivalent to those under the No Action Alternative (USBR 2015).

The change in X2 position and change in water quality (chloride) were assessed at CCWD, SWP, and CWP pump stations for the -37 ft and -38 ft alternative under Critical Year (2014) and Wet Year (2011) Conditions. For the Recommended Plan alternative (-38 ft alternative with outcrop removal and sediment trap), additional evaluation was done including simulation of a Below Normal Year (2012), a period of record evaluation of X2 changes, additional chloride compliance evaluation at Antioch, and evaluation of changes at the Emmaton, and Jersey Point electroconductivity compliance locations. The results of the modeling predictions are presented in detail in the Salinity Modeling Report that is included as **Appendix B, Water Resources- Attachment 1**. For measurable changes to water quality, the significance level for chloride is no increase levels that exceed 5 mg/L and 5 percent of the baseline concentration. For bromide, the significance level is 5 percent increase in estimated concentration. The significance of changes to bromide levels is evaluated using the percent change in chloride concentration. This is done using the relationship between bromide and chloride concentrations at Delta intakes developed by Denton (2005).

Since the exact weather, hydrology, and operations conditions for the base year cannot be accurately predicted, this analysis considered the effects on salinity during a wet WY, below normal WY, and a critical WY representative of the range of possible Year 0 conditions. The evaluation of effects on salinity during both the wettest, below normal, and driest conditions provides an assessment of the full range of effects on salinity that are likely to result from the alternatives.

### NO ACTION ALTERNATIVE

The No Action Alternative would continue ongoing use of the channel and maintenance dredging at the -35 foot MLLW depth and placement of dredged material in approved open water placement areas. Continuation of existing conditions in the study area would not result in impairment of municipal or industrial beneficial reuses. Therefore, there would be no negative impact to municipal or industrial uses.

### FUTURE WITH -37 FOOT ALTERNATIVE

A three-dimensional hydrodynamic model was used to evaluate the -37 foot MLLW Alternative's impacts on water quality at municipal and industrial water intake and export locations in the Delta (see **Figure 2-5** and **Appendix B, Water Resources**). The -37 foot MLLW Alternative was predicted to result in a maximum monthly-average change in chloride concentration of between 0.3 mg/L at the CCWD Middle River at Victoria Canal Intake to 0.7 mg/L at the CCWD Rock Slough Intake during a critical WY (**Table 4-2, Appendix B - Attachment 1**). During the wet WY evaluated, the predicted maximum monthly-average change in chloride concentration ranged from 0.0 mg/L at the CCWD Middle River at Victoria Canal Intake and the West Canal at the mouth of Clifton Court Forebay to 0.2 mg/L at the CCWD Rock Slough (**Table 4-6, Appendix B - Attachment 1**).

The D-1641 water quality objectives for municipal and industrial beneficial reuse stipulate a maximum allowable concentration of 250 mg/L Cl at the municipal water intakes. The critical year and wet year simulations show that at the CCWD, SWP, and CWP intakes there were no occurrences of chloride above 250 mg/L (**Figures 4.1-2 through Figure 4.1-6 and Figures 4.2-2 through Figure 4.2-6, Appendix B - Attachment 1**). The maximum monthly-average change in chloride concentration predicted to result from the -37 foot MLLW Alternative during the critical and wet years evaluated was less than 0.3 percent of the allowable chloride concentration. This 0.3 percent maximum monthly-average change in chloride concentration occurred during the critical WY, which has historically occurred in 13.8 percent of the years between 1906 and 2014. During the wet WY, which has historically occurred in 33 percent of the years between 1906 and 2014 (see **Section 2.2.3 and Appendix B, Water Resources – Attachment 1**), the maximum monthly-average change in chloride concentration was less than 0.1 percent of the allowable chloride concentration (250 mg/L).

Since these predicted maximum monthly average changes in chloride concentration (occurring during both wet and critical WY) are significantly less than either 5 percent or 5 mg/L, the long-term impact to water quality at the Delta intake and export locations would be less than significant as a result of the 37 foot MLLW Alternative as compared to the NEPA baseline.

The D-1641 criteria includes an evaluation of the number of days chloride must be below 150 mg/L which varies from 155 day/year for a critical year to 240 days for a wet year. A review of the chloride histograms for the FWO and -37 ft alternatives shows no difference in the number of days with chloride below 150 mg/L (**Figures 4.1-2 through Figure 4.1-6 and Figures 4.2-1 through Figure 4.2-6, Appendix B - Attachment 1**). Given no change in the number of days < 150 mg/L for the wet and critical year simulations, the impact of the -37 ft alternative on meeting this D1641 criteria is less than significant.

#### FUTURE WITH 38 FOOT ALTERNATIVE

The three-dimensional hydrodynamic model was also used to evaluate the 38 foot MLLW Alternative's impacts on water quality at municipal and industrial water intake and export locations in the Delta (see **Appendix B, Water Resources – Attachment 1**). For the 38 foot MLLW Alternative, the predicted maximum monthly-average change in chloride concentration ranged from 1.2 mg/L at the CCWD Middle River at Victoria Canal Intake and the Delta-Mendota Canal at Tracy Pumping Plant to 2.4 mg/L at the CCWD Rock Slough Intake during a critical WY (2014) (**Table 4-3, Appendix B - Attachment 1**). During the wet WY (2011) evaluated, the predicted maximum monthly-average change in chloride concentration ranged from 0.1 mg/L at the CCWD Middle River at Victoria Canal Intake to 0.8 mg/L at the CCWD Rock Slough Intake Slough (**Table 4-7, Appendix B - Attachment 1**).

The D-1641 water quality objectives for municipal and industrial beneficial reuse stipulate a maximum allowable concentration of 250 mg/L Cl at the municipal water intakes. The critical year and wet year simulations show that at the CCWD, SWP, and CWP intakes there were no occurrences of chloride above 250 mg/L (Figures 4.1-8 through Figure 4.1-12 and Figures 4.2-8 through Figure 4.2-12, Attachment 1, Appendix B). The maximum monthly-average change in chloride concentration predicted to result from the 38 foot MLLW Alternative during the 2 years evaluated was less than 1.0 percent of the allowable chloride concentration. This 1 percent maximum monthly-average change in chloride concentration occurred during a critical WY (2014), which has historically occurred in 13.8 percent of the years between 1906 and 2014. During a wet WY (2011), which has historically occurred in 33 percent of the years between 1906 and 2014, the maximum monthly-average change in chloride concentration was 0.3 percent of the

allowable chloride concentration (see **Section 2.2.3** and **Appendix B, Water Resources – Attachment 1**). Since these predicted maximum monthly average changes in chloride concentration (occurring during both wet and critical WYs) are significantly less than either 5 percent or 5 mg/L, the long-term impact to water quality at the Delta intake and export locations would be less than significant as a result of the 38 foot MLLW Alternative as compared to the NEPA baseline.

The D-1641 criteria includes an evaluation of the number of days chloride must be below 150 mg/L which varies from 155 day/year for a critical year to 240 days for a wet year. A review of the chloride histograms for the FWO and 38 ft alternatives shows no difference in the number of days with chloride below 150 mg/L (**Figures 4.1-8 through Figure 4.1-12 and Figures 4.2-8 through Figure 4.2-12, Appendix B - Attachment 1**). Given no change in the number of days < 150 mg/L for the wet and critical year simulations, the impact of the 38 ft alternative on meeting this D1641 criteria is less than significant.

### FUTURE WITH 38 FOOT ALTERNATIVE + SEDIMENT TRAP AND ROCKY OBSTRUCTION

The three-dimensional hydrodynamic model was also used to evaluate the Recommended Plan Alternative's impacts on water quality at municipal and industrial water intake and export locations in the Delta (see **Appendix B, Water Resources – Attachment 1**). For the Recommended Plan Alternative, the predicted maximum monthly-average change in chloride concentration ranged from 1.8 mg/L at the CCWD Middle River at Victoria Canal Intake and the Delta-Mendota Canal at Tracy Pumping Plant to 3.6 mg/L at the CCWD Rock Slough Intake during a critical WY (**Table 5-2, Appendix B - Attachment 1**). During the below normal WY evaluated, the predicted maximum monthly-average change in chloride concentration ranged from 1.1 mg/L at the CCWD Middle River at Victoria Canal Intake to 3.1 mg/L at the CCWD Rock Slough Intake (**Table 5-5, Appendix B - Attachment 1**). During the wet WY evaluated, the predicted maximum monthly-average change in chloride concentration ranged from 0.1 mg/L at the CCWD Middle River at Victoria Canal Intake to 1.1 mg/L at the CCWD Rock Slough Intake (**Table 5-8, Appendix B, Water Resources – Attachment 1**).

The D-1641 water quality objectives for municipal and industrial beneficial reuse stipulate a maximum allowable concentration of 250 mg/L Cl at the municipal water intakes. The critical year (2014), below normal year (2012) and wet year (2011) simulations show that at the CCWD, SWP, and CWP intakes there were no occurrences of chloride above 250 mg/L (**Figures 5.2-2 through 5.2-6, 5.3-2 through 5.3-6, and 5.4-2 through 5.4-6, Appendix B – Attachment 1**). The maximum monthly-average change in chloride concentration predicted to result from the Recommended Plan Alternative during the three years evaluated was 3.6 mg/L which is less than 1.5 percent of the allowable chloride concentration (**Table 5-1, Appendix B – Attachment 1**). This 1.5 percent maximum monthly-average change in chloride concentration occurred during a critical WY (2014), which has historically occurred in 13.8 percent of the years between 1906 and 2014. For the 2012WY, which is classified as a below normal year (historically occurred about 20 percent of the years between 1906 and 2014), the maximum monthly change in chloride concentration was 3.1 mg/L which is 1.2 percent of the allowable chloride concentration (Table 5-6, Attachment 1, Appendix B). During the wet WY (2011), which has historically occurred in 33 percent of the years between 1906 and 2014, the maximum monthly-average change in chloride concentration was less than 0.5 percent of the allowable chloride concentration (**Table 5-7, Appendix B - Attachment 1**).

Compliance with the D-1641 criteria regarding minimum number of days of chloride less than 150 mg/L was assessed at the CCWD Rock Slough pump stations (CHCCC06) and the Antioch intake (RSAN007) in

**Figures 5.2-7, 5.3-7, and 5.4-7 of Appendix B – Attachment 1.** To meet the Critical, Below Normal, and Wet water year water quality objectives, the number of days with daily concentration of Cl<sup>-</sup> is less than 150 mg/l should exceed 155 days, 175 days, and 240 days respectively at either CHCCC06 or RSAN007. For the critical year, the number of days below 150 mg/L meets the 155 day minimum at CHCCC06 for both the Recommended Plan and No Action Alternative though the Recommended Plan has 8 fewer days below 150 mg/L. The critical year results at RSAN007 do not meet the criteria for either the Recommended Plan or No Action Alternatives though there is no change in the number of days below 150 mg/L. Because this standard stipulates that daily mean chloride concentration must be less than 150 mg/l for at least 155 days during a critical water year at either at Contra Costa Canal at Pumping Plant #1 or at the Antioch Water Works intake, this standard is met for the Year 0 Recommended Plan scenario. For the below normal year, the number of days below 150 mg/L meets the 175 day minimum at CHCCC06 for both the Recommended Plan and No Action Alternative with no change in number of days meeting criteria. The below normal year results at RSAN007 do not meet the criteria for either the Recommended Plan or No Action Alternatives and the Recommended Plan has 4 fewer days with Cl below 150 mg/L. Because one of the two stations is in compliance, this standard is met for the below normal Year 0 Recommended Plan scenario. For the wet year, the number of days below 150 mg/L meets the 240 day minimum at both CHCCC06 and RSAN007 for both the Recommended Plan and No Action Alternative with no change in number of days meeting criteria. Because both of the stations are in compliance, this standard is met for the wet Year 0 Recommended Plan scenario.

Compliance with the D-1641 conductivity criteria at Emmaton were assessed in **Figures 5.2-8, 5.3-8, 5.4-8, of Appendix B - Attachment 1.** The Emmaton conductivity water quality objectives for agricultural beneficial reuse apply from April 1 through August 15. **Figure 5.2-8** shows the predicted 14-day running average electrical conductivity on the Sacramento River at Emmaton for the Critical Year No Action Alternative and the Critical Year Recommended Plan scenario. The bar chart shows both the Recommended Plan and No Action Alternative result in exceedance of the conductivity criteria. The Recommended Plan results in two additional days of potential exceedance relative to the No Action Alternative during the critical year (2014) which extends the predicted period of non-compliance from 64 to 66 days. It should be noted that in 2014 the State Water Resources Control Board (SWRCB) issued an Order that Approved a Temporary Urgency Change in License and Permit Terms that allowed exceedance of this criteria without violation. **Figure 5.3-8** shows the predicted 14-day running average electrical conductivity on the Sacramento River at Emmaton for the Below Normal Year No Action Alternative and the Below Normal Year Recommended Plan scenario. There is no assurance that the SWRCB would approve a Temporary Urgency Change for conductivity at Emmaton in the future. However, the impact of the Recommended Plan on Emmaton water quality compliance is still considered to be not significant given that the extended period of potential non-compliance only occurs during critical years which are infrequent (about 20 percent of time) and that the period of non-compliance only increases in duration by approximately three percent relative to existing conditions (2 days added to 64 days). **Figure 5.4-8** shows the predicted 14-day running average electrical conductivity on the Sacramento River at Emmaton for the Wet Year No Action Alternative and the Wet Year Recommended Plan scenario. There were no conductivity exceedances for the Recommended Plan or the No Action Alternative for the Wet year.

Compliance with the D-1641 conductivity criteria at Jersey Point were assessed in **Figures 5.2-9, 5.3-9, 5.4-9, of Appendix B - Attachment 1.** These figures show that there were no conductivity exceedances for the Recommended Plan or the No Action Alternative under any of the tested water supply scenarios (Critical, Below Normal, Wet).

The change in bromide concentration was evaluated using the predicted Chloride concentrations for the Recommended Plan (Tables 5-2, 5-5, and 5-8, Appendix B - Attachment 1) and a regression equation to predict bromide concentration using chloride (Denton, 2015). For the critical year, the expected percent change in bromide concentration is similar to that predicted for chloride. For the Rock Slough intake, a maximum monthly increase of 0.013 mg/L and average annual increase of 0.008 mg/L. At the Old River intake, the bromide increase for the critical year would be a maximum monthly increase of 0.006 mg/L and average annual increase of 0.003 mg/L. For the below normal year, the expected change in bromide concentration is similar for the Rock Slough intake is a maximum monthly increase of 0.011 mg/L and average annual increase of 0.004 mg/L. At the Old River intake, the bromide increase for the below normal year would be a maximum monthly increase of 0.009 mg/L and average annual increase of 0.003 mg/L. For The wet year, bromide at Rock Slough Intake increased by a maximum of 0.004 mg/L and 0.002 mg/L at Old River intakes though the average annual increased bromide at these stations was 0.0 at both stations. For the three simulation years, all of the projected monthly bromide increases at all five stations (Clifton Court, Tracy, Rock Slough, Old River, and Middle River) were lower than the 5 percent change significance threshold and are similar in magnitude to the Minimum Detection Limit for bromide using the standard EPA 300.1 laboratory method.

Since these predicted maximum monthly average changes in chloride concentration (occurring during wet, below normal, and critical WYs) are significantly less than either 5 percent or 5 mg/L, and less than 5 percent for bromide, and there is no significant change in D-1641 compliance conditions at any of the relevant stations (CCWD, SWP, and CWP), the long-term impact to water quality at the Delta intake and export locations would be less than significant as a result of the Recommended Plan Alternative as compared to the NEPA baseline.

***EVALUATION OF IMPACT OF WQ-06: SUBSTANTIALLY IMPAIR WATER EXPORTS AND OPERATIONS DUE TO SHIFTS IN X2***

The following discussion focuses on the effects of the alternatives on a shift in the position of X2 (see discussion above) as it relates to an impact on water quality that would require a significant change in water exports or operations. The effect of a shift of X2 on biological resources and sensitive species is evaluated separately in the Biological Resources section.

Changes to channel dimensions can affect salinity intrusion, which can result in impacts to water quality. Gravitational circulation is a primary mechanism that results in saltwater intrusion into the Delta. Freshwater is less dense than seawater and as a result, freshwater flows on top of salty water resulting in salinity stratification. This stratification and the resulting exchange of flows causes a mixing action that enhances salt intrusion. Because the strength of gravitational circulation, which is one of the primary mechanisms responsible for salinity intrusion, generally increases with water depth, incremental deepening of the channels from the existing -35 feet MLLW to -37 or -38 feet MLLW could potentially lead to increased salinity intrusion, resulting in an increase in X2 (i.e., a retreat farther upstream in the estuary of the location at which the daily-averaged 2 psu isohaline occurs near the bed (see **Section 2.2.3 and Appendix B, Water Resources - Attachment 1**).

Since water management operations are regulated during specific conditions in the spring and fall of some WYs, an increase in X2 may impact water operations if the changes in X2 were sufficient to affect exports or require changes to water operations to meet the X2 requirements mandated by either D-1641 or the

Biological Opinion (BO) for delta smelt. The 2010/2017 Los Vaqueros Expansion EIS/EIR used a significance threshold for X2 location of a change of more than 1.0 km (CCWD 2010, 2017). The 2015 Long-Term Water Transfers EIS/EIR used a 10 percent change in the location of X2 as its significance threshold; however, this project was projected to improve X2 positioning so its adverse impacts to Delta Smelt habitat would likely be minimal. For this project, the significance threshold for a change in X2 is identical to the one used by the CCWD and USBR for the Los Vaqueros Expansion project. A significance threshold for change in X2 of greater than 1 km, is reasonable in light of the accuracy of measuring X2 using surface salinity data and the inherent uncertainty in the estimate of net Delta Outflow which is a component of the operations decision tree used for the export pump stations and the upstream control structures.

Since the exact weather, hydrology, and operation conditions for the base year when the proposed project is constructed cannot be accurately predicted, the effects on X2 during both a wet WY, a below normal WY, and a critical WY are representative of the range of possible Year 0 conditions. To understand how the project will impact future conditions, Year 50 conditions are assessed for the Recommended Plan. The evaluation of effects on X2 during a recent 10 year period (2008-2017) as well as for the period of record (1906-2017) have also been evaluated for the Recommended Plan using a X2 regression equation that was validated using results from the UnTrim Bay Delta model. The evaluation of the changes in acreage of the Low Salinity Zone (LSZ) was prepared primarily for the biological impact assessment; however, it can be applied to the WQ-6 analysis to reinforce the low significance of changes in X2 (i.e., the location at which the daily-averaged 2 psu isohaline occurs near the bed) that result from the project. Each of these analyses are detailed in **Chapters 6, 7, and 8 of the Hydrodynamic and Salinity Intrusion Modeling Report (Appendix B - Attachment 1)**.

#### NO ACTION ALTERNATIVE

The No Action Alternative would continue ongoing use of the channel and maintenance dredging and placement of dredged material in approved open water placement areas, including continued use of the deep draft channels. The No Action Alternative would have no influence on any impairments of water exports and operations that may occur in the study area since this is the baseline condition for comparison. Such impairments, if they occur, would continue to be caused by larger exterior forces such as prolonged natural drought events similar to those that have occurred during critical WYs (see **Appendix B, Water Resources - Attachment 1**). Therefore, there would be no negative impact to water exports or operations due to a shift in X2 resulting from the No Action Alternative.

A discussion of the maintenance dredging effects on the position of X2 is warranted here because of differences between modeling assumptions and actual conditions. Maintenance of the existing 35 foot channel has limited influence on the position of X2. Maintenance of the navigation channel, particularly in the Bulls head reach of Suisun Bay is done on an annual basis in the fall to restore the authorized depth plus some advanced maintenance incremental depth. The position of X2 is influenced by the changing status of the channel bathymetry. While the actual bathymetry of the channel is constantly changing in portions that are subject to high rates of shoaling and annual fall dredging events, the hydrodynamic model uses a single bathymetric dataset that represents the maximum allowable depth for each alternative since it includes the authorized channel depth and two full feet of overdepth. Just after a maintenance dredging event, the authorized channel depth with overdepth provides the least resistance to upstream transport of saline bay water. Just before a maintenance event, resistance to upstream transport of saline water is at its greatest, since shoaling has reduced the overall depth of the channel. The position of X2 is influenced by the changing status of the channel bathymetry. For this alternative, the No Action Alternative model bathymetry assumed an authorized depth of -35 ft channel plus 2 ft of over-depth for all of the channel. Since 2009, USACE has been dredging a 2,600 ft section of Bulls head reach to a depth of approximately

-38 ft MLLW. In general, if the channel is shoaling over the winter, spring, and summer, the X2 position estimates provided by the model output for the No Action Alternative are likely somewhat higher than would be experienced in reality given a slightly shallower depth during the critical summer and early fall X2 periods. Additionally, since the actual dredging practice is to dredge Bulls Head Reach to -38 ft MLLW instead of the model assumption of -37 ft MLLW including overdepth, comparisons of change relative to the No Action Alternative are somewhat conservative since the depths in the Bulls Head Reach in the No Action Alternative are greater than -37 ft following advanced maintenance dredging.

#### FUTURE WITH -37 FOOT ALTERNATIVE

The three-dimensional hydrodynamic model was also used to conduct a detailed evaluation of the effect of the -37 Foot MLLW Alternative on X2 under both wet and critically dry conditions. Based on this analysis, the average annual predicted shift in X2 for the -37 Foot MLLW Alternative was 0.03 km downstream during a critical WY and 0.08 km downstream during a wet WY (See Tables 4-1 and 4-5, Figures 4.1-1 and 4.2-1). When only the portions of the year when X2 was greater than 64 km were considered (since there are no regulatory requirements that govern the position of X2 when X2 is west of Port Chicago and less than 64 km), the average predicted shift in X2 for the -37 Foot MLLW Alternative was 0.03 km during a critical WY and 0.05 km during a wet WY.

Since these predicted shifts in X2 are much smaller than the accuracy to which X2 can be measured operationally, it is not expected that deepening the existing channel an additional 2 feet (plus overdepth) would result in a significant shift in the timing or magnitude of water exports in order to maintain water quality conditions equivalent to those under baseline conditions. Based on this evaluation of the change in X2, the impact of the -37 foot MLLW Alternative on water exports or operations would be less than significant as compared to the NEPA baseline.

#### FUTURE WITH -38 FOOT ALTERNATIVE

The three-dimensional hydrodynamic model was also used to conduct a detailed evaluation of the effect of the -38 foot MLLW Alternative under both wet and critically dry conditions (See Tables 4-1 and 4-5, and Figures 4.1-7 and 4.2-7 in Appendix B – Attachment 1). Based on this analysis, the average annual predicted shift in X2 for the -38 foot MLLW Alternative was 0.11 km during a critical WY and 0.20 km during a wet WY. When only the portions of the year when X2 was greater than 64 km were considered (since there are no regulatory requirements that govern the position of X2 when X2 is west of Port Chicago and less than 64 km), the average predicted shift in X2 for the -38 foot MLLW Alternative was 0.11 km during a critical WY and 0.15 km during a wet WY.

Since these predicted shifts in X2 are on the same order of magnitude as the accuracy to which X2 can be measured operationally, it is not expected that deepening the existing channel three additional feet (plus overdepth) would result in a significant shift in the timing or magnitude of exports in order to maintain water quality conditions equivalent to those under the No Action Alternative. Based on this evaluation of the change in X2, the impact of the 38 foot MLLW Alternative on water exports or operations would be less than significant as compared to the NEPA baseline.

#### FUTURE WITH -38 FOOT ALTERNATIVE + SEDIMENT TRAP AND ROCKY OBSTRUCTION

The three-dimensional hydrodynamic model was also used to conduct a detailed evaluation of the effect of the 38 Foot MLLW Alternative plus the sediment trap and rocky obstruction under critically dry, below

normal, and wet conditions for Year 0 and the critically dry condition for Year 50. Based on this analysis, the average annual predicted shift in X2 for the Recommended Plan Alternative was 0.17 km during a critical WY, 0.21 km during a below normal WY, and 0.27 km during a wet WY (Year 0 conditions). When only the portions of the year when X2 was greater than 64 km were considered (since there are no regulatory requirements that govern the position of X2 when X2 is west of Port Chicago and less than 64 km), the average predicted shift in X2 for the Recommended Plan Alternative was 0.17 km during a critical WY, 0.21 km during a below normal WY, and 0.23 km during a wet WY (Year 0 conditions). For Year 50 conditions, the average predicted shift in X2 for the Recommended Plan Alternative was 0.17 km for all the year and for that portion of the year with X2 > 64 km; the difference between the Year 0 and Year 50 dry year model runs show the relative position of X2 moves down 4 km in the upstream area if there are no changes made to upstream releases and downstream pumping to account for climate and sea level change.

As discussed in the X2 assessment for the No Action Alternative, the predictions of change for the Recommended Plan are expected to be somewhat conservative because the No Action Alternative model bathymetry assumption of -37 ft MLLW depth (-35 feet + 2 foot of overdepth) for the 2,600 ft. Bullshead segment was used rather than the actual -38 ft MLLW depth the channel has been deepened to as part of the advanced maintenance dredging episodes in this segment since 2009 (similarly the X2 change predictions for the -37 ft and -38 ft alternatives are also likely somewhat conservative.)

In addition to the three simulated years, X2 was predicted for the 10 year period from 2008 to 2017 using a calibrated and validated X2 empirical function as detailed in Chapter 8 of the Hydrodynamic and Salinity Intrusion Model (**Appendix B - Attachment 1**). The results shown in Table 8-1 of the Salinity Model Report show that the annual average change in X2 for the Recommended Plan for these 10 years ranges from 0.18 to 0.22 km. This is an indication that the Recommended Plan change to X2 varies little (roughly 0.2 km) regardless of hydrologic loading. That the empirical equation predictions compare very favorably to the three years of UnTRIM simulation results provides the authors additional confidence in the overall analysis.

**Chapter 7 of the Hydrodynamic and Salinity Intrusion Modeling Report** includes an assessment of the change in the Low Salinity Zone (LSZ) of Suisun Bay. This analysis shows that the predicted change in X2 location due to the Recommended Plan for all three simulated years' results in average monthly changes that range from an additional 446 acres to a loss of 597 acres. The average monthly change in acreage across all 36 simulated months was a reduction of 45 acres out of a monthly average of 20,375 acres. If only months with losses are averaged, the loss in acreage due to the Recommended Plan is less than 1.1 percent of the average monthly acreage. These insignificant changes in LSZ acreage due to the Recommended Plan are another indication that the change in X2 position from the Recommended Plan is not significant.

Since these predicted shifts in X2 are on the same order of magnitude as the accuracy to which X2 can be measured operationally and the change in LSZ acreage is not significant as discussed in **Chapter 7 of the Hydrodynamic and Salinity Intrusion Modeling Report (Appendix B - Attachment 1)**, it is not expected that deepening the existing channel by three feet will result in a significant shift in the timing or magnitude of exports in order to maintain water quality conditions equivalent to those under the No Action Alternative. Based on this evaluation of the change in X2, the impact of the Recommended Plan Alternative on water exports or operations would be less than significant as compared to the NEPA baseline.

#### 4.1.4 AIR QUALITY

Using the assumptions and models discussed in **Sections 2.2.4**, air pollutant emissions from the proposed construction and operational activities were calculated using the most current emission factors and methods, then compared to the criteria identified in **Section 2.2.4** to determine their significance. For impacts that exceeded a significance criterion, measures were evaluated for their ability to mitigate the impacts to insignificance. No sensitive land uses are located in the study area—it primarily contains the existing ship channel and placement sites. No sensitive land uses are located within 1,000 feet of the proposed dredging footprints or within 1,000 feet of the docking locations for ships.

An alternative would be considered to have a significant impact on air quality if it would cause the following:

Impact AQ-01: Violate any air quality standard, or contribute substantially to an existing or projected air quality violation

Impact AQ-02: Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is nonattainment under an applicable Federal or state ambient air quality standard, including releasing emissions that exceed quantitative thresholds for ozone precursors

Impact AQ-03: Expose sensitive receptors to substantial pollutant concentrations

Impact AQ-04: Create objectionable odors affecting a substantial number of people

Impact AQ-05: Conflict with, or obstruct implementation of the applicable air quality plan

##### 4.1.4.1 THRESHOLDS

The purpose of the general conformity program is to ensure that actions taken by the Federal government do not undermine state or local efforts to achieve and maintain NAAQS. Before a Federal action is taken, it must be evaluated for conformity with the State Implementation Plan (SIP). All reasonably foreseeable emissions, both direct and indirect, predicted to result from the action are taken into consideration and must be identified with respect to location and quantity. Direct emissions occur at the same time and place as the action. Indirect emissions are reasonably foreseeable emissions that may occur later in time and/or farther removed from the action. The emissions are subject to conformity if the Federal agency can practicably control them and maintain control through a continuing program responsibility. If it is found that the action would create emissions above de minimis threshold levels specified in USEPA regulations, the action cannot proceed unless mitigation measures are specified that would bring the project into conformance.

General conformity applies in both Federal non-attainment and maintenance areas. In these areas, it applies to any Federal action not specifically exempted by the CAA or USEPA regulations. General conformity does not apply to projects or actions that are covered by the transportation conformity rule. If a Federal action falls under the general conformity rule, the Federal agency responsible for the action is responsible for making the conformity determination. In some instances, a state will make the conformity determination under delegation from a Federal agency.

The significance criteria used to evaluate NEPA air quality effects are based on the Federal general conformity thresholds. Currently, the SFAAB is classified as moderate nonattainment for the Federal 8-hour ozone standard, nonattainment for the 24-hour PM<sub>2.5</sub> standard, and maintenance for the Federal CO standards. Because sulfur dioxide is considered a precursor to PM<sub>2.5</sub>, the conformity threshold for SO<sub>2</sub> also applies. The portion of the SVAB under jurisdiction of YSAQMD is currently classified as severe non-attainment for the Federal 8-hour ozone standard, non-attainment for the 24-hour PM<sub>2.5</sub> standard, and maintenance for the Federal CO standards. **Table 4-3** shows the applicable general conformity thresholds that apply to the Recommended Plan in both air basins.

**Table 4-3. General Conformity de minimis Thresholds for Projects in the SFBAAB and SVAB.**

Pollutant	SFBAAB Threshold (tpy)	SVAB Threshold (tpy)
CO	100	100
NO <sub>x</sub>	100	25
ROG	50	25
PM <sub>2.5</sub>	100	100
PM <sub>10</sub>	--	100
SO <sub>2</sub>	100	100

Source: USEPA 2016

### NO ACTION ALTERNATIVE

**AQ-01: Would the alternative conflict with or Obstruct Implementation of the Applicable Air Quality Plan?** The No Action Alternative would continue maintenance dredging of the 35 foot deep navigation channel and existing shipping patterns. This alternative does not include construction, does not increase ship calls as compared to the 50-year NEPA baseline, and would not incrementally increase emissions within the study area. Therefore, the No Action Alternative would not violate any air quality standard or contribute to any violations.

**Impact AQ-02: Would the alterantive result in a cumulatively considerable net increase of any criteria pollutant for which the project region is nonattainment under an applicable federal or state ambient air quality standard?** The No Action Alternative would continue maintenance dredging of the 35 foot deep navigation channel and existing shipping patterns. This alternative does not include construction, does not increase ship calls as compared to the 50-year NEPA baseline, and would not incrementally increase emissions within the study area. Therefore, the No Action Alternative would not result in a net increase of any criteria pollutant for which the project region is in a nonattainment status or release emissions that exceed ozone precursor emissions.

**Impact AQ-03: Would the alternative expose sensitive receptors to substantial pollutant concentrations?** The No Action Alternative does not include construction and does not increase ship calls as compared to the NEPA baseline. There would be no incremental emissions because of the No Action Alternative. Therefore, the No Action Alternative would not expose sensitive receptors to substantial pollutant concentrations under NEPA.

**Impact AQ-04: Would the alternative result in other emissions (such as those leading odors) adversely affecting a substantial number of people?** The No Action Alternative would continue maintenance dredging of the 35 foot deep navigation channel and existing shipping patterns. This alternative does not include construction, does not increase ship calls as compared to the 50-year NEPA baseline, and would not incrementally increase emissions within the study area. Therefore, the No Action Alternative would create no objectionable odors affecting a substantial number of people under NEPA.

**Impact AQ-05: Would the Alternative Conflict With, Or Obstruct Implementation of The Applicable Air Quality Plan?** The No Action Alternative would continue maintenance dredging of the 35 foot deep navigation channel and existing shipping patterns. This alternative does not include construction, does not increase ship calls as compared to the 50-year NEPA baseline, and would not incrementally increase emissions within the study area. Therefore, the No Action Alternative would not conflict with any applicable

plans, policies, or regulations adopted to reduce emissions and there would be no impact as compared to the NEPA baseline.

### FUTURE WITH -37 FOOT ALTERNATIVE

**AQ-01: Would the alternative conflict with or Obstruct Implementation of the Applicable Air Quality Plan** Table 4-4 shows the annual construction emissions for the -37 Foot MLLW Alternative. The data show that construction emissions would not exceed the applicable general conformity thresholds for any of the applicable criteria pollutants in either the SFBAAB or SVAB, where construction activities would take place for the -37 foot MLLW Alternative.

**Table 4-4. Annual Construction Emissions for the -37 Foot MLLW Alternative as Compared to the De Minimis Thresholds.**

Operational Activities	Air Pollutant					
	ROG	NO <sub>x</sub>	CO	PM <sub>10</sub>	PM <sub>2.5</sub>	SO <sub>2</sub>
<b>Within SFBAAB</b>						
Dredging (tpy)	1.6	24.7	10.3	24.7	24.7	0.1
Worker Transport (tpy)	0	0.2	0.4	0	0	0
Sediment Transport (tpy)	2.4	19.6	32.6	0.5	0.5	0
Total Emissions (tpy)	<b>3.9</b>	<b>44.4</b>	<b>43.2</b>	<b>25.2</b>	<b>25.2</b>	<b>0.1</b>
SFBAAB de minimis Threshold (tpy)	50	100	100	--	100	100
Exceed?	No	No	No	No	No	No
<b>Within SVAB</b>						
Sediment Transport (tpy)	0.2	1.5	2.5	0.04	0.04	0.001
SVAB de minimis Threshold (tpy)	25	25	100	100	100	100
Exceed?	No	No	No	No	No	No

**Table 4-5** shows the annual operational emissions for the -37 Foot MLLW Alternative as compared to the No Action Alternative (NEPA baseline). As shown, for the years 2023, 2030, or 2040, as compared to the NEPA baseline, emissions would decrease under the -37 Foot MLLW Alternative. Therefore, emissions would not exceed the applicable general conformity thresholds for any of the applicable criteria pollutants in the SFBAAB. This comparison uses SFBAAB thresholds because: 1) most of the impacts would occur in this air basin; and 2) the SFBAAB has more stringent thresholds than the SVAB.

Because emissions would not exceed applicable NEPA thresholds, the -37 Foot MLLW Alternative would result in less-than-significant impacts.

**Table 4-5. Annual Operational Emissions under the -37 Foot MLLW Alternative Compared to the No Action Alternative (NEPA).**

Operational Activities	Air Pollutant

Tugs (tpy)	-0.13	-0.81	-0.03	-0.03
Total Emissions (tpy)	-0.43	-8.01	-0.21	-0.19
BAAQMD Thresholds (tpy)	50	100	100	100
Exceed?	No	No	No	No
<b>2040</b>				
Vessels (tpy)	-0.3	-7.2	-0.18	-0.16
Tugs (tpy)	-0.13	-1.14	-0.03	-0.03
Total Emissions (tpy)	-0.43	-8.34	-0.21	-0.19
BAAQMD Thresholds (tpy)	50	100	100	100
Exceed?	No	No	No	No

**Impact AQ-02: Would the alternative result in a cumulatively considerable net increase of any criteria pollutant for which the project region is nonattainment under an applicable federal or state ambient air quality standard?** As shown in **Table 4-4** and **Table 4-5**, construction and operations under the -37 Foot MLLW Alternative would not result in substantial emission increases. Consequently, the -37 Foot MLLW Alternative would not cause or contribute significant increases in air quality criteria pollutants as compared to the NEPA baseline.

**Impact AQ-03: Would the alternative expose sensitive receptors to substantial pollutant concentrations?** Construction activities would produce Diesel Particulate Matter (DPM) and PM<sub>2.5</sub> emissions from a variety of equipment, including dredging, boat operation, and pumps. These emissions could result in elevated concentrations of DPM and PM<sub>2.5</sub> at sensitive receptors. A health risk assessment was not conducted because the distance between the emission sources and sensitive receptors exceeds the 1,000 feet screening threshold established by the BAAQMD (BAAQMD 2012).

Construction activities would produce DPM and PM<sub>2.5</sub> emissions due to diesel combustion equipment such as dredging equipment, marine vessels, and sediment unloading equipment. These emissions could result in elevated concentrations of DPM and PM<sub>2.5</sub>.

BAAQMD uses the 1,000-foot screening threshold to determine whether a project's emissions of TACs during construction and operation merit a health risk assessment. YSAQMD does not require a health risk

assessment for projects that consist primarily of mobile source emissions. Construction emissions generated by the -37 foot MLLW Alternative would occur in water-based locations located substantially farther than 1,000 feet from sensitive receptors. Consequently, a quantitative health risk assessment was not performed for this alternative. The -37 foot MLLW Alternative would not expose sensitive receptors to substantial quantities of TACs or PM<sub>2.5</sub>, and impacts would be less than significant as compared to the NEPA baselines.

**Impact AQ-04: Would the alternative result in other emissions (such as those leading odors) adversely affecting a substantial number of people?** The -37 foot MLLW Alternative would include construction and a decrease in ship calls as compared to the No Action Alternative (NEPA baseline). Both activities would generate odors from diesel fuel combustion. However, construction dredging would occur in the ship channel, which is located at substantial distances from sensitive receptors. The placement sites are also located at considerable distances from sensitive receptors. Operationally, fewer ships would travel in the ship channel than under the No Action Alternative, and these ships would dock at industrial locations, distant from sensitive receptors. Therefore, there would be no incremental odor impacts as a result of the -37 foot MLLW Alternative.

**Impact AQ-05: Would the Alternative Conflict With, Or Obstruct Implementation of The Applicable Air Quality Plan?** The -37 foot MLLW Alternative includes construction and changes in operational emissions associated with ship calls. USEPA has established general conformity requirements that establish de minimis emission thresholds. Projects that exceed de minimis thresholds are required to prepare an in-depth conformity analysis that demonstrates that the project would not worsen existing violations or contribute to new violations of the NAAQS. As shown in **Table 4-4** and **Table 4-5**. The -37 foot MLLW Alternative does not exceed any de-minimis thresholds.

SIPs are the primary planning tool for areas that are nonattainment for one or more of the NAAQS. SIPs are also required for areas that were previously nonattainment but that have been reclassified as attainment-maintenance. The -37 foot MLLW Alternative would not conflict with BAAQMD's existing SIPs because marine transportation is typically not covered by SIPs and the alternative would not result in emissions that exceed the Federal conformity thresholds. Consequently, there would be no impact to existing federally required air quality plans.

#### [FUTURE WITH 38 FOOT AND 38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES](#)

**AQ-01: Would the alternative conflict with or Obstruct Implementation of the Applicable Air Quality Plan** The applicable Federal air quality plan is the general conformity program, which is to ensure that actions taken by the Federal government do not undermine state or local efforts to achieve and maintain NAAQS. Before a Federal action is taken, it must be evaluated for conformity with the SIP. Table 4-6 shows the annual construction emissions for the Recommended Plan. As shown, construction emissions would not exceed the applicable general conformity thresholds for any of the applicable criteria pollutants in the SFBAAB or SVAB under the Recommended Plan.

**Table 4-6. Annual Construction Emissions for the Recommended Plan as Compared to Conformity Thresholds.**

Construction Activities	Air Pollutant					
	ROG	NO <sub>x</sub>	CO	PM <sub>10</sub>	PM <sub>2.5</sub>	SO <sub>2</sub>
<b>Year 2023 Within BAAQMD</b>						
Dredging (tpy)	0.89	6.29	14.37	0.35	0.34	0.04
Worker Transport (tpy)	0.06	0.35	0.29	0.01	0.01	0.00
Sediment Transport (tpy)	1.46	29.43	9.64	0.21	0.2	0.05
Total Emissions (tpy)	<b>2.41</b>	<b>36.07</b>	<b>24.3</b>	<b>0.57</b>	<b>0.54</b>	<b>0.09</b>
SFBAAB de minimis Threshold (tpy)	50	100	100	--	100	100

Exceed?	No	No	No	No	No	No

**Table 4-7** shows the No Action Alternative (NEPA Baseline) and Recommended Plan emissions and **Table 4-8** shows the annual operational emissions for the Recommended Plan as compared to the No Action Alternative (NEPA baseline). As shown, for the years 2023, 2030, or 2040, emissions would not exceed the applicable thresholds for any of the applicable criteria pollutants in the SFBAAB. This comparison uses BAAQMD thresholds because: 1) most of the impacts would occur in the SFBAAB; and 2) BAAQMD has more stringent thresholds than YSAQMD.

**Table 4-7. Annual Operational Emissions for the No Action Alternative (NEPA Baseline) and RECOMMENDED PLAN.**

Total Emissions (tpy)	<b>-0.61</b>	<b>-11.22</b>	<b>-0.29</b>	<b>-0.27</b>
BAAQMD Thresholds (tpy)	50	100	100	100
Exceed?	No	No	No	No

Because emissions would not exceed applicable thresholds, the Recommended Plan would result in less-than-significant impacts.

**Impact AQ-02: Would the alternative result in a cumulatively considerable net increase of any criteria pollutant for which the project region is nonattainment under an applicable Federal or state ambient air quality standard?** Construction and operations under the Recommended Plan would not result in substantial emission increases. Consequently, the Recommended Plan would not cause or contribute to significant increases in air quality criteria pollutants as compared to the NEPA baseline.

**Impact AQ-03: Would the alternative expose sensitive receptors to substantial pollutant concentrations?** The Recommended Plan would include construction and a decrease in ship calls as compared to the No Action Alternative (NEPA baseline). However, emissions associated with construction are not expected to expose sensitive receptors to substantial pollutant concentrations because emissions would occur in the existing ship channel, more than 1,000 feet from sensitive receptors. This impact is considered less than significant.

**Impact AQ-04: Would the alternative result in other emissions (such as those leading odors) adversely affecting a substantial number of people?** The Recommended Plan would include construction and a decrease in ship calls as compared to the No Action Alternative (NEPA baseline). Both activities would generate odors from diesel fuel combustion. However, construction dredging would occur in the ship channel, which is located at substantial distances from sensitive receptors. Similarly, the placement sites

are also located at considerable distances from sensitive receptors. Operationally, fewer ships would travel in the ship channel than under the No Action Alternative, and these ships would dock at industrial locations, distant from sensitive receptors. Therefore, there would be no incremental odor impacts as a result of the Recommended Plan.

**Impact AQ-05: Would the Alternative Conflict With, Or Obstruct Implementation of The Applicable Air Quality Plan? The Recommended Plan includes construction and changes in operational emissions associated with ship calls. USEPA has established general conformity requirements that establish de minimis emission thresholds. Projects that exceed de minimis thresholds are required to prepare an in-depth conformity analysis that demonstrates that the project would not worsen existing violations or contribute to new violations of the NAAQS. As shown in Table 4-7 and Table 4-8, the Recommended Plan does not exceed any de minimis thresholds.**

State Implementation Plans (SIPs) are the primary planning tool for areas that are nonattainment for one or more of the NAAQS. SIPs are also required for areas that were previously nonattainment but that have been reclassified as attainment-maintenance. The Recommended Plan would not conflict with BAAQMD’s existing SIPs because marine transportation is typically not covered by SIPs and the alternative would not result in emissions that exceed the Federal conformity thresholds. Consequently, there would be no impact to existing federally required air quality plans.

**4.1.5 CLIMATE CHANGE INDUCED BY PROJECT**

The project specific analysis examines the environmental effects from construction associated with deepening the study area channels to either -37 or -38 feet MLLW + the sediment trap and rocky obstruction. The analysis also evaluates changes in shipping operations directly attributable to the alternatives. GHG emissions from the proposed construction and operational activities were calculated using the most current emission factors and methods, and then compared to the applicable criteria to determine their significance. For GHG emission impacts that exceeded a significance criterion, measures were evaluated for their ability to mitigate these impacts to insignificance.

**4.1.5.1 OPERATIONAL ASSUMPTIONS**

**Appendix D, Economic Analysis** projects that the volume of petroleum products (which are the dominant cargo in the project area) will grow at the same rate. The vessel mix, however, is projected to change if deepening is implemented. The predicted increase in petroleum product volumes is expected to be shipped primarily in vessels of the Panamax class. The deeper channel depth would allow those vessels to avoid some of the costly operational strategies currently in use, making them a more efficient option than the larger vessels. Therefore, the climate change analysis focuses on the change of Panamax vessels over time among alternatives as shown in **Table 4-9**, with the year 2023 as the construction start year, similar to the economic analysis.

**Table 4-9. Projected Annual Number of Panamax Ship Calls Over Time.**

Year	Total Panamax Ship Calls/Year		
	NEPA Baseline/No Action Alternative (35-Foot)	-37 foot MLLW Alternative	-38 foot MLLW Alternative
2023	127	116	113
2030	151	141	136
2040	179	169	165

The following assumptions were used to assess GHG emissions from operations:

- Annual ship calls are based on 2014 data, which represented the available full year of ship data in the USACE Waterborne Commerce Statistics Center (USACE 2016) at the time the analysis was conducted.
- The maximum tugboat engine size is assumed to be 3,600 hp for main engines and 235 hp for auxiliary engines, based on the maximum values in CARB's OFFROAD2014 model. A load factor of 50 percent for main engines and 31 percent for tugboats is assumed based on OFFROAD2014.
- Two tugboats would accompany each Panamax vessel (Port of Los Angeles 2008b).
- Marine vessel emissions are based on the CARB's Emission Estimation Methodology for Ocean-Going Vessels (2011). CARB's estimation procedure uses separate calculations for main and auxiliary engines.
- Average vessel characteristics for tankers assumes main engine power of 13,034 kilowatts and auxiliary power of 2,339 kilowatts (CARB 2011). Estimates assume a load factor of 83 percent for main engines and 26 percent for auxiliary engines (CARB 2011). Emission factors for main engines and auxiliary engines are based on medium marine distillate (0.1 percent sulphur) (CARB 2011). Main engines are assumed to operate for 2 hours per ship call and auxiliary engines for 34 hours per ship call.
- Annual ship calls are based on 2014 data, which represents the most recently available full year of ship data in the USACE Waterborne Commerce Statistics Center (USACE 2016).

Maintenance dredging of the channels to their maintained depths would continue to occur annually during the dredging window.

An alternative could have an impact on climate change if it would cause the following:

Impact CC-1: Directly or indirectly exceed applicable Federal or state GHG standards:

- NEPA: GHG emissions are compared to the CEQ reference point of 25,000 metric tons per year of CO<sub>2</sub> equivalent.

Impact CC-2: Conflict with an applicable plan, policy, or regulation adopted to reduce GHG emissions and climate change impacts

NO ACTION ALTERNATIVE**Table 4-10. Operational GHG Emissions for the No Action Alternative (Metric Tons per Year).**

Activities/yr.	CH <sub>4</sub>	N <sub>2</sub> O	CO <sub>2</sub>	CO <sub>2</sub> equivalent
<b>2023</b>

Total GHG Emissions	0.25	0.02	2,612	<b>2,623</b>
GHG Emissions Threshold				10,000
Exceed Threshold?				<b>No</b>

**Impact CC-1: Directly or indirectly exceed applicable Federal or state GHG standards:** Because the No Action Alternative does not include construction and does not increase ship calls as compared to the NEPA baseline, it would not result in additional GHG emissions. Therefore, the No Action Alternative would not conflict with any applicable plans, policies, or regulations adopted to reduce GHG emissions and there would be no impact as compared to the NEPA baseline.

**Impact CC-2: Conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions and climate change impact:** Under the No Action Alternative, there would be no construction-related GHG emissions and ship calls would be the same as compared to the NEPA baseline. This impact is considered less than significant because the level of increased ship activity would not conflict with applicable plans, policies, or regulations designed to reduce GHG emissions and climate change impacts.

FUTURE WITH -37 FOOT ALTERNATIVE

**Impact CC-1: Directly or indirectly exceed applicable Federal or state GHG standards:** The -37 foot MLLW Alternative would generate GHG emissions during construction and operation. Construction emissions would occur in 2021 and would include dredging emissions, worker transport on land and by boat to the dredging operation, and boat transport of dredged sediment to placement sites (**Table 4-11**). CO<sub>2</sub>

equivalent emissions of 11,778 metric tons per year are less than the CEQ reference point of 25,000 metric tons per year.

As compared to the No Action Alternative, the -37 foot MLLW Alternative would have fewer ship calls in 2023, 2030, and 2040 (Table CC-1), reducing GHG emissions from vessels and tugs (**Table 4-12**). Even though operation and maintenance emissions would increase to maintain the deeper ship channel, total GHG emissions would be substantially below the Federal threshold of 25,000 metric tons of CO<sub>2</sub> equivalent per year for all three future years considered in this analysis.

USACE has not adopted a significance threshold and has established the position that there are no science-based GHG significance thresholds. In the absence of an adopted or science-based GHG standard, in compliance with the CEQ and USACE NEPA implementing regulations, a significance determination regarding the -37 foot MLLW Alternative's GHG emissions is not made under NEPA.

BAAQMD Emissions Threshold				10,000
Exceed Threshold?				<b>No</b>

**Impact CC-2: Conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions and climate change impact:** GHG emissions generated by construction and operation of the -37 foot MLLW Alternative would not exceed the Federal GHG emission level of 25,000 metric tonnes of CO<sub>2</sub> equivalent per year. As a result, the -37 foot MLLW Alternative would not conflict with adopted plans aimed at reducing GHG emissions, and impacts would be considered less than significant.

## FUTURE WITH 38 FOOT AND 38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**Impact CC-1: Directly or indirectly exceed applicable Federal or state GHG standards:** The 38 foot MLLW Alternative would generate GHG emissions during construction and operation. The construction emissions would occur in 2021 and 2023 and include dredging emissions, worker transport on land and by boat to the dredging operation, and boat transport of dredged sediment to various placement sites (**Table 4-14. Construction GHG Emissions for the -38 foot MLLW Alternative (Metric Tons per Year)**). Although the 38 foot MLLW Alternative's emissions of 17,841 metric tons of CO<sub>2</sub> equivalent per year would be higher than that associated with construction of the -37 foot MLLW Alternative (see **Table 4-11. Construction GHG Emissions for the -37 foot MLLW Alternative (Metric Tons per Year)**), it would still be less than the Federal threshold of 25,000 metric tons per year.

**Table 4-14. Construction GHG Emissions for the -38 foot MLLW Alternative (Metric Tons per Year).**

Activities	CH <sub>4</sub>	N <sub>2</sub> O	CO <sub>2</sub>	CO <sub>2</sub> equivalent
Dredging	1.22	0.4	15,365.07	15,517.34
Worker Transport	0.01	0.01	239.01	243.65
Sediment Transport	0.12	0.05	2,061.23	2,080.17
Total GHG Emissions	1.34	0.46	17,665.31	<b>17,841.16</b>
GHG Emissions Threshold				25,000
Exceed Threshold?				<b>No</b>

As compared to the No Action Alternative, the -38 foot MLLW Alternative would have fewer ship calls in 2023, 2030, and 2040, thereby reducing GHG emissions from vessels and tugs (**Table 4-13 and Table 4-14**). Even though operation and maintenance emissions would increase to maintain the deeper ship channel, total GHG emissions would be substantially below the Federal threshold of 25,000 metric tons of CO<sub>2</sub> equivalent per year.

USACE has not adopted a significance threshold and has established the position that there are no science-based GHG significance thresholds. In the absence of an adopted or science-based GHG standard, in compliance with the CEQ and USACE NEPA implementing regulations, a significance determination regarding the -38 foot MLLW Alternative's GHG emissions is not made under NEPA.

**Table 4-15. Operational GHG Emissions for the 38 foot MLLW Alternative Minus Existing Conditions (Metric Tons per Year).**

Activities/yr.	CH <sub>4</sub>	N <sub>2</sub> O	CO <sub>2</sub>	CO <sub>2</sub> equivalent

BAAQMD Emissions Threshold				10,000
Exceed Threshold?				<b>No</b>
<b>2040</b>				
Vessels	0.2	-	1,561	1,565
Tugs	0.006	0.01	543	548
O&M <sup>1</sup>	0.159	0.058	2,226	2,248
Total GHG Emissions	0.36	0.07	4,330	<b>4,361</b>
BAAQMD Emissions Threshold				10,000
Exceed Threshold?				<b>No</b>

**Impact CC-2: Conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions and climate change impact:** GHG emissions generated by construction and operation of this alternative would not exceed the Federal GHG emission level of 25,000 metric tons of CO<sub>2</sub> equivalent per year. As a result, the 38 foot MLLW Alternative would not conflict with adopted plans aimed at reducing GHG emissions.

#### 4.1.6 BIOLOGICAL RESOURCES

Impacts on biological resources, including special status species, critical habitat, EFH, and other sensitive resources, were qualitatively evaluated based on the habitat preferences for various species known or suspected to occur in the study area, as well as the quantity and quality of existing habitat. Potential impacts were analyzed using recent CDFW, California Native Plant Society, NMFS, and USFWS data for special status species and habitats, fish surveys, literature reviews, and professional expertise and judgment in evaluating how the alternatives could interact with and impact aquatic biological resources. The decision in the alternatives to limit dredging within the programmatically established Long-Term Management Strategy (LTMS) environmental work windows constitutes a minimization and possibly avoidance measure with respect to Special Status Species and Essential Fish Habitat.

Under NEPA, an alternative would be considered to have a significant impact on biological resources if it would:

- Impact BR-01: Cause increased turbidity that adversely affects special status species and critical habitat; or
- Impact BR-02: Cause benthic habitat disturbance that adversely affects special status species, critical habitat, or habitat for commercially valuable marine species; or
- Impact BR-03: Cause underwater noise that adversely affects special status fish and marine mammals; or
- Impact BR-04: Adversely affect special status or commercially or recreationally important marine species through entrainment; or
- Impact BR-05: Result in the disturbance of EFH and “Special Aquatic Sites,” including eelgrass beds and mudflats; or
- Impact BR-06: Interfere with the movement of resident or migratory fish or wildlife species; or
- Impact BR-07: Adversely affect special status fish species, including their critical habitat, as a result of X2 shifts.

### NO ACTION ALTERNATIVE

**Impact BR-01: Cause increased turbidity that adversely affects special status species or critical habitat:**

The No Action Alternative would continue ongoing maintenance dredging and use of the channel, and would not result in turbidity changes above baseline conditions. Therefore, special status species or critical habitat would not be affected by turbidity above baseline conditions.

**Impact BR-02: Cause benthic habitat disturbance that adversely affects special status species, critical habitat, or commercially valuable marine species:**

The No Action Alternative would continue ongoing maintenance dredging and use of the channel, and would not result in changes to benthic habitat above baseline conditions. USACE would continue to implement applicable avoidance, minimization, and mitigation measures such as those described in section 1.3.4 of NMFS’s 2015 programmatic biological opinion on LTMS dredging activities. These include using species- and location-specific work windows; limiting hopper dredge return-water overflow to 15 minutes per dredging episode and allowing no overflow from barges receiving material from clamshell dredges to reduce turbidity; implementing turbidity control and/or monitoring measures when dredging within 250 m of eelgrass; ensuring that hopper dredge dragheads maintain contact with the benthic sediment when dredging, etc. Overall, the potential effects of benthic habitat disturbance would be short term and localized. Therefore, there would be no additional impacts to special status species, critical habitat, or commercially valuable marine species above baseline conditions.

**Impact BR-03: Cause underwater noise that adversely affects special status fish or marine mammals:**

The No Action Alternative would continue ongoing maintenance dredging and use of the channel. The existing baseline underwater noise levels associated with periodic dredging of the channels and regular ship traffic movements within the channels would not change. Therefore, there would be no additional noise related impacts to special status fish or marine mammals above baseline conditions. It is likely that most animals occurring within and near the channels have become adapted to the existing underwater navigation related noises that regularly occur throughout the year.

**Impact BR-04: Adversely affect special status or commercially or recreationally important marine species through entrainment:**

The No Action Alternative would continue ongoing maintenance dredging and use of the channel, and would not result in additional entrainment impacts. Therefore, there would be no

impacts to special status or commercially or recreationally important marine species above baseline conditions.

**Impact BR-05: Result in the disturbance of EFH and “Special Aquatic Sites,” including eelgrass beds and mudflats:** The No Action Alternative would continue ongoing maintenance dredging operations and shipping use of the channel, and would not result in additional disturbance of EFH or Special Aquatic Sites. Therefore, there would be no new impacts to EFH and Special Aquatic Sites above baseline conditions.

**Impact BR-06: Interfere with the movement of resident or migratory fish or wildlife species:** The No Action Alternative would continue ongoing maintenance dredging operations and shipping use of the channel, and would not result in additional changes that would interfere with the movement of resident migratory fish or wildlife species. Therefore, there would be no impacts to the movement of resident migratory fish or wildlife species.

**Impact BR-07: Adversely affect special status fish species, including their habitat, as a result of X2 shifts:** The No Action Alternative would continue ongoing maintenance dredging operations and shipping use of the channel. Continuation of those activities would not result in a shift in the X2. Therefore, compared to the NEPA baseline, there would be no additional impacts to special status fish species due to a shift in X2 under the No Action Alternative.

#### FUTURE WITH -37 FOOT ALTERNATIVE

**Impact BR-01: Cause increased turbidity that adversely affects special status species or critical habitat:** Background turbidity in the estuary is naturally high, with total suspended solids (TSS) levels varying from 10 mg/L to more than 100 mg/L (Robinson and Greenfield 2011). Turbidity plumes from dredging that could limit plankton productivity would be of short duration, as well as being localized and small in the area affected compared to surrounding areas of similar habitat. In San Francisco Bay, turbidity plumes would be quickly diluted to near or within background particulate concentrations. Any increases in turbidity associated with construction of the -37 foot MLLW Alternative would represent a negligible change from turbidity effects that now result from maintenance dredging under the No Action Alternative. Increased turbidity from dredging is therefore expected to have a negligible effect on plankton productivity.

The turbidity resulting from dredging to deepen the channels may affect some marine and estuarine organisms and aquatic wildlife during various life stages by affecting respiration (clogging gills), reducing visibility and the ability to forage or avoid predators, and altering movement patterns (due to avoidance of turbid waters). Suspended sediments have been shown to affect fish behavior, including avoidance responses, territoriality, feeding, and homing behavior.

Wilber and Clarke (2001) found that suspended sediments result in cough reflexes, changes in swimming activity, and gill flaring. Suspended sediments can have other impacts, including abrasion to the body and gill clogging. Generally, bottom-dwelling fish species are the most tolerant of suspended solids, and filter feeders are the most sensitive. The effect of dredging on fish can vary with life stage; early life stages tend to be more sensitive than adults. For example, pelagic eggs and larvae of fishes and shellfishes depend on local hydrodynamic conditions for transport into and out of dredging activity areas and have limited avoidance capabilities. Demersal eggs (eggs sinking to the bottom) and sessile, or non-motile life history stages, are perceived to be particularly susceptible because of their longer exposure to elevated suspended sediments or due to smothering by increased sedimentation. Motile organisms can generally avoid unsuitable conditions.

The USACE Waterways Experiment Station Technical Report DS785 Effects of Dredging on Aquatic Organisms (Hirsch et al. 1978), states that:

“...most organisms tested are very resistant to the effects of sediment suspensions in the water, and aside from natural systems requiring clear water such as coral reefs and some aquatic plant beds, dredging induced turbidity is not a major ecological concern.”

Pacific herring, a commercially important species, spawn in San Francisco Bay from November through March and so could be affected if spawning occurred in the area just before the end of the work window for maintenance dredging activities (i.e., November). Exposure of Pacific herring eggs to suspended San Francisco Bay dredged sediments at ecologically relevant concentrations of 250 or 500 milligrams per liter (mg/L) within their first 2 hours of contact with water has been documented to result in higher percentages of abnormal larvae, as well as an increase in larval mortality (Griffin et al. 2009). However, the suspended sediment from dredging in the shipping channel would need to travel into the shallow spawning areas for adverse effects to occur.

It should be noted that the eggs or larval life stages of steelhead, Chinook salmon, or green sturgeon are not expected to be present in any of the Federal navigation channels since those areas are not used as spawning habitat. In addition, large adult and juvenile fish (including steelhead, Chinook salmon, and green sturgeon) as well as marine mammals are motile enough to avoid areas of high turbidity plumes caused by dredging.

Increased turbidity and activity during dredging may disturb marine mammal foraging activities by temporarily decreasing visibility or causing the relocation of mobile prey from the area affected by the sediment plume. Marine mammals would not be substantially affected by dredging operations because they forage over large areas of San Francisco Bay and the ocean and can avoid areas of temporarily increased turbidity and dredging disturbance.

The deepening of the channel would involve only clamshell dredging during appropriate work windows and upland placement of dredged material for beneficial reuse. To minimize increases in turbidity, barges or scows receiving material for transport from clamshell dredging would not be allowed to overflow. Beneficial reuse would allow all turbidity associated with in-bay disposal to be avoided. Future maintenance dredging would continue to occur as part of the LTMS program. Therefore, compared to the NEPA baseline, impacts on special status species and critical habitat from localized and temporary increases in turbidity would be less than significant, and similar to the impacts resulting from maintenance dredging and ongoing use of the channel under the No Action Alternative.

**Impact BR-02: Cause benthic habitat disturbance that adversely affects special status species, critical habitat, or commercially valuable marine species:** Construction dredging would directly impact benthic communities through physical disruption and direct removal of benthic organisms, resulting in the potential loss of most, if not all, organisms in the dredged area. Benthic habitat within the existing Federal channels is highly disturbed because of regular maintenance dredging and the propeller wash of ship traffic. Organisms immediately adjacent to the dredged channels may also be lost during deepening because of smothering or burial from sediments re-suspended in the water column as a result of the dredging.

Critical habitat for steelhead, Chinook salmon, delta smelt, and green sturgeon overlaps with some or all of the estuarine/marine portions of the project area. Benthic habitat can be an important part of critical habitat for some species by providing foraging areas, especially for green sturgeon. The loss of benthic invertebrates

during dredging activities may decrease the forage value of critical habitat at the dredge location. No state-listed or federally-listed benthic epifauna and infauna are likely to occur in the study area. Because delta smelt feed in the water column, benthic habitat provides less of a function for that species than for species that forage in the benthos.

The -37 foot MLLW Alternative may impact two primary constituent elements<sup>1</sup> of delta smelt critical habitat: rearing habitat and adult migration. Rearing habitat includes shallow water river and tributary habitat extending eastward from Carquinez Strait, including Suisun Bay. Additional rearing habitat outside of the dredge footprint is present at Grizzly Bay, Honker Bay, Montezuma Slough and its tributary sloughs, up the Sacramento River to its confluence with Three Mile Slough, and south along the San Joaquin River including Big Break. Protection of this habitat is most important from February through summer. The entire study area is within the rearing habitat primary constituent element. With the exception of August, the work window for Bulls Head Reach (August 1 through November 30), which is a part of the Suisun Bay Channel is mostly protective of the delta smelt rearing life stage. However, rearing delta smelt may still be affected by the -37 foot MLLW Alternative to a minor degree.

With respect to adult migration, adults must be provided unrestricted access to suitable spawning habitat from December through July. Spawning areas include areas of the Sacramento and San Joaquin rivers and tributaries, Cache Slough, Montezuma Slough, and tributaries. Although spawning habitat is not found in the project area, adult delta smelt begin migrating from the study area to spawning grounds in September and October. Dredging activities may affect adults migrating through the study area to spawning grounds during this timeframe, since dredging would occur during the existing work windows of June 1 through November 30 in the Richmond and Pinole Shoal channels and August 1 through November 30 in the Bulls Head Reach (part of the Suisun Bay Channel). However, the affected area would be limited to the immediate dredging or placement zone and would not substantially limit the available habitat or movement of fish. Effects would be similar to those of ongoing maintenance dredging. As evidenced by Bay Study and the FMWT data (see **Table 4-16 and Table 4-17**), little or no delta smelt are expected to occur within the dredge footprint within the Pinole Shoal Channel (e.g., less than 1 percent of delta smelt have been collected in almost 50 years of trawling). Therefore, there is no potential for impact on delta smelt or delta smelt critical habitat from benthic disturbance.

**Table 4-16. Percent of Delta Smelt Caught in Pinole Shoal Channel Dredge Area During Fall Midwater Trawl and Bay Study 2000-2013 (June 1 to November 3).**

Following sediment-disturbing activities such as dredging, disturbed areas are usually recolonized quickly by benthic organisms (Newell et al. 1998). The species that recolonize first are usually characterized by rapid growth and reproduction rates. Marine benthic invertebrates often colonize disturbed sedimentary habitats via pelagic larvae that settle from the water column. Crustaceans, such as amphipods that are abundant in San Francisco Bay, brood young to much more advanced stages than pelagic larvae, releasing what are essentially miniature adults into the sediment. These can rapidly colonize adjacent disturbed areas.

Since recovery may be slower in deep water channels, there is potential for some loss of habitat and forage to organisms that use the channels. This potential is minimal, because the Federal deep-draft navigation channels are in a constant state of disturbance by deep draft vessels that travel through the channels at a maximum of 15 knots under their own power. At a minimum, oil tankers can be as close as 3 feet to the channel bottom and other vessels as close as 2 feet. Annually, approximately 3,800 vessel trips occur in the Oakland Harbor Channel; 2,300 vessel trips occur in the Richmond Harbor Channel; 2,300 to 4,000 vessel trips occur in the Pinole Shoal Channel; 800 vessel trips occur in the Suisun Bay and New York Slough channels; and 250 vessel trips occur on Redwood City Harbor Channels (**Appendix D, Economic Analysis**). Under these conditions, the benthos of these highly used channels, which are also dredged annually, is in a constant state of disruption. The potential for habitat loss in channels that are dredged less frequently would be slightly greater, but still small due to disruption of benthos from frequent vessel traffic.

Studies have indicated that even relatively large areas disturbed by dredging activities are usually recolonized by benthic invertebrates within 1 month to 1 year, with original levels of biomass and abundance developing within a few months to between 1 and 3 years (Newell et al. 1998). Following dredging, disturbed areas are recolonized, beginning with mobile and opportunistic species (Lenihan and Oliver 1995; Oliver et al. 1977). These species, characterized by rapid growth and reproduction, may or may not be the same species that were present in the area prior to the disturbance.

San Francisco Bay harbors more nonindigenous benthic invertebrate species than any other aquatic ecosystem in North America (Cohen and Carlton 1995). The introduced species range from approximately

20 to 80 percent of all species present (Lee et al. 1999). Therefore, depending on the area of San Francisco Bay, recolonization would likely include nonindigenous species already present in the area.

Under the -37 foot MLLW Alternative, USACE would continue maintenance dredging the project area. The frequency of dredging and volumes dredged may increase slightly in the future to account for the incrementally deeper channel.

Appropriate work windows and clamshell dredging would be used for deepening the channel. For maintenance dredging, USACE would continue to implement applicable avoidance, minimization, and mitigation measures such as those described in section 1.3.4 of NMFS's 2015 programmatic biological opinion on LTMS dredging activities (see NO ACTION ALTERNATIVE, Impact BR-02 of this document for an example list of measures). As described previously, the potential effects of benthic habitat disturbance would be short term and localized. Therefore, compared to the NEPA baseline, impacts on special status species, critical habitat, or commercially valuable marine species from localized and temporary disturbances of benthic habitat from the -37 foot MLLW Alternative and future maintenance dredging would be less than significant.

**Impact BR-03: Cause underwater noise that adversely affects special status fish or marine mammals:**

Mechanical and hydraulic dredges produce a complex combination of repetitive sounds that may be intense enough to cause adverse effects on fish and marine mammals. In addition, the intensity, periodicity, and spectra of emitted sounds differ among dredge types and the substrate being dredged. Clamshell dredges have a repetitive sequence of sounds generated by winches, bucket impact with the substrate, closing and opening the bucket, and sounds associated with dumping the dredged material into the barge. The most intense sound impacts are produced during the bucket's impact with the substrate, with peak Sound Pressure Levels (SPLs) of 124 dB being measured 150 meters from the bucket strike location (Dickerson et al. 2001; Reine et al. 2002).

The scientific knowledge of the effects of dredge-generated noise and sound waves on fishes is limited and varies depending on the species. Effects may include behavioral changes, neurological stress, and temporary shifts in hearing thresholds. Studies on the effects of noise on anadromous Pacific coast fishes are primarily related to pile-driving activities. The interagency Fisheries Hydraulic Working Group has established interim criteria for noise impacts from pile driving on fishes. A peak SPL of 206 dB is considered injurious to fishes. Accumulated SPLs of 187 dB for fishes that are greater than 2 grams, and 183 dB for fishes below that weight, are considered to cause temporary shifts in hearing, resulting in temporarily decreased fitness (i.e., reduced foraging success and reduced ability to detect and avoid predators). The NMFS uses 150 dB as the threshold for adverse behavioral effects.

Injury to fish from peak noise (e.g., rupture of swim bladder) is not expected to occur, but behavioral effects (e.g., changes in feeding behavior, fleeing, and startle responses) could occur. All fish, listed or otherwise, would experience the same effects. For reference, commercial shipping vessels present under baseline conditions can produce continuous noise in the range of 180 to 189 dB which exceeds the NFMS thresholds for adverse behavioral effects to fish and marine mammals (Reine and Dickerson 2014).

For marine mammals, the NMFS criteria define exposure to underwater noises from impulse sounds at or above 160 dB Root Mean Square (RMS)<sup>1</sup> and continuous sounds at or above 120 dB as constituting harassment to marine mammals. The NMFS has also determined that noises with SPLs above 180 dB RMS can cause injury to cetaceans (whales, dolphins, and porpoises), and SPLs above 190 dB RMS can cause injury to pinnipeds (seals and sea lions). Marine mammals are highly motile and would likely avoid areas of noise and disturbance from dredging operations.

The construction noise related impacts of the -37 foot MLLW Alternative would generate noise levels and produce behavioral reactions and effects to fish and marine mammals that would be similar to the existing conditions under the No Action Alternative. The -37 foot MLLW Alternative would take place in the Federal navigation channels, which already receive regular boat traffic, and have annual maintenance dredging occurring with clamshell dredges, and therefore have high background levels of underwater noise. Therefore, based on the analysis presented above, compared to the NEPA baseline, temporary adverse effects to special status fish or marine mammals from underwater noise would be less than significant during -37 foot MLLW Alternative construction and future maintenance dredging of slightly incrementally deeper channels.

**Impact BR-04: Adversely affect special status or commercially or recreationally important marine species through entrainment:** All forms of dredging have the potential to incidentally remove organisms from the environment along with the dredged material, a process referred to as entrainment. Mechanical dredging, as would occur under the -37 foot MLLW Alternative, is generally accepted to entrain far fewer fish than hydraulic dredging because little water is removed along with the sediment and it does not involve any suction. However, even a clamshell dredge may remove demersal fish and crustaceans that live in or on the sediment. Entrained fish are likely to suffer mechanical injury or suffocation during dredging, resulting in mortality. Organisms that can survive entrainment, such as small crustaceans, would be transported and released with the dredged material. Such organisms would be lost if the dredged material is disposed of in an upland location or in habitat unsuitable for the species.

The existing work windows include seasonal avoidance of Dungeness crab, Pacific herring, delta smelt, steelhead, coho salmon, and Chinook salmon for dredging conducted in various portions of San Francisco Bay. The work windows have been established to avoid sensitive periods for these species (i.e., migration periods and spawning periods). In the past, dredging schedules have occasionally slipped for logistical or financial reasons, and dredging occurred outside of the existing work window for one or more species. In the event that this should occur in any year covered by this EIS, USACE would initiate an additional consultation process with the appropriate agencies to obtain written authorization to work outside these windows.

Clamshell dredging would be conducted during appropriate work windows to reduce the potential for entrainment. USACE would also implement appropriate measures to minimize impacts to EFH, as detailed in the Agreement on Programmatic EFH Conservation Measures for Maintenance Dredging Conducted Under the LTMS Program (2011).

---

<sup>1</sup> Root-mean-square measures the average noise energy measured over a 35-millisecond period. Note that this is a different type of measurement than the peak sound or sound exposure level used to measure impacts to fish (NOAA 2012).

The following paragraphs address the potential for entrainment-related impacts to occur from the -37 foot MLLW Alternative on special status or commercially or recreationally important marine species potentially present as compared to the NEPA baseline:

**Dungeness crab (*Cancer magister*) and Pacific herring.** The commercially important Dungeness crab and Pacific herring may occur in the project area and could be entrained during dredging, if work was improperly managed. By using clamshell dredging and complying with the existing LTMS work windows intended to reduce the potential for entrainment, effects to Dungeness crab and Pacific herring would be less than significant.

**Steelhead and salmon.** Steelhead and salmon may occur in the project area. By using clamshell dredging and complying with the existing LTMS work windows intended to reduce the potential for entrainment, effects to steelhead and salmon would be less than significant.

**Sacramento splittail.** Sacramento splittail have been collected during the CDFW FMWT (1 encountered in 2017). By using clamshell dredging and complying with the existing LTMS work windows intended to reduce the potential for entrainment, effects to Sacramento splittail would be less than significant.

**Pacific and river lamprey.** Pacific and river lamprey are anadromous and may occur in the dredge footprint. There is currently no work window approved for Pacific and river lamprey. Although Pacific and river lamprey are likely to occur in the project area, due to their relative abundance and the limited potential for entrainment impacts to occur by using a mechanical dredge, there would be less than significant impacts on these species.

**Striped bass.** Striped bass individuals are regularly collected during the CDFW FMWT (560 age-0 bass encountered since 2010). Although striped bass are likely to occur in the project area, due to their relative abundance and the limited potential for entrainment impacts to occur by using a mechanical dredge, there would be less than significant impacts on striped bass.

**Sacramento perch.** Sacramento perch may be extirpated from its native Delta habitat. Since this species is not known to occur in the project area, individuals of this species should not be impacted.

**Demersal fish species.** Demersal fish species (e.g., Pacific staghorn sculpin and Pacific sanddab [*Citharichthys sordidus*]) which live and feed on and near the bottom, have a higher potential to be entrained with the sediment. Although some of these fish may be entrained, these are not special status species. The minimal mortality anticipated from these bottom species, if any, would have no significant effect on their population numbers or species survival. Therefore, there would be a less than significant impact of these species.

**Green sturgeon.** There is currently no work window approved for green sturgeon. This species is presumed to be present year round throughout the estuary. Green sturgeon spawn in the Sacramento River which is outside the project area. Although juvenile and adult green sturgeon are expected to be present in the estuary during dredging, it is generally believed they would be motile enough to avoid entrainment. The LTMS agencies are in the process of updating the LTMS Programmatic ESA consultation with the NMFS to include green sturgeon. The updated consultation would satisfy ESA compliance for green sturgeon for USACE's future maintenance dredging under the LTMS program. Therefore, there would be less than significant impacts on green sturgeon.

**Delta smelt.** Delta smelt have the potential to occur in the portions of the estuary that include the Napa River Channel, San Pablo Bay/Mare Island Straight, and Suisun Bay Channel dredge areas during certain seasons. Delta smelt occur in San Pablo Bay in lower numbers than in the Napa River or Suisun Bay. However, they may be present in San Pablo Bay in increased numbers during high water outflow years. Delta smelt are not expected to occur in the other Federal channels.

Due to their small size and fragile nature, any entrained individuals would likely be killed either through physical injury during entrainment or suffocation in the collected dredged material. Because delta smelt typically occur in the upper portion of the water column, entrainment is more likely when dredging in shallow waters (Sweetnam and Stevens 1993). To reduce delta smelt entrainment, the LTMS uses a depth of 10 feet to distinguish between “shallow” and deeper waters when implementing work windows for delta smelt. Furthermore, the agreed-upon LTMS work windows include seasonal avoidance of delta smelt for dredging conducted in various portions of San Francisco Bay. As evidenced by Bay Study and the FMWT data mentioned above, few or no delta smelt are expected to occur within the dredge footprint within the Pinole Shoal and Suisun Bay channels. As discussed, since less than 1 percent of delta smelt have been collected in the dredge footprint in almost 50 years of trawling, there is limited potential for entrainment to occur. Furthermore, the use of mechanical dredging will greatly reduce the likelihood of entrainment. Therefore, there is almost no potential for delta smelt to be entrained in this channel segment, and no impact is anticipated.

**Longfin smelt.** Longfin smelt have the potential to occur throughout much of the San Francisco Bay estuary, and populations are seasonally concentrated in certain portions of the estuary. The densities of longfin smelt in the estuary are lowest in the fall, when spawning adults have moved upstream and before larval smelt have moved down into the estuary. During the winter and spring months, larval longfin smelt are concentrated in Suisun and San Pablo bays, but are also present in the Central and South bays in lower densities. While juveniles and adults are present throughout the estuary at all times of year, the majority of the population is concentrated in the Suisun, San Pablo, and Central bays, as well as nearshore waters during the summer months.

As evidenced by Bay Study and FMWT data (see **Table 4-18 and Table 4-19**), longfin smelt are likely to occur within the proposed dredge footprints in the Pinole Shoal and Bulls Head Reach channels. Across all years of the Bay Study and FMWT data, as discussed above, over 11 percent of the total longfin smelt were collected in the dredge area. Although longfin smelt are likely to occur in the project area, because of their relative abundance and the limited potential for entrainment impacts by using a mechanical dredge, there would be less than significant impacts on longfin smelt.

**Impact BR-05: Result in the disturbance of EFH and “Special Aquatic Sites,” including eelgrass beds and mudflats:** All of the waterbodies in the project area are designated as EFH under one or more FMPs. The programmatic EFH agreement completed in 2011 includes a number of conservation measures that enhance the environmental protectiveness of the LTMS program.

Eelgrass beds and mudflats are considered special aquatic sites and are subject to jurisdiction under Section 404 of the CWA and San Francisco Bay Conservation and Development Commission jurisdiction under Section 66605 of the McAttee-Petris Act. Additionally, eelgrass beds and estuarine areas such as San Francisco Bay are considered special aquatic sites under EFH.

Eelgrass in San Francisco Bay provides spawning habitat for herring and serves as a nursery ground and shelter for juvenile fish, among other functions. Eelgrass has been identified as EFH for various life stages of fish species managed by FMPs. Although eelgrass does exist near the Richmond Inner Harbor Channel and Oakland Inner Harbor, there is no known eelgrass within any of the channel boundaries. Examination of surveys done over the last 15 years indicates that eelgrass has persisted in essentially the same locations and densities around Richmond Harbor (USACE 2012b). Pre- and post-surveys of eelgrass conducted at Oakland Harbor in 2010 and 2011 found an increase in eelgrass habitat area and in the density of existing beds, in comparison with several reference sites (Merkel & Associates 2011, 2012). These results indicate that there does not appear to be any adverse effect to, or decline in, eelgrass habitat resulting from annual maintenance dredging activities at Richmond Harbor and Oakland Harbor. Furthermore, mapping of eelgrass in San Pablo Bay indicates that it occurs almost entirely downbay of Point Pinole (i.e., at the far western end of the proposed project area) and at depths shallower than 6 feet (see Boyer and Wyllie-Echeverria 2010 for a discussion), and so would be unlikely to be affected by project activities.

Mudflats serve as important foraging areas for shorebirds species and provide shallow water habitat for juvenile fish. No loss of mudflat acreage would occur as a result of dredging activities under this alternative. Sensitive habitats (such as marshes and mud flats) that occur in the vicinity of some of the Federal navigation channels (e.g., the Napa River) would not be disturbed.

Dredging to -37 feet would result in a loss of benthic habitat considered EFH for Pacific Groundfish. This would occur due to the removal of sediment and benthic organisms with a clamshell dredge, which is unavoidable. Although essentially all of the effects of the proposed project may be considered temporary, the recolonization of disturbed areas by benthic invertebrates is thought to require several months at a minimum, and may take longer. Other effects such as the creation of noise or turbidity plumes would cease immediately or within minutes or hours of when active dredging stops, and may be avoided or minimized by fish (including prey fishes) exhibiting avoidance behavior.

The disturbance of the soft-bottom habitat and removal of sediment containing benthic invertebrates from dredging may be partially offset through the beneficial reuse of the dredged sediment, which is expected to be used to create 160 acres of wetland habitat and would increase food production in adjacent Bay waters.

Based on the analysis presented above, compared to the NEPA baseline, the -37 Foot MLLW Alternative would result in no impacts to mudflats or eelgrass, but may result in an impact to EFH.

**Impact BR-06: Interfere with the movement of resident or migratory fish or wildlife species:** Since the -37 Foot MLLW Alternative only involves deepening the existing channel by 2 feet, it would not permanently interfere with the movement of resident or migratory fish or other wildlife species. The extent to which dredging activities could impede migration because of entrainment is discussed in the analyses for **Impact Criteria BR-04 through BR-06**. The project will operate 24 hours per day, 7 days per week. However, active dredging will occur at most only approximately 3 out of every 4 hours due to the need to reposition the dredge and also to be move it out of the shipping channel to allow deep draft vessels to pass. Consequently, fish passage should be able to occur unimpeded 25% of the time in the shipping channel, however, the shipping channel is only a small portion of the bay's cross section. The noise and in-water disturbance associated with dredging could cause fish and wildlife species to temporarily avoid the immediate dredging or placement area while work is being conducted. However, these impacts would be short term and localized. Therefore, compared to the NEPA baseline, the -37 foot MLLW Alternative would have less than significant impacts related to movement of resident or migratory fish or wildlife species.

There would be no new impacts to non-aquatic species potentially associated with placement sites, as placement sites have been pre-authorized.

**Impact BR-07: Adversely affect special status fish species, including their habitat, as a result of X2 shifts:**

Previous analyses pertaining to effects of X2 shifts on special status fish species and their critical habitat (CCWD 2010) used a significance criterion based on the shift in X2 for the purposes of evaluating changes in habitat quantity and quality for estuarine species. In their analysis, an upstream change in X2 location within 1 km of baseline conditions was considered to be less than significant for estuarine species. The 1 km X2 criterion used in CCWD's analysis was derived from the criterion applied to the environmental analysis of the Environmental Water Account (U.S. Bureau of Reclamation et al. 2003). For purposes of this analysis, the established quantitative threshold as previously applied was considered, as well as other factors.

Because salinity intrusion generally increases with water depth, incrementally deepening the existing channel 2 additional feet below the -37 foot MLLW Alternative could potentially lead to increased salt intrusion which would result in an increase in X2. Since an increase in X2 may impact special status fish species, the distribution of which is influenced by salinity levels, a detailed evaluation of the effect of the -37 foot MLLW Alternative was conducted under both wet and critically dry conditions (see **Appendix B, Water Resources-Attachment 1, Salinity Model Report**). The average annual predicted shift in X2 was 0.03 km upstream during a critical dry water year and 0.08 km upstream during a wet water year. Estimating X2 from field observations has a measurement uncertainty of at least 0.05 km (see **Appendix B, Water Resources- Attachment 1, Salinity Model Report, page 38**). Since these predicted shifts in X2 are much smaller than the 1 km shift considered to be less than significant, as compared to the NEPA baseline, the shift in X2 resulting from the -37 foot MLLW Alternative would result in less than significant impact to special status fish species through X2 shifts.

#### FUTURE WITH 38 FOOT ALTERNATIVE

**Impact BR-01: Cause increased turbidity that adversely affects special status species or critical habitat:**

The incrementally greater deepening proposed under the 38 Foot MLLW Alternative would have no additional significant effect on turbidity or turbidity impacts compared to the -37 foot MLLW Alternative. Turbidity will be monitored, and work would be limited to the existing LTMS work windows. Therefore, compared to the baseline, impacts on special status species and critical habitat from localized and temporary increases in turbidity would be less than significant.

**Impact BR-02: Cause benthic habitat disturbance that adversely affects special status species, critical habitat, or commercially valuable marine species:**

The incrementally deeper -38 foot MLLW Alternative would have no significant additional disturbance on benthic habitat compared to the -37 foot MLLW Alternative. Although both the -38 foot MLLW Alternative and the -37 foot MLLW Alternative would remove and affect a greater amount of benthic organisms compared to the No Action Alternative, for maintenance dredging the impact minimization measures described in section 1.3.4 of NMFS's 2015 programmatic biological opinion on LTMS dredging activities (see NO ACTION ALTERNATIVE, Impact BR-02 of this document for an example list of measures) would be implemented and the potential effects of benthic habitat disturbance would remain short term and localized. Therefore, compared to the baseline, impacts on special status species, critical habitat, or commercially valuable marine species from localized and temporary disturbances of benthic habitat would be less than significant.

**Impact BR-03: Cause underwater noise that adversely affects special status fish or marine mammals:** The incrementally greater deepening proposed under the -38 foot MLLW Alternative may result in a commensurate increase in the duration of construction and associated underwater noise impacts. However, noise levels would be unchanged and behavioral effects of aquatic organisms, if any, would be similar to those effects associated with the -37 foot MLLW Alternative and would be less than significant.

**Impact BR-04: Adversely affect special status or commercially or recreationally important marine species through entrainment:** The incrementally deeper channel under the -38 foot MLLW Alternative would have no significant incremental entrainment effects compared to the -37 foot MLLW Alternative. Dredging would continue to occur during established construction windows designed to protect special status fish species, unless otherwise approved. Mechanical dredging would be the type of dredge machinery for this project. Similar to the -37 foot MLLW alternative, few or no delta smelt are expected to occur within the -38 foot MLLW Alternative dredge footprint during the proposed construction windows. Therefore, compared to the baseline, the -38 foot MLLW Alternative would result in less than significant impacts to special status and commercially important species resulting from entrainment, and no significant impacts to smelt and demersal species are expected.

**Impact BR-05: Result in the disturbance of EFH and “Special Aquatic Sites,” including eelgrass beds and mudflats:** The slightly greater deepening proposed under the -38 foot MLLW Alternative compared to the -37 foot MLLW Alternative would have no additional significant effects on mudflats or eelgrass compared to the No Action Alternative. Dredging would continue to occur in accordance with the provisions established through the formal programmatic Federal EFH consultations for the LTMS, and no new areas potentially containing mudflats or eelgrass would be dredged or used to contain dredged material. Therefore, the -38 foot MLLW Alternative would result in no impacts to mudflats or eelgrass.

The bottom ground that would be dredged to -38 feet would result in a loss of 318 acres of benthic habitat that would potentially affect EFH. Those are listed below and described in more detail in the Biological Assessment (**Appendix G – Attachment 4**).

***Pacific Groundfish EFH:*** Adverse effect under the Magnuson-Stevens Act “means any impact that reduces quality and/or quantity of EFH. Adverse effects may include direct or indirect physical, chemical, or biological alterations of the waters or substrate and loss of, or injury to, benthic organisms, prey species and their habitat, and other ecosystem components, if such modifications reduce the quality and/or quantity of EFH” (50 CFR § 600.810). The proposed action is *likely to adversely affect EFH for Pacific Groundfish*. This would occur due to the removal of sediment and benthic organisms with a clamshell dredge, which is unavoidable. Although essentially all of the effects of the proposed project may be considered temporary, the recolonization of disturbed areas by benthic invertebrates is thought to require several months at a minimum, and may take years. Other effects such as the creation of noise or turbidity plumes would cease immediately or within minutes or hours of when active dredging stops, and may be avoided or minimized by fish (including prey fishes) exhibiting avoidance behavior.

The disturbance of 318 acres soft-bottom habitat and removal of sediment containing benthic invertebrates from dredging may be partially offset through the beneficial reuse of the dredged sediment, which is expected to be used to create 160 acres of wetland habitat and would increase food production in adjacent Bay waters.

***Pacific Salmonid EFH:*** Potential effects to Pacific salmonid EFH are expected to be similar to those discussed under the ESA impacts to listed salmonid habitat and critical habitat (see NMFS EFH letter **Appendix G**). As

discussed in those sections, the proposed action would temporarily affect estuarine habitat and water quality during dredging. Additionally, salinity intrusion may slightly increase the salt content of water near the eastern portion of the salinity wedge; however, this is not likely to be perceptible to migrating and rearing salmonids transitioning between freshwater and saltwater. Therefore, the proposed action is *not likely to adversely affect Pacific Salmonid EFH*.

**Coastal Pelagic EFH:** Northern anchovy is one of the most abundant fishes in the San Francisco Bay and an important commercial fish and prey resource other commercial fisheries. During construction, the proposed action has the potential to temporarily increase noise and suspended sediment in the surrounding water column. However, these impacts would be localized and not permanently affect coastal pelagic EFH. Restoration of wetland habitat resulting from beneficial reuse of dredged material would ultimately benefit coastal pelagic EFH by improving the quality and quantity of food resources. Because of the localized and temporary impacts, it is expected that the proposed action is *not likely to adversely affect Coastal Pelagic EFH*.

**Impact BR-06: Interfere with the movement of resident or migratory fish or wildlife species:** The slightly greater deepening under the -38 foot MLLW Alternative would have no additional significant effects on fish or wildlife migration compared to the -37 foot MLLW Alternative. Entrainment impacts and, by extension migration impacts, would remain minimal as described in the preceding discussions. The work schedule would remain the same as proposed under the -37 foot MLLW alternative. Behavioral impacts from noise and in-water disturbance associated with dredging would remain short term and localized. No new structures that might impede fish or wildlife movement would be constructed. Therefore, the -38 foot MLLW Alternative would result in less than significant impacts related to movement of resident or migratory fish or wildlife species as compared to the baseline.

**Impact BR-07: Adversely affect special status fish species, including their habitat, as a result of X2 shifts:** The -38 foot MLLW Alternative represents a slight incremental increase over the previous -37 foot MLLW Alternative and a 3 foot incremental increase over the No Action Alternative of a -35 foot MLLW channel depth. The analysis contained in **Appendix B- Attachment 1** and discussed in Water Quality and Hydrology, also evaluated the effect of the -38 foot MLLW Alternative under both wet and critically dry conditions. Based on this analysis, the average annual predicted shift in X2 for the -38 foot MLLW Alternative was 0.11 km upstream during a critical water year and 0.2 km upstream during a wet water year. Since these predicted shifts in X2 are much smaller than the 1 km shift considered to be less than significant, the shift in X2 resulting from the -38 Foot MLLW Alternative would result in less than significant impacts to special status fish species with distributions determined by salinity levels.

#### [FUTURE WITH -38 FOOT ALTERNATIVE + SEDIMENT TRAP AND ROCKY OBSTRUCTION](#)

The addition of the sediment trap and removal of the rocky obstruction to the -38 foot MLLW alternative would have the potential to further impact X2 and increase noise impacts, respectively. Therefore, BR-03 and BR-07 are further discussed within this section. Impacts to BR-01, BR-02, BR-04, BR-05, and BR-06 result in similar effects to the -38 foot Alternative.

**Impact BR-03: Cause underwater noise that adversely affects special status fish or marine mammals:** Noise effects on fish from the removal of the rocky obstruction are discussed in detail in the BA, and are not likely to adversely affect special status species (**Appendix G- Attachment 4**). No effects to fish habitat are anticipated because the rocky obstruction currently does not protrude above the bottom substrate.

Noise effects from removal of the rocky obstruction on marine mammals may include complex changes in behavior or hearing loss which may easily be linked to reduced fitness. Specific impacts may include

changes in breeding, feeding, or predator-avoidance behaviors; changes in migration routes, dive times, or swimming speeds; changes in mating call frequency or duration; habitat avoidance; etc. (Erbe 2012; Johnson and Tyack 2003; NMFS 2018; Wursig et al. 1998). Impacts may be species specific (NMFS 2018).

Two pinniped marine mammal species may occur in the project area, California sea lion (*Zalophus californianus*) and harbor seal (*Phoca vitulina*). The SPL of 132 dB produced by removal of the rocky obstruction and discussed in the BA (**Appendix G- Attachment 4**) is well under NMFS's threshold of 190 dB rms for assessing auditory impacts to pinnipeds (NMFS 2018).

NMFS (2018) provides new guidance for assessing noise impacts to marine mammals. The associated new methodology focuses on identifying temporary threshold shifts (TTS) and permanent threshold shifts (PTS) that may be induced by anthropogenic noise. Also, marine mammals are categorized according to their hearing abilities to account for species-specific differences. The California sea lion and harbor seal fall into different categories based on their taxonomic families (i.e., *Otariidae* and *Phocidae*, respectively). Specifically, harbor seals are expected to have an extended range of hearing compared to California sea lions, and also are better adapted to underwater hearing and presumably more vulnerable to noise impacts.

The new TTS and PTS thresholds are based on measurements of peak sound pressure level (PK) and cumulative sound exposure level (SEL cum). Using NMFS's companion spreadsheet tool (<https://www.fisheries.noaa.gov/national/marine-mammal-protection/marine-mammal-acoustic-technical-guidance>), the noise impacts of the project (i.e., PTS SEL cum isopleth to threshold [meters]; NMFS 2018) were determined to be 0 and hence well under the more conservative threshold of 185 meters for phocid pinnipeds. The second measurement of noise impacts (i.e., PTS PK isopleth to threshold (meters); NMFS 2018) generated an "NA" result compared to the 218 meter PK threshold for phocid pinnipeds. Results were the same whether dB rms values were used for noise 50 feet or 400 feet from the source. In summary, noise impacts from the proposed removal of the rocky obstruction are not likely to adversely affect California sea lion or harbor seal.

The buried rocky obstruction is located just outside of the current deepening footprint but is still within the existing Federal navigation channel, and already experiences regular boat traffic producing high background levels of underwater noise. Therefore, compared to the baseline, temporary adverse effects to special status fish and marine mammals from underwater noise would be less than significant.

**Impact BR-07: Adversely affect special status fish species, including their habitat, as a result of X2 shifts:**

With the inclusion of the sediment trap, the average annual predicted shift in X2 was 0.17 km upstream during a critical dry water year and 0.27 km upstream during a wet water year (see **Appendix B, Water Resources- Attachment 1, Salinity Model Report**). Since these predicted shifts in X2 are much smaller than the 1 km shift considered to be less than significant, as compared to the baseline, the shift in X2 resulting from the -38 Foot MLLW Alternative + Sediment Trap and Rocky obstruction would result in a less than significant impact to special status fish species through X2 shifts.

It should be noted that channel deepening must occur immediately after completion of O&M dredging, or possibly concurrently. Although feasible, dredging contract acquisition approach and timing is tight for accomplishment of both O&M dredging and channel deepening in one environmental work window therefore, this avoidance measure does carry some risk. Should dredging extend past the environmental work window, additional coordination would immediately be initiated with the appropriate agencies.

#### 4.1.7 LAND USE AND PLANNING

Project components were evaluated with regard to consistency with Federal, state, and local plans, policies, and regulations pertaining to land use. Land use was also evaluated for compatibility of the alternatives with county General Plans and physical division of existing communities.

An alternative would be considered to have a significant impact if it would cause the following:

Impact LU-01: Introduce land uses or activities incompatible with existing or adjacent land uses.

#### NO ACTION ALTERNATIVE

**LU-01: Introduce land uses or activities incompatible with existing or adjacent land uses:** Under the No Action Alternative land uses would remain the same as they currently exist at both the dredging and placement sites. There would be no introduction of new land uses or activities incompatible with existing or adjacent land uses. Therefore, no land use impacts would occur under the No Action Alternative.

#### FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**LU-01: Introduce land uses or activities incompatible with existing or adjacent land uses:** Under this alternative there would be no introduction of new land uses. Expected dredging activities and use of placement sites would be consistent with designated land uses. Dredging equipment would be temporarily present in areas used for commercial navigation and recreational boating. This may result in an ongoing and/or temporary condition, but considered as an insignificant impact since there would be no new land uses or activities introduced. Consequently, impacts to land use would be less than significant.

#### 4.1.8 MINERAL RESOURCES

The analysis of potential impacts to mineral resources included review and evaluation of maps, reports and other relevant data for mineral resources in the study area. Known deposits of mineral resources that may be impacted were evaluated for their relative importance in a regional as well as national context. To ascertain the compatibility of the alternatives with county General Plans, the proposed alternatives were compared to the mineral conservation goals and policies identified in the General Plans.

An alternative would be considered to have a significant impact if it would cause the following:

Impact MIN-01: Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the State, or a locally important mineral resource recovery site delineated in a county General Plan, specific plan, or other land use plan.

#### NO ACTION ALTERNATIVE

**Impact MIN-1: Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the State or a locally important mineral resource recovery site delineated in a county General Plan, specific plan, or other land use plan:** Under the No Action Alternative, activities associated with the proposed channel deepening would not occur. There would be no change in the existing maintenance dredging and placement of dredged material practices and no change in use of the proposed placement sites. Therefore, no impacts to mineral resources would occur.

## FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**Impact MIN-1: Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the State or a locally important mineral resource recovery site delineated in a county General Plan, specific plan, or other land use plan:** Under these alternatives, dredging activities would occur entirely within the existing alignment of the channel and dredged material placement during construction would occur at established beneficial reuse sites. Subsequent maintenance of the deepened channel would follow current practices used for the existing channel. The areas identified for channel dredging would not overlap with areas identified for in-water mining of sand in the bays or in the Delta. There would also be no change to land uses as a result of this alternative and there would be no change in availability or access to mineral resources in the area. As such, no impacts to mineral resources would occur under this alternative.

### 4.1.9 AGRICULTURE

The California Agricultural Land Evaluation and Site Assessment Model (CDC 1997) provides an accepted methodology to assess the effects of proposed projects on agricultural resources. The Model determines a proposed activity's projected impact on the adequacy of soils for agriculture. However, the Model does not readily apply in the case of navigation channels. If the Model were used, the maximum impact score would be far below the threshold score required for a determination of significant impact. Rather than use the Model, for this analysis, the impacts to agricultural resources are evaluated based on a qualitative assessment of potential effects of construction, operation and maintenance activities conducted for the alternatives considered. This evaluation considers possible effects to soils and irrigation systems, changes in vulnerability to drought, and induced land use changes.

Any alternative would be considered to have a significant impact on the agricultural resources in the affected area if the alternative would:

**Impact AG-01:** Degrade the quality, or agricultural productivity, of Important Farmland or farm resources (including irrigation water systems, levees, drainage systems), or directly or indirectly cause lands presently in agricultural production (including Important Farmland) to convert to non-agricultural uses.

### NO ACTION ALTERNATIVE

**Impact AG-01: Degrade the quality, or agricultural productivity, of Important Farmland or farm resources (including irrigation water systems, levees, drainage systems), or directly or indirectly cause lands presently in agricultural production (including Important Farmland) to convert to non-agricultural uses:** Under the No Action Alternative, activities associated with proposed deepening of the existing channel would not occur. There would be no change in the existing maintenance dredging and placement of dredged material practices, and no change in use of the proposed placement sites. Therefore, no impacts to agricultural resources would occur under the No Action Alternative.

However, even in the absence of Federal action to deepen the shipping channels, agricultural lands in the study area and region are impacted by a variety of factors, many of which threaten the viability of farmlands in the future. Among the threats is increasing urbanization and other developmental pressures over the next 50 years that could result in the conversion of some marginal farmlands to more intensive land uses. Aside from the potential of direct farmland conversion, other future threats to agriculture in the study area include drought, salinity intrusion, soil subsidence, and sea level rise, none of which are influenced by the continued maintenance of the existing -35 feet navigation channel.

Future extended droughts are likely to continue to periodically occur, affecting the study area and a large portion of California. Such droughts will reduce the availability of irrigation water. The more extreme drought events may also allow higher salinity waters from the San Francisco Bay system to extend farther upstream into the Delta, creating temporary problems for irrigation users in the most downstream reaches of the lower Delta. Salinity intrusion is already a water supply management issue affecting the use and management of Delta agricultural lands. A variety of existing factors interact to influence salinity levels in the Delta waterways and groundwater. Major factors include:

- Flows from the San Joaquin and Sacramento Rivers
- Tidal fluctuations and exchanges from San Francisco Bay
- Levees originally built to reclaim tidal wetlands for agricultural uses
- Sub-surface agricultural irrigation and drainage systems
- Subsidence due to oxidation of peat soils behind levees
- Operation by the Central Valley Project and the State Water Project of large water supply intakes in the south Delta
- Releases of freshwater from the Delta Cross Channel, New Melones Dam and other similar facilities, and
- Temporary salinity barriers

These factors, which are unrelated to maintenance of the existing -35 feet channel, are anticipated to continue contributing, in varying degrees, to the existing salinity intrusion problems in the Delta.

Projected sea level rise will likely contribute to the existing salinity intrusion problem in the future, which would adversely affect agricultural activities and production within the Delta. Sea level rise would make Delta waters too saline for irrigation use, groundwater could become too saline, or the water table could become elevated. The result would be that lands currently in agricultural production may become unusable for current crops and could be converted to other land uses.

Soil subsidence has the potential to undermine the structural integrity of the levees that protect farmlands in areas influenced by seasonal flooding, in addition to reducing the subsurface distance between the root zone and the ambient water table.

#### [FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES](#)

**Impact AG-01: Degrade the quality, or agricultural productivity, of Important Farmland or farm resources (including irrigation water systems, levees, drainage systems), or directly or indirectly cause lands presently in agricultural production (including Important Farmland) to convert to non-agricultural uses:**

The -37 foot and -38 foot MLLW Alternatives would have no significant adverse impacts on agricultural resources because they would not directly or indirectly contribute to the conversion of farmland to non-agricultural uses and would not contribute to increased salinity intrusion into the Delta (see **Section 4.1.3 Water Quality and Hydrology**).

The environmental effects, both in the short-term and the long-term, are very similar to the impacts projected for the No Action Alternative. The principal difference between these two alternatives is that new work dredged material removed during to provide the -37 and -38 feet MLLW channel would be placed

in established beneficial reuse sites, none of which contain farmland. All future maintenance dredged materials would continue to be placed in existing approved open-water sites. As a result, neither Alternative would have no significant adverse impact on agricultural resources.

#### 4.1.10 AESTHETICS

The visual character of a project site is typically evaluated with respect to its physical components and an analysis of its compatibility with the land uses of the immediate surrounding areas. Visual impacts are also analyzed through an examination of views and/or viewsheds. Viewshed impacts are typically characterized by the loss and/or obstruction of existing scenic vistas or other major views in the area available to the general public.

The analysis of impacts on aesthetics for the study area included a general comparison of existing conditions to conditions that would result from implementation of the alternatives. Aerial photography, other photographs, land use maps, and topographical data were reviewed to collect data to determine the impacts to the affected environment. Impacts to aesthetic resources were qualitatively evaluated based on the potential for the various alternatives to temporarily or permanently alter or result in the loss of aesthetic resources in the study area. In addition, general construction impacts were assessed within the immediate area of the navigation channels to be dredged. Light and glare impacts were also analyzed by considering the qualitative aesthetic characteristics of the existing nighttime lighting and daytime glare environments on the site and any modifications the proposed alternatives would make to those environments.

An alternative would be considered to have a significant impact if it would cause the following:

Impact AE-01: Have a substantial adverse effect on a scenic vista or substantially degrade the existing visual character or quality of the site and its surroundings; or

Impact AE-02: Create a new source of substantial light or glare that would adversely affect day or nighttime views in the area.

#### NO ACTION ALTERNATIVE

**Impact AE-01: Have a substantial adverse effect on a scenic vista or substantially degrade the existing visual character or quality of the site and its surroundings:** The No Action Alternative would result in no additional construction dredging equipment in the various waterways. Annual operations and maintenance dredging would continue to occur within the established work windows for the respective channels. No impacts to scenic vistas would result.

**Impact AE-02: Create a new source of substantial light or glare that would adversely affect day or nighttime views in the area:** The No Action Alternative results in no additional construction dredging equipment for this project throughout the various waterways. Therefore, no light or glare impacts would result.

#### FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**Impact AE-01: Have a substantial adverse effect on a scenic vista or substantially degrade the existing visual character or quality of the site and its surroundings:** Construction dredging equipment would be visible to various visual receptors along the project route during the construction phase. As described more fully in the project description, the dredging equipment that would be seen from varying distances would

likely include a 26-cubic yard clamshell dredge working in tandem with up to four 2,000 to 5,000 cubic yard capacity scows (depending on the beneficial reuse site used) and two or three tug boats. It is likely that there would be one scow at the dredge plant and at least one scow in transit to or from the off-loading facility, while one scow would be at the off-loading facility to be unloaded.

During construction, viewers would see a mechanical clamshell dredge and the above identified auxiliary vessels involved in construction activities. Construction would occur throughout the day and night. At night, lighting would be required for the work areas and for navigational aids. It is expected that low-intensity industrial lighting would be used in the work areas.

The views of construction equipment would be from a distance. They would vary depending on the location of the viewing point, and the construction-related aesthetic impacts would be temporary. Viewers of the shipping channel commonly see various shipping operations, including the transport of dredging, industrial and commercial equipment. With the exception of differences in the type of equipment used, construction activities viewed would be similar to those seen in historical and current routine maintenance dredging of the navigation channels within the study area.

The operational phase would result in a similar number of ships traveling along the waterway as occurs during existing conditions. There would likely be fewer oil tankers and other types of ships passing by viewers. This is because a deeper channel would result in fewer tankers filled to a higher capacity, reducing the number of trips required to transport the same tonnage of commodities. In addition, following construction, the type and duration of future channel maintenance dredging activities would continue essentially unchanged from existing operations. Therefore, no adverse impacts to vistas and scenic character are expected to occur during the construction or operation phase.

**Impact AE-02: Create a new source of substantial light or glare that would adversely affect day or nighttime views in the area:** Construction would occur both day and night, with night lighting being required to illuminate the work areas and be used as navigational aids. These are expected to consist of low-intensity, industrial lighting, which would focus upon the work areas. The views would be temporary and would not result in nighttime glare or permanent changes in the viewshed. No new lights are expected at any of the ports, as existing facilities would continue to serve the shipping needs. No significant impacts to day or nighttime views as a result of additional glare or light would occur.

#### 4.1.11 CULTURAL RESOURCES

The analysis of impacts of the -37 foot, -38 foot, and -38 foot with sediment trap and rocky obstruction removal (Recommended Plan) on cultural resources and historic properties for the study area was completed through a review of existing databases, reports, and other information sources to determine if any cultural resources exist in the area. A review of CEQA/NEPA documents that previously evaluated impacts of channel dredging and placement practices on cultural resources was also completed, including the EA/EIR addressing maintenance dredging of the Federal navigation channels in San Francisco Bay for the period 2015 through 2024 (USACE and RWQCB 2015). A separate analysis of the impacts on cultural resources for the beneficial reuse areas at Montezuma Wetlands Project and Cullinan Ranch included the EIR/EIS for Montezuma Wetlands and is ongoing (USACE 1998; USFWS and CDFW 2008).

Pursuant to Section 106 of the National Historic Preservation Act (NHPA) (36 CFR § 800.8), USACE is employing a phased process to identify and evaluate historic properties and assess effects. Ongoing consultation and consideration of effects will occur during PED as the area of potential effects (APE) may be subject to change based on final designs or modifications of project features. Cultural resources

assessments will be conducted in areas that have not been previously surveyed with a high potential for containing historic properties. During PED and prior to construction, these surveys and a final determination of effects for any historic properties within the APE will be coordinated with the California State Historic Preservation Officer (SHPO), Native American Tribes, and other consulting parties. Due to the timing of the San Francisco to Stockton Navigation Improvement project, USACE is currently unable to identify and evaluate cultural resources and determine effects of the alternatives on historic properties prior to completion of the EIS. Therefore; pursuant to 54 U.S.C. 306108 and § 800.4(b)(2), USACE is deferring the final identification and evaluation of historic properties until after project approval, additional funding becomes available, and prior to construction. These obligations are stipulated within the Programmatic Agreement with the California State Historic Preservation Officer, executed for the study on February 14, 2020.

USACE's Dredging Guidance Letter No. 89-01 (USACE 1989) directs USACE to make a reasonable and good faith effort to identify submerged cultural resources that may be affected by project implementation. The review of project documents, the California Historical Resources Information System (CHRIS) database, and historical records has determined that there is a high potential for submerged cultural resources to be present within the APE.

The project does not propose demolition of existing structures or the introduction of features that would be incompatible with the historic setting of the built environment. The placement of dredge material within the Montezuma Wetlands and Cullinan Ranch will assist in the restoration of the landscape to its historical elevations prior to the twentieth-century construction of levees. The effects on the landward side of levees is considered as part of USACE's compliance with Section 106 of the National Historic Preservation Act (NHPA); however, this NEPA analysis only considers the effects of the project on the submerged archaeological resources because previous NEPA studies have been completed on these placement areas. The three shipwreck databases were searched for any known shipwrecks located in the areas that might be affected by the alternatives. The significance of effects was determined based on the presence of a historical resource potentially affected and the type of anticipated impacts.

For the purposes of NEPA, to determine whether cultural resources could be adversely affected, the historical significance and integrity of the resource itself must first be evaluated.

### NO ACTION ALTERNATIVE

**Impact of CR-01: Cause a substantial adverse effect to a historic property.** Under the No Action Alternative, all activities associated with proposed deepening of the existing channel would not occur. There would be no change in the existing maintenance dredging and placement of dredged material practices and no change in use of the proposed placement sites. Therefore, no impacts to historic properties would occur under the No Action Alternative. Since no individual impacts would occur from the No Action Alternative; that alternative would not contribute to any cumulative impacts from other past, present, and reasonably foreseeable future activities that could have substantial adverse impacts on historic properties in the study area.

**Evaluation of Impact CR-02: Disturb any human remains, including those interred outside of formal cemeteries.** Under the No Action Alternative, activities associated with proposed deepening of the existing channel would not occur. There would be no change in the existing maintenance dredging and placement of dredged material practices and no change in use of the proposed placement sites. Since there would be

no additional construction dredging to deepen the existing navigation channel, no human remains, including those interred outside of formal cemeteries should be encountered or disturbed. Therefore, no impacts would occur to human remains. Because the No Action Alternative would not disturb any human remains, including those interred outside of formal cemeteries, continued maintenance and use of the navigation channels would not incrementally contribute to the cumulative effects of other unrelated past, present, and reasonably foreseeable actions within the study area having the potential to adversely affect human remains.

#### FUTURE WITH -37 FOOT ALTERNATIVE

**Impact of CR-01: Cause an adverse effect to a historic property.** Under the Future with -37 Foot Alternative, activities associated with proposed deepening of the existing channel have the potential to cause an adverse effect to historic properties, if present. Analysis of CHRIS data shows a previously recorded shipwreck, which is identified as the Baldwin Channel Wreck (P7-002760 and 21-000598), within 500 feet of the Pinole Shoal Channel APE; however, there is some question as to the location of the wreck. The wreck was identified during a USACE sponsored submerged cultural resource survey of portions of proposed Baldwin Channel Navigation improvements (Sullivan and Allan 1996). Sullivan and Allan (1996) tentatively identified the wreck and indicated that portions of the wreck were located within the existing Pinole Shoal Federal Navigation Channel. The wreck site was tentatively identified as the *Sagamore*, a schooner which foundered in 1864. Although this wreck was reported in the vicinity, it could also be one of several other ships that were reported sunk in the area (USACE and RWQCB 2013). The California State Lands Commission (CSLC) database identified 24 shipwrecks that sank near the channel dredging and placement areas, three of which are reported within the APE. The *Harry*, which sank in 1904, and the *Alden Anderson*, a steam screw which sank in 1924, were reportedly lost within what is now the navigation channel. The gas screw *Cavina*, which was reported lost in 1926, was located within 0.25 miles of MWRS (see **Table 2-11**).

Globally, sea levels began rising at the end of the Late Glacial Maximum (LGM). The present configuration of San Francisco Bay began forming between 15,000 to 18,000 BP, with the inundation of the Sacramento and San Joaquin river valleys (Masters and Aiello 2007). By the end of the Holocene (8000 BP) sea levels were approximately 20 meters below the present-day levels. Locally, these levels may have varied considerably due to tectonic instability in the San Francisco Bay region. In general, this rise resulted in the submergence of prehistoric sites throughout the Bay area. No prehistoric archaeological sites are recorded in the immediate vicinity of the existing navigation channel. However, an early twentieth century map showing the locations of shell mounds sites in the San Francisco Bay region show multiple shell mounds located along the north and south shores of the Carquinez Strait (Nelson 1909). While these sites are located outside the APE, they do indicate that the area was a nexus for prehistoric settlements in the late prehistoric period. Earlier sites can be expected to have been situated on former ridges and hills which were located adjacent to the Pleistocene and Holocene paleochannels. Preliminary analysis of bathymetry data within the APE indicates the possible presence of inundated ridges and islands directly adjacent to the Suisun Bay navigation channel. Some of these areas can be considered to have a moderate to high probability of containing inundated prehistoric sites.

At those locations along the channels where prevailing bottom depths are 35 feet or less MLLW, dredging the channel to -37 feet could disturb a narrow width of existing bottoms paralleling both sides of the existing navigation channel to accommodate a deepened dredging prism. In some instances over-depth dredging may disturb a larger footprint than anticipated. Additionally, sloughing of the channel side slopes may occur over time as the overall channel cross section adjust to the altered sediment conditions. This

unavoidable process has a potential to adversely impact any shipwreck or inundated prehistoric site that may be located near the edge of the existing navigation channels. Based on the proximity of 24 known wrecks in the project vicinity, the presence of the Baldwin Channel wreck within the APE, and the presence of several landforms which appear to have a moderate to high probability of containing prehistoric resources it is possible that dredging may cause an adverse change effect to historic properties, if present. Any submerged archaeological site or submerged historic resource that has remained in California State waters for more than 50 years will require evaluation for eligibility for listing on the National Register of Historic Places (NRHP).

Although no previously identified historic properties are located within the APE, the locations of historic shipwrecks that are listed in the CSLC database are imprecise and in some instances inaccurate. Therefore, it is possible that additional unknown shipwrecks and submerged archaeological sites occur within the project APE. Deepening the existing maintained -35 foot MLLW channel segments to -37 feet, has the potential to have adverse impacts to historic properties. Additional archaeological resource investigations will be required as a component of future detailed design studies of this alternative to either confirm the absence of shipwrecks or submerged prehistoric sites within the APE.

**Evaluation of Impact CR-02: Disturb any human remains, including those interred outside of formal cemeteries.** Under the Future with -37 Foot Alternative there is no evidence of the presence of human remains within the study area. However, activities associated with the proposed deepening of the existing channel have the potential inadvertently disturb human remains with implementation of this alternative. Therefore, the potential to disturb unidentified human remains would be a significant adverse impact. If human remains of Native American origin are discovered during dredging, it would be necessary to comply with state laws relating to the disposition of Native American burials, which fall under the jurisdiction of the Native American Heritage Commission (PRC Section 5097). In addition, pursuant to State law (CEQA Guidelines Section 15064.5, PRC 5097.87, and the Health and Safety Code Section 7050.5) mitigation measure, MM-CR-02 would be implemented if any human remains are discovered.

Globally, sea levels began rising at the end of the Late Glacial Maximum (LGM). The present configuration of San Francisco Bay began forming between 15,000 to 18,000 BP, with the inundation of the Sacramento and San Joaquin river valleys (Masters and Aiello 2007). By the end of the Holocene (8000 BP) sea levels were approximately 20 meters below the present-day levels. Locally, these levels may have varied considerably due to tectonic instability in the San Francisco Bay region. In general, this rise resulted in the submergence of prehistoric sites throughout the Bay area. No prehistoric archaeological sites are recorded in the immediate vicinity of the existing navigation channel. However, an early twentieth century map showing the locations of shell mounds sites in the San Francisco Bay region show multiple shell mounds located along the north and south shores of the Carquinez Strait (Nils 1906). Shell mounds can contain Native American burials. While the mounds identified on the Nils (1906) map are located outside the APE, they do indicate that the area was a nexus for prehistoric settlements in the late prehistoric period. Earlier sites can be expected to have been situated on former ridges and hills which were located adjacent to the Pleistocene and Holocene Paleochannels. Preliminary analysis of bathymetry data within the APE indicates the possible presence of inundated ridges and islands directly adjacent to the Suisun Bay navigation channel. Some of these areas can be considered to have a moderate to high probability of containing inundated prehistoric sites.

At those locations along the channels where prevailing bottom depths are -35 feet or less MLLW, dredging the channel to -37 feet could disturb a narrow width of existing bottoms paralleling both sides of the existing navigation channel to accommodate a deepened dredging prism. In some instances over-depth

dredging may disturb a larger footprint than anticipated. Additionally, sloughing of the channel side slopes may occur over time as the overall channel cross section adjust to the altered sediment conditions. This unavoidable process has a potential to adversely impact inundated prehistoric sites or burials that may be located near the edge of the existing navigation channels. Potential impacts to cultural resources from anchoring or spudding during dredging and off-loading operations are possible beyond the limits of the dredging. Any submerged archaeological site or submerged historic resource within the APE more than 50 years will require evaluation for eligibility for listing on the NRHP.

Although no human remains have been identified within the APE submerged terrestrial archaeological sites may occur within the project APE. Deepening the existing maintained -35 foot MLLW channel segments to -37 feet, has the potential to have impact human remains. Additional archaeological resource investigations will be required as a component of future detailed design studies of this alternative to either confirm the absence of submerged prehistoric sites within the APE.

Cultural resources assessments will be conducted in areas that have not been previously surveyed with a high potential for containing historic properties. During PED and prior to construction, these surveys and a final determination of effects for any historic properties within the APE will be coordinated with the California SHPO, Native American Tribes and other consulting parties. Discovery of historic properties may also lead to the development of avoidance, minimization, and/or mitigation plans in consultation with the SHPO. Due to the timing of the San Francisco Navigation Improvement project planning, USACE is currently unable to identify and evaluate cultural resources and determine effects of deepening the channel to -37 feet on historic properties prior to completion of the EIS.

#### FUTURE WITH -38 FOOT ALTERNATIVE

Under the Future with -38 Foot Alternative, activities associated with proposed deepening of the existing channel have the same potential as those of the -37 foot MLLW Alternative, although they would occur on proportionally larger scales due to the larger volume of dredged material.

#### FUTURE WITH -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION

Under the Future with -38 foot MLLW Alternative, sediment trap, and removal of rocky obstruction activities associated with proposed alternative have the same potential as those of the -37 foot MLLW Alternative, although they would occur on proportionally larger scales due to the larger volume of dredged material from the inclusion of the sediment trap and rocky obstruction removal. In addition, the analysis of CHRIS) data shows that a previously recorded shipwreck, which is identified as the Baldwin Channel Wreck (P7-002760 and 21-000598), is located within the rocky obstruction APE; however, there is some question as to the location of the wreck. A submerged cultural resource survey of this site will be required to provide an accurate location of this resource. If this site is identified within the APE a diver identification and evaluation survey will be required to assist USACE determine the eligibility of the site for listing on the NRHP.

If an archaeological resource cannot be avoided, the Project archaeologist shall consult with the appropriate agencies and tribes as described within the Programmatic Agreement to resolve adverse effects to a potential historic property. USACE shall evaluate the potential of the resource to meet the criterion for eligibility for listing on the NRHP and CRHR. USACE shall complete a determination of effects Report, which shall be submitted to USACE for review upon completion.

#### 4.1.12 ENVIRONMENTAL JUSTICE AND COMMUNITY EFFECTS

Executive Order 12898 mandates that each Federal agency make environmental justice (EJ) part of the agency mission and to address, as appropriate, disproportionately high and adverse human health or environmental effects of the programs and policies on minority and low-income populations. Significance thresholds that may be used to evaluate the effects of a proposed action related to EJ are not specifically outlined. However, Council on Environmental Quality (CEQ) guidance requires an evaluation of a proposed action's effect on the human environment and USACE must comply with Executive Order 12898.

The methodology for conducting the EJ impact analysis included review of the impact conclusions presented in Chapter 4 of this report for each of the environmental resource categories considered. An EJ analysis was accomplished to determine if minority populations or low-income populations could experience disproportionately high and adverse effects where the following effect scenarios were identified: (1) significant impacts would occur to a specific environmental resource; (2) could contribute to a cumulatively significant impact on a study area resource when considered in combination with other projects; and/or (3) impacts are judged to be high and adverse, even if not significant.

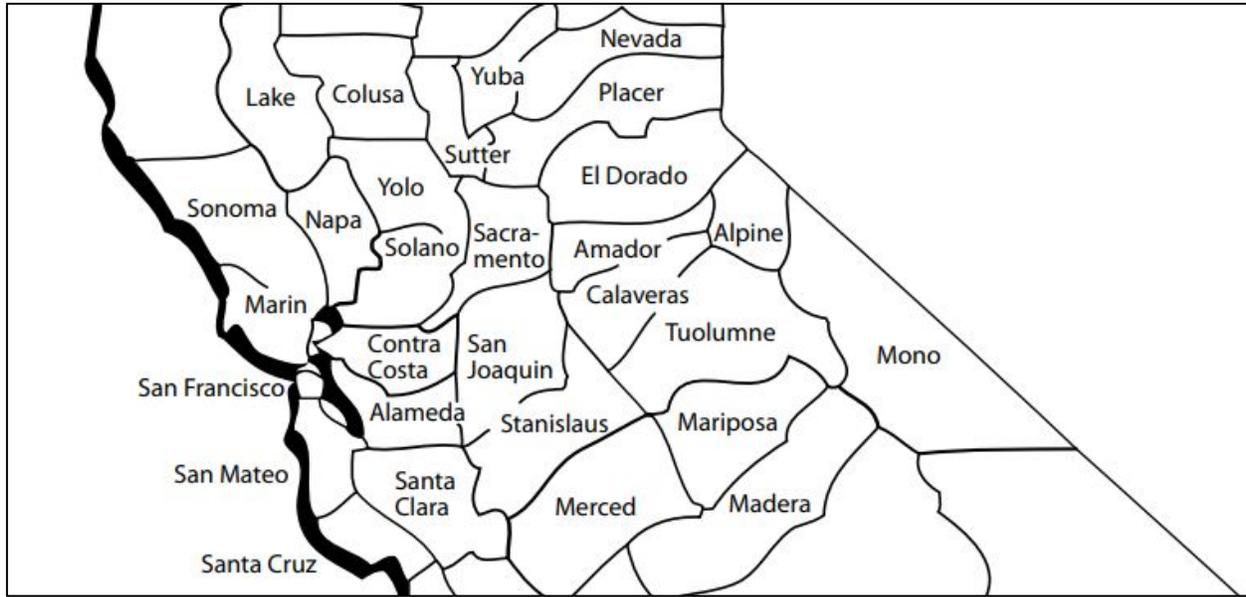

Potential EJ impacts were analyzed through the following ordered process:

1. Identify types of impacts that may occur,
2. Describe the portion of the study area in which impacts may occur,
3. Identify potentially affected populations, and
4. Determine whether environmental impacts are disproportionate to low-income or minority populations.
5. To determine whether impacts are disproportionate, the APE was compared to surrounding geographic entities to determine if it contains disproportionately low-income or minority populations. The results were compared to the impact analyses from other resource categories to determine the likelihood of disproportionate impacts to low-income or minority populations.

An alternative would be considered to have a significant EJ impact if it would cause the following:

Impact EJ-01: Disproportionate environmental effects to communities within the APE when compared to surrounding areas.

**Figure 4-1. Counties within the Bay Area.**

The population growth trends from 1980 through 2010 for the San Francisco Bay area (**Figure 4-1**) are shown in **Table 4-20** below. The region as a whole has experienced a rapid rate of growth since 1980. According to 2010 U.S. Census data, the Bay Area has a 49.8 percent growth between 1980 and 2010, with a net population increase of 1,064,877 residents.

**Table 4-20. Bay Area Population Growth, 1980-2010.**

Bay Area Population Growth, 1980-2010					
	Population				Percent Increase 1980-2010
Geography	1980	1990	2000	2010	
San Francisco County	678,974	723,959	776,733	805,235	18.6%
Marin County	222,592	230,096	247,289	252,409	13.4%
Contra Costa County	656,331	803,732	948,816	1,049,025	59.8%
Solano County	235,203	340,421	394,542	413,344	75.7%
San Joaquin County	347,342	480,628	563,598	685,306	97.3%
Bay Area	2,140,442	2,578,836	2,930,978	3,205,319	49.8%
California	23,667,902	29,760,021	33,871,648	37,253,956	57.4%
United States	226,542,199	248,709,873	281,421,906	308,745,538	36.3%

Population density varied extensively for the five counties from a low of 485 persons per square mile in Marin County to a high of 17,179 persons per square mile in San Francisco County.

As shown in **Table 4-21** below, the Bay Area and the State of California have mostly higher percentages of minority populations than the United States according to the 2010 U.S. Census. In the Bay Area, San

Francisco County has a higher percentage of minority populations than the other counties. In 2010, the Bay Area as a whole had more of a diverse racial composition compared to the U.S., where approximately 55 percent of the population identified as White, 8.3% of the population identified as Black or African American, 18.5 percent of the population identified as Asian, and 11.1 percent of the population identified as Other.

**Table 4-21. Racial Composition in the Bay Area, 2010.**

Racial Composition 2010		San Francisco County	Marin County	Contra Costa County	Solano County	San Joaquin County	Bay Area	California	U.S.
White	No.	390,387	201,963	614,512	210,751	349,287	1,766,900	21,453,934	223,553,265
	%	48.5%	80.0%	58.6%	51.0%	51.0%	55.1%	57.6%	72.4%
Black or African American	No.	48,870	6,987	97,161	60,750	51,744	265,512	2,299,072	38,929,319
	%	6.1%	2.8%	9.3%	14.7%	7.6%	8.3%	6.2%	12.6%

The age characteristics of the Bay Area are shown in **Table 4-22** below. As a whole, the Bay Area in 2010 had a higher median age than the State of California and equaled the median age for the United States. San Francisco County, Marin County, and Contra Costa County all had median ages higher than or equal to the State and National median age. Solano County's median age was higher than the State level, but lower than the National level. San Joaquin County was the only area to have a median age lower than both State and National levels.

**Table 4-22. Age Distribution in the Bay County, 2010.**

Age Distribution 2010		San Francisco County	Marin County	Contra Costa County	Solano County	San Joaquin County	Bay Area	California	U.S.
Under 18	No.	124,570	56,452	287,513	113,222	223,585	805,342	10,452,042	74,181,467

Median Age		38.5	37.2	38.5	36.9	32.7	37.2	35.2	37.2

The 2010 U.S. Census income and poverty data for the Bay Area and the State of California are summarized in **Table 4-23** below. All counties had higher median household incomes than the State of California, with the exception of San Joaquin County at \$59,900.

**Table 4-23. 2010 U.S. Census Income & Poverty Data for the Bay Area.**

Regional Income and Poverty Data	San Francisco County	Marin County	Contra Costa County	Solano County	San Joaquin County	California	U.S.
Median Household Income	\$75,604	\$90,839	\$78,756	\$67,177	\$59,900	\$61,094	\$53,046
Per Capita Income	\$48,486	\$56,791	\$38,219	\$28,929	\$22,589	\$29,527	\$28,155
Percent of People Below Poverty Level	13.5%	7.7%	10.5%	13.0%	18.2%	15.9%	15.4%

Marin County had the highest median household income and per capita income, while San Joaquin County had the lowest median household income and per capita income. San Joaquin County had the highest percentage of people living below poverty level (18.2 percent) when compared to other counties in the region and to the State of California. San Francisco County, Marin County, Contra Costa County, and Solano County all had lower percentages of people living below poverty level compared to the State of California. As shown in **Table 4-24** below, all counties in the Bay Area had a higher percentage of people over the age of 25 that graduated high school or higher when compared to the State of California and the United States, except for San Joaquin County. San Francisco County, Marin County, and Contra Costa County had higher percentages of people over the age of 25 that earned a Bachelor's Degree or higher when compared to the State of California and the United States. Solano County and San Joaquin County had lower percentages of people over the age of 25 that earned a Bachelor's Degree or higher, at 24.3 percent and 18.1 percent, respectively.

**Table 4-24. Distribution of Education in the Bay Area.**

<b>Geography</b>	<b>High School Graduate or Higher - Persons 25 Years or Older</b>	<b>Bachelor's Degree or Higher - 25 Years and Older</b>
San Francisco County	86.3%	52.4%
Marin County	92.4%	54.6%
Contra Costa County	88.8%	39.0%
Solano County	87.2%	24.3%
San Joaquin County	77.3%	18.1%
California	81.2%	30.7%
U.S.	86.0%	28.8%

As defined in Executive Order 12898 and the CEQ guidance, a minority population occurs where one or both of the following conditions are met within a given geographic area:

- The American Indian, Alaskan Native, Asian, Pacific Islander, Black, or Hispanic population of the affected area exceeds 50 percent; or
- The minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis.

For this study, the geographic location used in determining demographics was the San Francisco Bay area. Based on 2010 census data, as shown in Table 25 in the Economic Analysis appendix, (Socioeconomic and Regional Analysis section), the aggregate minority population is 44.9 percent of the total population in the San Francisco Bay area. The aggregate minority population in the State of California is 42.4 percent. Therefore, the aggregate minority population percentage for the San Francisco Bay area does not exceed 50 percent and is not meaningfully greater than the aggregate minority population in the State of California, so the study area does not contain a high concentration of minority populations.

Executive Order 12898 does not provide criteria to determine if an affected area consists of a low-income population. For the purpose of this assessment, the CEQ criterion for defining a minority population has been adapted to identify whether or not the population in an affected area constitutes a low-income population. An affected geographic area is considered to consist of a low-income population (i.e. below the poverty level for purposes of this analysis) where the percentage of low income persons:

- Is at least 50 percent of the total population; or
- Is meaningfully greater than the low-income population percentage in the general population or other appropriate unit of geographic analysis.

Based on 2010 census data, as shown in Table 27 in the Economic Analysis appendix (Socioeconomic and Regional Analysis section), 13 percent of the individuals in the San Francisco Bay area are considered below the poverty level. Since the percentage of individuals below the poverty level in the San Francisco area does not exceed 50 percent and is less than both the State of California and all of the United States (15.9 percent and 15.4 percent, respectively), the San Francisco Bay area does not have a high concentration of

low-income individuals. In summary, the study area which comprises the San Francisco Bay area is not an EJ community.

#### NO ACTION ALTERNATIVE

**Impact EJ-01: Disproportionately disrupt economic vitality or community cohesion:** No significant impacts compared to the No Action Alternative would result from increased ship calls in the future. Any operational air quality impact would be equally borne by all populations. Therefore, there would be no disproportionate impacts to the communities within the APE compared to surrounding areas under the No Action Alternative.

#### FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**Impact EJ-01: Disproportionately disrupt economic vitality or community cohesion:** No significant impacts compared to the No Action Alternative would result from increased ship calls in the future. Any operational air quality impact would be equally borne by all populations. Therefore, there would be no disproportionate impacts to the communities within the APE compared to surrounding areas under the No Action Alternative.

#### 4.1.13 NAVIGATION, TRANSPORTATION, AND CIRCULATION

Impacts on navigation, transportation and circulation were assessed by determining the net increase in vessel traffic resulting from both phases of the study compared to vessel safety, as well as the potential to increase risks to vessel traffic during both construction and operation. This analysis also examined the potential changes in maintenance dredging requirements as a result of channel deepening. As discussed previously, deepening will primarily affect crude oil tankers.

An alternative would be considered to have a significant impact if it would cause the following:

Impact NT-01: Change vessel traffic patterns, resulting in unplanned or regularly occurring delays, adverse change in freedom of movement, increase safety risks, or introduction of safety hazards

Based on the environmental setting of the study area and the characteristics of the alternatives under evaluation, there would be no adverse impacts to the navigation, transportation, and circulation topics described below; therefore, they are not discussed further in this section:

- **Increase land-based traffic on roadways, railways, and recreational pathways.** The alternatives would not affect roadways, railways, and recreational pathways on land.
- **Increase roadway and rail traffic due to changes in bridge operations.** Roadway traffic in the study area is not affected by vessel traffic because existing roadway bridges are all of fixed height. Rail traffic is not expected to be affected because vessel traffic would be reduced under the alternatives.

#### NO ACTION ALTERNATIVE

**Impact NT-1: Change vessel traffic patterns, resulting in unplanned or regularly occurring delays, adverse change in freedom of movement, increase in safety risks, or introduction of a safety hazards:** The No Action Alternative represents the current and future conditions assuming channel deepening does not take

place. No construction would occur, so there would be no temporary impacts to vessel traffic patterns as a result of construction activities under the No Action Alternative.

Because the primary impacts to marine navigation are expected to be borne by tankers carrying petroleum products, projections about changes in petroleum shipping and the effect on the vessel fleet mix are used to determine the vessel traffic and commodity movements with the No Action Alternative. Both imports and exports of petroleum products are expected to increase modestly based on global economic conditions with or without channel deepening. **Table 4-25** shows projected changes in commodity imports and exports under the No Action Alternative (see **Appendix D, Economic Analysis**).

**Table 4-25. Commodity Forecast for No Action Alternative (Metric Tons).**

Commodity	Forecast		
	2020	2030	2040
Total Crude Imports	7,736,000	7,892,000	8,052,000
Total Petroleum Exports	2,311,074	2,930,000	3,714,000

The commodities identified in **Table 4-25** would move through the project area in a mix of vessels. Under the No Action Alternative, the number of larger Aframax and Suezmax vessels is forecasted to remain the same through 2040 (approximately 50 and 30, respectively). The number of Panamax vessels are projected to increase modestly from approximately 125 in 2020 to 175 in 2040.

Recreational vessel traffic would continue throughout the study area under the No Action Alternative. No forecasts are available for recreational traffic, but it would be expected to change proportionally with population in the Bay Area. According to the Plan Bay Area 2040, a joint planning document, the population of the nine-county San Francisco Bay area is projected to increase by 29 percent by 2040 (ABAG and MTC 2013). Therefore, a corresponding increase in recreational vessel traffic could be expected. However, recreational traffic is separated from commercial traffic under the governing international and inland rules of navigation, so changes affecting large commercial vessels would not be expected to affect recreational traffic.

Under the No Action Alternative, the existing maintenance dredging program would continue as it has historically occurred throughout the study area. The manner in which the existing 35 foot MLLW channel is maintained has been determined to have negligible effect on marine navigation (USACE 2014a). Based on the above analysis, the No Action Alternative would have no impact on the vessel traffic patterns, safety risks, safety hazards, freedom of movement or safety issues for either commercial or recreational vessels.

**FUTURE WITH -37 FOOT ALTERNATIVE**

**Impact NT-1: Change vessel traffic patterns, resulting in unplanned or regularly occurring delays, adverse change in freedom of movement, increase in safety risks, or introduction of a safety hazards:** **Appendix D, Economic Analysis** projects that the volume of petroleum products (which are the dominant cargo in the project area) will grow at the same rate whether the proposed project is implemented or not. However, the vessel mix is projected to change if deepening is implemented. Specifically, additional cargo volume would be accommodated by vessels between 35,000 DWT and 77,000 DWT (Panamax), the main class of vessels that would benefit from the deepening. The deeper channel depth would allow those vessels to avoid some of the costly operational strategies currently in use, making them a more efficient option than

the larger vessels. In the future with project condition, the design vessel (Panamax) with a sailing draft greater than 34 feet (37 foot channel minus 3 feet underkeel clearance) will encounter tidal delays, rather than at 32 feet (35 foot channel minus 3 feet underkeel clearance) in the future without project condition. Therefore, the increased loading capacity in the future-with project condition reduces the number of vessel calls and partially reduces tidal delays.

**Table 4-26** shows the predicted maximum traffic volumes of bulk tankers in the project area (see **Appendix D, Economic Analysis**). Compared to the No Action Alternative, the number of vessels transiting this area may actually decrease under the -37 foot MLLW alternative. Because no increases in traffic are expected and traffic will continue to be controlled by Vessel Traffic Services implementing Federal and state rules of navigation, no adverse impacts are likely to commercial shipping, freedom of movement, and/or safety associated with operations with the -37 foot MLLW Alternative compared to the baseline.

**Table 4-26. Bulk Vessel Fleet Volume Forecast.**

Vessel Type	No Action Alternative			-37 Foot MLLW Alternative			-38 Foot MLLW Alternative		
	2020	2030	2040	2020	2030	2040	2020	2030	2040
Panamax	125	150	175	116	141	169	113	136	165
Aframax	50	50	50	56	56	56	56	56	56
Suezmax	30	30	30	33	33	33	33	33	33
<b>Total</b>	<b>205</b>	<b>230</b>	<b>255</b>	<b>205</b>	<b>230</b>	<b>258</b>	<b>202</b>	<b>225</b>	<b>254</b>

Recreational traffic is separated from commercial traffic under governing international and inland rules of navigation, so changes affecting large commercial vessels are not expected to affect recreational traffic.

Dredged material from construction deepening would be placed at existing beneficial reuse sites which have all permits. Use of these sites would result in short-term increases in tug and barge movement. These effects would be limited to the year that it could take to deepen the channel if work is performed during only the established work window that spans June 1 to November 30 in San Pablo Bay and August 1 through November 30 in Bulls Head Reach. After construction is complete, regular maintenance dredging would continue to be conducted on an annual basis in the project area. Maintenance dredging would essentially resemble that now performed with the existing 35 foot channel and would continue to have a negligible impact on marine navigation. All dredging equipment would be required to comply with local safety requirements including publication of construction announcements in the USCG Local Notice to Mariners. Thus, impacts would be temporary and less than significant.

#### [FUTURE WITH 38 FOOT AND 38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES](#)

**Impact NT-1: Change vessel traffic patterns, resulting in unplanned or regularly occurring delays, adverse change in freedom of movement, increase in safety risks, or introduction of a safety hazards:** According to **Appendix D, Economic Analysis**, the -38 foot MLLW Alternative would result in a slight decrease in commercial vessel traffic compared to the -37 foot MLLW Alternative and the No Action Alternative. This reduction is forecast because vessels between 35,000 DWT and 77,000 DWT (Panamax) would be able to travel the channel more fully loaded, avoiding some currently used operational strategies such as lightering and tidal delay. Because of this projected reduction in the number of vessels, no adverse impacts are expected to commercial shipping or recreational vessel traffic. In the future with project condition, the design vessel (Panamax) with a sailing draft greater than 35 feet (38 foot channel minus 3 feet underkeel clearance) will encounter tidal delays, rather than at 32 feet (35 foot channel minus 3 feet underkeel

clearance) in the future without project condition. Therefore, the increased loading capacity in the future-with project condition reduces the number of vessel calls and partially reduces tidal delays.

Impacts under the -38 foot MLLW Alternative would be similar in nature to those that would occur under the -37 foot MLLW Alternative. The removal of the rocky obstruction would reduce the safety risk to vessels traversing the shipping channel. Therefore, impacts would be temporary and less than significant.

#### 4.1.14 NOISE

The analysis of noise includes a general comparison of existing noise conditions to potential noise levels during the construction. The U.S. Federal Transit Administration guidelines for assessment of noise impacts for construction activities provide commonly accepted thresholds for construction noise impacts to residential and industrial areas. These thresholds were adopted as significance thresholds for this analysis.

Impact NOI-01: Result in a 90 dBA equivalent continuous sound level over a 1-hour period in a residential or public park area or a 100 dBA equivalent continuous sound level over a 1-hour period in an industrial area.

#### NO ACTION ALTERNATIVE

**Impact NOI-01: Result in a 90 dBA equivalent continuous sound level over a 1-hour period in a residential or public park area or a 100 dBA equivalent continuous sound level over a 1-hour period in an industrial area:** The No Action Alternative would not result in any construction dredging activities to deepen the various channel segments and would not result in the off-loading of dredged soils. Annual operations and maintenance dredging would continue to occur within the established work windows for the respective channels. Noise impacts from annual maintenance dredging were analyzed for the period 2015-2024 in the San Francisco Bay Federal Channels Maintenance and Operations EA/EIR (USACE and RWQCB 2015) and found to be less than significant.

#### FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**Impact NOI-01: Result in a 90 dBA equivalent continuous sound level over a 1-hour period in a residential or public park area or a 100 dBA equivalent continuous sound level over a 1-hour period in an industrial area:** The effects of the -37 foot MLLW Alternative on noise would be similar to the No Action Alternative, although the timeframe within which higher noise levels would be generated would be extended because of the larger quantities of sediments that would be dredged during initial construction. However, subsequent noise generated during routine maintenance would be essentially the same as that associated with the No Action Alternative. Thus, noise impacts that would be produced by this alternative along the open water route of the navigation channels would be less than significant.

At the placement sites, sensitive receptors could include recreational users and non-motorized boaters. While the noise level in the immediate vicinity of the tug (within approximately 400 feet) may periodically exceed the applicable noise threshold, the presence of tugs at the off-loader would be episodic, and of limited duration. In addition, there is extensive availability of alternative recreation locations and recreational users and non-motorized boat users have ample opportunities for recreational activities in areas away from the off-loading location. Therefore, impacts to sensitive receptors at the placement sites would be less than significant. The potential impacts to wildlife from the proposed project due to noise is discussed in Biological Resources as well as **Appendix G- Attachment 4, Biological Assessment**.

#### 4.1.15 PUBLIC HEALTH AND ENVIRONMENTAL HAZARDS

Potential impacts to the study area from hazardous releases or storage of such materials were analyzed using a qualitative approach based on information compiled from known hazardous materials sites and current operations within the study area. This analysis considered changes or impacts to these conditions that may occur as a result of implementing navigation improvements. Potential impacts were analyzed using professional expertise and judgment in evaluating how construction and operational activities could impact known hazardous material sites and existing operations and potentially cause hazardous releases or exposure of individuals to hazards.

Alternatives are considered to have a significant impact if implementation or operations activities would:

- Impact PH-01: Occur on a site that is included on a list of hazardous material sites compiled pursuant to Government Code Section 65962.5 and, as a result, create a significant hazard to the public or the environment; or
- Impact PH-02: Create a significant hazard to the public or the environment by disrupting the routine transport, use, or placement or storage of hazardous materials or wastes; or
- Impact PH-03: Impair implementation of, or physically interfere with, an adopted emergency response plan or emergency evacuation plan.

#### NO ACTION ALTERNATIVE

**Impact PH-01: Occur on a site that is included on a list of hazardous material sites compiled pursuant to Government Code Section 65962.5 and, as a result, create a significant hazard to the public or the environment:** Although two existing hazardous sites may overlap with the No Action Alternative maintenance dredging footprint, impacts to those hazardous sites would be avoided by coordinating ongoing maintenance dredging and placement operations with any active cleanup activities. This includes existing or future cleanup efforts at the U.S. Army MOTCO MRS 8 and MRS 10 sites or at hazardous materials sites in the shoreline or nearshore areas. There is no pathway for existing dredging or placement practices to impact other listed hazardous sites. Therefore, the No Action Alternative would have no impact related to hazardous material sites.

**PH-02: Create a significant hazard to the public or the environment by disrupting the routine transport, use, disposal, or storage of hazardous materials or wastes:** Operation and maintenance activities would remain unchanged under the No Action Alternative, and new hazardous material exposure pathways would not be introduced. Therefore, the No Action Alternative would have no impacts to the routine transport, use, disposal or storage of hazardous materials or wastes.

**Impact PH-03: Impair implementation of, or physically interfere with, an adopted emergency response plan or emergency evacuation plan:** The No Action Alternative would not impair implementation or interfere with any emergency response or evacuation plans. In the event of an emergency, dredge equipment would be removed from the channel or positioned in such a manner as to not impede the navigation of emergency response or evacuation vessels. Maintenance of the existing 35 feet MLLW channel depth would have a long-term beneficial impact by removing shoaled sediment and maintaining the navigability of the Federal channels for use by vessels during emergency response operations. Therefore, the No Action Alternative would have no adverse impacts on emergency plans.

## FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**Impact PH-01: Occur on a site that is included on a list of hazardous material sites compiled pursuant to Government Code Section 65962.5 and, as a result, create a significant hazard to the public or the environment:** There are no existing hazardous sites, and existing cleanup or hazardous material enforcement actions at the shoreline or nearshore area would be unaffected by this alternative. The Alternatives would introduce no new uses that would increase exposure to hazardous material sites. Therefore, the Alternatives would have no impacts related to hazardous material sites.

**PH-02: Create a significant hazard to the public or the environment by disrupting the routine transport, use, disposal, or storage of hazardous materials or wastes:** Under all Alternatives, the channel would be able to accommodate vessels with deeper drafts, allowing vessels to carry heavier loads. This could potentially include increased volumes of hazardous material cargo compared to baseline conditions. This could result in increased hazardous material discharges in the event of a spill or vessel collision. Although the amount of hazardous material cargo may increase in individual vessels, the overall amount of hazardous cargo is not projected to increase (see **Appendix D, Economic Analysis**). Therefore, hazardous cargo shipping demands could potentially be accommodated with fewer vessels carrying greater cargo loads. The economic analyses completed for this alternative predict that the overall number of shipping vessels is projected to remain nearly the same or even decrease slightly compared to the No Action Alternative, and the risk for vessel accidents would not increase. Furthermore, vessel accidents in the project area are rare, as supported by NOAA records. Transport of hazardous materials would continue to occur in compliance with all Federal, state, and local regulations. Hazardous material use associated with vessel operation (e.g., fuels, oils and solvents) would be unchanged from existing conditions and would continue to occur according to established best management practices and in compliance with applicable regulations, as discussed in Water Quality and Hydrology.

In addition, all sediment to be dredged as part of the Alternatives would undergo extensive testing in advance of dredging to ensure that it meets the requirements for beneficial reuse. Based on the analysis presented above, the Alternatives would have no impacts to the routine transport, use or disposal of hazardous materials or wastes and/or hazardous sites.

**Impact PH-03: Impair implementation of, or physically interfere with, an adopted emergency response plan or emergency evacuation plan:** Same as No Action Alternative.

### 4.1.16 RECREATION

Environmental effects on recreational resources were assessed by evaluating the potential for direct interference with recreational activities (e.g., blocking access to a marina entrance) and reduced access to recreational facilities and areas (e.g., through the presence of construction equipment in the waterways). Information was obtained for each county from the Delta Protection Commission's Inventory of Recreational Facilities, County General Plans, and other publically available information on local recreation.

An alternative would be considered to have a significant impact if it would cause the following:

- Impact RE-01: Substantially reduce or restrict the availability or quality of existing recreation opportunities; or
- Impact RE-02: Conflict with Federal, state, and/or local agency regulations and policies regarding recreational resources.

The following recreation topic will not be discussed because there would be no adverse impacts.

**RE-02: Conflict with Federal, state, and/or local agency regulations and policies regarding recreational resources.** Activities proposed would comply with current Federal, state, and local agency regulations and policies. While it is possible that the cities and counties in the study area could amend regulations specific to recreational resources in their General Plans, it is unlikely that the regulations pertaining to recreational resources would be modified to prohibit dredging or dredged material placement activities in the identified placement sites. Thus, as compared to the baseline conditions, proposed activities should conform with Federal, state, and local agency regulations and policies regarding recreational resources. In addition, the alternatives would not be anticipated to contribute incrementally to any cumulative adverse effects on such regulations and policies when considered in combination with other activities within the study area.

### NO ACTION ALTERNATIVE

**Impact RE-01: Substantially reduce or restrict the availability or quality of existing recreation opportunities:** Under the No Action Alternative recreation features would continue to function as they do currently. Any short-term impacts associated with the dredging activities would be inconsequential. Therefore, based on a worst case analysis, existing recreation resources and activities could experience occasional, less than significant, adverse impacts during dredging events. Over time, an increase in ship traffic could also have less than significant effects on recreational boat use. Overall, impacts of the No Action Alternative on recreation would be less than significant.

### FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**Impact RE-01: Substantially reduce or restrict the availability or quality of existing recreation opportunities:** The proposed dredging and placement activities under this alternative would not create a demand for new recreational facilities and would not result in increased use or deterioration of existing recreational facilities. Dredging would create a long-term beneficial impact for watercraft by ensuring safe navigation. However, these benefits would be less than significant.

Construction activities under this alternative may occasionally delay or temporarily impede recreational watercraft during dredging and placement activities. However, in most locations, there would be sufficient room for recreational vessels to maneuver around the dredge equipment, and therefore, impacts from dredging activities are expected to be negligible. Compared to the baseline conditions, there would be short-term impacts to the use, quality, and availability of recreational opportunities due to the presence of construction equipment. However, these types of activities are typical and impacts would be less than significant.

#### 4.1.17 SOCIO-ECONOMICS

NEPA does not provide specific thresholds of significance for socioeconomic impact assessment. Significance is understood to vary depending on the setting of the proposed action (40 CFR 1508.27[a]).

For the purposes of this analysis, the effects of the alternatives on socioeconomic factors are considered to be significant if an alternative would result in any of the following socioeconomic impacts:

- **Impact SOC-01:** Result in a rapid or sizeable shift in population trends or would notably affect regional employment, spending and earning patterns, or community resources in a manner that could not be easily absorbed or accommodated by the economy as a whole.

**Measurable and/or prolonged change in local job supply or change in revenue from leading industries.**

Navigation improvements would provide access to oil terminals and industry in Pittsburg and the Port of Stockton. Dredging of the navigation channels would provide a beneficial socioeconomic impact by maintaining navigability of the channels and access to local ports and harbors critical to maritime commerce and the regional economy.

Dredging and associated construction activities are expected to result in economic benefits related to a small, local increase in jobs. The majority of these jobs would likely be associated with the dredging activities, while a few temporary jobs would also be created at the sediment delivery location if a beneficial reuse site is used. Subsequent shipping operations and maintenance of the channels are not expected to result in a large increase in local employment placing added demands on housing and/or public services.

**NO ACTION ALTERNATIVE**

**Impact SOC-01: Result in a rapid or sizeable shift in population trends or would notably affect regional employment, spending and earning patterns, or community resources in a manner that could not be easily absorbed or accommodated by the economy as a whole:** There would be no new dredging activities or new use of the placement sites under the No Action Alternative. The existing deep draft channel dimensions would continue to be maintained, existing activities at facilities called on by commercial vessels would continue, and the number of vessels would increase slightly into the future. Existing beneficial effects of navigation transportation would continue to be enjoyed by local ports and the industries that transport commodities through the ports as well as by the port and industrial workers that depend upon the availability of the existing navigation channels. Thus, there would be no effect on population in the study area as a result of routine maintenance of the existing navigation channels.

**FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES**

**Impact SOC-01: Result in a rapid or sizeable shift in population trends or would notably affect regional employment, spending and earning patterns, or community resources in a manner that could not be easily absorbed or accommodated by the economy as a whole:** This alternative would create a small, local, temporary increase in jobs. However, it is expected that all jobs would largely be filled by local workers and there would be no impact on regional employment. Any spending and earning in the local area from the temporary increase in jobs would not have the ability to impact regional spending or earning patterns. Similarly, there would be no additional demand on community resources that could not be accommodated by the economy as a whole. Dredging of the navigation channel would provide a beneficial socioeconomic impact by maintaining navigability of the channels and access to local ports and harbors critical to maritime commerce and the regional economy. There is likely to be increased efficiency in use of the channels from the deepening of the channel for importing and exporting of materials. However, no noticeable change in maritime infrastructure or regional economy associated with this alternative is expected.

**4.1.18 UTILITIES AND PUBLIC SERVICE**

The significance threshold used in this analysis focuses on impacts that navigation channel deepening could have on buried utility cables, buried pipelines, and/or overhead power transmission lines. Implementation of an alternative would be considered to have a significant impact on the utilities considered if the alternative would:

- **UTIL-01:** Interfere with operations of, cause damage to, or otherwise disrupt the use of any buried/underwater cable or pipeline, or overhead power transmission line.

#### NO ACTION ALTERNATIVE

**Impact UTIL-01: Interfere with operations of, cause damage to, or otherwise disrupt the use of any buried/underwater cable or pipeline, or overhead power transmission line:** In the absence of Federal action to deepen the existing -35 feet MLLW navigation channels, continuation of regular maintenance dredging would have no adverse impacts to buried underwater cables and pipelines, water supply infrastructure, or overhead power transmission lines. Commercial ships would continue to navigate the marked ship channels using the same precautions as at present.

#### FUTURE WITH -37 FOOT, -38 FOOT, AND -38 FOOT + SEDIMENT TRAP AND ROCKY OBSTRUCTION ALTERNATIVES

**Impact UTIL-01: Interfere with operations of, cause damage to, or otherwise disrupt the use of any buried/underwater cable or pipeline, or overhead power transmission line:** For the alternatives, the utilities that have the potential to be impacted by channel deepening are: (1) the Trans Bay Cable and 2) the Rodeo Sanitary District sewer outfall. The height clearance of the two overhead power transmission lines that cross the channels exceeds the low clearance of some bridges in the study area. That means the transmission lines would not be affected by implementation of either channel deepening alternatives.

The Rodeo sanitary sewer outfall is located in the Carquinez Straight at the edge of the naturally deep channel in between where the Pinole Shoal ends and the Bulls Head Reach begins, and will not be investigated further. Therefore, the only utility that was analyzed to determine effects from the alternatives is the trans-bay cable utility owned by Trans Bay Cable.

The utility survey that was conducted in 2011 (*Utility Investigation Report – San Francisco to Stockton Deep Water Ship Channel*, dated May 2011) provided As-Built drawings from Trans Bay Cable for their 10 inch diameter direct current (DC) transmission line that was constructed in 2010. The As-Built drawings were reviewed and compared with the USACE hydrographic condition survey that was performed at approximately the same period that the trans-bay cable was installed. The drawings indicate that the trans-bay cable crosses the Pinole Shoal in two locations: STA 62+00 and from STA 468+00 to STA 547+11. In both locations, the channel is naturally deeper than the alternative depths. The As-Built drawings indicate the trans-bay cable was buried to a depth that is approximately -48 to 49 feet MLLW (which is 6 feet below existing natural channel bottom, where the existing natural channel bottom is between -42 and -43 MLLW) for both crossing locations. The cable utility does not intersect the other Federal channels in the remainder of the project footprint. Therefore, it has been determined that the trans-bay cable utility will not be impacted by the alternatives and no relocations would be needed.

During design of the channels, consultations will be initiated with all owners and operators of the known buried/underwater cables and pipelines under or near the navigation channels.

Implementation of these actions would not impact any utilities.

## 4.2 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

The resource commitments needed for the -38 foot MLLW + sediment trap and rocky obstruction (Recommended Plan) are neither irreversible nor irretrievable, with most impacts being short-term and temporary. The only expected irretrievable resource commitment from is the consumptive use of non-renewable fossil fuels for the operation of dredge, tugs, and related support equipment during construction and future maintenance dredging. There is no other expected commitment of irretrievable resources.

## 4.3 UNAVOIDABLE ADVERSE ENVIRONMENTAL EFFECTS

The alternatives would not result in any significant and unavoidable adverse environmental impacts. The salinity would shift due to the proposed project, however, it is considered a less than significant effect supported by hydrodynamic modeling (see discussion in **Appendix B, Water Resources - Attachment 1 Salinity Modeling Report and Section 4.1.2 and 4.1.3 of the main report**).

## 4.4 COMPATIBILITY WITH FEDERAL, STATE, AND LOCAL OBJECTIVES

As described in above, the Recommended Plan is compatible with Federal, state, and local objectives. The alternatives do not conflict with any stated plans or policies. By facilitating wetland creation through beneficial reuse of dredged sediment, both the -37 foot MLLW and -38 foot MLLW Alternatives are furthering Long-term Management Strategy objectives for managing dredging in the San Francisco Bay Area. Therefore, the alternatives would maintain consistency of future vessel operational emissions in the Bay Area with applicable plans and objectives.

## 4.5 CONFLICTS AND CONTROVERSY

Extensive coordination undertaken by USACE and the Port of Stockton with Federal, state, and local agencies, water managers, businesses, organizations, and the general public prior to preparation of this report identified the following key issues of known concern and expected controversy:

- Salinity intrusion in the Delta, particularly related to impacts on drinking water and designated critical habitat of the Federal and state listed endangered delta smelt.
- Impacts to threatened and endangered species including longfin smelt, green sturgeon, and salmonids.
- The potential to beneficially use dredged material in existing habitat restoration projects within the study area.
- Effects of sea level rise within the study area.

## 4.6 UNCERTAIN, UNIQUE, OR UNKNOWN RISKS

The Recommended Plan is not unique or unusual, and understanding of the resources in the area is thorough. The effects of dredging activities are well understood; USACE has extensive experience evaluating the environmental effects associated with dredging projects. The environmental analysis did not identify any highly uncertain, unique, or unknown risk effects on the human environment which would result from implementing the project.

## 4.7 CUMULATIVE EFFECTS

EPA requires the consideration of cumulative effects of the proposed action combined with those of other projects. NEPA defines a cumulative effect as an environmental effect that results from the incremental effect of an action when combined with other past, present and reasonably foreseeable future actions, regardless of what agency (Federal or non-Federal) or person undertakes such other actions (40 CFR 1508.7).

Cumulative effects can result from individually less than significant, but collectively significant, actions taking place over a period of time. Cumulative effects can result in unintended adverse environmental effects despite efforts to mitigate for an individual action's specific direct and indirect impacts. The purpose of a cumulative impacts analysis is to identify the potential for incremental increased environmental effects caused by a series of actions.

An inherent part of the cumulative effects analysis is the uncertainty surrounding actions that have not yet been fully developed. The CEQ (1997) regulations provide for the inclusion of uncertainties in the EIS analysis, and state that "(w)hen an agency is evaluating reasonably foreseeable significant adverse effects on the human environment in an EIS and there is incomplete or unavailable information, the agency shall always make clear that such information is lacking" (40 CFR Part 1502.22). The CEQ regulations do not say that the analysis cannot be performed if the information is lacking. Consequently, the analysis contained in this section includes what could be reasonably anticipated to occur given the uncertainty created by the lack of detailed investigations to support all cause and effect linkages that may be associated with the Proposed Action/Recommended Plan.

The cumulative effect analyses include considerations of the past, present, and reasonably foreseeable future actions listed in **Table 4-27**. Potential cumulative effects were evaluated by comparing the effects of the alternatives with those of the actions identified in **Table 4-27**. The analyses do not specifically address each action listed unless the impacts of the alternative under evaluation, combined with those of a specifically identified action could result in a cumulative effect.

**Table 4-27** summarizes cumulative effects on the geographic scope by identifying the past, present, and reasonably foreseeable future projects. Resources listed in the table (**Table 4-28**) are only the resources that would be expected to potentially have effects in relation to cumulative effects. Resources discussed in Chapter 4, but not listed in the cumulative effects table includes Geology and Seismicity, Air Quality, Mineral Resources, and Agriculture.

**Table 4-27. Past, Present, and Reasonably Foreseeable Future Projects.**

<b>Project Name</b>	<b>Location</b>	<b>Lead Agency</b>	<b>Summary</b>
Bay-Delta Water Quality Control Plan Update	Sacramento-San Joaquin Delta	State Water Resources Control Board (SWRCB)	SWRCB is updating the plan to modify water quality objectives for the Lower San Joaquin, Stanislaus, Tuolumne, and Merced Rivers, evaluate and potentially amend existing water quality objectives that protect beneficial reuses and the program of implementation to achieve those objectives, require changes to water rights and other measures to implement changes from the first two phases, and evaluate and potentially establish water quality criteria and flow objectives that protect beneficial reuses on tributaries to the Sacramento River.
Cache Slough Area Restoration	Cache Slough	California Department of Water Resources (CDWR)	Evaluation of restoring areas within the Cache Slough Complex as part of the CDWR and California Department of Fish and Wildlife (CDFW) Fish Restoration Program. The 53,000-acre Cache Slough Complex is located in the northwest corner of the Delta at the downstream end of the Yolo Bypass.
CALFED Bay-Delta Program (CALFED) Levee Stability Program	Sacramento-San Joaquin Delta	USACE	Management of levees to protect agricultural and other resources. Implementation is ongoing.
CALFED Levee System Integrity Program	Sacramento-San Joaquin Delta	CDWR, CDFW, and USACE	Provides for long-term protection of natural resources through maintenance and improvement of the Delta levee system. Goals are to protect life, infrastructure, and properties, and to reduce the risk to land use and associated economic activities, water supply, infrastructure, and ecosystem from catastrophic breaching of Delta levees. Implementation is ongoing.
Calhoun Cut/Lindsey Slough Tidal Habitat Restoration	Cache Slough (Delta)	CDFW	Excavation and placement of fill over 927 acres at the historic Lindsey Slough in the Calhoun Cut Ecological Reserve to reestablish tidal connection to the historic marsh and channel system and enhance existing marsh habitat and associated vernal pools and grassland. Completed in November 2014.

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

<b>Project Name</b>	<b>Location</b>	<b>Lead Agency</b>	<b>Summary</b>
California EcoRestore	Sacramento-San Joaquin Delta	California National Resources Agency (CNRA)	Initiative to help coordinate and advance at least 30,000 acres of critical habitat restoration in the Sacramento-San Joaquin Delta. Includes implementation of existing mandates for habitat restoration. Planned to occur through 2020.
California Water Action Plan	State-wide	CDWR	Presents the status and trends of California's water-dependent natural resources; water supplies; and agricultural, urban, and environmental water demands for a range of plausible future scenarios. Evaluates different combinations of regional and statewide resource management strategies to reduce water demand, increase water supply, reduce flood risk, improve water quality, and enhance environmental and resource stewardship. Existing plan was initiated in January 2014; plans are revised every 5 years.
California Water Fix	Sacramento / San Joaquin River Basins	CDWR, BOR, CNRA	Project diverts Sacramento River water at Cortland and Clarksburg into twin tunnels that discharge at Clinton Court Bay 40 miles south. Goal is to make more reliable water deliveries to the State Water Project and the Central Valley Project and better meet the environmental flow requirements in the lower San Joaquin Delta. Project EIS has been released for public review in 2017. Expect implementation to begin in 2025 and 10 years to construct.
Chippis Island Tidal Marsh Restoration	Suisun Marsh	Fishery Foundation of California	Returning 750 acres of island to tidal marsh habitat that can be used by estuarine fish for spawning and rearing.
Cullinan Ranch Restoration Project	Solano County	Ducks Unlimited and U.S. Fish and Wildlife Service (USFWS)	Restoration of diked baylands to tidal marsh. Would serve as a beneficial reuse placement site for millions of cubic yards of dredged material. Construction ongoing since 2011.
Decker Island Tidal Habitat Restoration	East Decker Island	CDWR	Acquisition and restoration of approximately 140 acres of tidal wetlands on Decker Island. Includes breaching the island's perimeter levee to restore tidal hydrology to the site. Construction anticipated for completion in 2020.

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

<b>Project Name</b>	<b>Location</b>	<b>Lead Agency</b>	<b>Summary</b>
Delta Islands and Levees Feasibility Study	Sacramento-San Joaquin Delta	USACE	Restoration of approximately 89.5 acres of lost or degraded tidal marsh habitat in the west/central Delta. Involves transporting and placing dredged material (from annual dredging of the Stockton Deep Water Ship Channel [DWSC] and previously stockpiled dredged material from existing dredged material placement sites) into open water. Draft Feasibility Study and EIS released in April 2014.
Delta Long Term Management Strategy	Sacramento-San Joaquin Delta	USACE	Interagency program focused on the development of a comprehensive, long-term management plan for dredged material management in the Delta to maximize beneficial reuse of dredged sediment and streamline permitting.
Delta Wetlands Projects	Sacramento-San Joaquin Delta	Semitropic Water Storage District	Transformation of two low-lying islands to reservoirs to store 215,000 acre-feet of water, and two other islands into 9,000 acres of protected wetlands and wildlife habitat. Reservoir islands will store available water in winter months for beneficial reuse during summer months. Final EIR released in 2011.
Dutch Slough Tidal Marsh Restoration	West Delta	CDWR	Seasonal wetland and tidal marsh restoration of 1,166 acres in the western Delta. Final EIR was released in September 2014.
Franks Tract Project	Sacramento-San Joaquin Delta	CDFW and BOR	Evaluation of installing operable gates to reduce seawater intrusion and positively influence movement of fish species to areas that provide favorable habitat conditions in the Delta. Gates would be operated seasonally and during certain hours of the day, depending on fisheries and tidal conditions. Currently on hold.
Hamilton/Bel Marin Keys Wetlands Restoration - Phase III	Marin County	State Coastal Conservancy and USACE	Placement of dredged material to raise elevations, develop wetlands, and to construct additional levees to protect neighboring communities. Implementation of tidal connectivity via levee breaching. Wetlands restoration has already occurred at the Hamilton Airfield.
Hill Slough Tidal Habitat Restoration	Suisun Marsh	CDFW and private partners	Restoration of tidal marsh and enhancement of upland managed wildlife habitat over 1,750 acres. Design consists of breaching levees, lowering levee segments, and other improvements. Road improvements and

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

Project Name	Location	Lead Agency	Summary
			interior site work will begin in 2018, with all inwater construction work taking place in 2019.
In-Delta Storage Project	Sacramento-San Joaquin Delta	CDWR and BOR	Would provide capacity to store approximately 217,000 acre-feet of water in the south Delta for water supply, water quality, and ecosystem benefits. Project includes two storage islands and two habitat islands. Design is similar to the Delta Wetlands proposal from a decade prior, but would also include new embankment design, consolidated inlet and outlet structures, new project operations, and revised Habitat Management Plans. Suspended since July 2006 due to funding issues.
Liberty Island Conservation Bank	Liberty Island	Wildlands, Inc.	Restoration of 186 acres to mitigate permitted impacts to tidal fisheries habitat throughout the Delta, with a permanent conservation easement and a non-wasting long-term endowment to manage the property in perpetuity. Bank is currently active.
Long Term Water Transfers	State-wide, San Luis and Sacramento-San Joaquin Delta	Mendota Water Authority and BOR	Would facilitate transfer of up to 600,000 acre-feet of water per year from willing sellers north of the Delta to buyers south of the Delta or in the Bay Area over a 10-year period. Transfer methods could include groundwater substitution, reservoir release, cropland idling, crop shifting, and conservation. Final EIS/EIR released in March 2015.
Los Vaqueros Reservoir Expansion Project	Los Vaqueros Reservoir	Contra Costa Water District and BOR	Increased the storage capacity of Los Vaqueros Reservoir and diverted additional water from the Delta intake near Rock Slough for additional storage volume. Originally constructed in 1998 and expanded in 2012 to 160,000 AF. CCWD and BOR currently in process of planned expansion to 275,000 AF (2017 Supplemental EIS, BOR).
Lower San Joaquin Feasibility Study	Sacramento-San Joaquin Delta	USACE	Evaluation of whether there is a Federal interest in providing flood risk management and ecosystem restoration improvements along the Lower San Joaquin River.
Lower Yolo Restoration Project	Cache Slough	Westlands Water District	Restoration of approximately 1,670 acres on a site that has historically been used for pasture/cattle grazing. Currently on hold pending ownership issues; expected completion by the end of 2017.

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

<b>Project Name</b>	<b>Location</b>	<b>Lead Agency</b>	<b>Summary</b>
Meins Landing Tidal Habitat Restoration	Suisun Marsh	CDWR	Restoration of 666 acres of seasonally managed (non-tidal) marsh in Suisun Marsh, Solano County, to provide a diversity of habitats. Identified as part of the Delta Ecosystem Enhancement Program.
Navigation Improvement from Avon to Stockton	Avon to Stockton – Stockton Deep Water Ship Channel	Port of Stockton	The Port of Stockton may propose to deepen the Stockton Deep Water Ship Channel from Avon to the Port of Stockton in the reasonably foreseeable future. The Port would have to address alternatives and their environmental effects through a separate NEPA and CEQA analysis and obtain approvals and permits from the appropriate resource agencies. The project would be responsible for avoidance, minimization, and mitigation requirements determined to be necessary based on the outcome of the NEPA/CEQA analysis completed for the project. At this time, the project is undefined as to the proposal for navigational depth improvements, as well as timing of proposal.
North Bay Aqueduct Alternative Intake	Sacramento River	CDWR	Construction and operation of an alternate intake that will draw water from the Sacramento River and connect it to the existing North Bay Aqueduct system to provide reliable delivery of water to the Solano County Water Agency and the Napa County Flood Control and Water Conservation District. Would operate in conjunction with the existing North Bay Aqueduct intake at Barker Slough. Final EIR anticipated for release in summer 2016.
Ongoing Maintenance Dredging of Port of Stockton Docks	Stockton	Port of Stockton	Annual maintenance dredging is conducted at the Port of Stockton’s 19 docks. Authorized depths are -35 feet MLLW at 17 docks and -40 feet MLLW at Docks 12 and 13 to accommodate a sediment trap. Dredged material is typically placed at upland placement sites on Roberts and Rough and Ready islands.
Ongoing Operations and Maintenance Dredging of Federal Navigation Channels	Stockton, Sacramento, and John F. Baldwin DWSCs	USACE	Annual maintenance dredging is conducted throughout the Stockton, Sacramento, and John F. Baldwin DWSCs to maintain existing depths, which range from -30 to -35 feet MLLW. Depending on the channel, dredged material is either placed in-bay, at the San Francisco Deep Ocean

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

Project Name	Location	Lead Agency	Summary
			Disposal Site, at separately permitted beneficial reuse sites, or at upland placement sites.
Prospect Island Tidal Habitat Restoration	Cache Slough	CDWR	Restoration of 1,316 acres to freshwater tidal wetland and open water (subtidal) habitats to benefit native fish and improve aquatic ecosystem functions. Includes interior grading, vegetation management, possible clean fill import for subsidence reversal, possible weir installation, and breaching of exterior levees. Draft EIR was released in August 2016.
Recovery Plan for the Sacramento-San Joaquin Delta Native Fishes	Sacramento-San Joaquin Delta	USFWS	Addressing recovery needs for several fish species in the Delta. Recovery actions involve increasing freshwater flows; reducing entrainment losses to water diversions; reducing the effects of dredging, contaminants, and harvesting; developing additional shallow-water habitat, riparian vegetation zones, and tidal marsh; reducing effects of toxic substances from urban non-point sources; reducing the effects of introduced species; and conducting research and monitoring. Released in 1996.
Rush Ranch Tidal Habitat Restoration	Suisun Marsh	Solano Land Trust	Restoration, management, and monitoring of wetlands and other shoreline habitat, including the mouth of Spring Branch Creek. Installation and management of public trails over a 2,070-acre area. Initial Study/Mitigated Negative Declaration was released in 2015.
Sacramento River DWSC Deepening	Sacramento River	USACE and Port of Sacramento	Evaluation of deepening and widening the Sacramento River DWSC to improve transportation efficiencies. Draft EIS/EIR released in 2011. Currently on hold.
San Joaquin River Restoration Program: Salmon Conservation and Research Facility	San Joaquin River	CDFW	Program involves construction and operation of the salmon conservation and research facility, reintroducing and managing Chinook salmon in the restoration area, conducting fisheries research and monitoring in the restoration area, and managing and supporting recreation within the restoration area. Draft Environmental Assessment released in January 2016.

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

<b>Project Name</b>	<b>Location</b>	<b>Lead Agency</b>	<b>Summary</b>
San Joaquin River Restoration Program	San Joaquin River	San Joaquin River Restoration Program	Comprehensive long-term effort to restore flows to the San Joaquin River from Friant Dam to the confluence of Merced River and restore a self-sustaining Chinook salmon fishery in the river while reducing or avoiding adverse water supply impacts. First water releases from Friant Dam began in 2009. Restoration flows began in 2014.
Suisun Marsh Habitat Management, Preservation, and Restoration Plan	Suisun Marsh	CDFW, USFWS, BOR, and Suisun Marsh Charter Group	Completed in 2014, plan balances goals of Bay-Delta Program, Suisun Marsh Preservation Agreement, and Federal and state endangered species programs within the Suisun Marsh. Would provide for simultaneous protection and enhancement of: (1) existing wildlife values in managed wetlands; (2) endangered species; (3) tidal marshes and other ecosystems; and (4) water quality (including maintenance and improvement of levees). Implementation occurring over 30 years.
Tule Red Restoration	Suisun Marsh	Westervelt Ecological Services, Inc.	Will restore over 400 acres of tidal wetlands in the Suisun Marsh. Construction was completed in the fall of 2018.
Upgrade of Facilities to Restore Delta Smelt and Other Native Aquatic Species	Rio Vista	USFWS, BOR, CDWR, and CDFW	Development of a permanent fish restoration facility in Rio Vista as part of the 2009 Interim Federal Action Plan for the Delta and upgrades to the existing facility to serve as an interim restoration propagation facility until the Rio Vista facility is operational.
Upper San Joaquin River Basin Storage Investigation	San Joaquin River	BOR	Investigation considered alternatives for storage of water from the upper San Joaquin River watershed. Goals are improving water supply reliability and operational flexibility in the Central Valley, San Joaquin Valley, and other regions of California, and enhancing water temperature and flow conditions in the San Joaquin River. Draft EIS released in August 2014.

**Table 4-28. Cumulative Effects.**

Resource	Past and Present (Existing Condition)	Proposed Action (Recommended Plan)	Cumulative Effects (with consideration of future projects)
Sediment and Sedimentation	Continued dredge maintenance and use of the navigation channels will continue but would not incrementally contribute to any cumulative effects on sediment quality within the study area.	Sediment testing has shown low levels of contamination and was determined suitable for in-bay, wetland, or upland beneficial reuse. All required testing and coordination will be completed prior to construction of the project.	Projects in <b>Table 4-27</b> may affect sediment quality within the study area. Any such projects would be required to undergo separate environmental review and to implement avoidance and minimization measures as needed to address such impacts. Therefore, it is therefore anticipated that any present or foreseeable projects would result in less than significant impacts to these water quality parameters.
Water quality and Hydrology	Present conditions would not degrade water quality through alteration of temperature, salinity, pH, and dissolved oxygen/ increased turbidity, or nutrient loading; continued maintenance and use of the navigation channels would not incrementally contribute to any cumulative adverse effects.	The Recommended Plan-related shift of X2 of between 0.17 and 0.27 km would not be individually significant and should not contribute to cumulatively significant impacts when considered in combination with other known past, present, or future activities within the study area. This small change in X2 position is likely to intermittently result in relatively small reductions in Delta Export pumping when other export constraints are not controlling. However, these reductions are expected to not be significant and may be partially or wholly mitigated by small increases in export pumping during periods when X2 and other constraints are not limiting.	The less than significant change in X2 position from the Recommended Plan is likely to be relatively unaffected in the future due SWP/CVP responses to climate change. The Year 50 analysis shows that due primarily to projected sea level rise, the X2 isohaline will move upstream by a distance of 4 km unless significant changes are made to water management operations. However, despite this large change in X2 due to sea level rise under future baseline conditions the predicted effect of the Recommended Plan under these conditions was predicted to be similar to the effect under existing conditions. This suggests that the Recommended Plan effects are likely to be relatively unaffected by cumulative changes resulting from other projects in the Delta. The change in X2 is more

			<p>than 10 times greater than the predicted change in X2 associated with implementation of this project. This is an indication that the current water management operations and facilities will have to undergo significant change under any scenario if environmental and water quality/supply targets are to be met in the future. The California Water Fix project currently planned for implementation by 2035, is an example of the kind of large-scale infrastructure project needed to ensure delivery of SWP/CVP water and protect the Delta ecosystem. If the Waterfix project or a similar project is implemented, a large fraction of SWP/CVP water will be diverted from Sacramento River water will bypass the Delta. In this case, the less than significant impact of this project on water supply operations could be diminished since Delta export pumping will be less influenced by the X2 position criteria.</p> <p>The depth, timing, and complete project description associated with a navigational deepening project from Avon to the Port of Stockton is currently unknown. In 2016, prior to the reduction in scope for the current Recommended Plan, a salinity analysis considering depths ranging from -37 feet to -38 feet was developed. The modeling scenarios to deepen the channel to -37 and -38 feet showed slightly greater impacts than</p>
--	--	--	---

			<p>the recommended plan. Additional modeling would need to be completed by the project to assess and understand the Avon to Port of Stockton deepening project's impacts and how those impacts would contribute to cumulative effects on water quality and salinity intrusion in conjunction with projects throughout the area. Depending on the proposed project depth (and other project description variables), the potential Avon to Port of Stockton deepening project may result in significant cumulative effects to water quality. Further study is needed. The project would be responsible for environmental documentation and, if necessary, implementing avoidance, minimization, and/or mitigation measures to offset or reduce environmental impacts that would result from channel deepening.</p>
Climate change	<p>Because the existing conditions does not include construction and does not increase ship calls as compared to the NEPA baseline, it would not result in additional GHG emissions. Therefore, the No Action Alternative would not conflict with any applicable plans, policies, or regulations adopted to reduce GHG emissions and there would be no impact as compared to the NEPA baseline.</p>	<p>GHG emissions are inherently cumulative and any incremental amount of emissions contributes to global warming. No specific cumulative quantitative level of GHG emissions from related projects in the region or state-wide has been identified which no impacts would occur. Therefore, it is conservatively assumed that any additional emissions related to the proposed project would represent a short term cumulative impact.</p>	<p>Current and future projects would incorporate a variety of GHG reduction measures in response to a variety of rules and measures. However, because GHG emissions are inherently cumulative and any incremental amount of emissions contributes to global warming, no specific cumulative quantitative level of GHG emissions from related projects in the region or statewide has been identified to which no impacts would occur. Therefore, it is conservatively assumed that the any</p>

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

			additional emissions represent a significant cumulative impact.
Biological Resources	Current maintenance dredging would continue to alter the bottom habitat without the proposed project. The maintenance dredging of the current navigation channel for Pinole Shoal is a two year cycle and for Bulls Head Reach a one year cycle.	The proposed project would deepen the existing channel by 3 feet, with maintenance dredging every 2 years. Effects would be similar to the current maintenance dredging operations. The additional 3 feet in Pinole Shoal and 4-5 feet of dredging in Bulls Head Reach would affect delta and longfin smelt habitat (see BA in the Environmental Appendix) by removing some existing habitat along the bottom of Suisan Bay and the side slopes in Pinole Shoal. These impacts are expected to be offset by the use of dredged material at Cullinan Ranch and Montezuma Wetlands, which have both been shown to benefit smelt and other listed species.	The proposed project may result in a cumulative effect in concert with reasonably foreseeable future projects, specifically channel deepening from Avon to the Port of Stockton. Based on the existing 2019 salinity modeling for the Recommended Plan and modeling conducted in 2016, effects of deepening from Avon to the Port of Stockton would be greater than the current Recommended Plan, depending on the channel depth proposed. Depending on the effect of the deepening the channel to the Port of Stockton on the change in X2, the EIS/EIR for the Avon to the Port of Stockton project would be responsible for addressing any environmental or biological effects. If the Port of Stockton pursues a deepening from Avon, additional analysis on the X2 position would likely be performed. The Port of Stockton would address any environmental impacts related to their proposed alternatives under a separate NEPA and CEQA analysis and consultation with the appropriate resource agencies.
Land Use and Planning	The No Action would be unchanged from present conditions and does not introduce land uses or activities that are incompatible with existing land uses within the study area,	Dredging to 38 feet and subsequent maintenance and use of the deepened channel would be very similar to the No Action Alternative. The potential for incompatible land use conflicts to occur	No significant cumulative effects are expected to land use due to implementation of the proposed action or future actions within the existing navigation channel.

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

	continued maintenance of the navigation channels would not add incremental impacts to any cumulative land use conflicts that may occur when considered in combination with other actions within the study area.	would be less than significant. As a result, this alternative is not expected to contribute incrementally to land use conflicts that may occur within the study area when considered in combination with other unrelated activities.	
Aesthetics	The No Action Alternative would be unchanged from present conditions and does not impact existing scenic vistas, continued maintenance of the navigation channels would not add any incremental aesthetic issues.	The views of construction equipment would be from a distance, depending on the location of the viewing point, and these views would be temporary. Views of various maritime activities are typical along the route. The proposed project would not result in individual or cumulative impacts to existing scenic vistas and/or visual character when considered in combination with other unrelated activities within the study area.	The proposed project would not result in individual or cumulative impacts to existing scenic vistas and/or visual character when considered in combination with other activities within the study area.
Cultural Resources	Existing conditions would not change due to the maintenance dredging of the existing navigation channels.	The proposed project is not expected to result in significant cumulative impacts to cultural resources.	The proposed project is not expected to result in significant cumulative impacts to cultural resources when considered in combination of other past, present, and reasonably foreseeable impacts in the future.
Environmental Justice	The No Action Alternative would not disproportionately affect communities within the APE, continued maintenance and shipping use of the navigation channel would remain the same.	The proposed project would not disproportionately affect communities within the APE. The proposed project is within a current Federal navigation channel that is routinely dredged on a yearly basis.	The proposed project would not result in cumulatively considerable impacts when considered in combination with other past, present, and reasonably foreseeable future activities within the APE, the study area as a whole, and the surrounding 7-county region.

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

<p>Navigation, Transportation, and Circulation</p>	<p>The No Action Alternative would be unchanged from present and anticipated future conditions, it would not contribute to any cumulative effects related to changes in vessel traffic patterns, unplanned or regularly occurring delays, freedom of movement, increased safety risks, or safety hazards.</p>	<p>Vessel traffic would not increase under the proposed project and traffic would continue to be controlled by Vessel Traffic Services implementing Federal and state rules of navigation.</p>	<p>Numerous types of vessel use occur in the Bay, and increases in these uses over time are expected. Construction or operation of other projects described in Table 4-27 could contribute to a short- or long-term increase in vessel traffic in the Bay.</p> <p>The Recommended Plan could contribute to changes in vessel traffic patterns if the SDWSC were deepened by others subsequent to construction. However, unplanned or regularly occurring delays or freedom of movement should not be affected. In addition, the Recommended Plan should decrease navigational safety risks/hazards when considered in combination with other past, present, and reasonably foreseeable future activities within the study area.</p>
<p>Noise</p>	<p>Continued maintenance dredging would continue to occur within the navigation channel.</p>	<p>Noise generated by construction activities would have a slightly longer duration in any given area along the path of the navigation channels compared to routine existing maintenance dredging operations. The rocky obstruction would be removed using a jackhammer, producing underwater noise that is discussed in the Biological Resources section and the Biological Assessment.</p>	<p>The proposed project would not result in significant individual or cumulative noise impacts within the study area when considered in combination with other noise generating activities.</p>
<p>Public Health and Environment</p>	<p>Continued maintenance and use of the navigation channels would not affect public health.</p>	<p>The proposed project is not expected to affect any hazardous material sites.</p>	<p>It is unlikely that the present or foreseeable future projects listed in <b>Table 4-27</b> would be located on hazardous material sites, or would</p>

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

<p>ntal Hazards</p>			<p>affect management of any such sites. The proposed project should not incrementally contribute to any significant cumulative hazards to the public or the environment when considered in combination with other past, present, and/or reasonably foreseeable actions within the study area.</p>
<p>Recreation</p>	<p>Continued maintenance of the navigation channels would not contribute incrementally to any cumulative adverse effects on recreation when considered in combination with other activities within the study area.</p>	<p>The proposed project would comply with current Federal, state, and local agency regulations and policies regarding recreation and would not contribute incrementally to any cumulative adverse effects on recreation when considered in combination with other activities within the study area.</p>	<p>Activities associated with implementation of this alternative would comply with current Federal, state, and local agency regulations and policies regarding recreation and would not contribute incrementally to any cumulative adverse effects on recreation when considered in combination with other activities within the study area.</p>
<p>Socioeconomics</p>	<p>Continued maintenance of the navigation channels would have no influence on population trends, regional employment, spending patterns, or community resource needs.</p>	<p>The proposed project would not affect regional employment, spending and earning patterns, or community resources. Other projects in the area would have a greater cumulative influence on these socioeconomic variables.</p>	<p>Due to the size and stability of the regional economy, the cumulative effects of this alternative in combination with all other reasonably foreseeable activities would remain less than significant.</p>
<p>Utilities and Public Service</p>	<p>The existing conditions would not affect buried underwater cables and pipelines or overhead transmission lines Continued maintenance and use of the navigation channels would not incrementally contribute to any cumulative effects that other unrelated actions within the study</p>	<p>The proposed project is not expected to adversely affect the utilities that cross the navigation channels.</p>	<p>The channel deepening activities would not add to any cumulative impacts on utilities within the study area when considered in combination with the effects of other past, existing, and/or future projects and activities in the area regardless of their origin.</p>

CHAPTER 4.0 COMPARISON OF ENVIRONMENTAL EFFECTS OF ALTERNATIVE PLANS

	area may have on these utility resources.

## 4.8 RECOMMENDED PLAN

Under the definition of the National Economic Development (NED), the -38 foot deepening alternative with the sediment trap and removal of the Pinole Shoal channel rocky obstruction reasonably maximizes net benefits, and is therefore identified to be the NED plan. Since there is not a locally preferred plan, this is also the Recommended Plan.

The environmental evaluation shows minimal changes between the -37 foot, -38 foot, and -38 foot with sediment trap and removal of rocky obstruction alternatives, with the exception of the shift in X2. The sediment trap produces a slightly greater shift in the X2 from the -38 foot alternative, however, the addition of the sediment trap removes the need for interim emergency dredging operations in the Bulls Head Reach area. The beneficial reuse of material in each alternative is the least cost placement alternative. Additionally beneficial reuse contributes to habitat needed for several species throughout the Delta, including the endangered delta smelt. Because effects from the Recommended Plan were found to be less than significant, mitigation is not expected to be required.

5

The Recommended Plan

## 5 THE RECOMMENDED PLAN

This chapter discusses the details of The Recommended Plan discussed in this chapter include material quantities and classifications, operations and maintenance, dredged material placement, cost, risk and uncertainty.

### 5.1 OVERVIEW OF THE RECOMMENDED PLAN

Refer to the Executive Summary foldout as a reference map and consolidated graphic.

No locally preferred plan (LPP) has been identified. Therefore, the Recommended Plan is the -rocky obstruction. The Recommended Plan proposes to deepen the existing maintained channel depth of the Pinole Shoal Channel and the Bulls Head Reach portion of the Suisun Bay Channel from -35 feet MLLW to -38 feet MLLW, with approximately 13.2 miles of new regulatory depths. Approximately 10.3 miles of the Pinole Shoal Channel (stations 0+00 to 548+00) and all 2.9 miles of the Bulls Head Reach to Avon (stations 0+00 62+00 and 88+00 to 160+00) would be dredged. A 2,600 foot-long sediment trap (width = 300 feet) would be constructed at Bulls Head Reach (located between stations 62+00 and 88+00 of the Bulls Head Reach in the area currently subject to annual advance maintenance dredging to a depth of -38 feet), with a depth of -42 feet MLLW, plus 2 feet of overdepth. The sediment trap would be maintained at -42 feet MLLW during future maintenance dredging to reduce rapid shoaling in the channel and emergency maintenance.

The Recommended Plan proposes the following:

- Deepen the existing maintained channel depth of the Pinole Shoal Channel and Bulls Head Reach (Suisun Bay) from -35 feet to -38 feet MLLW, with approximately 13.2 miles of new regulatory depths
- Dredge a 2,600 foot sediment trap at Bulls Head Reach with a depth of -42 feet MLLW, plus 2 feet of overdepth.
- Level the rocky obstruction located to the west of Pinole Shoal from -39.7 ft. MLLW to -43 feet MLLW
- Beneficially reuse the dredged material

If the entire overdepth prism were dredged, the Recommended Plan would result in approximately 1.6 million cubic yards of dredged material from an approximate 318-acre footprint. The breakout of volumes for each feature is shown as follows:

- Pinole Shoal Channel deepening = 1,443,900 cy
- Bulls Head Reach deepening = 38,700 cy
- Bulls Sediment Trap & Overdepth 2 feet = 120,600 cy
- Rocky obstruction (Pinole Shoal Channel) = 40 cy of rock (950 sq. ft.).

All construction is expected to occur during the existing environmental work windows developed by the San Francisco Bay Long Term Management Strategy for the Placement of Dredged Material unless other work windows are developed during consultation with the resource agencies. The environmental work window for the Pinole Shoal Channel is from June 1 through November 30 and the work window for the

Bulls Head Reach portion of the Suisun Bay Channel is from August 1 through November 30. All dredging for this channel deepening project will be conducted using a clamshell dredge including at Pinole Shoal, which typically is maintained using a hopper dredge.

It is assumed that the timing of the channel deepening will occur immediately after completion or concurrent with the O&M dredge cycle within each reach. Although feasible, dredging contract acquisition approach and timing is tight for accomplishment of both O&M dredging and channel deepening in one environmental work window therefore, this avoidance measure does carry some risk. Should dredging extend past the environmental work window, additional coordination would immediately be initiated with the appropriate agencies.

The environmental work window for O&M dredging is the same as the work window for the deepening project, which begins 1 June. O&M dredging in Pinole Shoal Channel can be completed within approximately 10 to 20 days with a hopper dredge, depending on the volume of material to be dredged. O&M material would be placed at in-bay sites SF-10 and SF-16, according to the Federal standard.

New construction dredging for the Recommended Plan could begin as early as the beginning of June, with an estimated construction duration of 3.5 months. New construction material from Pinole Shoal channel would be placed at Cullinan Ranch; new construction material from deepening Bulls Head Reach would be beneficially used at a suitable and permitted site, currently assumed to be Montezuma Wetlands. The beneficial reuse placement at Cullinan Ranch and Montezuma Wetlands is currently assumed to minimize effects to special status species and essential fish habitat, offsetting the minimal effects of the change in salinity. The Recommended Plan has estimated average annual net benefits of \$10.5 Million (fiscal year 2020 price levels, 2.75% discount rate).

The only utility within the vicinity of the project footprint is the Trans Bay Cable. As-built drawings indicate that the trans-bay cable crosses the Pinole Shoal in two locations; however, in both locations, the As-Built drawings indicate the trans-bay cable is buried to a depth that is approximately -48 to 49 feet MLLW for both crossing locations. The cable utility does not intersect the other Federal channels in the remainder of the project footprint. Therefore, it has been determined that the trans-bay cable utility will not be impacted by the Recommended Plan and no relocations would be needed.

## 5.2 MATERIAL QUANTITIES AND CLASSIFICATIONS

The Recommended Plan proposes dredging and placement of a total of approximately 1.6million cubic yards (cy) of material. Of that total amount, approximately 1,443,900 cy material would be placed in the Cullinan Ranch Site and roughly 159,300 cy of material would be used in Montezuma Wetlands Restoration Site, as shown in **Table 5-1**.

**Table 5-1. Project Features and Associated Dredging Volumes.**

<b>CHANNEL</b>	<b>QUANTITY (CY)</b>	<b>PROPOSED PLACEMENT</b>	<b>CLASSIFICATION</b>
Pinole Shoal Channel (STA 0+00 to STA 547+00)	1,443,900	Cullinan Ranch	Silty Sand/Clayey Sand
Suisun Bay Channel (STA 0+00 to STA 62+00 and STA 88+00 to 160+00)	38,700	Montezuma Wetland	Silty Sand/Clayey Sand
Bulls Head Reach Sediment Trap (STA 62+00 to 88+00)	120,600	Montezuma Wetland	Silty Sand/Clayey Sand
Rocky Obstruction Leveling	40 cy	Sidecast	Rock
<b>TOTAL ESTIMATED DREDGING QUANTITIES</b>	<b>1,603,200</b>		

## 5.3 MITIGATION

The Recommended Plan was determined to have less than significant effects on all resources, as described further in Chapter 4 of this integrated document. As such, mitigation is not expected to be required.

## 5.4 CONSTRUCTION ASSUMPTIONS

### INITIAL DEEPENING WORK/DREDGING

It is assumed that the timing of the channel deepening will occur immediately after completion or concurrent with the O&M dredge cycle within each reach. Although feasible, dredging contract acquisition approach and timing is tight for accomplishment of both O&M dredging and channel deepening in one environmental work window therefore, this avoidance measure does carry some risk. Should dredging extend past the environmental work window, additional coordination would immediately be initiated with the appropriate agencies.

The O&M dredging event in Pinole Shoal Channel will remove the material above -35-ft MLLW plus up to 2-ft overdepth, to be disposed at the “Federal standard” placement site in San Pablo Bay, SF-10. The environmental work window for O&M dredging is the same as the work window for the deepening project, which begins 1 June. O&M dredging in Pinole Shoal Channel can be completed within approximately 10 to 20 days with a hopper dredge, depending on the volume of material to be dredged. O&M material would be placed at in-bay sites SF-10 and SF-16, according to the Federal standard.

The following construction assumptions were used for cost estimating purposes for the channel deepening elements of the Recommended Plan:

- Two dredge plants will be used with 21-CY clamshell buckets in the Pinole Shoal Channel
- Four 2,000 CY scows and two 1,800 HP tug boats will be used for dredged material placement at Cullinan Ranch from Pinole Shoal Channel
- One 21-CY clamshell dredge plant will be used in the Bulls Head Reach Channel

- Two 4,000 CY scows and one 1,800 HP tug boat for placement at Montezuma Wetlands Restoration Project From the Bulls Head Reach Channel

The dredged material will be hauled by scow from the Pinole Shoal channel to the Cullinan Ranch beneficial reuse placement site, and dredged material from the Bulls Head Reach channel will be hauled to the Montezuma Wetlands Restoration Project site where off-loaders will be stationed to unload scows and pump the dredged material into both sites. The Napa River that leads to the Cullinan Ranch site is too shallow for fully loaded 4,000 CY scows, so it is assumed that the scows will be loaded to only 65 percent of their capacity, or less, in order to transit to the off-loader location. It is also possible that the contractor may use 2,000 CY scows that can be fully loaded.

Utilizing two dredge plants for dredging in Pinole Shoal Channel and placement of dredged material at the Cullinan Ranch site, and one dredge plant in Bulls Head Reach channel with dredged material placement at the Montezuma wetlands site, the total construction duration for the dredging component of the Recommended Plan is estimated at 4.6 months.

Although the method described above is assumed for cost estimating purposes, other methods could be used during construction and are described in the **Appendix A, Civil Site**.

All dredging is assumed to begin at the western end of the Pinole Shoal Channel, where the previously discussed rock formation is located, and progress easterly to the end of the project boundary at the Avon terminal in the Bulls Head Reach channel.

A brief bulking analysis has been conducted for initial placement of material in **Appendix A, Civil Site** and concludes that the effect of bulking of the material from this project is significantly low. A more detailed analysis will be performed during the pre-construction and engineering design (PED) phase to reevaluate the dredge material quantity from the new work and other factors that may impact project cost including bulking.

### ROCKY OBSTRUCTION

A buried rock formation posing a potential navigation hazard per San Francisco Bay Bar Pilots just outside of the Recommended Plan footprint but within the Federal Channel was recently surveyed and was found to be at approximately -39.7-ft MLLW. The rock formation will be lowered so that there is a minimum of 3-ft of additional clearance below the 2-ft of overdepth tolerance, to approximately -43-ft MLLW for the -38-ft depth. Although the rock formation has not been specifically sampled, it is assumed that because of its predicted hardness, the removal will likely require using a pneumatic jack-hammer attachment that would be mounted to an excavator mounted on a work barge. The jack-hammer would chisel the rock down to the desired elevation and the material would likely fall to the bay floor where it is naturally deep. The estimated quantity of rock to be removed is approximately 40 cubic yards (CY) to achieve a safe navigation depth of -43-ft MLLW for the -38-ft Recommended Plan depth, within an area of approximately 950 square feet.

### AIDS TO NAVIGATION

In addition to the utilities discussed above, eight of the existing navigation aids along the Pinole Shoal Channel and Bulls Head Reach were found to be within the channel slope. The aids can be moved out of

the way temporarily until the dredging of the proposed project side slopes is completed and repositioned to the appropriate location. The cost associated with the temporary removal and reinstallation for these navigation aids has been included in the project first cost estimate; however, Relocation, establishment, and disestablishment of aids to navigation are to be funded by the United States Coast Guard (USCG). Coordination between USACE and the USCG will be initiated during the feasibility phase and will continue during Pre-construction, Engineering, and Design (PED) phase.

## 5.5 DREDGED MATERIAL PLACEMENT SITES

During initial construction, the Recommended Plan must use placement sites that are cost effective and can also accept the dredged material from these channels. The following sections outline where material will be placed during initial construction and assumptions to date.

For the purposes of cost estimating, it is assumed that material will be beneficially used at Montezuma Wetlands and Cullinan Ranch, which was determined to be the least cost placement option. Confirmatory sediment testing of the dredged material will take place during PED, and based upon testing results, these sites could require reevaluation at that time. Other beneficial reuse sites (i.e. Delta Islands) may be more appropriate and will be re-assessed during PED.

### 5.5.1 MONTEZUMA WETLAND RESTORATION SITE (MWRP)

Placement at Montezuma Wetlands Restoration Project (MWRP) meets one of the project objectives to beneficially use material. The approximately 1,800-acre Montezuma Wetlands Restoration Project is a privately owned and operated wetland restoration project located adjacent to Montezuma Slough in northern Honker Bay. It is located on the eastern edge of Suisun Marsh, west of Collinsville, in Solano County. In the early 1900s, the site was diked, drained, and used for agriculture. Since the site was diked, the land has subsided up to 10 feet and dredged material is being used to raise site elevations for wetland restoration. The site can take both clean cover material and material with elevated concentrations of constituents of concern, as long as this sediment is buried under 3 feet of clean cover material. Montezuma Wetlands has approximately 12 million tasks associated with removing sediment from the scows, drawing water from Montezuma Slough to slurry material in the scows, managing the sediment on-site including decanting water and water quality monitoring are separately permitted under the Montezuma Wetland water quality certification. The average haul distance from the Suisun Bay Channel area to the MWRP off-loader is 13 miles. MWRP contains its own plan in phases to achieve restoration; therefore, once the material is offloaded onto the site, MWRP is responsible for any monitoring and restoration achievements. This project is contributing to the restoration benefits by providing dredged material.

### 5.5.2 CULLINAN RANCH TIDAL RESTORATION SITE

Placement at Cullinan Ranch Wetland Tidal Restoration Site meets one of the project objectives to beneficially use material. Cullinan Ranch Wetland Restoration Site is a 1,575 acre parcel in the San Pablo Bay National Wildlife Refuge. It was originally purchased by the USFWS for the purpose of increasing habitat for salt marsh harvest mouse and California clapper rail. Located in Solano County near the city of Vallejo, the southern property boundary of the parcel is a naturally formed levee that is the base for State Highway 37. The western property boundary of the parcel comprises Dutchman Slough and South Slough, both of which flow into nearby Napa River. Cullinan Ranch is a tidal restoration project with the goal of restoring diked baylands to historic tidal marsh conditions by using dredged material to raise site elevations by approximately 6 feet. There is currently capacity for up to 2.4 million cubic yards of dredged

material. The sediment from the project will be used to raise up to 290 acres of the site to marsh plain elevation. The site has two permitted locations for an off-loader to moor, both located in Napa River, north and south of the mouth of Dutchman Slough, respectively. The average haul distance from the Pinole Shoal Channel area to the Cullinan off-loader is 10 miles. Cullinan Ranch contains its own plan in phases to achieve restoration; therefore, once the material is offloaded onto the site, Cullinan Ranch is responsible for any monitoring and restoration achievements. This project is contributing to the restoration benefits by providing dredged material. Cullinan Ranch is a tidal restoration project with the goal of restoring diked baylands to historic tidal marsh conditions.

### 5.5.3 SAN FRANCISCO DEEP OCEAN DISPOSAL SITE (SF-DODS)

It is not anticipated that this site will be used – however, should the above sites not be available at the time of construction, and should other beneficial reuse sites not be available, this site does have adequate capacity and would be used as a last option. The SF-DODS is located in the Pacific Ocean, approximately 55 nautical miles west of the Golden Gate Bridge. The site is approximately 70 nautical miles from the beginning of the Pinole Shoal Channel and approximately 88 miles from the beginning of the Suisun Bay Channel. The site was established in 1994 by the Long Term Management Strategy agencies, and is managed by the EPA Region 9.

## 5.6 OPERATION AND MAINTENANCE

Existing O&M dredging requirements would increase by the amounts as shown in **Table 5-2**. O&M material from Pinole Shoal and Suisun Bay will continue to be placed in the in-bay placement sites SF-10 and SF-16, respectively. The water quality permit issued to USACE for programmatic O&M dredging in the region shows that USACE is currently permitted to use a 3.5 MCY capacity of in-bay disposal over a 5 year period. It is estimated that Pinole Shoal Channel O&M volumes will increase from 127,500 to 175,900 cy to be dredged every other year and Bulls Head Reach O&M volumes will increase from 25,000 to 54,600 cy to be dredged annually (inclusive of the sediment trap), as shown in **Table 5-2**.

The water quality permit for the regional O&M program is currently in the process of being re-negotiated for the next 5 year period. Coordination between the study team and San Francisco Bay Regional Dredge Technical Specialist will continue to ensure the revised permit includes O&M estimates for this project. See **Appendix J, Plan for Management of Dredged Materials**, for additional detail. This information will be incorporated into the next San Francisco Bay Dredged Material Management Plan (DMMP) update.

**Table 5-2. Estimated Future O&M Volumes.**

Channel	Dredge Type	Typical O&M Dredging Frequency (years)	Median O&M Volume Dredged Annually (CY)	Estimated O&M Annual Increase (cy)	Future Estimated Annual O&M Total (cy)	Federal Placement Site
Pinole Shoal Channel (STA 0+00 to STA 547+00)	Hopper	2 <sup>15</sup>	127,500	48,400	175,900	SF-10 (San Pablo Bay)
Bulls Head Reach (STA 0+00 to STA 62+00 and STA 88+00 to 160+00)	Clamshell	1	25,000	20,700	45,700	SF-16 (Suisun Bay)
Bulls Head Reach (Advance Maintenance Area) Sediment Trap*(STA 62+00 to 88+00)	Clamshell	1	0	8,900	8,900	SF-16 (Suisun Bay)
<b>TOTAL DREDGING QUANTITIES</b>			<b>152,500</b>	<b>78,000</b>	<b>230,500</b>	
<b>*Sediment trap currently does not exist, but material is removed annually from the advance maintenance area.</b>						

**5.6.1 SEDIMENT TRAP**

The shoal rate for the Bulls Head Reach was determined independently based on the shoal analysis in **Appendix B, Water Resources**. The analysis determined that if a sediment trap was excavated to a depth 4-ft deeper than the rest of the Bulls Head Reach channel, the sediment trap would provide sufficient capacity for the annual channel shoaling that has been typically encountered. This will allow the entire Suisun Bay Channel to be maintained with dredge events only 2 out of every three years (ie: annual dredging for two years sequentially and able to forego the consecutive dredging event each third year), and without the need for interim emergency dredging.

<sup>15</sup> The Corps proposes to return to annual dredging of Pinole Shoal beginning in 2020. However, coordination with State agencies is ongoing. Therefore, this document will assume that Pinole Shoal dredging is biannual.

## 5.7 BENEFITS OF THE RECOMMENDED PLAN

### 5.7.1 ECONOMIC COSTS AND BENEFITS

**Table 5-3** below, shows the economic Recommended Plan, The economic cost shown below varies slightly from the project first cost shown earlier in Chapter 3 for a few reasons. First, the sediment trap costs as well as the sediment trap savings benefits were included in the below final analysis (and were not included in the Chapter 3 final array analysis). Second, this summary includes Interest During Construction (IDC), described in the section below, as well as OMRR&R. Finally, this table shows a refinement in project first cost, to include a risk-based contingency which is periodically updated as new information becomes available. The benefit to cost ratio is justified (over 1.0) at 4.4 to 1. More details on this analysis can be found in the **Appendix D, Economics Analysis**.

**Table 5-3. Summary of Economic Costs - Recommended Plan Net Benefits and BCR.<sup>16</sup>**

Project (Depth)	38 foot deepening
Project First Cost	\$ 57,240,000
Interest During Construction (IDC)	\$ 470,000
Total Economic Costs with IDC	\$ 57,710,000
Annualized Economic Cost & IDC	\$ 2,053,000
OMRR&R Cost	\$ 1,030,000
TOTAL ECONOMIC AVERAGE ANNUAL COST	\$ 3,083,000
Annualized Transportation Cost Savings (Benefits)	\$ 12,885,000
Annualized Sediment Trap Cost Savings (Benefits)	\$ 682,000
TOTAL AVERAGE ANNUAL BENEFITS (Deepening + Sediment Trap)	\$ 13,567,000
AA Net NED Benefits	\$ 10,484,000
BCR (x:1)	4.4

### INTEREST DURING CONSTRUCTION

Interest during construction (IDC) accounts for the opportunity cost of expended funds before the benefits of the project are available and is included among the economic costs that comprise the recommended plan project costs. The amount of the pre-base year cost equivalent adjustments depends on the interest rate; the construction schedule, which determines the point in time at which costs occur; and the magnitude of the costs to be adjusted. Pre-construction, Engineering, and Design (PED) costs are included in the IDC as well as construction costs and durations. The IDC calculation includes 6 months for construction activities.

<sup>16</sup> The summary reflects the FY2020, 2.75% discount rate, annualized over 50 years.

## 5.7.2 BENEFITS WITH REGARD TO THE FOUR P&G ACCOUNTS

As mentioned earlier in the Plan Formulation Rationale, the four accounts NED, RED, EQ and OSE are always used as criteria in formulation and selection of a plan, in addition determining the plan with the highest net benefits and a justified benefit to cost ratio. These points are listed and briefly summarized below.

### NATIONAL ECONOMIC DEVELOPMENT (NED)

This project reasonably maximizes net benefits in the amount of \$10.5 million average annual net benefits. The project allows tankers to utilize more of their existing capacity, reducing the amount of vessel transits in the future with-project compared to the future without-project scenario. By doing so, it provides transportation cost savings to the oil refineries, which is then passed on to the regional and national consumers who use the end product of the crude oil for gasoline, etc.

### ENVIRONMENTAL QUALITY (EQ)

This project reduces the amount of vessel transits in the future with-project scenario, and by reducing the number of vessels could also reduce any disruptions to the environment as vessels transit, as well as further reducing the risk of oil spills. Beneficial reuse of material would not only offset any immediate effects but would contribute to the creation of additional habitat for delta smelt.

### REGIONAL ECONOMIC DEVELOPMENT (RED)

This project would likely temporarily stimulate the regional economy during construction.

### OTHER SOCIAL EFFECTS (OSE)

Through beneficially using material to wetland sites, this project would also help provide resiliency and storm surge protection of the established infrastructure in the developed areas that surround the general bay area. One viable beneficial reuse for the dredged material from this project is as fill material to raise grades in the wetlands and tidal marsh areas adjacent to the bays in order to accelerate their development. Additionally, benefits of removing the rocky obstruction will greatly add to the navigability of the channels for harbor pilots.

## 5.7.3 INCREMENTAL ANALYSIS OF THE SEDIMENT TRAP

A shoal analysis was performed on this area of the channel in 2015, entitled Bulls Head Deposition HydroSurvey Tech Memo, April 2015. The analysis recommends continuing advance maintenance (currently at -37 feet MLLW + 2 feet of overdepth in the advance maintenance area), or construct a permanent sediment trap between STA 62+00 and STA 88+00 to a depth of -42 feet MLLW for the -38 feet MLLW Recommended Plan depth. The proposed sediment trap in Bull Head Reach channel will be excavated to a depth that will be 4ft below the selected alternative depth and will also have 2 ft of allowable overdepth, and side slopes that are cut at a 3H: 1V horizontal to vertical ratio. The location of the proposed sediment trap is based on historical hydrographic survey data from the previous 17 years. The historical survey data indicates that this area of the Bulls Head Reach channel shoals in at a much higher rate than the rest of the Suisun Bay Channel.

The sediment trap is an added benefit for channel users and is included as a feature of the alternative plans as a separable element with stand-alone benefits and savings (**Table 5-1**). It is proposed in an area that typically needs to be dredged annually, at an estimated cost of \$1 million each year (based on historical use of a clamshell dredge). The sediment trap would reduce the maintenance requirements to 2 dredging cycles every 3 years, resulting in a cost savings associated with a reduction in the frequency of maintenance dredging. This creates a net present value savings of \$18 million, with an average annual equivalent savings of \$680,000 per year over a 50 period of analysis at a FY2020 discount rate of 2.75%.

A more detailed incremental analysis of the costs and benefits associated with the proposed sediment trap are included in **Appendix D, Economic Analysis**, while additional information on the historical and annual dredging activities can be found in **Appendix A, Civil Site**.

**Figure 5-1. Sediment Trap Cost Savings Analysis.**

O&M Alternatives	Total Present Value	Average Annual O&M Cost
Maintenance Costs without Project, with existing emergency maintenance	\$26,997,170	\$1,000,000
Maintenance Costs with-Project, without Sediment Trap	\$26,997,170	\$1,000,000
Maintenance Costs with-Project, with Sediment Trap	\$8,586,679	\$318,058
Savings (Benefits)	\$18,410,491	\$681,942
Sediment Trap Net Benefits	-	\$363,884
Sediment Trap BCR	-	1.9

## 5.8 FEDERAL IMPEMENTATION RESPONSIBILITIES

Under the Water Resources Development Act (WRDA) 1986, as amended by Section 201 of WRDA 1996, Federal participation in navigation projects is limited to sharing costs for design and construction of the general navigation features (GNF) consisting of breakwaters and jetties, entrance and primary access channels, widened channels, turning basins, anchorage areas, locks, and dredged material placement areas with retaining dikes.

## 5.9 NON-FEDERAL IMPLEMENTATION RESPONSIBILITIES

Non-Federal interests are responsible for and bear all costs for acquisition of necessary lands, easements, rights-of-way and relocations; terminal facilities; and dredging berthing areas and interior access channels to those berthing areas.

## 5.10 RECOMMENDED PLAN COST

The cost was estimated using MII<sup>17</sup>. **Table 5-4** addresses USACE cost sharing guidelines while **Table 5-5** displays the total project first cost. The estimate used for the cost sharing table shown is based on the “constant dollar basis” (second column) on the Total Project Cost Summary (TPCS spreadsheet (Appendix C, Cost Engineering and Risk Analysis) which reflects program year 2020 at effective price level 1 Oct 19. The project first cost is referenced in this report and represents the most refined level of cost detail, with added contingency, which was determined through the Cost and Schedule Risk Analysis (CSRA). More details on the cost estimate can be found in **Appendix C, Cost Engineering and Risk Analysis**, as can details of cost assumptions, and risks that factored into the contingency.

The cost estimate below reflects all Recommended Plan project features, including but not limited to removal of the rocky obstruction, construction of the sediment trap, cultural resource surveys during PED, and relocation of 8 aids to navigation (ATONS)<sup>18</sup>. There are no local facility costs associated with the project cost. Environmental windows factored heavily into construction windows and construction sequencing.

The project first cost, with added contingency, is estimated to be \$57,240,000.

---

<sup>17</sup> MII is the second generation of the Micro-Computer Aided Cost Estimating System (MCACES). It is a detailed cost estimating software application that was developed in conjunction with Project Time & Cost, Inc. (PT&C). MII is one of several modules of an integrated suite of cost engineering tools called Tri-Service Automated Cost Engineering Systems (TRACES). It interfaces with other PC based support modules and databases used by the Tri-Service Cost Engineering community. MII provides an integrated cost estimating system (software and databases) that meets the U.S. Army Corps of Engineers (USACE) requirements for preparing cost estimates.

**Table 5-4. Cost Share Guidelines.**

Feature	Federal Cost % <sup>1</sup>	Non-Federal Cost % <sup>1</sup>
<b>General Nav. Features (GNF)</b>	· 90% from 0' to 20'	· 10% from 0' to 20'
	· 75% from 20' to 50'	· 25% from 20' to 50'
	· 50% from 51; and deeper <sup>18</sup>	· 50% from 51' and deeper
Mitigation (if needed)	· 75%	· 25%
GNF's costs for this project include: mobilization, all dredging costs, and all placement area construction costs.		
<b>Navigation Aids</b>	· 100%	· 0%
<b>Operation and Maintenance</b>		
GNF	· 100% except cost share 50% costs for maintenance > 50 feet	· 0% except cost share 50% for maintenance > 50 feet
(1) The Non-Federal Sponsor shall pay an additional 10% of the costs of GNF over a period of 30 years, at an interest rate determined pursuant to Section 106 of WRDA 86. The value of LERR shall be credited toward the additional 10% payment.		

<sup>18</sup>Per Section 2102(b) of WRRDA 2014 and Section 1111 of WRDA 2016

**Table 5-5. Project Cost and Cost Sharing, -38 foot deepening project (RECOMMENDED PLAN).**

(October 1, 2019 Price Levels, Program Year 2020) <sup>1</sup>						
WBS Number	General Navigation Features	Project Cost	Contingency	Total Project Cost	Federal Share	Non-federal Share
					75%	25%
12	Mob, Demob, Dredging	\$45,548,000	\$9,115,000	\$54,663,000	\$40,997,000	\$13,666,000
30	Pre-Construction, Engineering, and Design	\$1,591,000	\$318,000	\$1,909,000	\$1,432,000	\$477,000
31	Construction Management (S&I)	\$501,000	\$100,000	\$601,000	\$451,000	\$150,000
	<b>Subtotal Construction of GNF<sup>2</sup></b>	<b>\$47,640,000</b>	<b>\$9,533,000</b>	<b>\$57,173,000</b>	<b>\$42,880,000</b>	<b>\$14,293,000</b>
1	Lands, Easements, Right-of-Ways, Relocations (LERR)3 - Federal	\$23,000	\$2,000	\$25,000	\$18,750	\$6,250
1	Lands, Easements, Right-of-Ways, Relocations (LERR)3- Non-Federal	\$23,000	\$2,000	\$25,000	\$0	\$25,000
	<b>Total Project First Costs</b>	<b>\$47,663,000</b>	<b>\$9,535,000</b>	<b>\$57,200,000</b>	<b>\$42,880,000</b>	<b>\$14,320,000</b>
12	Aids to Navigation <sup>4</sup>	\$16,000	\$3,000	\$19,000	\$19,000	\$0
	Credit for Non-Federal LERR <sup>5</sup>	\$0			\$0	-\$31,250
	10% GNF Non-Federal <sup>6</sup>	\$0			(\$5,717,300)	\$5,717,300
	<b>Total Cost Apportionment</b>	<b>\$47,680,000</b>	<b>\$9,540,000</b>	<b>\$57,220,000</b>	<b>\$37,180,000</b>	<b>\$20,010,000</b>
<p>1. Cost is based on Project First Cost (constant dollar basis) on Total Project Cost Summary Spreadsheet, at an effective price level 1 Oct 2019 (Cost Appendix). Aids to Navigation broken out and shown as a separate cost.</p>						
<p>2. 75% Federal/25% non-federal including the cost of the sediment trap.</p>						
<p>3. RE admin costs. There are no actual lands and damages but per USACE regulations, RE admin costs will be placed in the 01 account. Additional RE costs will be cost shared according to the GNF. Escalation from the TPCS accounts for some numerical differences.</p>						
<p>4. Navigation Aids - 100% Federal (U.S. Coast Guard cost, not USACE cost). Includes 8 relocations at \$2,000 each.</p>						
<p>5. Credit is given for the incidental costs borne by the non-Federal sponsor for lands, easements, rights of way and relocations (LERR) per Section 101 of WRDA 86, not to exceed 10% of the GNF.</p>						
<p>6. The Non-Federal Sponsor shall pay an additional 10% of the costs of GNF of the NED plan, pursuant to Section 101 of WRDA 86. The value of LERR shall be credited toward the additional 10% payment except in the case of LERR for GNF.</p>						

## 5.11 LANDS, EASEMENTS, RIGHT-OF-WAY & RELOCATION (LERR) SUMMARY

This section serves as a summary of **Appendix F, Real Estate Plan**, which can be referenced for more detailed information. Navigation Servitude will be applied to this project as it meets the dominant right

of the Government under the Commerce Clause of the U.S. Constitution (U.S. CONST. art. I, §, cl.3) to use, control and regulate the navigable waters of the United States and the submerged lands thereunder for various commerce related purposes including navigation and flood control provided in paragraph 12-7 of ER 405-1-12. This project serves a purpose to improve navigation by deepening of the Pinole Shoal Channel and Bulls Head Reach Channel, which are located below the mean or ordinary high water mark of a navigable watercourse.

Policy Guidance Letter 44 Revisions, September 27, 2017 (PGL 44) provides guidance to set forth current U.S. Army Corps of Engineers policy regarding the relocation and removal of utilities located in or under navigable water of the U.S. that interfere with Federal navigation improvements implemented under Section 101 of the Water Resources Development Act of 1986, as amended (33 U.S.C. 2211). Specifically, the memorandum modifies guidance on the interaction between Federal powers under the navigation servitude and Section 10 of the Rivers and Harbors Act of 1899 (33 U.S.C. 403) and the non-Federal sponsor's performance and payments responsibilities for utility relocation. Based current information, PGL 44 does not apply as the current project does not impact any utilities. The Trans Bay Cable is located in the West Richmond Channel which, currently is not dredged. Additional investigations will be conducted during PED to confirm the location and depth of the utility during PED and if impact is identified then the non-Federal sponsor is responsible for performing, or assuring the performance of all utility relocations necessary for the project and PGL 44 would then apply.

All material dredged from the project would be beneficially reused at one or more existing permitted dredged material beneficial reuse I sites – either at Cullinan Ranch Tidal Wetlands or Montezuma Wetlands Restoration Site.

Currently, additional real estate is not required for the project; however the non-Federal sponsor will be required to acquire the minimum interest in real estate that will support the construction and subsequent operation and maintenance of the proposed USACE project should additional real estate be required.

An estimated \$25K for Federal and \$25K non-Federal administrative fees is for real estate certification.

There are no Public Law 91-646 Relocations required in connection with the project.

## 5.12 FINANCIAL ANALYSIS OF NON-FEDERAL SPONSOR'S CAPABILITIES

A financial analysis is required for any plan being considered for USACE implementation that involves non-Federal cost sharing. The ultimate purpose of the financial analysis is to ensure that the non-Federal sponsor understands the financial commitment involved and has reasonable plans for meeting that commitment. By memorandum dated April 24, 2007, the Assistant Secretary of the Army (Civil Works), granted approval of the self-certification of non-Federal sponsors for their ability to pay the non-Federal share of projects. The self-certification is required prior to submission of the Project Partnership Agreement, typically during the PED phase of the project. Included with the self-certification, the financial analysis shall include the non-Federal sponsor's statement of financial capability, the non-Federal sponsor's financing plan, and an assessment of the sponsor's financial capability. The appropriate self-certification form has been provided to USACE by the Port of Stockton.

## 5.13 VIEWS OF THE NON-FEDERAL SPONSOR

The Port of Stockton, the non-Federal sponsor, greatly supports this project both financially through cost sharing and legislatively through project authorization. A letter of support is included in **Appendix I, Pertinent Correspondence Part 1**.

## 5.14 RISK AND UNCERTAINTY

Engineering Regulation 1105-2-100 directs planners to identify areas of risk.

Economics. For the economics portion of the study, a sensitivity analyses was done for each of the major commodity forecasts to show alternative scenarios for crude oil imports and petroleum exports, and confirm Federal Interest with a positive BCR in each scenario. All topics described above can be found in more detail in **the Appendix D, Economic Analysis**.

Engineering. A potential area of risk is sediment testing of the dredge material. One source (USFSW 1998) indicates material at a 49 foot depth may have elevated levels of Chromium. However, this sediment was sampled at a deeper depth than what the project depth will be. Additionally, risk to using information from this report alone is inherent due to different sampling methods than which are currently used. Another source (ERDC 2000) indicates suitability of dredged material from Pinole Shoal and Bulls Head Reach as follows "Overall, the wetland mesocosms tests indicated that creating wetlands with Pinole Shoal Channel sediments will produce plants or animals with tissue metal concentrations in the range of those found in existing San Francisco Bay area wetlands; PAH concentrations were negligible; PCBs and butyltins were not detected in mesocosms organisms. Use of Pinole Shoal sediments for wetland creation would produce wetlands comparable to existing wetlands in the Bay area." Therefore, this is considered to be a medium risk at this time. Sediment testing will take place during PED. If testing shows levels of chromium are not acceptable for cover material at one or both sites, other combinations of placement/disposal are available (ex: non-cover at Montezuma, all SF-DODS, or other beneficial reuse sites willing to take the material). This has been modeled in the Cost and Schedule Risk Assessment and would be covered by the project contingency if needed.

Environmental. Risks during construction to threatened and endangered species have been minimized within the proposed plan (using beneficial reuse to offset effects) and cost estimate by avoiding seasons of peak activity, using a clamshell dredge, and incorporating other management methods such as observers. Risks as a result of salinity changes were incorporated early in the plan formulation process and were avoided by considering depths which would not incur large scale salinity effects. Remaining salinity risks have been addressed through modeling to verify assumptions along with coordination with water user groups and resource agencies.

Cost. Each of the above factors, as well as a thorough analysis of each project element, were incorporated into the Cost and Schedule Risk Assessment (CSRA) process, where the purpose of the CSRA is to develop a more statistically based project contingency. Therefore, areas of specific risk detail on the CSRA can be found in **Appendix C, Cost Engineering and Risk Analysis**.

### 5.14.1 RESIDUAL RISK

Residual risks are risks that remain after all risk reduction actions have been completed. In this case, it applies to risks which would happen in the future without-project condition, but would also be the same with implementation of the Recommended Plan.

#### SEA LEVEL RISE

Following procedures outlined in ER 1110-2-8162 and ET 1100-2-1, low, intermediate, and high sea level rise values were estimated over the life of the project using the official USACE sea level change calculator tool. Projections for sea level rise are based on a start date of 1992, which corresponds to the midpoint of the current National Tidal Datum Epoch of 1983-2001. In the future without-project conditions, sea level rise could be expected to increase by 0.5 feet (low), 1 foot (intermediate), and 2.7 feet (high) by year 2070 with respect to the above mentioned present local mean sea level tide datum. The potential impacts of rising sea level include increased salinity intrusion into the Sacramento-San Joaquin Delta, overtopping of waterside structures, increased shoreline erosion, and flooding of low lying areas. A positive potential impact of sea level rise on the project is a reduction in required maintenance due to increased depth in the channel.

The highest sea level change scenario was chosen for evaluation in the model because it was anticipated to have the most impact to hydrodynamics and salinity for the Recommended Plan (See Appendix B for more information). As demonstrated in Appendix B, the modeling results found that there would be no changes to hydrodynamics for the Recommended Plan when compared to without-project conditions for the high scenario, and it is anticipated a similar result would occur for the low and medium scenarios if they were run over the 50 year period of analysis. The modeling results found that the changes to salinity for the Recommended Plan when compared to without-project conditions would not be significant for the high scenario, and it is anticipated a similar result would occur for the low and medium scenarios if they were run over the 50 year period of analysis. Regional sea level rise will not affect the function of the project alternatives or the overall safety of the design vessel and the structural aspects of the project will generally be unaffected. Therefore, sea level rise is expected to be the same in both the future with-project and future without-project conditions and additionally sea level rise is not anticipated to impact costs or benefits of the Recommended Plan.<sup>19</sup> (Reference Appendix B, Water Resources).

As a note, the project is not claiming habitat benefits for project justification. However, the description below explains how the material is expected to contribute to restoration sites and what could be expected in sea level rise scenarios. The beneficial reuse of the dredged material would contribute to restoring salt marsh and tidally influenced habitat used by upland, wetland, and tidal wetland species at sites which are both owned, managed, and monitored by other entities. This project does not claim habitat benefits from the beneficial reuse of material on these sites. In the future without-project conditions (which would be the same in the future with-project as well), sea level rise could range from 0.5 to 2.8 ft by year 2070 with respect to the present local mean sea level tide datum. The contribution of increased acreage of restored habitat would likely still serve the same species in any of the sea level rise scenarios or could be adapted

---

<sup>19</sup> Vertical clearance of bridges were also assessed for projected regional sea level change (RSLC) under the USACE high curve scenario, found in Table 2-20 of Chapter 2. All numbers are referenced to high tide. In this event, Panamax vessels in the current fleet which are also the vessels which would benefit from the recommended plan would not be impacted, or vessels could choose to sail at a lower tide.

as needed by the private owner of the site. Additionally, established marshes could be expected to accrete with sea level rise over time through on-going accretion of sediment and organic matter.

### STORM SURGE

The USACE Deep Water Shipping Scenario Report (2011) predicted water stage at San Francisco Fort Point NOAA station (9414290) for the baseline scenario under 2007-2008 historic conditions. A tidally-averaged stageplot noted a storm surge of almost 1.64 feet (0.5 m), which was used under the baseline scenario for existing and future without-project conditions.

Relative to the baseline (existing) surge at Fort Point, no significant change in stage was predicted for deepening of -45 feet plus 2 feet of overdepth, which is what the above cited report assumed at the time. The Recommended Plan in this report proposes to deepen the channel to -38 feet MLLW + 2 feet of overdepth, which is less than what was modeled in the above mentioned report. Therefore, it can be assumed that no significant change would be expected with the implementation of the Recommended Plan. However, in the both the future without-project condition and Recommended Plan, storm surge could increase additionally with increased sea level rise.

6

Environmental  
Compliance

## 6 ENVIRONMENTAL COMPLIANCE

This chapter discusses the status of coordination and compliance of The Recommended Plan with environmental requirements. Additionally, it shows how the Recommended Plan meets USACE environmental operating principles.

### 6.1 SCOPING & PUBLIC INVOLVEMENT

Scoping included publication in the Federal Register of a Notice of Intent to prepare an Environmental Impact Statement/Environmental Impact Report on March 4, 2016. At that time, the project included deepening the navigation channel to Stockton. Based upon salinity modeling results and public controversy, the scope of the project was reduced to deepen the navigation channel only to Avon. Salinity modeling was revisited to include deepening only to Avon, while also including a sediment trap at Bulls Head Reach. The results of the salinity modeling are presented in **Appendix B, Water Resources-Attachment 1**, as well as in Chapter 4. An additional Notice of Intent to prepare an Environmental Impact Statement/Environmental Impact Report was published December 4, 2017 to announce the reduction in scope on this navigation project. All agency and public scoping comments from 2016 and 2017, with a comment response matrix, are included in **Appendix I, Pertinent Correspondence Part 1**. Because this study has been ongoing since prior to 2016, the baseline conditions were not updated to include the most recent data for economics, greenhouse gases, socio-economics, or air quality. In efforts to minimize expenditure of funds to repeat extensive analyses, a qualitative assessment was completed to compare the most up to date data with what was previously used in analysis and found to be similar enough not to change the results significantly.

Agency meetings were held in December 2018 to discuss the scope of the project, as well as the updated salinity information that is contained within the draft and final GRR/EIS.

A Notice of Availability was published for the draft GRR/EIS in the Federal Register on May 10, 2019, a press release to announce the location and comment period of the document, and it was also published on the California State Clearinghouse website. A letter was sent to the general public to notice release of the draft GRR/EIS (mailing list available upon request) and to also notice the public meeting time and location that occurred on June 11, 2019 from 6pm-8pm at the Contra Costa County Conservation and Development office in Martinez, at 30 Muir Road, Martinez, CA 94553. Hard copies of the draft GRR/EIS were made available at the following libraries:

Cesar Chavez Central Library, 605 N El Dorado St, Stockton, CA 95202

Contra Costa County Library, Martinez Branch 740 Court St, Martinez, CA 94553

Comments on the draft GRR/EIS were received from May 10, 2019 through June 24, 2019 for a 45 day public review period. Comments received after June 24 through August 31, 2019 are included in the comment response matrix, located in **Appendix I, Pertinent Correspondence Part 2**. These comments and responses also include comments from the Dredge Material Management Plan (DMMP) meeting that occurred in San Francisco in July 2019.

## 6.2 LIST OF RECIPIENTS

The draft EIS was made available to appropriate stakeholders and agencies by letter with the location of the document on the internet at:

(<https://www.saj.usace.army.mil/About/Divisions-Offices/Planning/Environmental-Branch/Environmental-Documents/>). From the link provided, go to “Other Locations”, then SF Bay to Stockton. Hard copies of the document were made available to the public at the following libraries. A list of stakeholders who received notification is available upon request.

### **Libraries where a hard copy is available to view:**

Cesar Chavez Central Library 605 N El Dorado St, Stockton, CA 95202

Contra Costa County Library – Martinez Branch 740 Court St, Martinez, CA 94553

## 6.3 COMMENTS RECEIVED AND RESPONSE

Comments received from the public scoping meeting or on draft EIS are located in the **Appendix I Pertinent Correspondence Part 1 and Part 2, respectively.**

## 6.4 ENVIRONMENTAL COMMITMENTS

The proposed project minimizes risk to environmental resources, and threatened and endangered species by:

- Working with the approved USFWS environmental work window for delta smelt, listed salmonids and green sturgeon
- Using a clamshell dredge to avoid entrainment of species
- Placing all dredged material from deepening onto beneficial reuse sites to create/enhance wetland habitats and conditions for species within the delta, including delta and longfin smelt
- Commitments in the Programmatic Agreement for Cultural Resources

Other environmental commitments related to threatened and endangered species are discussed in the Biological Opinion (BO) from the USFWS. The BO contains one non-discretionary term and condition which is to implement the conservation measures listed on pages 2 and 3 of the BO. These conservation measures are already incorporated into the project description and will be followed.

## 6.5 COMPLIANCE WITH ENVIRONMENTAL REQUIREMENTS

The status of the proposed action’s compliance with applicable Federal environmental requirements is summarized below. Prior to initiation of construction, the project will be in compliance with all applicable Federal laws and Executive Orders.

### 6.5.1 NATIONAL ENVIRONMENTAL POLICY ACT (NEPA) OF 1969

Environmental information on the project has been compiled and this EIS/EIR has been prepared. The draft EIS was circulated for review by NOA in the Federal Register in Spring 2019. All correspondence has been included as **Appendix I, Pertinent Correspondence Part 1**. The project is in compliance with the National Environmental Policy Act (NEPA).

### 6.5.2 ENDANGERED SPECIES ACT OF 1973

USACE obtained a list of the federally threatened and endangered species and critical habitat that have potential to occur within the project area on November 27, 2017 (**Appendix G - Attachment 4**). USACE submitted the Biological Assessments to the National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) (**Appendix G-Attachment 4**) at the time of release of the draft report. A Biological Opinion was provided by USFWS on October 3, 2019 and a letter of concurrence was provided by NMFS on December 6, 2019. The proposed project is therefore in compliance with the Act.

### 6.5.3 FISH & WILDLIFE COORDINATION ACT OF 1958

Coordination with the USFWS under the FWCA is ongoing. The Final Coordination Act Report is located in **Appendix G-Attachment 4**. USACE will continue to coordinate future actions with the USFWS. The project is in compliance with the Act.

### 6.5.4 NATIONAL HISTORIC PRESERVATION ACT OF 1966 (*INTER ALIA*)

The SHPO in each state is responsible for ensuring that Federal agencies comply with Section 106 of this Act, which requires that they consider the effects of a proposed undertaking on properties that have been determined to be eligible for, or included in, the NRHP. The Section 106 review process consists of four steps: (1) identification and evaluation of historic properties; (2) assessments of the effects of the undertaking on historic properties; (3) consultation with the SHPO, Native American Indian Tribes, and appropriate agencies to develop a plan to address the treatment of historic properties; and (4) concurrence from the SHPO regarding the agreement or results of consultation.

Pursuant to Section 106 of the NHPA (36 CFR § 800.8), USACE is employing a phased process to identify and evaluate historic properties and assess effects. Ongoing consultation and consideration of effects will occur during Preconstruction, Engineering and Design (PED) as the APE may be subject to change based on final designs or modifications of project features. Therefore; pursuant to 54 U.S.C. 306108 and § 800.4(b)(2), USACE is deferring final identification and evaluation of historic properties until after project approval, additional funding becomes available, and prior to construction through a Programmatic Agreement (PA) executed on February 14, 2020 with the California State Historic Preservation Office.

USACE shall avoid, minimize, and mitigate adverse effects to historic properties that could be affected by activities associated with the implementation of the project, including dredging and pipeline placement. During the PED phase of the project, the specific location of the proposed work (e.g., alignment, width, and depth) shall be developed in consultation with the California SHPO, and Native American Tribes. USACE shall make reasonable attempts to identify cultural resources through remote sensing surveys to determine whether the dredging activities would adversely affect archaeological resources or historic properties. If a potential site is identified near or within the channel or project feature, after consultation with the SHPO, additional investigations will be undertaken to evaluate the site for eligibility for listing on the NRHP. Should the site be determined to be historically significant, the project design would be modified to either avoid or mitigate the site. If necessary, additional NHPA documentation would be prepared at that time to disclose the adverse effects that would result from the undertaking. If the activities are proposed to take place in an area that would affect the site(s), USACE shall not complete that part of the proposed action until the site is evaluated for NRHP eligibility, the appropriate environmental review is completed, and a follow-on course of action is agreed upon through consultation with all appropriate entities and outlined in the PA.

The potential always exists that during construction, a previously unknown archaeological sites could be discovered even after cultural resource surveys have been completed. In such a situation, the following measures would be incorporated into the dredging contract(s) to mitigate any potential impacts during construction to shipwrecks, Native American, and/or historical archaeological resources

As discussed in **Section 4.2.12 Cultural Resources**, both archeological and historic sites were found in the vicinity of the project. USACE has reviewed site records for the Project areas, which includes all proposed work areas for this study. Consultation with interested Indian tribes was initiated via letters dated January 31, 2019. Two Tribal bands were identified to have ancestral affiliation to the landscape and cultural resources residing within the study area. USACE is still coordinating between the two identified Indian tribes and will continue to make a good faith effort in leaving tribal consultation open during PED. Based on archival and historic records research, correspondence with local Indian Tribes, and past field investigations conducted in the study area, the project will be in compliance with the National Historic Preservation Act of 1966 through an executed PA that defers final identification and evaluation of historic properties and assessing the study's effects to occur during PED. A programmatic agreement describing the phased approach of USACE's compliance with Section 106 following 36 CFR 800.14 [b][1] is currently being reviewed by the SHPO as of January 28, 2020. USACE has provided several Indian tribes the opportunity to comment on the draft PA and incorporated any necessary corrections made. USACE has also provided the public and local historic societies an opportunity to review the draft PA online on November 15, 2019. The Advisory Council on Historic Preservation responded to the USACE's request to be an Invited Signatory for the PA and believes their participation as an Invited Signatory to execute the agreement is not needed. An executed PA signed by the SPN District Engineer and SHPO occurred on February 14, 2020. This agreement document requires USACE to complete necessary surveys and evaluations during PED and prior to project construction, following 36 CFR 800.4 [b][2]<sup>20</sup>. Once surveys and evaluations have been completed consultations will be updated with the SHPO, concurring parties, and interested tribes. Correspondence to date and the executed PA can be found in **Appendix H, Cultural Resources Correspondence**.

### 6.5.5 CLEAN WATER ACT OF 1972

The Federal CWA (33 U.S.C. § 1257 et seq.) requires states to set standards to protect water quality. The objective of the Federal CWA is to restore and maintain the chemical, physical, and biological integrity of the nation's waters. Specific sections of the CWA control discharge of pollutants and wastes into marine and aquatic environments, as further discussed in Section 3.4.1. USACE has initiated Section 401 Water Quality Certification with the Regional Water Board (see **Appendix I, Pertinent Correspondence Part 1** for email correspondence). Staff from the Regional Water Quality Control Board participated in an early meeting with local agencies to help determine the scope of the water quality impact assessment. More recently in Spring and Fall of 2019, USACE received correspondence from the Regional Board indicating they typically would not issue a water quality certification without completion of CEQA documentation and design-level detail for the project being available. CEQA compliance is a non-Federal responsibility and the Port of Stockton is pursuing this compliance on a separate timeline. In January 2020, USACE met via teleconference call with representatives of the Regional Board regarding the path forward for obtaining 401 water quality certification of the recommended plan, and the timing of completion for the final report. During this meeting, the Regional Board representatives indicated that submittal of the WQC application would need to be deferred until the design phase of work and committed to transmittal of a letter to USACE in February 2020 confirming inter-agency coordination and the path forward for 401 water

<sup>20</sup> Survey cost estimates during PED have been incorporated into the total project cost.

quality certification upon completion of CEQA compliance and design detail. Feedback received from Regional Board staff and other agencies at the USACE December 2016 agency workshop was wrapped into technical analyses and modeling as contained within this report, and considered in the development of report recommendations. Upon receipt this letter will be included in the final report package prior to the Director's signing. USACE is in compliance with this Act.

### 6.5.6 CLEAN AIR ACT OF 1972

The USEPA is the Federal agency responsible for managing the Nation's air quality. USEPA establishes national ambient air quality standards, and oversees the air quality plans developed and implemented by the states. BAAQMD is responsible for developing local district air quality management plans and enforcing regulations pertaining to air emissions in the study area. As discussed in Section 5.2.5, the proposed action would not exceed national air quality standards based on modeled estimates of emission rates during construction of the project.

On November 30, 1993, the USEPA promulgated final general conformity regulations at 40 CFR 93B for Federal activities. These regulations apply to a Federal action in a nonattainment or maintenance area if the total emissions of the criteria pollutants and precursor pollutants caused by the action equal or exceed certain de minimis amounts, thus requiring the Federal agency to make a determination of general conformity. As discussed in Section 4.2.5, at least part of the Delta is in non-attainment for ozone, PM10, and PM2.5. As discussed in Section 5.5, the proposed action would not exceed de minimis thresholds based on modeled estimates of emission rates during construction of the project, and would be in full compliance with the CAA.

### 6.5.7 COASTAL ZONE MANAGEMENT ACT OF 1972

The CZMA, established in 1972 and administered by the NOAA's Office of Ocean and Coastal Resource Management, provides for management of the nation's coastal resources through a state and Federal partnership. Under the Federal consistency provisions of the CZMA, Federal projects need to be consistent with the state's coastal zone management program and policies to the maximum extent practicable (16 U.S.C. § 1456); this determination is made by the lead Federal agency, and concurrence is requested from the state or local agency responsible for implementing the CZMA. For San Francisco Bay, the Bay Area Coastal Development Conservation District (BCDC) is the state's coastal zone management agency responsible for issuing concurrence with consistency determinations under the CZMA. The San Francisco Bay Plan is BCDC's policy document specifying goals, objectives, and policies for BCDC jurisdictional areas. For portions of the study area outside of San Francisco Bay, concurrence with consistency determinations is issued by the California Coastal Commission. USACE has prepared a CZMA Evaluation within this EIS, located in **Appendix G, Attachment 2**, and has requested a consistency determination concurrence from the BCDC or California Coastal Commission prior to commencing dredging activities. USACE has had several coordination meetings with the San Francisco Bay Conservation and Development Commission (BCDC). The typical process for BCDC would be to issue a final Consistency Concurrence during the USACE Pre-construction, Engineering and Design (PED) phase when detailed project design information is available. In the interim, BCDC has verbally indicated that a letter from the Chair of the Commission will be sent to USACE for inclusion in this report, which will summarize USACE coordination with BCDC to date and confirm their intent to consider CZMA Consistency when CEQA compliance has been completed and more detailed design information is available. BCDC feedback on the Recommended Plan is consistent with comments received during public review, for which substantive responses have been provided in this report. Responses to these comments have been considered in the decision put forth for action by the Director.

### 6.5.8 FARMLAND PROTECTION POLICY ACT OF 1981

The NRCS is the Federal agency responsible for administering this act, which requires Federal agencies to coordinate a Farmland Conversion Impact form with the NRCS whenever their projects or programs would affect land designated as prime or unique farmland. The proposed action would not remove or alter any land that is protected under this Act. As a result the proposed project is in full compliance with this Act.

### 6.5.9 WILD AND SCENIC RIVER ACT OF 1968

No wild or scenic river reaches would be affected by the proposed project related activities. This Act is not applicable.

### 6.5.10 MARINE MAMMAL PROTECTION ACT OF 1972

The Marine Mammal Protection Act (MMPA) prohibits takes of all marine mammals in the U.S. (including territorial seas) with a few exceptions. Sections 101(a)(5)(A) and (D) of the MMPA (16 U.S.C. 1361 et seq.) directs the Secretary of Commerce (Secretary) to allow, upon request, the incidental, but not intentional taking of small numbers of marine mammals by U.S. citizens who engage in a specified activity (other than commercial fishing) within a specified geographical region if certain findings are made and regulations are issue or, if the taking is limited to harassment, notice of a proposed authorization is provided to the public for review.

Authorization for incidental takings may be granted if NMFS finds that the taking will have a negligible impact on the species or stock(s), will not have an unmitigable adverse impact on the availability of the species or stock(s) for certain subsistence uses, and if the permissible methods of taking and requirements pertaining to the mitigation, monitoring, and reporting of such takings are set forth. NMFS has defined “negligible impact in 50 CFR 216.103 as: “an impact resulting from the specified activity that cannot be reasonably expected to, and is not reasonably likely to, adversely affect the species or stock through effects on annual rates of recruitment or survival.”

Under the MMPA, harassment is defined as any act of pursuit, torment, or annoyance which has the potential to: (i) injure a marine mammal or marine mammal stock in the wild (Level A harassment); or (ii) disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering (Level B harassment). An Incidental Harassment Authorization (IHA) may be issued, except for activities that have the potential to result in serious injury or mortality (i.e., it may only authorize Level A and B harassment), for a period of no more than one year, following a 30-day public review period. Alternatively, regulations may be granted for a period of five years and may include takes by serious injury and mortality. Upon rulemaking (i.e., defining regulations), Letters of Authorization (LOAs) will be issued to the authorization holder. The rulemaking and associated LOAs cannot be valid for a period of more than five consecutive years. For both an IHA and regulations, authorization shall be granted if the Secretary finds that the taking will have a negligible impact on a species or stock, and that the IHA or regulations are prescribed setting forth the permissible methods of taking, the means of effecting the least practicable adverse impact, and requirements pertaining to monitoring and reporting.

In order to minimize effects below threshold requiring an IHA, protective measures for marine mammals such as sea lions and dolphins would be implemented during construction activities. Additional information can be found in Chapter 4 and Section 6.4 of this report. Coordination with the USFWS and NMFS under the MMPA is ongoing.

#### 6.5.11 ESTUARY PROTECTION ACT OF 1968

The National Estuary Program was created by Congress in the 1987 amendments to the Clean Water Act. The Program consists of 28 local estuary programs, managed federally by the USEPA, with a focus of improving the waters, habitats, and living resources of estuaries of national significance. The National Estuary Program is a non-regulatory program. The San Francisco Estuary, consisting of the San Francisco and Suisun Bays, the Suisun Marsh, and the Sacramento and San Joaquin River Delta, is one such estuary. The San Francisco Estuary program is managed by the USEPA, State of California, and locally by the San Francisco Estuary Partnership. Management of the estuary is guided by the San Francisco Estuary Project Comprehensive Conservation and Management Plan (CCMP). Since the purpose of the Delta Study is to restore historically lost tidal wetlands and reverse the effects of subsidence, which is included as one of the restoration goals of the CCMP, the proposed project is in full compliance with the intent of this Program.

#### 6.5.12 FEDERAL WATER PROJECT RECREATION ACT

Recreation opportunities and potential impacts to current recreation were considered during the planning processes for this study. Although the study area provides recreational benefits, the principles of this Act (Public Law 89-72) as amended, are not applicable to this project.

#### 6.5.13 MAGNUSON-STEVENSON FISHERY CONSERVATION AND MANAGEMENT ACT OF 1976

The Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) establishes a management system for national marine and estuarine fishery resources. This legislation mandates the identification, conservation, and enhancement of EFH, which is defined as “waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity,” for all managed species.

Federal agencies consult with NMFS on proposed actions that may adversely affect EFH and NMFS typically provides EFH conservation recommendations. The main purpose of the EFH provisions of the act is to avoid loss of fisheries due to disturbance and degradation of the fisheries habitat. USACE EFH assessment is incorporated into Section 4.1.6 of this report and is included in the Biological Assessment (**Appendix G-Attachment 4**). Coordination with NMFS occurred concurrently with release of the draft report and USACE received the EFH response from NMFS with two conservation recommendations on December 6, 2019 (**Appendix G**). USACE responded to NMFS on January 6, 2020 describing the methods for implementing the conservation recommendations (**Appendix G**). The proposed project is in compliance with this Act.

#### 6.5.14 COASTAL BARRIER RESOURCES ACT AND COASTAL BARRIER IMPROVEMENT ACT OF 1990

There are no designated coastal barrier resources in the project area that will be affected by this project. These Acts are not applicable.

#### 6.5.15 RIVERS AND HARBORS ACT OF 1899

Rivers and Harbors Act refers to a conglomeration of many pieces of legislation and appropriations passed by Congress since the first such legislation in 1824. The Rivers and Harbors Act of 1899 was the first Federal water pollution act in the United States. It focuses on protecting navigation, protecting waters from pollution, and acted as a precursor to the CWA of 1972. Section 10 of the Rivers and Harbors Act of 1899 regulates alteration of and prohibits unauthorized obstruction of navigable waters of the United States.

#### 6.5.16 ANADROMOUS FISH CONSERVATION ACT

The project is not expected to have a significant impact and is discussed in Section 4.1.6. The project is in coordination with NMFS and is in compliance with the Act.

#### 6.5.17 MIGRATORY BIRD TREATY ACT AND MIGRATORY BIRD CONSERVATION ACT

No migratory birds will be affected by project activities. The USACE standard MBPP will be used to minimize potential impacts to migratory birds. The project is in compliance with these Acts.

#### 6.5.18 PROTECTION AND SANCTUARIES ACT MARINE PROTECTION AND SANCTUARIES ACT MARINE PROTECTION AND SANCTUARIES ACT MARINE PROTECTION AND SANCTUARIES ACT

The Marine Protection and Sanctuaries Act (MPRSA) is the United States' implementation of an international treaty, the Convention on the Prevention of Marine Pollution by Dumping of Waste and Other Matter (also known as the "London Convention"). Section 102 of the MPRSA authorizes USEPA to establish criteria for evaluating all dredged material proposed for ocean dumping. These criteria are published separately in the Ocean Dumping Regulations at 40 C.F.R. pt. 220-228. Section 102 also authorizes the USEPA to designate permanent ocean-dredged material placement sites in accordance with specific site selection criteria designed to minimize the adverse effects of ocean placement of dredged material. Section 103 of the MPRSA authorizes USACE to issue permits, subject to USEPA concurrence or waiver, for dumping dredged materials into the ocean waters. It requires public notice, opportunity for public hearings, compliance with criteria developed by the USEPA (unless a waiver is granted), and the use of designated sites whenever feasible. Although USACE does not issue itself permits, USACE and USEPA apply these standards to USACE projects as well. This EIS does not evaluate the impacts of the ocean placement of dredged material from USACE-maintained Federal navigation channels in San Francisco Bay, because the project proposes to only place the dredged material on beneficial reuse sites.

#### 6.5.19 EXECUTIVE ORDER (EO) 11990, PROTECTION OF WETLANDS

No wetlands would be negatively affected by project activities. Cullinan Ranch and Montezuma Wetlands would benefit from this project, by placing the dredged material onto the restoration sites. The proposed project is in compliance with the goals of this Executive Order (E.O.).

#### 6.5.20 E.O 11988, FLOOD PLAIN MANAGEMENT

This EO directs Federal agencies to avoid, to the extent possible, long- and short-term adverse effects associated with the occupancy or modification of the base flood plain (1% annual event), as well as to avoid direct and indirect support of development in the base flood plain, wherever there is a practicable alternative. The proposed action would have no measurable effect on the (FEMA's 100-year) floodplain in the Bay Area. In addition, because of the nature of the proposed work, the proposed action would not directly or indirectly support development in the floodplain. The proposed project would be in full compliance with this order.

#### 6.5.21 E.O. 12898 ENVIRONMENTAL JUSTICE

The purpose of the proposed action is to provide increased safety, efficiency, and lower costs for navigation while protecting the environment. The proposed activity would not (a) exclude persons from participation in, (b) deny persons the benefits of, or (c) subject persons to discrimination because of their race, color or national origin, nor would the proposed action adversely impact "subsistence consumption of fish and wildlife." The proposed project would benefit shipping and the general economy including

minority and low income populations. Furthermore, construction activities and any additional trucking/commerce that would be associated with project improvements is not anticipated to disproportionately affect economically disadvantaged residential areas or persons belonging to minority groups. Construction traffic and logistic traffic use commercial traffic routes immediately adjacent to the Port, including U.S. Highways and Interstate highways. Construction activities and any additional trucking/commerce that would be due to the project are not expected to disproportionately affect economically disadvantaged residential areas of persons belonging to minority groups. More details on the evaluation can be found in Section 4.1.12. The proposed project is in compliance with the goals of this E.O.

#### 6.5.22 E.O. 13045, PROTECTION OF CHILDREN

This E.O. requires each Federal agency to “identify and assess environmental risks and safety risks [that] may disproportionately affect children” and ensure that its “policies, programs, activities, and standards address disproportionate risks to children that result from environmental health risks or safety risks.” This project has no environmental or safety risks that may disproportionately affect children and is in compliance.

#### 6.5.23 E.O. 13089 CORAL REEF PROTECTIONECTION

This project would not impact those species, habitats, and other natural resources associated with coral reefs as defined in the E.O. The deepening would occur within the already authorized and regularly maintained navigation channel. The proposed project is in compliance with the goals of this E.O.

#### 6.5.24 E.O. 13112, INVASIVE SPECIES

This project would not introduce or affect the status of any invasive species and is therefore in compliance with the goals of this E.O.

#### 6.5.25 ENVIRONMENTAL OPERATING PRINCIPLES

Consistent with NEPA, USACE has reaffirmed its commitment to the environment by formalizing a set of “Environmental Operating Principles” applicable to all its decision making and programs. These principles foster unity of purpose on environmental issues and ensure that environmental conservation, preservation, and restoration are considered in all USACE activities.

USACE Environmental Operating Principles are:

1. Foster sustainability as a way of life throughout the organization.  
*Throughout the planning process, the team strived for minimization of impacts to the surrounding environment, with a key focus on salinity effects.*
2. Proactively consider environmental consequences of all USACE activities and act accordingly.  
*Throughout the planning process, the interdependence of the built environment, navigation environment, economics environment, and living environment remained evident and each project measure was carefully considered for all elements.*
3. Create mutually supporting economic and environmentally sustainable solutions.

*Beneficial reuse of material will offset any effects during construction and could expand habitat for the delta smelt.*

4. Continue to meet our corporate responsibility and accountability under the law for activities undertaken by USACE, which may impact human and natural environments.

*Each element of human health, welfare, and viability of natural systems was thoroughly assessed throughout this report in a responsible manner.*

5. Consider the environment in employing a risk management and systems approach throughout the life cycles of projects and programs.

*Cumulative impacts to the environment were thoroughly assessed in this report and any effects have been thoroughly evaluated.*

6. Leverage scientific, economic and social knowledge to understand the environmental context and effects of USACE actions in a collaborative manner.

*USACE collected a great deal of information throughout the preparation of this study which has been thoughtfully prepared and organized in a manner so as to facilitate a greater knowledge base about the area, its challenges, and the opportunities which can be achieved.*

7. Employ an open, transparent process that respects views of individuals and groups interested in USACE activities.

*USACE worked with many agencies, individuals, and groups throughout this study, sharing scientific, economic and social information and exchanging ideas for the betterment of a design that will find solutions to the problem while maintaining the level of quality within the surrounding environment.*

7

Recommendations

## 7 RECOMMENDATIONS

I have given consideration to all significant aspects in the overall public interest including engineering feasibility, economic, social, cost and risk analysis, and environmental effects. The Recommended Plan described in this report provides the optimum solution for National Economic Development (NED) benefits within the study area that can be developed with the framework of the formulation concepts. Implementation of the Recommended Plan described in this the San Francisco Bay to Stockton Navigation Study is recommended at this time, with such modification as in the discretion of the Commander, Headquarters, U.S. Army Corps of Engineers (HQUSACE), may be advisable.

### 7.1 ITEMS OF LOCAL COOPERATION

The Recommended Plan conforms to the essential elements of the U.S. Water Resources Council's Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies and complies with other Administration and legislative policies and guidelines on project development. If the project were to receive funds for Federal implementation, it would be implemented subject to the cost sharing, financing, and other applicable requirements of Federal law and policy for navigation projects including WRDA 1986, as amended; and would be implemented with such modifications, as the Chief of Engineers deems advisable within his discretionary authority. Federal implementation is contingent upon the non-Federal sponsor agreeing to comply with applicable Federal laws and policies. Prior to implementation, the non-Federal sponsor shall agree to:

- a. Provide, during the periods of design and construction, funds necessary to make its total contribution for commercial navigation equal to:
  - (1) 25 percent of the cost of design and construction of the general navigation features (GNFs).
- b. Provide all lands, easements, rights-of-way, relocations, and placement areas (LERRDs), including those necessary for the borrowing of material and the placement of dredged or excavated material, and perform or assure the performance of all relocations, including utility relocations, all as determined by the Federal government to be necessary for the construction or operation and maintenance of the GNFs.
- c. Pay with interest, over a period not to exceed 30 years following completion of the period of construction of the GNFs, an additional amount equal to 10 percent of the total cost of construction of the GNFs less the amount of credit afforded by the Government for the value of the LERRD is provided by the sponsor for the GNFs. If the amount of credit afforded by the Government for the value of LERRD, and relocations, including utility relocations, provided by the sponsor equals or exceeds 10 percent of the total cost of construction of the GNFs, the sponsor shall not be required to make any contribution under this paragraph, nor shall it be entitled to any refund for the value of LERRD and relocations, including utility relocations, in excess of 10 percent of the total cost of construction of the GNFs.

- d. Provide, operate, and maintain, at no cost to the Government, the local service facilities in a manner compatible with the project's authorized purposes and in accordance with applicable Federal and state laws and regulations and any specific directions prescribed by the Federal government.
- e. Give the Federal government a right to enter, at reasonable times and in a reasonable manner, upon property that the Sponsor owns or controls for access to the project for the purpose of completing, inspecting, operating and maintaining the GNFs.
- f. Hold and save the United States free from all damages arising from the construction or operation and maintenance of the project, any betterments, and the local service facilities, except for damages due to the fault or negligence of the United States or its contractors.
- g. Keep and maintain books, records, documents, or other evidence pertaining to costs and expenses for a minimum of three years after the final accounting and assure that such materials are reasonably available for examination, audit, or reproduction by the Government.
- h. Perform, or ensure performance of, any investigations for hazardous substances that are determined necessary to identify the existence and extent of any hazardous substances regulated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 USC 9601–9675, that may exist in, on, or under LERRD that the Federal government determines to be necessary for the construction or operation and maintenance of the GNFs. However, for lands, easements, or rights-of-way that the Government determines to be subject to the navigation servitude, only the Government shall perform such investigations unless the Federal government provides the sponsor with prior specific written direction, in which case the sponsor shall perform such investigations in accordance with such written direction.
- i. Assume complete financial responsibility, as between the Federal government and the sponsor, for all necessary cleanup and response costs of any hazardous substances regulated under CERCLA that are located in, on, or under LERRD that the Federal government determines to be necessary for the construction or operation and maintenance of the project.
- j. Agree, as between the Federal Government and the non-Federal sponsor, that the non-Federal sponsor shall be considered the operator of the local service facilities for the purpose of CERCLA liability.
- k. To the maximum extent practicable, perform its obligations in a manner that will not cause liability to arise under CERCLA.
- l. Comply with Section 221 of Public Law 91-611, Flood Control Act of 1970, as amended, (42 U.S.C. 1962d-5b) and Section 101(e) of the WRDA 86, Public Law 99-662, as amended, (33 U.S.C. 2211(e)) which provide that the Secretary of the Army shall not commence the construction of any water

resources project or separable element thereof, until the sponsor has entered into a written agreement to furnish its required cooperation for the project or separable element.

- m. Comply with the applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public Law 91-646, as amended, (42 U.S.C. 4601-4655) and the Uniform Regulations contained in 49 CFR Part 24, in acquiring lands, easements, and rights-of-way necessary for construction, operation, and maintenance of the project including those necessary for relocations, the borrowing of material, or the placement of dredged or excavated material; and inform all affected persons of applicable benefits, policies, and procedures in connection with said act.
- n. Comply with all applicable Federal and state laws and regulations, including, but not limited to: Section 601 of the Civil Rights Act of 1964, Public Law 88-352 (42 U.S.C. 2000d), and Department of Defense Directive 5500.11 issued pursuant thereto; Army Regulation 600-7, entitled “Nondiscrimination on the Basis of Handicap in Programs and Activities Assisted or Conducted by the Department of the Army”; and all applicable Federal labor standards requirements including, but not limited to, 40 U.S.C. 3141-3148 and 40 U.S.C. 3701-3708 (revising, codifying and enacting without substantive change the provisions of the Davis-Bacon Act (formerly 40 U.S.C. 276a et seq.), the Contract Work Hours and Safety Standards Act (formerly 40 U.S.C. 327 et seq.), and the Copeland Anti-Kickback Act (formerly 40 U.S.C. 276c)).
- o. Not use funds from other Federal programs, including any non-Federal contribution required as a matching share therefore, to meet any of the sponsor’s obligations for the project unless the Federal agency providing the Federal portion of such funds verifies in writing that such funds are authorized to be used to carry out the project.

CHAPTER 7.0 Recommendations

The recommendation contained herein reflects the information available at this time and current departmental policies governing formulation of individual projects. It does not reflect program and budgeting priorities inherent in the formulation of a national civil works construction program or the perspective of higher review levels within the executive branch.

A handwritten signature in black ink, appearing to read 'R. Clark', is positioned above the printed name.

List of Preparers

## 8 LIST OF PREPARERS

### 8.1 PREPARERS

This GRR/EIS was prepared by the following U.S. Army Corps of Engineers:

Stacie Auvenshine/Paul DeMarco	Environmental, NEPA Compliance
Stacey Roth	Plan Formulation
Beth Campbell	ESA, Biologist
David Doak/Legese Abebe	Civil Design
Patrick Sing	Coastal Hydraulics
Pam Castens	Project Manager
Caitlin Bryant	Economics
Tu Nguyen	Geotechnical
Sherman Fong	Cost Engineering
Bonivee Delapaz	Real Estate
Jason Moser/Ruzel Ednalino	Cultural Resources
Mark Shafer	Water Quality

### 8.2 REVIEWERS

This report was reviewed by the following personnel:

Paul DeMarco	Environmental, NEPA Compliance
Eldon Gatwood	Plan Formulation
Cynthia Fowler/Paul DeMarco	ESA, Biologist
Joseph Ryan	Civil Design/Cost Engineering
Philip Sylvester	Coastal Hydraulics
Jay Kinberger	Project Manager
Daniel Abecassis	Economics
Jennifer Coor	Geotechnical
William Casale	Real Estate
S. Joe Griffin	Cultural Resources
Paul DeMarco	Water Quality

## **NOTICE OF PREPARATION (NOP) OF A DRAFT ENVIRONMENTAL IMPACT REPORT FOR THE OAKLAND WATERFRONT BALLPARK DISTRICT PROJECT**

The City of Oakland's Bureau of Planning is preparing an Environmental Impact Report ("EIR") for the Oakland Waterfront Ballpark District Project ("Proposed Project") at Howard Terminal. The City is requesting comments on the scope and content of the EIR. A description of the Proposed Project and its location, together with a summary of the probable environmental effects that will be addressed in the EIR are included herein. Pursuant to California Environmental Quality Act Guidelines §15063(a), the City has **not** prepared an Initial Study.

The EIR for the Proposed Project is being prepared in compliance with the California Environmental Quality Act (CEQA) (California Public Resources Code §§21000 et. seq.) and the State CEQA Guidelines (Guidelines) (California Code of Regulations, Title 14, Division 6, Chapter 3, §§15000 et. seq.). The EIR for the Proposed Project is also being prepared under the new California Assembly Bill 734 judicial streamlining legislation (California Environmental Quality Act: Oakland Sports and Mixed-Use Project) that added new provisions to CEQA as Public Resources Code § 21168.6.7 for the Proposed Project. The City of Oakland is the public agency that would consider approval of an amendment to the Oakland General Plan required for the Proposed Project, and as such, it is the Lead Agency for the Proposed Project. Pursuant to Guidelines §15082(a), upon deciding to prepare an EIR, the City as lead agency must issue a Notice of Preparation (NOP) to inform the Governor's Office of Planning and Research, trustee and responsible agencies, and the public of that decision.

The purpose of the NOP is to provide information describing the project and its potential environmental effects to those who may wish to comment regarding the scope and content of the information to be included in the EIR. Guideline §15082(b) states: "... [E]ach responsible and trustee agency and the Office of Planning and Research shall provide the lead agency with specific detail about the scope and content of the environmental information related to the responsible or trustee agency's area of statutory responsibility that must be included in the draft EIR. The response at a minimum shall identify: (A) The significant environmental issues and reasonable alternatives and mitigation measures that the responsible or trustee agency, or the Office of Planning and Research, will need to have explored in the Draft EIR; and (B) Whether the agency will be a responsible agency or trustee agency for the project." This notice is being sent to responsible or trustee agencies and other interested parties. Responsible and trustee agencies are those public agencies, besides the City of Oakland, that have a role in considering approval and/or carrying out the project. The City encourages responsible and trustee agencies and the Office of Planning and Research to provide this information to the City, so that the City can ensure that the Draft EIR meets the needs of those agencies. Once the Draft EIR is published, it will be sent to all responsible or trustee agencies and to others who respond to this NOP or who otherwise indicate that they would like to receive a copy. The Draft EIR will also be available for review at the City of Oakland at the address identified immediately below.

**SUBMITTING COMMENTS IN RESPONSE TO THIS NOP: The City encourages comments to be submitted electronically via the following link: <http://comment-tracker.esassoc.com/tracker/oaklandsportseir/>.** Comments that address the scope of the Draft EIR may also be directed in writing to: Peterson Vollmann, Planner IV, City of Oakland Bureau of Planning, 250 Frank H. Ogawa Plaza, Suite 2214, Oakland, CA 94612, by hand

delivery or mail, by email to PVollmann@oaklandca.gov, or by fax to (510) 238-4730. Mr. Vollmann may be reached by phone at (510) 238-6167. Time limits mandated by State law require that the City must receive comments within 30 days after publication of this notice; however, the City will receive comments through January 7, 2019, 38 days after publication of this notice. Responses to the NOP must be received via the above web address, mailing or e-mail address or fax by 5:00 p.m. on **Monday, January 7, 2019**. Please reference Case File Number **ER18-016** in all correspondence. Comments and suggestions as to the appropriate scope of analysis in the EIR are invited from all interested parties and will be received at the EIR Scoping Meetings to be held before the City Planning Commission, as noticed below.

Commenters should focus comments on potential impacts of the Proposed Project on the physical environment. Commenters are encouraged to identify ways that potential adverse effects resulting from the Proposed Project might be minimized and to identify reasonable alternatives and mitigation measures to the Proposed Project.

**EIR SCOPING MEETINGS:**

The **City of Oakland Planning Commission** will conduct a public scoping meeting on the EIR for the Oakland Waterfront Ballpark District Project on **Wednesday December 19, 2018 at 6:00 p.m.** in the Council Chambers in **Oakland City Hall, 1 Frank H. Ogawa Plaza, Oakland, CA.**

The **City of Oakland Landmarks Preservation Advisory Board** will conduct a public scoping meeting on the historic and cultural resource aspects of the Proposed Project on **Monday December 17, 2018 at 6:00 p.m.** in the Council Chambers, **Oakland City Hall, 1 Frank H. Ogawa Plaza, Oakland, CA.**

**PROJECT TITLE:** Oakland Waterfront Ballpark District Project (Case File No. **ER18-016**)

**PROJECT LOCATION:** Approximately 55 acres that comprises the Charles P. Howard Terminal and adjacent parcels, located at the Port of Oakland along the Inner Harbor of the Oakland-Alameda Estuary (See Figure 1, Site Location). The site is bound generally by the Oakland Estuary Middle Harbor on the south; Jack London Square on the east; Union Pacific railroad tracks and the Embarcadero on the north; and the heavy metal recycling center, Schnitzer Steel, on the west (see Figure 2, Site Boundary and Context).

**PROJECT SPONSOR:** Oakland Athletics Investment Group, LLC d/b/a The Oakland Athletics

**PROJECT SITE OWNERS:** City of Oakland acting by and through the Port of Oakland, Dynegy Oakland, LLC, and PG&E

**EXISTING CONDITIONS:** Maritime support uses for short term tenants. Existing uses and activities include but are not limited to: truck parking, loaded and empty container storage and staging, and longshore training facilities. The Project Site was previously used as a maritime container terminal until 2014. Howard Terminal is designated as Berths 67 through 69 within the Port of Oakland. Berths 67 and 68 were constructed in the early 1980's, and Berth 69 was constructed in the mid 1990's. The site includes a marginal wharf structure approximately 75' wide. A below grade rock dike sits adjacent to the Oakland Inner Harbor as the site's shoreline. The remaining site is

understood to be on grade pavement. Four cranes are located on Howard Terminal that were used to load/unload ships when the area was an active shipping facility. Howard Terminal is currently used by short term tenants.

Existing regional access to the Project Site exists via both Interstate 880 and Interstate 980, with on-ramps to each within one mile of the Project Site. The Project Site is located about one mile, a 20- to 25-minute walk, from three BART stations including West Oakland, 12th Street Downtown, and Lake Merritt. Railroad tracks are adjacent to the north boundary of the Project Site and there are several at-grade crossings of the railroad tracks nearby, including two directly into the Project Site. There is an Amtrak / Capital Corridor train station about one-half mile from the Project Site, transit bus service is within one-quarter mile, and the Jack London Ferry Terminal is immediately adjacent to the east of the Project Site.

The City of Oakland, acting by and through the City Council, controls the General Plan designation of the Project Site, which currently has a land use designation of “General Industrial” and the “Industrial General (IG)” zoning designation. In addition, areas of Howard Terminal fronting the Oakland Estuary (to the south) are designated within the Bay Conservation and Development Commission (BCDC) jurisdiction and are State Public Trust lands.

The Project Site is included in the list of Hazardous Waste and Substances sites in the Department of Toxic Substances Control (DTSC) EnviroStor database, one of the lists meeting the “Cortese List” requirements (<http://www.calepa.ca.gov/sitecleanup/corteselist/>, accessed October 2018).

**PROJECT DESCRIPTION:** The Project Sponsor proposes to develop the Howard Terminal property with the following key initial plan elements:

- Demolish existing buildings on the Project Site, except the existing power plant and the existing container cranes, which may be retained;
- Address any hazardous materials that may be present on the Project Site;
- Construct:
  - A new privately funded, open-air, approximately 35,000 person capacity Major League Baseball park;
  - Up to 4,000 residential units of varying affordability and types
  - Approximately 2.27 million square feet of adjacent mixed use development, including retail, commercial, office, cultural, entertainment, flex light industrial/manufacturing, and recreational uses;
  - A performance venue with a capacity of up to 3,500 individuals;
  - A 300 to 400-room hotel;
  - New and expanded utility infrastructure; and
  - New signage and lighting;
- Construct/provide improved access from the surrounding neighborhood and regional transportation networks, which could include, but may not be limited to:
  - an expanded shuttle and/or bus service (“rubber-tire trams”); and

- a new network of public streets and sidewalks that provide connectivity to and through the Project Site, and pathways that lead directly to the waterfront and related amenities.
- Construct/provide new waterfront public access, enhanced water views, and on-site open space;
- Comply with AB 734 regarding implementation of sustainability measures, development of a LEED Gold ballpark, and no net increase of greenhouse gas (GHG) emissions; and
- Phase development of the Proposed Project, with a target completion date of Spring 2023 for construction of Phase 1, including the ballpark, associated infrastructure, and potentially some ancillary development.

The Proposed Project may also consider one or more variants or options, potentially including but not limited to:

- New elevated pedestrian connections over the railroad tracks and improvements to existing at-grade crossings;
- An aerial tram or gondola above Washington Street extending from downtown Oakland near 12<sup>th</sup> Street BART to Jack London Square;
- Development of a portion of an existing power plant and removal of adjacent tanks;
- Altered edge configuration of the existing wharf to enhance public views and provide additional boat access/active water uses; and/or
- Extension of Embarcadero West to Middle Harbor Road and a new ramp from the existing Adeline Street overpass for new direct access to the Project Site.

**ANTICIPATED ENTITLEMENTS AND APPROVALS:** Discretionary approvals required for development of the Proposed Project are anticipated to include, but may not be limited to, the following:

- City Council approval of amendments to the General Plan and Planning Code after recommendation by the Planning Commission;
- Board of Port Commissioners approval of project transactional documents (e.g. leases and conveyance agreements);
- All necessary development permits and entitlements from the City & the Port;
- Port and State Lands Commission approval of a Trust Settlement and Exchange Agreement addressing public trust issues affecting the Project Site; and
- Bay Conservation and Development Commission (BCDC) Major Permit and Amendment to the BCDC and Metropolitan Transportation Commission (MTC) Seaport Plan.

**PROBABLE ENVIRONMENTAL EFFECTS AND PROPOSED SCOPE OF THE EIR:** The EIR will analyze and disclose the direct and indirect potentially significant impacts that would result from construction and operation of the Proposed Project under Existing Plus Project and Cumulative conditions (Guidelines §§15126.2, 15130), in addition to other analysis scenarios that may be appropriate for the EIR. Where significant impacts are identified, the EIR will describe potentially feasible mitigation measures that could minimize significant adverse impacts (Guidelines §15126.4). It is anticipated that the Proposed Project may have environmental impacts on aesthetics, air quality, biological resources, cultural resources, hazards, land use, noise and vibration, population and housing, public services, public utilities, transportation and circulation, hydrology and water quality, and growth inducement. It is anticipated that the Proposed Project would have no impact or less-than-significant impacts on

agricultural and forestry resources. Nevertheless, the EIR will evaluate the full range of environmental issues contemplated for consideration under CEQA and the CEQA Guidelines, including but not limited to the following:

- Aesthetics, Shadow and Wind (including Light, and Glare)
- Agricultural and Forestry Resources
- Air Quality
- Biological Resources
- Cultural and Historic Resources (including Tribal Cultural Resources)
- Geology and Soils (including Geological and Seismic Hazards)
- Greenhouse Gas Emissions /Global Climate Change
- Hazards and Hazardous Materials
- Hydrology and Water Quality
- Land Use and Planning
- Mineral Resources
- Noise and Vibration
- Population and Housing (including Growth Inducement)
- Public Services (including Police Services, Fire Protection Services, Parks and Schools);
- Recreation
- Transportation and Circulation
- Public Utilities and Service Systems (including Energy Demand and Conservation)

The Draft EIR will evaluate cumulative impacts of the Proposed Project, including the effects of other past, present, and reasonably foreseeable projects in the vicinity (Guidelines §15130).

The Draft EIR will also identify and examine a range of reasonable alternatives to the Proposed Project, including, but not limited to, a No Project Alternative (Guidelines §15126.6) and an alternative site (e.g. the Oakland Coliseum site).

Subject: Proposed Control Measure for Ocean-Going Vessels At Berth

I am a resident of downtown San Diego, along with 40,000 other people. The cruise ships dock extremely close to our high-density neighborhood and the pollution caused when the ships are not connected to shore power is toxic. The ships contaminate the whole downtown, but are especially dangerous for residents in the half-mile radius of the terminal, including the high-density populations of Columbia, Marina and Little Italy Districts, with high-rise condominiums, apartment complexes and hotels. Over 1400 hotel rooms are across the street from the ships and many residents are literally one block from the cruise ship terminal, a distance of about 800 ft.

I don't believe CARB is considering the proximity of the ships to the residential population in its rule making. A one size fits all scenario for rule-making does not work since the health and welfare of thousands of people is being put at risk. The San Diego cruise ship terminal is very different than LA's and should be treated differently.

1. I am pleased that ships in fleets will be required to connect to shore power Jan 1, 2021. I want ALL cruise ships to meet this requirement, no exceptions, at the San Diego cruise ship terminal. Cruise lines already had years to convert their ships. If they want to dock in San Diego they should not pollute the neighborhood and people's lungs and homes.
2. Maintain the current timeframe standards, or make them tougher, to connect to shore power. One hour after the ship docks to berth is acceptable. Changing this connection time to 2 hours after Ready to Work, in our situation, is unacceptable. Vessels and the Port need to make sure that the connections are maintained and labor is available to connect in one hour. Please do not lower standards and allow more than two hours to connect to shore power.
3. San Diego's Port Authority allows cruise ships to re-engage their engines 1/2 hour before leaving the berth. I want that to continue. A one hour timeframe to pollute, is not necessary. Every hour the cruise ships are allowed to pollute downtown, puts our health at increased risk.
4. In order for the Port of San Diego to meet the connection requirements already proposed, it needs money to build the

additional infrastructure to provide a second connection to shore power. Please provide the resources to make this happen before Jan 1, 2021.

Sincerely,

In case you aren't aware of the toxins in diesel pollution

California Air Resources Board  
P.O. Box 2815  
Sacramento, CA 95812-2815  
Submitted Via Electronic Comment Log

Subject: Comments on March 26, 2020 Notice of Availability of Modified Text for Proposed Control Measure for Ocean-Going Vessels at Berth (15-day changes)

Dear Ms. Csondes:

The Port of Oakland (Port) appreciates the opportunity to comment on the rulemaking materials posted March 26, 2020, for the Proposed Control Measure for Ocean-Going Vessels At Berth (Proposed Control Measure). The Port understands that the California Air Resources Board (CARB) is planning for the Proposed Control Measure to replace the current Airborne Toxic Control Measure for Auxiliary Diesel Engines Operated on Ocean-Going Vessels At Berth in a California Port (current At-Berth Regulation), with the goal of having the new rule in place in 2021.

The Port of Oakland has a very successful shore power program, underscoring the effectiveness of the current At-Berth Regulation. In 2018, 83% of regulated vessel calls<sup>1</sup> at the Port of Oakland drew shore power, surpassing the regulatory requirement of 70% compliance. The plug-in rates at the Port of Oakland are increasing as more carriers retrofit their vessels for shore power. In 2019, the success rate for the regulated fleet was 84% and year to date for 2020, the rate is tracking at 83%. Once safety exemptions are taken into consideration, compliance is much higher, surpassing 90% at some berths.

Before listing comments on the regulation, the Port questions whether CARB's timeline for implementing the Proposed Control Measure is still appropriate and feasible. As CARB is aware, California and U.S. seaports and goods movement industry stakeholders are responding to an unprecedented global economic and public health crisis. The maritime industry, which

---

<sup>1</sup> Steamships and infrequent callers (<25 calls/year) are exempt from the current regulation.

includes California and U.S. seaports, is included within the transportation critical infrastructure sector defined by the Department of Homeland Security. The maritime industry, operating under extraordinarily challenging public health, safety and financial conditions due to the COVID-19 pandemic, has swiftly reprioritized and reallocated scarce personnel and financial resources to ensure the continuity of essential supply chain services to the public, communities, businesses and local, state and federal government agencies around the United States. It seems problematic and inattentive to these challenges for CARB to require California seaports, terminal operators, and shipping companies to divert their limited resources and attention to this rulemaking process when lives and jobs are at risk, especially since many of the proposed measures are not due to take effect for several years. We respectfully request that CARB place the rulemaking process on “pause” to allow the maritime industry to focus its resources and attention on the performance of its critical supply chain functions and services in response to the COVID-19 pandemic.

**Specific Comments and Questions on the Proposed Control Measure**

1. One of the Port of Oakland’s main concerns about the Proposed Control Measure is its potential to create conflict and failure rather than collaboration among terminal operators, vessel operators and a local seaport. The Port of Oakland has expressed this concern in previous correspondence to CARB (see attachments to this letter, below). Specifically, the proposed complex regime of TIEs and VIEs has the potential to lead to disputes, rather than collaboration, among terminal operators, vessel operators, and a local seaport. Similarly, the proposed requirement for each port to prepare a “Port plan” and agree upon a “division of responsibilities” between terminal operators and the local seaport adds another potential arena of conflict for each port and its terminal tenants. It is doubtful whether CARB enforcement staff possess the necessary dispute resolution expertise to referee the foreseeable conflicts. The Port of Oakland recommends that CARB maintain the framework of the existing At-Berth Regulation in place for containerships. California’s container shipping industry has successfully coalesced around this existing regulation and has demonstrated consistent overcompliance with the rule.
2. According to the 15-day changes, the Innovative Concepts provision provides a pathway “for regulated vessel fleets to continue using fleet averaging methods to comply with the Proposed Regulation.” If the current regime is already acceptable as an Innovative Concept, why not let the current regime stay in place? Why force the carriers to re-apply every three years for a proven method that is already working? The Port suggests that CARB allow current fleet averaging methods to stay in place for all carriers who desire it without the need to constantly re-apply every three years. The shipping industry thrives on certainty.
3. According to CARB’s own analysis, the Port of Oakland has no feasible alternative compliance method at three out of four of its terminals (representing 83% of the Port’s call volume). This means that carriers relying on a barge-mounted bonnet system for compliance at the San Pedro Bay Ports (SPBP) will not be able to call Oakland, where the only feasible compliance method is shore power. This puts the Port of Oakland at a real disadvantage, especially as compared to its competitor ports in Tacoma, Seattle, Vancouver, and Prince Rupert. Diverting cargo to distant seaports only serves to increase emissions, undermining the purpose of the regulation.

48-1

4. The inventory that serves as the foundation for this rule is flawed. It underestimates the efficacy of the current regulation and overstates the benefit of the Proposed Control Measure. The discrepancies listed below invalidate the conclusions of CARB's analysis.
  - a. CARB's 2016 baseline data do not seem reliable. Comparing summaries by vessel class size to the Port of Oakland's own data (used for billing and subject to audit), the values are off by up to 40% in critical areas.
  - b. The inventory calculation caps the benefit of the current regulation at 80%, which disregards current overcompliance primarily due to 1) the provision requiring every vessel capable of plugging in to do so, 2) the long call durations at the SPBP resulting in ~96% emission reductions, and 3) the fact that some infrequent callers are in fact plugging in even though they are not required to do so.
  - c. As recognized by CARB staff, the assumed growth rate for the Port Oakland is too high. The inventory assumes a 5% compounded annual growth rate (CAGR) for the Port of Oakland, which CARB staff have agreed should be lowered to 2.2%. Considering the current COVID-19 crisis and the related documented decline in cargo throughput at California seaports, it is evident that the 5% CAGR is speculative at best and should not serve as the analytical basis to estimate projected emissions reductions and cost-effectiveness of the Proposed Control Measure.

CARB inventory staff have acknowledged these issues in a variety of phone calls and emails to Port of Oakland staff. CARB staff members have said that they will address these issues in Summer 2020, which is obviously too late to make the required adjustments or revisions under the proposed rulemaking and adoption schedule.

The Port suggests that CARB take the time available now during the COVID-19 crisis to reassess its baseline data, compliance assumptions, and inventory calculations. The Port has kept meticulous shore power records and would be happy to share information and provide reliable data sets to CARB.

5. Lastly, the Port of Oakland notes that today's May 1, 2020, letter is the Port's fifth letter to CARB providing comments and expressing concerns regarding the Proposed Control Measure. (See attachments to this letter, below.) The Port has expended considerable time and personnel resources combing through the proposed regulation and raising substantive concerns and questions about many different details of the proposed regulation and the data upon which it is based. To date, CARB staff have not provided written responses to the questions and comments posed in the Port of Oakland's first four letters. The Port has attached the previous four letters to today's letter, and specifically requests detailed responses to each of the questions raised in all the Port's letters. The Port believes that CARB's intention to provide meaningful stakeholder engagement requires that CARB timely and diligently provide substantive written responses to questions raised and comments made by the Port of Oakland and other stakeholders.

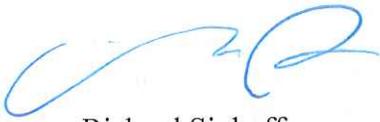

## **Closing**

The Port of Oakland appreciate the opportunity to review the 15-day changes to the Proposed Control Measure. As the Port of Oakland's maritime air quality policies and plans – Maritime

Air Quality Improvement Plan (2009) and Seaport Air Quality 2020 and Beyond Plan (2019) – emissions inventories, and shore power records and data show, among other policies and documents, the Port of Oakland is fully engaged and committed to reducing at-berth emissions and increasing shore-power usage. However, the Port believes that California seaports can achieve the desired outcomes of the existing shore power rule without getting mired in an unnecessarily complicated new regulation that is analytically flawed and presents the potential for conflict among seaports, terminal operators and vessel owners and operators.

The Port of Oakland looks forward to working with CARB on the emissions inventory and associated analyses. Please contact Tracy Fidell, P.E., Port Associate Environmental Planner/Scientist at [tfidell@portoakland.com](mailto:tfidell@portoakland.com) with any follow-up questions and responses.

Sincerely,

Richard Sinkoff  
Director of Environmental Programs and Planning

Submitted Via Electronic Comment Log

Subject: Comments on May 10, 2019, Draft Proposed Control Measure for Ocean-Going Vessels At Berth and Supporting Documents

Dear Ms. Csondes:

The Port of Oakland (“Port”) appreciates the opportunity to comment on the rulemaking materials posted May 10, 2019, for the Proposed Control Measure for Ocean-Going Vessels At Berth (“Proposed Control Measure”). The Port understands that the California Air Resources Board (“CARB”) is planning for the Proposed Control Measure to replace the current Airborne Toxic Control Measure (“ATCM”) for Auxiliary Diesel Engines Operated on Ocean-Going Vessels At Berth in a California Port (the “At-Berth Regulation”), with the goal of taking the Proposed Control Measure to the CARB Governing Board in December 2019. On May 10, 2019, CARB posted the revised text of the Proposed Control Measure, and provided, as supporting documents, the presentation from the May 14 and May 16, 2019 public workshops, Cost Inputs and Assumptions in PDF format, and Cost Estimates in Excel format.

The Port supports CARB’s ongoing efforts to reduce emissions from ocean-going vessels (“OGVs”) at berth and is working diligently to maximize the number of vessel visits using shore power. Port staff work collaboratively with shipping lines to provide education and resources about the shore power program. Port staff also track shore power usage in real time, collecting detailed information from marine terminal operators. The Port posts shore power usage statistics, reasons for equipped vessels not plugging in, and cost information on our shore power website: <https://www.oaklandseaport.com/development-programs/shore-power/>. In 2018, 75% of all calls to the Port drew shore power.

Public comments on the Proposed Control Measure are due to CARB June 10, 2019. Port staff understand CARB will then finalize the regulatory language and prepare an Initial Statement of

Reasons (“ISOR”) to release on October 18, 2019, with public comment on the ISOR closing on December 2, 2019. The CARB Governing Board is scheduled to hear the Proposed Control Measure on December 5, 2019. Do CARB staff intend to respond to public comment on the ISOR? Three days does not leave time for meaningful CARB response to public comment or public review of subsequent changes to the Proposed Control Measure. Port staff suggest a minimum of 14 days for CARB staff to review and respond to public comment, and for the public to review any changes, before the Proposed Control Measure can be heard.

The Proposed Control Measure includes the concept of an Incident Exemption, which is new since CARB published its draft Proposed Control Measure in August 2018. Vessel fleets would be granted Vessel Incident Exemptions (VIEs) and terminals would be granted Terminal Incident Exemptions (TIEs). Starting in 2021 for container ships and terminals, VIEs and TIEs would be granted at levels of 5% of the previous calendar year’s calls. CARB stated at the May 14, 2019, public workshop that the expected plug-in level for the container fleet is 90% in 2021.

Port staff submit the following comments and questions, divided into the topic areas of the draft regulatory text of the Proposed Control Measure, the presentation from the May 14, 2019 and May 16, 2019 public workshops, and the Cost Inputs and Assumptions in PDF format.

### **Comments and Questions on the Draft Regulatory Text of the Proposed Control Measure**

1. Port staff request clarification on the definition of “necessary infrastructure...that will enable a terminal to comply with this Control Measure” in Section 93130.10(b) of the Proposed Control Measure and what, in this context, “subject to verification by [CARB] enforcement staff” means. From Table XI Berth and Terminal Counts, Anticipated Infrastructure Needs, and Unique Vessels of the CARB Cost Inputs and Assumptions in PDF format, it appears that CARB believes that three new shore power vaults “would be installed in response to the Draft Regulation [Proposed Control Measure]...” at the Port. Accordingly Port staff request documentation supporting CARB staff’s berth-by-berth infrastructure analysis and determination that three new shore power vaults would be required at the Port in response to the Proposed Control Measure.
2. Regarding the Terminal and Port Plans required for Container terminals in Section 93130.11 of the Proposed Control Measure, the deadline of June 1, 2020 does not allow for sufficient time after the anticipated adoption of the Proposed Control Measure for ports and terminals to submit plans. Port staff object to the text in Section 93130.11(a) that “[a]s an alternative, Ports may submit plans for their terminal operators.” Ports should not be expected to submit plans for terminal operators. In addition, the statement in Section 93130.10(b) of the Proposed Control Measure that “Ports should use terminal plans as [the] basis for developing port plans” seems to indicate that the deadline for Port Plans should be adjusted to come after the deadline for Terminal Plans.
3. The definition of “Fleet” in Section 93130.2(b)(22) of the Proposed Control Measure does not explain how fleets will be established. What will CARB require at the beginning
